Unit 2, Subunits A, B, and C: Old Mans Run, Jefferson and Bullitt Counties, Kentucky: Unit 2 consists of three subunits totaling 1,014 ac (410 ha) in Bullitt and Jefferson Counties, Kentucky. It is located just south of the Jefferson/Bullitt County line and extends north of Old Mans Run. This critical habitat unit includes four element occurrences. Subunit 2B represents the best remaining populations and habitat for L. exigua var. laciniata in Jefferson County. Subunits 2A and 2C are important areas at the northern extent of the species' range. These three subunits represent the northeastern extent of the population's range and increase population redundancy within the species' range. The features essential to the conservation of the species in Unit 2 may require special management considerations or protection to address potential adverse effects associated with development on private land, incompatible agricultural or grazing practices, ORV or horseback riding, competition from lawn grasses, and forest encroachment. Subunit 2A is 102 ac (41 ha) in size and is located west of US 150 and northwest of Floyds Fork. It is in private ownership. While all PCEs are present within this subunit, it contains few native plant associates for L. exigua var. laciniata, and the increased competition from lawn grasses may decrease the ability of L. exigua var. laciniata to persist. This subunit is important for maintaining the northern distribution of L. exigua var. laciniata. Subunit 2B is 870 ac (352 ha) in size and is located east of US 150 and extends north and south of Old Mans Run. It is in private ownership. This is the largest of the subunits and contains the two highest ranked (1–B and 1–C) occurrences in Jefferson County. It represents the best remaining habitat in this portion of the range and may contain more than half of the total L. exigua var. laciniata population based on a 2011 survey by KSNPC, which estimated more than 20,000 individuals at 4 sites within this subunit. In this subunit, competition from lawn grasses impacts L. exigua var. laciniata and may decrease the plant's ability to persist. Subunit 2C is 42 ac (17 ha) in size and is located west of US 150 and east of Floyds Fork, extending into both Bullitt and Jefferson Counties. It is in private ownership. This subunit is primarily pasture, and habitat for L. exigua var. laciniata is impacted by competition from lawn grasses. Habitat management within this subunit to improve habitat for L. exigua var. laciniata is important for maintaining the northern distribution of the species.

Unit 3, Subunits A, B and C: Mount Washington, Bullitt County, Kentucky: Unit 3 consists of 42 ac (17 ha) and includes three subunits in Bullitt County, Kentucky, primarily within or adjacent to the city limits of Mount Washington. This critical habitat unit includes three element occurrences and provides an important link between the northern and southern portions of the species' range. Within Unit 3, the features essential to the conservation of the species may require special management considerations or protection to address potential adverse effects associated with development on private land, incompatible agricultural or grazing practices, ORV or horseback riding, competition from lawn grasses, and forest encroachment due to fire suppression. Subunit 3A is 25 ac (10 ha) in size and is located northeast of Mount Washington. It is in private ownership. Habitat for L. exigua var. laciniata within this subunit is degraded and would improve with management. It represents important habitat on the eastern extent of the species' range. In this subunit, habitat conversion and ORV use impact L. exigua var. laciniata habitat and may decrease the species' ability to persist at this site. Subunit 3B is 7 ac (3 ha) in size and is located east of Hubbard Lane and south of Keeneland Drive. It is in private ownership. The glade habitat has been degraded by adjacent land use and would benefit from improved management. The subunit represents an important link between other subunits. Subunit 3C is 10 ac (4 ha) in size and is located east of US 150 and south of Highway 44E. It is in private ownership. The subunit represents an important and high quality cedar glade in an area of ongoing, intensive development. Land use surrounding the glade remnant appears stable and the glade contains several native plant species associated with L. exigua var. laciniata.

Unit 4, Subunits A, B, C, D, E, F, G, and H: Cedar Creek, Bullitt County, Kentucky: Unit 4 consists of 547 ac (221 ha) and includes eight subunits, all in Bullitt County, Kentucky. This unit is located south of the Salt River and northeast of Cedar Grove and seems to represent the core of the remaining high-quality habitat for L. exigua var. laciniata. It includes eight element occurrences. In addition to being a stronghold for the species, these subunits are generally within close proximity (less than 0.5 miles (0.8 km)) to each other and represent the best opportunity for genetic exchange between occurrences. Within Unit 4, the features essential to the conservation of the species may require special management considerations or protection to address potential adverse effects associated with development on private land, incompatible agricultural or grazing practices, ORV or horseback riding, competition from lawn grasses, and forest encroachment due to fire suppression. Subunit 4A is 91 ac (37 ha) in size and is located south of Cedar Creek and west of Pine Creek Trail. This subunit is owned by The Nature Conservancy and encompasses most of the Pine Creek Barrens Preserve. This excellent-quality glade represents the only remaining ‘‘A’’ rank occurrence for L. exigua var. laciniata. Subunit 4B is 69 ac (28 ha) in size and is located along an unnamed tributary to Cedar Creek, and south of KY 1442. This good-quality glade includes the Apple Valley Glade State Nature Preserve, owned by KSNPC (approximately 30 percent of subunit), as well as private land, including some under permanent conservation easement (approximately 41 percent of subunit) to protect L. exigua var. laciniata. Approximately 29 percent of this subunit is under private ownership without any protections for L. exigua var. laciniata. Subunit 4C is 83 ac (34 ha) in size and located north of Cedar Creek and south of Apple Valley State Nature Preserve. It is in private ownership. This subunit contains high-quality glades with a community of native plants present. Subunit 4D is 46 ac (19 ha) in size and is located north of Cedar Creek and south of Victory Church. It is in private ownership. This subunit has been degraded and would benefit from improved management. Native plants associated with L. exigua var. laciniata occur within this subunit, but competition from lawn grasses, as well as forest encroachment due to fire suppression, impacts L. exigua var. laciniata and may decrease its ability to persist. Subunit 4E is 102 ac (41 ha) in size and is located southeast of subunit 4D and across Cedar Creek. It is in private ownership. It contains a large number of L. exigua var. laciniata (several thousand), but the habitat has been degraded by adjacent land use and would benefit from improved management. Competition from lawn grasses, as well as forest encroachment due to fire suppression, affects L. exigua var. laciniata and may decrease the plant’s ability to persist. Subunit 4F is 120 ac (49 ha) in size and is south of the confluence of Cedar Creek and Greens Branch. It is in private ownership. This is a degraded glade that still contains native plants associated with L. exigua var. laciniata. The subunit is disturbed by existing and surrounding land uses, as well as utility line maintenance and ORV use, which may decrease the species’ ability to persist. Subunit 4G is 20 ac (8 ha) in size and is located along either site of KY 480 near White Run Road. It is in private ownership. This site contains a large number of plants; however, improved habitat conditions are needed for longterm viability of the L. exigua var. laciniata occurrence. Impacts to L. exigua var. laciniata, which may decrease its ability to persist at this site, include incompatible agricultural or grazing practices, ORV use, competition from lawn grasses, and forest encroachment due to fire suppression. Subunit 4H is 16 ac (6 ha) in size and is located 0.95 miles southeast of the KY 480/KY 1604 intersection. It is in private ownership. Within this subunit, several patches of good habitat for L. exigua var. laciniata remain as well as a good diversity of native plant associates. However, competition from lawn grasses, as well as forest encroachment due to fire suppression, affects L. exigua var. laciniata and may decrease its ability to persist.

Unit 5, Subunits A and B: Cox Creek, Bullitt County, Kentucky: Unit 5 consists of 58 ac (23 ha) and includes two subunits, both in Bullitt County, Kentucky. It includes two element occurrences, representing the most easterly occurrences south of the Salt River. These subunits are important for maintaining the distribution and genetic diversity of the species. Within Unit 5, the features essential to the conservation of the species may require special management considerations or protection to address potential adverse effects associated with illegal waste dumps, development on private land, incompatible agricultural or grazing practices, ORV or horseback riding, competition from lawn grasses, and forest encroachment due to fire suppression. Subunit 5A is 8 ac (3 ha) in size and is located east of Cox Creek and west of KY 1442. It is in private ownership. This site is threatened by ORV use and would benefit from improved habitat management. Subunit 5B is 50 ac (20 ha) in size and is located west of Cox Creek near the Bullitt/Spencer County line. It is in private ownership. Incompatible agricultural practices and ORV use impacts L. exigua var. laciniata and may decrease its ability to persist. The native flora is mostly intact, and L. exigua var. laciniata would benefit from improved habitat management.

Unit 6: Rocky Run, Bullitt County, Kentucky: Unit 6 consists of 374 ac (151 ha) in Bullitt County, Kentucky. This critical habitat unit includes habitat that is under private ownership, including one 16-acre registered natural area. It includes one element occurrence. This unit appears to represent the largest intact glade habitat remaining within the range of the species. Within Unit 6, the features essential to the conservation of the species may require special management considerations or protection to address potential adverse effects associated with development on private land, incompatible agricultural or grazing practices, competition from lawn grasses, and forest encroachment due to fire suppression.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Leavenworthia exigua laciniata critical habitat consists of two components (79 FR 25689-25707):

(i) Cedar glades and gladelike areas within the range of L. exigua var. laciniata that include: (A) Areas of rock outcrop, gravel, flagstone of Silurian dolomite or dolomitic limestone, and/or shallow (1 to 5 centimeters (0.393 to 1.97 inches)), calcareous soils; (B) Intact cyclic hydrologic regime involving saturation and/or inundation of the area in winter and early spring, then drying quickly in the summer; (C) Full or nearly full sunlight; and (D) An undisturbed seed bank.

(ii) Vegetated land around glades and gladelike areas that extends up and down slope and ends at natural (e.g., stream, topographic contours) or manmade breaks (e.g., roads).

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. Threats to those features that define primary constituent elements for L. exigua var.

laciniata include (but are not limited to): (1) Residential and commercial development on private land; (2) construction and maintenance of roads and utility lines; (3) incompatible agricultural or grazing practices; (4) off-road vehicle (ORV) use or horseback riding; (5) encroachment by nonnative plants or forage species; and (6) forest encroachment due to fire suppression. These threats are in addition to random effects of droughts, floods, or other natural phenomena. Special management considerations or protection are required within critical habitat areas to address these threats. Management activities that could address these threats include (but are not limited to): (1) Avoiding cedar glades (or suitable gladelike habitats) when planning the location of buildings, lawns, roads (including horse or ORV trails), or utilities; (2) avoiding aboveground construction and/or excavations in locations that would interfere with natural water movement to suitable habitat sites; (3) protecting and restoring as many glade complexes as possible; (4) research supporting the development of management recommendations for grazing and other agricultural practices; (5) technical or financial assistance to landowners that may help in the design and implementation of management actions that protect the plant and its habitat; (6) avoiding lawn grass or tree plantings near glades; and (7) habitat management, such as brush removal, prescribed fire, and/or eradication of lawn grasses to maintain an intact native glade vegetation community.

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: 1 year (USFWS, 2016)

**Breeding Season**

Adult: Begins in March (USFWS, 2016)

**Reproduction Narrative**

Adult: A winter annual. L. exigua var. laciniata persist through the winter as rosettes, and flowering begins in late February to early March (Baskin and Baskin 1981; Evans and Hannan 1990). Seeds are set and plants die in April and May as the glade habitats dry out (Baskin and Baskin 1985; Solbrig 1971). At maturity, most of these seeds are dormant and will not germinate following dispersal, even if the soils are moist (Baskin and Baskin 1985). During the summer, these seeds undergo physical changes known as after-ripening and move from dormancy to conditional dormancy and finally, become non-dormant for fall germination (Baskin and Baskin 1985). (USFWS, 2016)

**Habitat Type**

Adult: Terrestrial (USFWS, 2016)

**Habitat Vegetation or Surface Water Classification**

Adult: Cedar glades (USFWS, 2016)

**Geographic or Habitat Restraints or Barriers**

Adult: Shade intolerant and prefers sparse vegetation (USFWS, 2016)

**Environmental Specificity**

Adult: Very Narrow (USFWS, 2016)

**Habitat Narrative**

Adult: L. exigua var. laciniata appears to be adapted to environments with shallow soils interspersed with flat-bedded, Silurian dolomite and dolomitic limestones, which is an uncommon geological formation in Kentucky (Rollins 1963; Evans and Hannan 1990). The soil on these horizontally bedded limestone areas is often only a few inches in depth or may be completely lacking in some areas (Rollins 1963). Because of the thin soils and underlying limestones, these habitats, called cedar or limestone glades, are extremely wet from late winter to early spring and quickly become dry in May and June. The natural habitat for L. exigua var. laciniata is these cedar glades (Baskin and Baskin 1981), but the taxon is also known from overgrazed pastures, eroded shallow soil areas with exposed bedrock, and areas where the soil has been scraped off the underlying bedrock (Evans and Hannan 1990). L. exigua var. laciniata does not appear to compete well with other vegetation and is shade intolerant (Evans and Hannan 1990) (USFWS, 2016).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available.

***Population Information and Trends***

**Population Trends:**

Short-term trends suggest declines of 10-50% (NatureServe, 2015)

**Number of Populations:**

77 (USFWS, 2020)

**Population Size:**

1000 - 100,000 individuals (NatureServe, 2015)

**Population Narrative:**

The Kentucky glade cress is endemic to a portion of Jefferson and Bullitt counties, Kentucky and is currently known to occur in 77 extant populations. After the taxon was listed as threatened in 2014, 12 new populations have been found. More than half of the known extant occurrences are considered to have poor resiliency. (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The greatest threat to Leavenworthia exigua var. laciniata is the destruction and degradation of glades through development, roads, utilities, and conversion to lawns. Documented impacts from horseback riding, off-road vehicle use, and changes in grazing practices have resulted in the loss or degradation of several L. exigua var. laciniata occurrences.

These activities are expected to continue in the future but to an unknown extent. Forest encroachment is expected to continue in areas without active management. Climate change has the potential to impact this species, but to what extent cannoted be predicted (USFWS, 2014).

**Stressor:** Narrow range and small populations (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Leavenworthia exigua var. laciniata has a narrow range, occurring in only small portions of two counties. Within this range, L. exigua var. laciniata is restricted to cedar glades and similar shallow-soiled areas that occur sporadically across the range. More than half of the remaining occurrences had low (fewer than 100 individuals) population counts at the time of the most recent survey. Additionally, the presumed low genetic diversity within individual occurrences of L. exigua var. laciniata could place those occurrences at a high risk of extirpation as their capacity for adaptation to change is reduced (USFWS, 2014).

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

Recovery Priority Number: 9

**Delisting Criteria:**
Criterion 1. At least 40 Kentucky Glade Cress populations1 , distributed across its range, exhibit a stable or increasing trend over 10 years of monitoring (Factors A and E). Criterion 2. At least 20 of the populations from Criterion 1 occur on natural or restored high-quality glade habitat and have 1,000 or more plants during 5 of the past 10 years of monitoring. Criterion 3. All of the populations in Criterion 1 are permanently protected and managed under an agreement such that threats are abated to the extent to ensure population viability for the foreseeable future. (USFWS, 2022)

**Recovery Actions:**

- 1. Permanently protect Kentucky Glade Cress populations and immediate surrounding habitat from destruction and degradation by development, with an emphasis on those in designated critical habitat and other areas of high-quality glade habitat. Estimated Cost $17,000,000 . 2. Conduct routine monitoring of Kentucky Glade Cress populations. Estimated Cost: $100,000. 3. Implement management activities to restore degraded glades and maintain high-quality glades that contain Kentucky Glade Cress populations. Estimated Cost: $50,000. 4. Encourage measures to avoid Kentucky Glade Cress patches in proposed developments. 5. Foster public appreciation for Kentucky Glade Cress and glade habitat through public outreach within and in the vicinity of its range. Estimated Cost: $15,000. 6. Research the biology of Kentucky Glade Cress. Estimated Cost: $259,000. 7. Reintroduce or introduce populations in suitable habitat within the taxon’s range. Estimated Cost: $10,000 (USFWS, 2022)
- Conservation measures are not available.

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The following recovery actions should be made a priority over the next 5 years: 1. Complete a recovery plan. 2. Continued public outreach to provide education on the species and its habitat and to explore opportunities for conservation on private property. 3. Look for opportunities to protect existing populations through voluntary conservation easements or other voluntary mechanisms. 4. Develop and implement management strategies for the taxon and its habitat. 5. Develop a program to monitor trends in population resiliency. 6. Establish methods and a plan to effectively reintroduce or introduce the taxon into suitable habitat within its range. 7. Enhance the suitability of known sites and potential reintroduction sites. 8. Define population regulation factors. (USFWS, 2020)

# SPECIES ACCOUNT: *Leavenworthia texana* (Texas golden Gladecress)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/11/2013; Southwest Region (Region 2)

**Physical Description**

A weakly rooted, glabrous (smooth, glossy), winter annual (completes its life cycle in 1 year). Texas golden gladecress is small in stature, less than 3.9 inches (in) (10 centimeters (cm)) in height, making it difficult to find except during flowering or when it bears fruit. The leaves are 0.8-3.1 in (2-8 cm) long and 0.4-0.6 in (1-1.5 millimeters (mm)) wide, forming rosettes at the base of the plant. Terminal leaf segments are wider-than-long, and usually distinctly lobed, with angular teeth. Flowers are bright yellow and borne on scapes (leafless flowering stems or stalks arising from the ground) that are 1.2-3.5 in (3-9 cm) long early in the flowering season. Later in the season, the flowers occur on unbranched flower clusters that come off a single central stem from which the individual flowers grow on small stalks, at intervals. The four petals are bright golden-yellow with a slightly darker base, narrowly obovate (tongue-shaped), 0.3-0.4 in (7-10 mm) long and 0.1-0.2 (3.5-5 mm) wide. The fruit is a slender seed capsule, known as a silique, with a length (0.6-1.2 in (15-30 mm)) that is more than twice its width (0.08-0.22 in (2-5.5 mm)) and that contains 5 to 11 flattened, circular or spherically shaped seeds. (USFWS, 2013a)

**Taxonomy**

In the mustard family (Brassicaceae). Dr. M. C. Leavenworth, an Army physician, first collected the taxon in Choctaw County, Oklahoma, in 1835, and the specimens were later described as a new species, Leavenworthia aurea, by Torrey (Mahler 1981, pp. 76-77). From 1836 to 1837, Leavenworth collected similar specimens near the present-day town of San Augustine, San Augustine County, Texas, and these were also identified as L. aurea. E. J. Palmer (1915 and 1918), and D. S. and H. B. Correll (1961 to 1962) as cited by Mahler (1981, pp. 83) made later collections of the plant in the San Augustine area. George and Nixon (1990, pp. 117-127) studied and mapped populations in this area between 1979 and 1980. W. H. Mahler studied the collected specimens and their habitat, and described the Texas plants as a new species, Leavenworthia texana (Mahler 1987, pp. 239-242), based on differences in morphological characteristics of flowers and leaves, and in chromosome number, between the Oklahoma and Texas plants (Mahler 1987, pp. 239-242). According to Mahler (1987, p. 240), Texas golden gladecress flower petals were a brighter, deeper yellow than those of L. aurea, and the petals were egg-shaped and flat instead of being broad and notched. The L. texana had wider-than-long terminal leaf segments that were usually distinctly lobed while L. aurea' s terminal leaves were essentially unlobed, flat, and more circular. Texas plants had a chromosome number of 2n = 22 (Nixon 1987, pers. comm. in Mahler 1987, pp. 239, 241) while the Oklahoma L. aurea had 2n = 48 (Rollins 1963, pp. 9-11; Beck et al. 2006, p. 156). We are aware that a recently completed monograph of the genus may have taxonomic implications for the Texas and Oklahoma Leavenworthia species in the future, but several questions, including the differences in chromosome number, remain unresolved and no supporting information that would change the current status of Texas golden gladecress has been published to date (Poole 2011a, pers. comm.). (USFWS, 2013a)

**Historical Range**

Texas golden gladecress is known from eight locations (historic and extant), including one introduced population, all within a narrow zone that parallels SH 21 in San Augustine, Sabine, and Nacogdoches Counties (Texas Natural Diversity Database (TXNDD) 2012b). (USFWS, 2013a)

**Current Range**

San Augustine and Sabine Counties in eastern Texas, on a particular geologic formation (the Weches Formation). (USFWS, 2013a)

**Critical Habitat Designated**

Yes; 10/11/2013.

**Legal Description**

On September 11, 2013, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective October 11, 2013) for Leavenworthia texana (Texas golden Gladecress) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes four critical habitat units (CHUs), in Sabine and San Augustine Counties, Texas. (USFWS, 2013b)

**Critical Habitat Designation**

The critical habitat designation for Leavenworthia texana includes four CHUs in Sabine and San Augustine Counties, Texas. This species critical habitat encompasses approximately 1,353 acres (ac) (548 hectares (ha)). Brief descriptions are provided below; maps depicting these areas are included in the Final Rule. (USFWS, 2013b)

Unit 1: Geneva: Unit 1 consists of 388 ac (157 ha) of private and State land located in northwest Sabine County, Texas. The unit is located 1.5 mi (2.3 km) south of Geneva, Texas, and 4.8 mi (7.7 km) north of Milam, Texas, and is bisected by SH 21.

Unit 2: Chapel Hill: Unit 2 consists of 150 ac (61 ha) of privately owned land, with one county road ROW, in northwestern San Augustine County, Texas. This unit is located 1.0 mi (1.6 km) south of SH 21, due west of the San Augustine-Sabine County line, and lies alongside County Road (CR) 151. This unit is linear in shape, running from southeast to northwest. Aside from CR 151, all other land in Unit 2 is privately owned. Current land cover appears to be approximately 70 percent woody cover; much of the forest being rows of pine trees.

Unit 3: Southeast Caney Creek Glades: Unit 3 consists of 39.9 ac (16.2 ha) just southeast of the City of San Augustine, San Augustine County, Texas. Approximately 99 percent of the land within this unit is privately owned, with the other 1 percent being county ROW under the management of TXDOT. This unit is located 0.8 mi (1.2 km) south from SH 21 near San Augustine, Texas, along the north side of FM 3483. This unit is located across Sunrise Road from a glauconite quarry.

Unit 4: Northwest Caney Creek Glades: Unit 4 consists of 775.3 ac (313.7 ha) that extends in a diagonal line from northeast to southwest, to the north and south of SH 21 just east of the City of San Augustine, San Augustine County, Texas. The unit is approximately 0.7 mi (1.1 km) wide.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Leavenworthia texana critical habitat consists of three components (USFWS, 2013b):

(i) Exposed outcrops of the Weches Formation within Weches prairies. Within the outcrop sites, there must be bare, exposed bedrock on top-level surfaces or rocky ledges with small depressions where rainwater or seepage can collect. The openings should support Weches Glade native herbaceous plant communities.

(ii) Thin layers of rocky, alkaline soils, underlain by glauconite clay (greenstone, ironstone, bluestone), that are found only on the Weches Formation. Appropriate soils are in the series classifications Nacogdoches clay loam, Trawick gravelly clay loam, or Bub clay loam, ranging in slope from 1– 15 percent.

(iii) The outcrop ledges should occur within the glade such that Texas golden gladecress plants remain unshaded for a significant portion of the day, and trees should be far enough away from the outcrop(s) that leaves do not accumulate within the gladecress habitat. The habitat should be relatively clear of nonnative and native invasive plants, especially woody species, or with only a minimal level of invasion.

**Special Management Considerations or Protections**

Texas golden gladecress may require special management considerations or protection to reduce the following threats: quarrying or other excavations, including pipeline installations; building over the top of occupied glades; construction or excavation upslope that alters water movement (sheet flow or seepage) downslope to Texas golden gladecress sites; pine tree plantings near glades; and invasive (native and nonnative) plants. Refer to the five-factor analysis in the listing determination for the Texas golden gladecress for more information on these threats. The features essential to the conservation of Texas golden gladecress may require special management considerations or protection to reduce the following threats: • Actions that remove the soils and alter the surface geology of the glades; • Building or paving over the glades; • Construction or excavation upslope that alters water movement (sheet flow or seepage) downslope to Texas golden gladecress sites; • Planting trees adjacent to the edges of an outcrop resulting in shading of the glade and accumulations of leaf litter and tree debris; • Encroachment by nonnative and native invading trees, shrubs, and vines that shade the glade; • The use and timing of application of certain herbicides that can harm Texas golden gladecress mature plants and seedlings; and • Fence placement such that livestock are likely to be directed through gladecress sites where habitat and plants may be trampled. Management activities that could ameliorate these threats include (but are not limited to): • Avoiding Weches glades when planning the location of quarries, well pads, roads, other facilities or structures, or pipeline routes, through glade complexes; • Avoiding above-ground construction or excavations in locations that would interfere with natural water movement to Texas golden gladecress habitat sites; • Locating suitable habitat and determining the presence or absence of the species and identifying areas with glade complexes and protecting or restoring as many complexes as possible; • Extending outreach to all landowners, including private and State, to raise awareness of the plant and its specialized habitat; • Providing technical or financial assistance to landowners to help in the design and implementation of management actions that protect the plant and its habitat; • Avoiding pine tree plantings near glades; and • Brush removal, to maintain an intact native glade vegetation community. (USFWS, 2013b)

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: March to April (NatureServe, 2015)

**Reproduction Narrative**

Adult: A winter annual, 2-10 cm tall, that produces bright yellow flowers in March and April. (NatureServe, 2015)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Wet glades, herbaceous communities (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Vernally wet environment (NatureServe, 2015)

**Environmental Specificity**

Adult: Very narrow. Specialist or community with key requirements scarce. (NatureServe, 2015)

**Habitat Narrative**

Adult: Herbaceous communities in vernally wet glades with shallow, calcareous soils on Weches Formation ironstone outcrops. Associated species include the rare white bladderpod (Lesquerella pallida), as well as flat stemmed spike-rush (Eleocharis compressa), and rock stonecrop (Sedum pulchellum). (NatureServe, 2015)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available.

***Population Information and Trends***

**Population Trends:**

Long-term trends indicate a decline of 30-70%, whereas short-term trends suggest a decline of 30-50% (NatureServe, 2015)

**Number of Populations:**

4 (USFWS, 2024)

**Population Size:**

250 - 1000 individuals (NatureServe, 2015)

**Population Narrative:**

Long-term population trends indicate a decline of 30-70%, whereas short-term trends suggest a decline of 30-50%. The small population size and low number of sites make this taxon vulnerable to effects of stochastic phenomena and catastrophic events; it has very low numbers in drought years (USFWS, 2004). At least two historical sites have been lost due to glauconite mining (USFWS 2012). Numbers of (growing) plants vary somewhat year-to-year. In 2009, the three extant sites had 98, 29, and 260 plants respectively (USFWS 2012). Three natural occurrences with intact habitat as of 2011 (USFWS 2012). An introduced site had plants through 2009 but a 2011 survey found the plants had been removed by a pipeline installation (USFWS 2012). Seed banks may persist at two historical sites (USFWS 2012). (NatureServe, 2015). The Texas golden gladecress is an annual plant and member of the family Brassicaceae. The best available information suggests that 4 extant populations occur in Texas on private and state-owned lands within San Augustine, Sabine, and Nacogdoches counties, Texas. Three of these populations are natural, and 1 introduced (Nacogdoches County). These populations are represented by Texas Parks and Wildlife Department's Element of Occurrence (EO) IDs from the Texas Natural Diversity Database (TXNDD; 2020, pp. 1-18. These populations are distributed across the Weches geologic formation that loosely parallels Texas State Highway 21 within these counties (Figure 1). Sites are relatively bare (treeless) and host a diverse set of associated species that vary throughout the annual cycle of the Texas golden gladecress. The species depends on cool, wet winter months to aid in its growth, promoting a short flowering season in February and March each year. When temperatures warm in summer, Texas golden gladecress withers away, and drought-tolerant species emerge. Glade exposures on the Weches geology are naturally small, giving rise to smaller population sizes, and therefore increasing the species' chances of negative effects from stochastic events. Due to its annual nature, plant numbers fluctuate each year. Little is known about the species' seed biology, reproductive strategies (i.e., need of pollinators), and/or genetic relatedness among and within populations. Known threats to the species include habitat loss, modification, degradation; climate change; and ineffective management strategies (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The most significant threat to habitat of Texas golden gladecress is surface quarrying of glauconite and the exploration and development of oil and natural gas wells and associated roads and pipelines have destroyed 50 percent of the known populations between the mid-1990s and 2011. In addition, excavations may occur when pipelines for water, sewer lines, gas connections to homes, and communication lines are installed may damage populations and habitat. Texas golden gladecress also faces threats throughout its range from competition for light and nutrients from both native and nonnative, invasive, woody plants, including the nonnative Macartney rose. Additionally, herbicides used to control Macartney rose may be a threat to the Texas golden gladecress if applied to or persisting in the soil during the species' period of growth, from late fall through early summer. A recent, ongoing trend in local land use is the conversion of open pasture to pine plantations. However, densely planted pine trees may degrade the species' habitat due to competition for light and nutrients and by contributing masses of leaf litter onto formerly sparsely vegetated glades. Finally, the information regarding climate change is not yet specific enough for us to determine the potential long-term effects to the Texas golden gladecress's habitat. However, long-term drought has negatively affected and will likely continue to negatively affect the reproduction and germination of Texas golden gladecress seeds (USFWS, 2013).

**Stressor:** Small populations (USFWS, 2013a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Texas golden gladecress is a historically rare species with some adaptations, such as a mixed mating system, that help to alleviate part of the inherent risks of small population size. The continued existence of Texas golden gladecress is negatively impacted by natural factors including being limited to only a few remaining populations that contain very small numbers of individual plants with a distribution restricted to extremely small areas of outcrop. The species' current, reduced occurrences across a range that has been highly fragmented by past and ongoing human activities increase its vulnerability. With only three remaining populations, loss of an entire population could be catastrophic for this species' long-term viability. Therefore, the small number of remaining populations, all of which are small in size, in conjunction with the threats to habitat, constitutes a threat to the species and greatly exacerbates other the threats identified for this species (USFWS, 2013a).

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

Recovery Priority Number: 5

**Delisting Criteria:**
Delisting criteria are not available.

**Recovery Actions:**
- Recovery actions are not available.
- Conservation measures are not available.

# SPECIES ACCOUNT: *Lepidium papilliferum* (Slickspot peppergrass)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 09/16/2016; Pacific Region (R1)

**Physical Description**

An intricately branched, tap-rooted plant, averaging 2 to 8 in. tall, but occasionally reaching up to 16 in. tall. Leaves and stems are covered with fine, soft hairs, and the leaves are divided into linear segments. Flowers are numerous, 0.11 to 0.15 in. in diameter, white, and four-petalled. Fruits (silicles, which are seed capsules that are less than twice as long as they are wide) are 0.10 to 0.15 in. wide, round in outline, flattened, and twoseeded (Moseley 1994, pp. 3, 4; Holmgren et al. 2005, p. 260). (USFWS, 2020)

**Taxonomy**

Slickspot peppergrass is a member of the Mustard Family (Brassicaceae). . Louis Henderson originally described slickspot peppergrass as L. montanum var. papilliferum in 1900. It was renamed L. papilliferum by Aven Nelson and J. Francis Macbride in 1913 based on its distinctive growth habit, short lifespan, and unusual pubescence (Nelson and Macbride 1913, p. 474). Hitchcock regarded slickspot peppergrass as L. montanum var. papilliferum influencing several publications including Flora of Idaho and Flora of the Pacific Northwest (Davis 1952, p. 347; Hitchcock et al. 1964, p. 516; Hitchcock and Cronquist 1973, p. 170; Steele 1981, p. 55; Moseley 1994, p. 2). In a 1993 review of taxa in the mustard family (Brassicaceae), Reed Rollins maintained the species based on differences in the physical features between the slickspot peppergrass and L. montanum (mountain pepperweed): • Slickspot peppergrass has trichomes (hair-like structures) occurring on the filaments of stamens (part of flower that produces pollen), but mountain pepperweed does not; • All the leaves on slickspot peppergrass are pinnately divided whereas mountain pepperweed has some leaves that are not divided; • The shape of the silicle [silique] (seed capsule) of slickspot peppergrass is different from that of mountain pepperweed; and • The silicle of slickspot peppergrass has no wings, or even vestiges of wings, at its apex (end of the capsule), unlike that of mountain pepperweed (Rollins 1993, p. 578; Moseley 1994, p. 2). Common names for this plant include slickspot peppergrass (Holmgren et al. 2005, p. 259), slick spot peppergrass (Moseley 1994, p. 1), and Idaho pepperweed (ITIS 2018, p. 1). The common name refers to its typical habitat—in or near slick spot microsites, and the peppery taste of the seeds. 'Grass' is a misnomer, and most members of the genus Lepidium are referred to as peppercress, pepperweed, or pepperwort (IDFG in litt. 2018, p. 2). Throughout this SSA, we refer to the species as slickspot peppergrass. (USFWS, 2020)

**Historical Range**

Historical extent is unknown. (USFWS, 2020)

**Current Range**

Slickspot peppergrass occurs only in southwestern Idaho in Ada, Canyon, Gem, Elmore, Payette, and Owyhee counties. This species is from three geographic areas based on landform: the Foothills geographic area, the Snake River Plain geographic area, and the Jarbidge geographic area. (USFWS, 2020)

**Critical Habitat Designated**

Yes; 6/5/2023.

**Legal Description**
We, the U.S. Fish and Wildlife Service (Service or USFWS), finalize the designation of critical habitat for slickspot peppergrass (Lepidium papilliferum) under the Endangered Species Act of 1973 as amended (Act). In total, approximately 31,569 hectares (78,009 acres) in Ada, Elmore, Gem, Payette, and Owyhee Counties in Idaho fall within the boundaries of the final critical habitat designation. The effect of this final rule is to designate critical habitat for the slickspot peppergrass, which is a threatened species under the Act.

**Critical Habitat Designation**

pilliferum (Slickspot Peppergrass) (1) Critical habitat units are depicted for Ada, Elmore, Gem, Owyhee, and Payette, Counties, Idaho

**Primary Constituent Elements/Physical or Biological Features**

Within these areas, the specific physical or biological features (PBFs) essential to the conservation of slickspot peppergrass consist of four components:

(i) Ecologically functional microsites or ‘‘slick spots’’ that are characterized by: (A) A high sodium and clay content, and a three-layer soil profile, which allows for successful seed germination, seedling growth, and maintenance of the seed bank. The surface horizon consists of a thin, silty vesicular, pored (small cavity) layer that forms a physical crust (the silt layer). The subsoil horizon is a restrictive clay layer, with an abruptic (referring to an abrupt change in texture) boundary with the surface layer, that is natric or natric-like in properties (a type of argillic (clay-based) horizon with distinct structural and chemical features); this is the restrictive layer. The second argillic subsoil layer (that is less distinct than the upper argillic horizon) retains moisture through part of the year (the moist clay layer). (B) Sparse vegetation, with invasive, nonnative plant species cover absent or limited to low to moderate levels.

(ii) Relatively intact, native Wyoming big sagebrush (Artemisia tridentata ssp. wyomingensis) vegetation assemblages, represented by native bunchgrasses, shrubs, and forbs, within 500 m (1,640 ft) of slickspot peppergrass element occurrences to protect slick spots and slickspot peppergrass from disturbance from wildfire, slow the invasion of slick spots by nonnative plant species and native harvester ants, and provide the habitats needed by slickspot peppergrass' pollinators.

(iii) A diversity of native plants whose blooming times overlap to provide pollinator species with flowers for foraging throughout the seasons and to provide nesting and egg-laying sites; appropriate nesting materials; and sheltered, undisturbed places for hibernation and overwintering of pollinator species. In order for genetic exchange of slickspot peppergrass to occur, pollinators must be able to move freely between slick spots. Alternative pollen and nectar sources (other plant species within the surrounding sagebrush vegetation) are needed to support pollinators during times when slickspot peppergrass is not flowering, when distances between slick spots are long, and in years when slickspot peppergrass is not a prolific flowerer.

(iv) Sufficient pollinators for successful fruit and seed production, particularly pollinator species of the sphecid and vespid wasp families, species of the bombyliid and tachnid fly families, and halictid bee species, most of which are solitary insects that nest outside of slick spots in the surrounding sagebrush-steppe vegetation, both in the ground and within the vegetation.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features which are essential to the conservation of the species and which may require special management considerations or protection. A detailed discussion of the threats affecting the PBFs essential to the conservation of slickspot peppergrass, and that may require special management consideration or protection, can be found in the final listing rule published in the Federal Register on October 8, 2009 (74 FR 52014), the 2016 final rule reinstating threatened status for the species under the Act (81 FR 55058, August 17, 2016), in the recently completed SSA report (USFWS 2020, pp. 59–83, 85–103), and in the latest 5- year review (USFWS 2021). The primary threats to the PBFs for slickspot peppergrass include the following direct and indirect effects: the current wildfire regime (i.e., increasing frequency, size, and duration), invasive, nonnative plant species (e.g., cheatgrass), and habitat loss and fragmentation due to agricultural and urban development. One of the indirect threats experienced by slickspot peppergrass is the negative impact on insect pollinators caused by conversion and fragmentation of native habitats due to invasive, nonnative plant species and various forms of development. Another indirect threat is the potential increase in seed predation by Owyhee harvester ants resulting from the conversion of sagebrush-steppe to grasslands. Livestock pose a threat to slickspot peppergrass, primarily through mechanical damage to individual plants and slick spot habitats; however, current livestock management conditions and associated conservation measures address this potential threat such that it does not pose a significant risk to the viability of the species as a whole. In the 2009 listing rule (74 FR 52014, October 8, 2009), climate change in and of itself was not considered to represent a significant range-wide threat to slickspot peppergrass; however, it was acknowledged that climate change potentially plays an important supporting role in intensifying the primary threats to the species. Information identified in the SSA (USFWS 2020, pp. 79–82) indicated that climate change has already amplified the effects of wildfire and invasive, nonnative plants on slickspot peppergrass, and through its influence on invasive, nonnative annual grass spread, climate change may have been a factor in the continuing downward trend in slickspot peppergrass population numbers observed over the past decade. Other, less significant factors that have the potential to impact the species include the effects from rangeland revegetation projects, wildfire management practices, recreation, and military use. All areas of critical habitat may require some level of management to address current and future threats to slickspot peppergrass and to maintain or restore the PBFs. Special management to protect the features essential to the conservation of slickspot peppergrass from the effects of the current wildfire regime may include preventing or restricting the establishment of invasive, nonnative plant species, post-wildfire restoration with native plant species, and reducing the likelihood of wildfires affecting the nearby plant community components. Rapid response to wildfires from local and government fire agencies can potentially limit the size of wildfires and the spread of wildfire into slickspot peppergrass habitat. For fires that do occur in critical habitat, post-fire restoration plans can identify ways to limit invasive, nonnative vegetation and restore habitat using native plants. Special management to protect the features essential to the conservation of slickspot peppergrass from the effects of invasive, nonnative unseeded plant species and seeded nonnative plants (also referred to as ‘‘highly competitive nonnative seeded plants’’ (USFWS 2020, p. 68)) may include the following: (1) protecting remnant blocks of native vegetation, (2) educating the public about invasive, nonnative species, (3) supporting research and funding for nonnative plant species control and native species restoration, (4) preventing or restricting the establishment of nonnative plant species, (5) washing vehicles prior to travel into areas containing slickspot peppergrass, and (6) reducing the likelihood of wildfires. Special management to protect the features essential to the conservation of slickspot peppergrass from the effects of livestock use may include conservation measures and actions to minimize the effects of livestock use on these lands. Existing conservation plans and land use plans contain numerous measures to avoid, mitigate, and monitor the effects of livestock use on slickspot peppergrass. For example, livestockgrazing conservation measures are implemented through the conservation agreement between the Bureau of Land Management (BLM) and the Service (BLM 2014, pp. 8–12) and the Mountain Home Air Force Base Integrated Natural Resources Management Plan (INRMP; U.S. Air Force 2017, p. 192). Existing conservation measures include prescribing a minimum distance for the placement of salt and water troughs, identifying livestock use restrictions to reduce trampling of slick spots during wet periods, constructing fences, or potentially modifying current livestock use. We recognize the potential for negative impacts to slickspot peppergrass populations and slick spots that may result from seasonal, localized trampling events. However, under current management conditions, we do not consider livestock use to pose a significant threat to slickspot peppergrass. We encourage the continued implementation of conservation measures and associated monitoring to ensure potential impacts of livestock trampling to slickspot peppergrass are avoided or minimized. Special management to protect the features essential to the conservation of slickspot peppergrass from the effects of residential and agricultural development may include the following: (1) creating managed plant reserves and open spaces, (2) limiting disturbances to and within suitable habitats, (3) increasing compliance inspections with livestock grazing permit holders, (4) requiring project fencing with adjacent construction activities, (5) disallowing new roads, and (6) evaluating the need for, and conducting, restoration efforts or revegetation of native plants in open spaces, plant preserves, or disturbed areas. Special management to protect the features essential to the conservation of slickspot peppergrass from the effects of Owyhee harvester ant seed predation are addressed under the special management considerations for the current wildfire regime and invasive nonnative plants. Finally, the protection of pollinators and their habitat is essential to the conservation of slickspot peppergrass. General pollinator management practices include: (1) maintaining a diversity of native plants with overlapping bloom times to provide flowers for foraging throughout the pollinators’ active season, (2) nesting and egg-laying sites (e.g., bare ground, hollow stems, bunchgrasses, and larval host plants), (3) sheltered, undisturbed places for overwintering, (4) a landscape free of pesticides and high levels of pathogens, and (5) connected habitat patches (The Xerces Society 2018, pp. 15–17). The designation of critical habitat does not imply that lands outside of critical habitat do not play an important role in the conservation of slickspot peppergrass. Activities with a Federal nexus that may affect those areas outside of critical habitat, such as development, agricultural, or road construction activities, are still subject to review under section 7 of the Act if they may affect slickspot peppergrass.

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

Adult: Seed Production: Depending on an individual plant’s vigor, the effectiveness of its pollination, and whether it is functioning as an annual or a biennial, each slickspot peppergrass plant produces varying numbers of seeds (Quinney 1998, pp. 15, 17). Biennial plants normally produce many more seeds than annual plants (Meyer et al. 2005, p. 15). Average seed output for annual plants at the Idaho Army National Guard's (IDARNG) Orchard Combat Training Center (OCTC) was 125 seeds per plant in 1993 and 46 seeds per plant in 1994. In contrast, seed production of biennials at this site in 1993 and 1994 averaged 787 and 105 seeds per plant, respectively (Meyer et al. 2005, p. 16). Based on data collected from a 4-year demography study on the OCTC, survivorship of the annual form of slickspot peppergrass was demonstrated to be higher than survivorship of biennials (Meyer et al. 2005, p. 16). Meyer et al. (2005, p. 21) hypothesize that the reproductive strategy of slickspot peppergrass is a plastic response, meaning that larger plants will flower and produce seed in their first season, whereas smaller plants that stand less chance of successfully setting seed in their first season will delay reproduction until the following year. Thus, the biennial life form is maintained, despite the higher risk of mortality. Like many short-lived plants growing in arid environments, above-ground numbers of slickspot peppergrass individuals can fluctuate widely from year to year, depending on seasonal precipitation patterns (Mancuso and Moseley 1998, p. 1; Meyer et al. 2005, pp. 4, 12, 15; Palazzo et al. 2005, p. 9; Menke and Kaye 2006a, p. 8; Menke and Kaye 2006b, pp. 10, 11; Sullivan and Nations 2009, p. 44). Mancuso and Moseley (1998, p. 1) note that sites with thousands of above-ground plants one year may have none the next, and vice versa. Above ground plants represent only a portion of the population; the seed bank (a reserve of dormant seeds generally found in the soil) contributes the other portion and in many years, constitutes the majority of the population (Mancuso and Moseley 1998, p. 1). Seed banks are adaptations for survival in a "risky environment" because they buffer a species from stochastic (random) impacts, such as lack of soil moisture (Baskin and Baskin 2001, p. 160). Seed Viability and Germination: The seeds of slickspot peppergrass are found primarily within the slickspot microsites where the plants are found (Meyer and Allen 2005, pp. 5–6). Slickspots, also known as mini-playas or natric (high sodium content) sites, are visually distinct openings in the sagebrush-steppe created by unusual soil conditions characterized by significantly greater sodium and clay content relative to the surrounding area (Moseley 1994, p. 7). The vast majority of slickspot peppergrass seeds in slickspots have been located near the soil surface, with lower numbers of seeds located in deeper soils (Meyer et al. 2005, p. 19; Palazzo et al. 2005, p. 3). Slickspot peppergrass seeds have been found in slickspots even if no above-ground plants are present (Meyer et al. 2005, p. 22; Palazzo et al. 2005, p. 10). When above-ground plants are present, flowering usually occurs in late April and May, fruit set occurs in June, and the seeds are released in late June or early July. Seeds produced in a given year are dormant for at least a year before any germination takes place. Following this year of dormancy, approximately 6 percent of the initially viable seeds produced in a given year germinate annually (Meyer et al. 2005, pp. 17–18). When combined with an average annual 3 percent loss of seed viability, approximately 9 percent of the original seed cohort per year is lost after the first year. Thus, after 12 years, all seeds in a given cohort will likely have either died or germinated, resulting in a maximum estimated longevity of 12 years for seeds in the seed bank (Meyer et al. 2005, p. 18). The primary seed dispersal mechanism for slickspot peppergrass is not known (Robertson and Ulappa 2004, p. 1708), although viable seeds have been found outside of slickspots, indicating that some seed dispersal is occurring beyond slickspot habitat (Palazzo et al. 2005, p. 10). Slickspot peppergrass seeds located near the soil surface show higher rates of germination and viability (Meyer and Allen 2005, pp. 6–8; Palazzo et al. 2005, p. 10) and the greatest seedling emergence success rate (Meyer and Allen 2005, pp. 6–8). Viable seeds were more abundant and had greater germination rates from the upper 2 in. of soil (Palazzo et al. 2005, pp. 8, 10), while Meyer and Allen (2005, pp. 6–8) observed the upper 0.08 in. as optimal for germination. Deep burial of slickspot peppergrass seeds (average depths greater than 5.5 in.) can entomb viable seeds and may preserve them beyond the 12-year period previously assumed as the maximum period of viability for slickspot peppergrass seeds (Meyer and Allen 2005, pp. 6, 9). However, seeds buried at such depth, even if they remain viable, are unlikely to regain the surface for successful germination. The effects of environmental factors, such as wildfire, on slickspot peppergrass seed dormancy and viability are unknown although slickspot peppergrass abundance is reduced in burned areas. Pollination: Slickspot peppergrass is primarily an outcrossing species requiring pollen from separate plants for more successful fruit production and has a low seed set in the absence of insect pollinators (Robertson 2003, p. 5; Robertson and Klemash 2003, p. 339; Robertson and Ulappa 2004, p. 1707; Billinge and Robertson 2008, pp. 1005–1006). Slickspot peppergrass is able to self-pollinate, with a selfing rate (rate of self-pollination) of 12 to 18 percent (Billinge 2006, p. 40; Robertson et al. 2006a, p. 40). In pollination experiments where researchers moved pollen from one plant to another, fruit production was higher when pollen from distant sources was used (4 to 12.4 miles (mi)) between patches of plants) than when pollen from plants within the same patch was used (246 to 330 feet (ft)) between plants within the same patch) (Robertson and Ulappa 2004, p. 1705; Robertson et al. 2006a, p. 3). Fruits produced from fertilized flowers reach full size approximately two weeks after pollination (Robertson and Ulappa 2004, p. 1706). Each fruit typically bears two seeds that drop to the ground when the fruit dehisces (splits open) in midsummer (Billinge and Robertson 2008, p. 1003). Known slickspot peppergrass insect pollinators include several families of bees (Hymenoptera), including Apidae, Halictidae, Sphecidae, and Vespidae; beetles (Coleoptera), including Dermestidae, Meloidae, and Melyridae; flies (Diptera), including Bombyliidae, Syrphidae, and Tachinidae; and others (Robertson and Klemash 2003, p. 336; Robertson et al. 2006b, p. 6). In slickspot peppergrass insect pollinator studies conducted at three study sites, seed set was not limited by the number of pollinators at any study site (Robertson et al. 2004, p. 14). Studies have shown a strong positive correlation between insect diversity and the number of slickspot peppergrass plants flowering at a site (Robertson and Hannon 2003, p. 8). Measuring fruit set per visit revealed considerable variability in the effectiveness of pollination by different types of insects, ranging from 0 percent in dermestid beetles to 85 percent in honeybees (Apis mellifera) (Robertson et al. 2006b, p. 15).

**Habitat Type**

Adult: Volcanic plains

**Environmental Specificity**

Adult: Moderate (inferred from USFWS, 2016)

**Habitat Narrative**

Adult: The range of slickspot peppergrass is restricted to the volcanic plains of southwest Idaho, occurring primarily in the Snake River Plain and its adjacent northern foothills, with a single disjunct population on the Owyhee Plateau. The plant occurs at elevations ranging from approximately 2,200 to 5,400 ft in Ada, Canyon, Gem, Elmore, Payette, and Owyhee Counties (Moseley 1994, pp. 3–9). Based on differences in topography, soil, and relative abundance, we have divided the extant slickspot peppergrass populations into three physiographic regions: the Boise Foothills, the Snake River Plain, and the Owyhee Plateau. The nature and severity of factors affecting the species also vary between the three physiographic regions for the purposes of analysis. For example, urban and rural development, agriculture, and infrastructure development has been substantial in the sagebrush-steppe habitat of the Boise Foothills and the Snake River Plain regions, while very little of these types of development have occurred within the Owyhee Plateau region. The biological soil crust, also known as a microbiotic crust or cryptogamic crust, is one component of quality habitat for slickspot peppergrass. Such crusts are commonly found in semiarid and arid ecosystems and are formed by living organisms, primarily bryophytes, lichens, algae, and cyanobacteria, that bind together surface soil particles (Moseley 1994, p. 9; Johnston 1997, p. 4). Microbiotic crusts play an important role in stabilizing the soil and preventing erosion, increasing the availability of nitrogen and other nutrients in the soil and regulating water infiltration and preventing the establishment of invasive plants (Brooks and Pyke 2001, p. 4 and references therein; Serpe et al. 2006, pp. 174, 176). These crusts are sensitive to disturbances that disrupt crust integrity, such as compression due to livestock trampling or off highway vehicle (OHV) use and are subject to damage by fire; recovery from disturbance is possible but occurs very slowly (Johnston 1997, pp. 10–11). Slickspot peppergrass occurs in slickspot habitat microsites scattered within the greater semiarid sagebrush-steppe ecosystem of southwestern Idaho. On a broad scale, the Snake River Plains and the Owyhee Plateau physiographic regions are volcanic in nature and underlain by Tertiary basalt or rhyolite; the adjacent Boise Foothill sites are underlain by Pliocene/Quaternary lacustrine deposits (Moseley 1994, p. 8). Slickspots are visually distinct openings characterized by natric soils and distinct clay layers; they tend to be highly reflective and relatively light in color, making them easy to detect on the landscape (Fisher et al. 1996, p. 3). Slickspots are distinguished from the surrounding sagebrush matrix as having the following characteristics: microsites where water pools when rain falls (Fisher et al. 1996, pp. 2, 4); sparse native vegetation, distinct soil layers with a columnar or prismatic structure, higher alkalinity and clay content, and natric properties (Fisher et al. 1996, pp. 15–16; Meyer and Allen 2005, pp. 3–5, 8; Palazzo et al. 2008, p. 378); and reduced levels of organic matter and nutrients due to lower biomass production (Meyer and Quinney 1993, pp. 3, 6; Fisher et al. 1996, p. 4). Fisher et al. (1996, p. 11) describe slickspots as having a “smooth, panlike surface” that is structureless and slowly permeable when wet, moderately hard and cracked when dry. Although the low permeability of slickspots appears to help hold moisture (Moseley 1994, p. 8), once the thin crust dries out, slickspot peppergrass seedling survival depends on its ability to extend its taproot into the argillic horizon (soil layer with high clay content) to extract moisture from the deeper natric zone (Fisher et al. 1996, p. 13). How long slickspots take to form is unknown, but is hypothesized to take several thousands of years (Nettleton and Peterson 1983, p. 193; Seronko 2006, in litt. p. 2). Climate conditions that allowed slickspot formation in southwestern Idaho are thought to have occurred during a wetter Pleistocene period. Holocene additions of wind-carried salts (often loess deposits) produced the natric soils characteristic of slickspots (Nettleton and Peterson 1983, p. 191; Seronko 2006, in litt., p. 2). Several hundred years may be necessary to alter or lose slickspots through natural climate change or severe natural erosion (Seronko 2006, in litt. p. 2). However, some researchers hypothesize that new slickspots are no longer being created given current climatic conditions (Nettleton and Peterson 1983, pp. 166, 191, 206). As slickspots in southwest Idaho appear to have formed during the Pleistocene and current climate conditions may not allow for the formation of new slickspots, the loss of slickspot microsites appears to be permanent. Some slickspots subjected to past light disturbance may be capable of reforming (Seronko 2006, in litt. p.2). However, disturbances that alter the physical properties of the soil layers, such as deep disturbance and the addition of organic matter, may lead to the destruction and permanent loss of slickspots. For example, deep soil tilling and adding organic matter and gypsum have been recommended for eliminating slickspots from agricultural lands in Idaho (Peterson 1919, p. 11; Rasmussen et al. 1972, p. 142). Slickspot soils are especially susceptible to mechanical disturbances when wet (Rengasamy et al. 1984, p. 63; Seronko 2004, in litt. pp. 1–2). Such disturbances disrupt the soil layers important to slickspot peppergrass seed germination and seedling growth and alter hydrological function. Meyer and Allen (2005, p. 9) suggest that if sufficient time passes following the disturbance of slickspot soil layers, the slickspot soil layers may regain their pre-disturbance configuration yet not support the species. Thus, while the slickspot appears to have regained its former character, some essential component required to sustain the life history requirements of slickspot peppergrass has apparently been lost, or the active seed bank is no longer present. Most slickspots are between 10 and 20 square feet (ft2) in size although some are as large as 109 ft2 (Mancuso et al. 1998, p. 1). Slickspots cover a relatively small cumulative area within the larger sagebrush-steppe matrix, and only a small percentage of slickspots are known to be occupied by slickspot peppergrass. Slickspot peppergrass has infrequently been documented outside of slickspots on disturbed soils, such as along graded roadsides and badger mounds. These are rare observations and the vast majority of plants documented over the past 19 years of surveys and monitoring for the species were within slickspot microsite habitats (USFWS 2006b, p. 20). For example, in 2002, a complete census of an 11,070-ac area recorded approximately 56,500 slickspots (Air Force 2003 in litt., p. 15), of which approximately 2,450 (about 4.0 percent) were occupied by slickspot peppergrass plants (Bashore, pers. comm. 2003, p. 1). Of the approximately 11,300 slickspot peppergrass plants documented during the survey effort, only 11 plants (less than 1 percent) were documented outside of slickspots (Air Force 2002, summary attachment, entire). Not all potential slickspot peppergrass habitats in southwest Idaho have been surveyed, and additional slickspot peppergrass sites may be found outside of areas known to be occupied. Recent modeling was completed to develop a high-quality, predictive-distribution model of slickspot peppergrass to identify potential habitat (Colket 2008, p. 1). The Bureau defines potential habitat as areas within the known range of slickspot peppergrass that have certain general soil and elevation characteristics that indicate the potential for the area to support slickspot peppergrass although the presence of slickspots or the plant is unknown (USBLM 2009, p. B–2). Although surveys were conducted in 2008 in some areas identified as previously unsurveyed habitat with potential to contain the species, these surveys did not result in any new locations of the species (Colket 2008, pp. 4–6). Slickspot peppergrass has also been surveyed for in eastern Oregon, but the species has never been found there (Findley 2003 in litt., p. 1). We have no historical records indicating that slickspot peppergrass has ever been found anywhere outside of its present range in southwestern Idaho.

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Decline of 30 to 70 percent

**Species Trends:**

Declining

**Resiliency:**

The majority of slickspot peppergrass populations do not meet minimum viability criteria for population size (at least 1,000 plants) and minimum patch size (at least 500 acres) suggested in this SSA. However, some populations may be unique; and therefore, important for population representation and redundancy. For example, none of the populations in the Foothills geographic area met Service minimum population viability criteria due to their low acreages.

Due to the high levels of habitat fragmentation in the Foothills geographic area associated with wildfire, invasive nonnative plants, and development as well as the patchwork of land ownership, it likely would not be feasible to achieve the 500-acre patch size suggested for minimum viability criteria at slickspot peppergrass Foothills populations. As some Foothills populations represent the lower elevation extent of the species, their conservation would be important to preserve slickspot peppergrass genetic diversity and unique habitats despite smaller habitat patch sizes (and in some cases, lower plant numbers). A combination of habitat enhancement or threat reduction actions within populations considered to be unique, regardless of whether they meet suggested minimum population viability criteria, may be appropriate to maintain (and possibly increase) population representation and species redundancy over time. Although based on essentially the same type of baseline data and calculation as MVP, Population Viability Analysis (PVA) addresses the survival probability of specific populations. Viability of slickspot peppergrass populations is important as populations with higher viability also have higher resiliency, and have a higher likelihood of regaining plant numbers following random stochastic events such as drought or localized ground disturbance. PVA is not an absolute measure of whether a population is or is not viable, but rather is a tool used to assess how natural or man-caused changes in conditions may influence population viability. Using IDFG rangewide population assessments, we identified six groupings of good to fair viability populations in relatively close geographic proximity that are scattered across the species' range (Table 8, see also Figure 2). These groupings of higher viability populations are indicative of population strongholds, and may provide for genetic exchange among populations within the same grouping. EOs and subEOs identified as having higher population viability within these six groupings increase resiliency to stochastic events, and their distribution across the range of the species contributes to species representation and redundancy. With the exception of the two groupings within the Jarbidge geographic area, these groupings of higher viability populations are located too distant for insect pollinators to facilitate genetic exchange among the groupings. In addition, some lower viability EOs either within a grouping or in a more isolated location may also be important for population representation and redundancy due to their genetic uniqueness or other characteristics. (USFWS, 2020)

**Representation:**

While genetic studies suggest that representation of the disjunct Jarbidge geographic area populations is high, representation is more limited for smaller populations located in the Snake River Plain and Foothills geographic areas, where smaller populations separated by greater geographic distances have lower genetic diversity. Maintaining connectivity within and between populations to the extent possible would be important to continued genetic diversity of slickspot peppergrass populations (USFWS, 2020).

**Redundancy:**

Using these NatureServe protocols, IDFG assessment of individual EOs and subEOs resulted in EOs and subEOs ranked as having good viability (B-ranked) to poor viability (D-ranked) (Table 6). Overall, there appears to be a relatively high level of population redundancy, as good to fair viability populations (B-, BC-, and C-ranked EOs and subEOs) are well distributed across the range of the species (Table 6, see also Figure 2). The majority of the 115 extant populations (66 percent) ranked by IDFG fall within the good to fair population viability categories. When considering the combined acreage of populations rangewide, 83 percent (13,402 acres) of slickspot peppergrass EO and subEO acreage is ranked as having good viability (B-ranked) (Figure 13). No EOs or subEOs were ranked A (excellent viability) or AB (excellent to good viability)

(USFWS, 2020).

**Number of Populations:**
19 (USFWS, 2021)

**Population Size:**
45,569 (USFWS, 2016)

**Population Narrative:**
The number of above-ground plants fluctuates widely from year to year and is strongly correlated with spring precipitation (Menke and Kaye 2006). Seeds can remain viable in the seed bank for at least 12 years (USFWS 2007). The persistent seed bank appears essential for population persistence in this species (Meyer et al. 2006). Also, the species may rely on years with extremely favorable environmental conditions to restock this seed bank; if every year were average in its desert environment, the species might not persist (Meyer et al. 2006). In 2011, 2012, and 2013 the total number of Lepidium papilliferum plants counted was the lowest since 2005, when complete counts for this species were initiated (16,462 plants in 2011; 9,245 plants in 2012; and 6,351 in 2013) (Kinter 2012, in litt.; Kinter 2015, in litt.). In 2014, however, 45,569 total plants were counted, which represented the third highest number of plants observed over the 10 years of HIP monitoring (Kinter 2015, in litt.). Previously, the lowest total number of plants counted occurred in 2006, with 17,543 plants, and the highest count was in 2010, with 58,921 plants (Idaho Department of Fish and Game (IDFG) 2012, p. 5) (USFWS, 2016). Based on IDFG's 2016 assessment of slickspot peppergrass populations, 19 EOs and subEOs contained 1,000 or more slickspot peppergrass plants during IDFG assessment field reviews or during annual monitoring in at least one of the six years between 2010 and 2015. The Service considers these 19 EOs and subEOs (17 B-ranked and 2 BC-ranked) to have the highest viability of all slickspot peppergrass populations. Habitat patch sizes for these 19 slickspot peppergrass EOs and subEOs range from about 2 acres to 7,164 acres. Only 6 of these 19 populations are greater than 500 acres in area. The area of the remaining 13 EOs, documented to support 1,000+ plants, range from 2 to 91 acres. Relative to larger acreage populations, these smaller acreage populations are expected to be more vulnerable to stochastic or catastrophic events, such as ground disturbance or wildfire, respectively. (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Increased Frequency and Intensity of Wildfire (USFWS, 2020)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The altered wildfire regime is one of the two primary causes of reduced quality of habitat for slickspot peppergrass. Across the intermountain west, increased frequency, severity, intensity, and extent of wildfire has converted vast areas of former sagebrush steppe ecosystem to nonnative annual grasslands. Invasive nonnative annual grasses, such as cheatgrass and medusahead, have contributed to increases in the amount and continuity of fine fuels across the landscape. As a result, the wildfire frequency interval of sagebrush steppe habitat has been drastically shortened from a historical range of approximately 60 to over 300 years (depending on the species of sagebrush and other site specific characteristics) to less than 5 years in many areas of the sagebrush steppe ecosystem (Billings 1990, pp. 307–308; Whisenant 1990, p. 4;

USGS 1999, in litt., pp. 1–9; West and Young 2000, p. 262; Bukowski and Baker 2013, p. 557). Not only are wildfires burning far more frequently, but these wildfires tend to be larger and burn more uniformly than those that occurred historically, resulting in fewer patches of unburned vegetation, which affects the post-fire recovery of native sagebrush steppe vegetation (Whisenant 1990, p. 4). However, because estimates of increased fire frequency are critically dependent on the spatial area and period over which authors use for their computations, each estimate of fire frequency in sagebrush steppe provides a perspective on the role of fire in the sagebrush ecosystem that must be interpreted using the appropriate scale (Miller et al. 2011, p. 165). (USFWS, 2020)

**Stressor:** Introduction and Spread of Invasive Nonnative Plants (USFWS, 2020)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasive, nonnative annual grasses can alter various attributes of ecosystems including geomorphology, wildfire regime, hydrology, microclimate, nutrient cycle, and productivity (for a summary, see Dukes and Mooney 2003, entire). Additionally, invasive nonnative annual grasses can negatively affect native plants, including rare plants such as slickspot peppergrass, through competitive exclusion, niche displacement, hybridization, and competition for insect pollinators. Examples of these negative effects are widespread among different taxa, locations, and ecosystems (D'Antonio and Vitousek 1992, pp. 63–87; Olson 1999, p. 5; Mooney and Cleland 2001, p. 1). (USFWS, 2020)

**Stressor:** Highly Competitive Nonnative Seeded Species (USFWS, 2020)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Highly competitive nonnative seeded species are considered separately from invasive nonnative unseeded species, which includes annual invasive nonnative grasses and perennial noxious weeds. Both native and nonnative deep-rooted perennial bunchgrasses can play key roles in the ecological resilience of habitat to disturbances (such as wildfire and improper livestock grazing) and of ecological resistance to invasive nonnative annual grass establishment. Established perennial plants with well-developed root systems (Figure 17) can effectively compete with invasive nonnative annual grasses for water and nutrients. Both established native and nonnative deep-rooted perennial grasses can limit the spread of invasive nonnative annual grasses such as cheatgrass (Davies and Johnson 2017, p. 748; Clements et al. 2017, pp. 179-180, Ott et al. In press, pp. 6, 10). Seeded deep-rooted nonnative perennial species, such as crested wheatgrass and forage kochia, have been extensively used for post-fire soil stabilization efforts in the Great Basin, including within the range of slickspot peppergrass, due to their ability to decrease soil erosion risk, exclude cheatgrass at a lower cost than native species, and their relative ease of establishment compared with native perennial bunchgrasses (Davies et al. 2013, p. 472). (USFWS, 2020)

**Stressor:** Development (USFWS, 2020)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** In the Service's 2009 listing rule, residential, commercial, and agricultural development was identified as a secondary threat to slickspot peppergrass in the Foothills and Snake River Plain geographic areas (74 FR 52036-52037). More recently, residential and commercial development, inclusive of infrastructure, was identified as one of the most extreme and widespread disturbances documented to impact the species within the Foothills and Snake River Plain geographic areas (Miller and Kinter 2018, p. 38). Development can affect slickspot peppergrass through direct destruction of populations and loss of slick spot microsites. Development can also have indirect impacts by contributing to nonnative plant invasions, particularly along associated utility lines and roads, which act as corridors for nonnative plant invasions (Forman and Alexander 1998, p. 210; Gelbard and Belnap 2003, pp. 424-425, 430-431; Bradley and Mustard 2006, p. 1142); increased human-caused ignition of wildfires, presumably by increasing the area of the urban-wildland interface (e.g., Keeley et al. 1999, p. 1829; Romero-Calcerrada et al. 2008, pp. 341, 351; Syphard et al. 2008, pp. 610-611); increased off road vehicle use; and increased habitat fragmentation, which can pose problems for slickspot peppergrass by creating barriers in the landscape to pollinators that prevent effective genetic exchange within or among populations (Robertson et al. 2004, pp. 2-4). (USFWS, 2020)

**Stressor:** Owyhee harvester ants (USFWS, 2020)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** While effects of herbivory on slickspot peppergrass by mammals and most insects has not been identified as a significant stressor (IDFG in litt. 2018, p. 6), in recent years, concern has emerged over potential detrimental effects of seed predation by Owyhee harvester ants. Owyhee harvester ants are a native species that thrive in open grassy areas throughout southwest Idaho, including areas occupied by slickspot peppergrass where shrubs have been lost. These ants consume the seeds of small-seeded species (including slickspot peppergrass) preferentially over large-seeded species such as cheatgrass (Schmasow and Robertson 2016, p. 955). Studies have shown that Owyhee harvester ants can remove up to 90 percent of slickspot peppergrass fruits and seeds from individual plants, either directly from the plant or by scavenging seeds that drop to the ground (White and Robertson 2009b, p. 511; Robertson and Crossman 2012, pp. 14-15; Jeffries 2016, entire). The extent to which seed predation by harvester ants impacts slickspot peppergrass seed recruitment within slick spots and populations is currently under investigation. Slick spots with low numbers of flowering slickspot peppergrass plants are likely to suffer high levels of seed loss in a given year (based on the results of White and Robertson 2009b, Robertson and Crossman 2012, and Jeffries 2016), whereas slick spots with large numbers of plants may overwhelm the ants' capacity to consume seeds (Robertson 2018, personal communication). (USFWS, 2020)

**Stressor:** Improper Livestock Grazing (USFWS, 2020)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Livestock use is widespread across the range of slickspot peppergrass. Livestock use in areas that contain slickspot peppergrass can result in both positive and negative effects on the species, depending on factors such as intensity, timing, and duration of use. Livestock grazing may be used as a tool to ameliorate the primary threats of wildfire and invasive annual grasses on slickspot peppergrass. Domestic cattle are not known to feed on slickspot peppergrass, and

domestic sheep have been observed uprooting but not consuming plants (D. Quinney and J. Weaver pers. comm. 1998). Although direct herbivory of slickspot peppergrass by livestock has not been documented to occur, livestock grazing can impact slickspot peppergrass through trampling and interactions with the nonnative invasive plant cycle. (USFWS, 2020)

**Stressor:** Climate Change (USFWS, 2020)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Warmer temperature regimes and changes in precipitation associated with global climate change represent another risk factor for slickspot peppergrass. Consequences of climate change, if current projections occur, are likely to exacerbate existing primary threats (modified wildfire regime and invasive nonnative plants, particularly cheatgrass) to slickspot peppergrass conservation. Researchers confirmed “experimentally that, in an intact ecosystem, elevated carbon dioxide may enhance the invasive success of Bromus spp. in arid ecosystems,’’ and suggest that this enhanced success will then expose these arid areas to accelerated wildfire cycles (Smith et al. 2000, p. 81). Chambers and Pellant (2008, p. 32) also suggest that higher carbon dioxide levels are likely increasing cheatgrass fuel loads due to increased productivity, with a resulting increase in wildfire frequency and extent. Furthermore, current climate change models predict future climatic conditions within the range of slickspot peppergrass will favor further invasion by cheatgrass (Smith et al. 1987, pp. 142-143; Smith et al. 2000, p. 81; Brown et al. 2004, p. 384; Neilson et al. 2005, pp. 150, 156; Chambers and Pellant 2008, pp. 31-32). These and other models (Littell et al. 2009, p. 1019; Abatzoglou and Kolden 2013, p. K; Westerling et al. 2014, p. 91; McKenzie and Littell 2017, p. 29) also project that wildfire frequency will continue to increase, and the extent and severity of wildfires may increase as well. Thus, the projected consequences of climate change are acting to exacerbate the primary threats of frequent wildfire and invasive nonnative plant species on slickspot peppergrass throughout its range. (USFWS, 2020)

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 11C

**Delisting Criteria:**
Not available; a Recovery Plan has not been issued.

**Recovery Actions:**
- Not available; a Recovery Plan has not been issued.

***Conservation Measures and Best Management Practices:***
- Currently, there are six formalized plans that incorporate specific conservation measures for slickspot peppergrass: • The Candidate Conservation Agreement for Slickspot Peppergrass between the State of Idaho, BLM, Idaho Army National Guard and nongovernmental cooperators (private landowners who also hold livestock grazing permits on BLM lands) (State of Idaho et al. 2003, as updated in 2006); • The BLM and U.S. Fish and Wildlife Service Conservation Agreement for existing BLM land use plans (USBLM and USFWS 2006, as updated in 2009, 2013, and 2014). Once conservation measures of identical or greater conservation value are incorporated into all applicable

BLM land management plans, the term of this Conservation Agreement will be concluded. One applicable BLM land management plan where conservation measures have yet to be incorporated (the Four Rivers Resource Management Plan) remains. Conservation measures with identical or greater conservation value than this Conservation Agreement have been incorporated into two recent BLM land use plans: o The 2008 Morley Nelson Snake River Birds of Prey National Conservation Area Resource Management Plan (as contained within Appendix 8 of the 2008 Record of Decision), and o The 2015 Jarbidge Approved Resource Management Plan. • The Idaho Army National Guard's Integrated Natural Resource Management Plan for the Orchard Combat Training Center (National Guard 1991, as updated in 1997, 2004, 2008, and 2013); and • The Mountain Home Air Force Base's Integrated Natural Resource Management Plan, which includes the Juniper Butte Range (Air Force 2004, as updated in 2012 and 2018). (USFWS, 2020)

- The BLM's Jarbidge and the Paradigm fuel break projects have the potential to reduce the risk of wildfires within portions of the range of slickspot peppergrass. However, these fuel break projects do not address the co-occurring effects of existing invasive nonnative annual grasses, one of two primary threats identified for the species, or the conservation need for sagebrush steppe habitat restoration. Considering all of these factors, it is unlikely that these large fuel break projects on their own will adequately address threats such that future population viability is maintained or improved in this portion of the species range. Although fire suppression, including Rangeland Fire Protection Associations, and fuels management efforts currently in place are a positive conservation step for slickspot peppergrass and its habitat, they are not sufficient at this time to offset effects of current and future extent of invasive nonnative plants or other threats across the range of the species. Effective control of the most significant threats to slickspot peppergrass (wildfire and invasive nonnative plant species, especially invasive nonnative annual grasses) may require efforts that extend beyond the boundaries of slickspot peppergrass populations since these threats are naturally expansive and occur throughout the Great Basin at landscape levels. (USFWS, 2020)
- Approximately 45 percent of slickspot peppergrass habitat is currently located within RFPA or Mutual Aid boundaries, and 70 percent of EO acres located on State Endowment Trust Lands are within fire protection boundaries (1.015 of 1,454 acres) (IDL in litt. 2018, p. 1). However, these areas continue to be at a high risk of large catastrophic wildfires based on conditions associated with low ecological resistance and resilience areas (Chambers et al. 2014a, entire). In addition, while RFPAs have the potential to influence the overall effect of wildfires, they do not address the threat from existing invasive nonnative plant species, the second of two primary threats identified for the species, or the conservation need for sagebrush steppe habitat restoration. Therefore, while the formation of RFPAs are a positive conservation step for sagebrush steppe habitat, RFPAs have not yet shown to be sufficiently effective to offset the primary threat of wildfire to the species. (USFWS, 2020)
- While the Jarbidge and the Paradigm fuel breaks projects have the potential to reduce the risk of wildfires within portions of the range of slickspot peppergrass, these fuel break projects do not address the co-occurring effects of existing invasive nonnative plant species, one of two primary threats identified for the species, or the conservation need for sagebrush steppe habitat restoration. Addressing existing invasive nonnative plants and the restoration of sagebrush steppe habitat are not within the scope of these fuel breaks projects. Considering all of these factors, it is unlikely that these large fuel break projects on their own will adequately address threats such that rangewide future species viability is maintained or improved. Although wildfire suppression, including RFPAs, and fuels management efforts currently in place are a positive conservation step for slickspot peppergrass and its habitat, they are not sufficient at this time to offset effects of current and future extent of invasive nonnative plants or other threats across the range of the species. (USFWS, 2020)

- RECOMMENDATIONS FOR FUTURE ACTIONS Proceed with the development of a Recovery Plan and an associated Recovery Implementation Strategy for the slickspot peppergrass that includes specific, objective, and quantifiable recovery criteria and actions. • Collaborate with the Slickspot Peppergrass Technical Team and other experts to determine recovery requirements for the species. • Develop a strategy for maintaining or restoring Wyoming big sagebrush habitat within and adjacent to slickspot peppergrass element occurrences, which emphasizes the use of native shrubs, grasses, and forbs to benefit slickspot peppergrass and its insect pollinators. • Investigate rangewide population genetics using recent technologies to identify and prioritize conservation of slickspot peppergrass element occurrences essential for maintaining genetic diversity of the species into the future. # SPECIES ACCOUNT: *Lespedeza leptostachya* (Prairie bush-clover)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 01/09/1987; Great Lakes - Big Rivers Region (R3) (USFWS, 2016). Recommended for delisting (2021a)

**Physical Description**

Herbaceous perennial; sericeous stems of mature plants are erect, up to a meter tall, and may be either simple or branched. The linea ror narrowly oblong leaflets of the trifoliate leaves are 2-4 cm long and 2-8 mm wide with appressed pubescence above and silky hairs below. The longer terminal leaflets are lss than half as wide as long, with petioles 2-10mm long. Petals of the chasmogamous (open, potentially outcrossing) flowers are white, or yellowish-white to light pink with a magenta mark in the center of the keel and are between 4 and 6 mm in length. The cream-colored petals of closed, obligately self-pollinating cleistogamous flowers develop within and are usually surrounded by the calyx, which reaches a length of 4.5 to 5 mm when fully developed. Both types of flowers may occur on a single plant or an individual plant may exhibit cleistogamous flowers only (USFWS, 1988).

**Taxonomy**

In the pea family (Fabaceae). There are 40 members o fthis genus, of which 12 are native to North America. Also known as slender-leaved bush clover (USFWS, 1988)

**Historical Range**

Former range included 27 counties in Minnesota, Wisconsin, Iowa, and Illinois (USFWS, 1988).

**Current Range**

Prairie bush-clover has been found across four states: Illinois, Iowa, Minnesota, and Wisconsin (Figure 1.2). Populations considered historical around the time of listing (1988) were documented in 28 counties across all four states (USFWS 1988, p. 4). The number of known extant populations has increased in Iowa, Minnesota, and Wisconsin. Additional populations were found in Minnesota as a result of increased survey effort post-listing. For example, seven new prairie bush-clover populations were discovered in 1990 (Sather 1991, p. 1). (USFWS, 2021)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: self-pollination, cross-pollination (NatureServe, 2015)

**Lifespan**

Adult: 30 years (USFWS, 2021)

**Breeding Season**

Adult: July - September (NatureServe, 2015; USFWS, 1988), Seed germination begins in May and continues through July (USFWS 1988, p. 12; Figure 1.5), the production of chasmogamous flowers lasts until mid-August and the production of cleistogamous flowers occurs into September

**Key Resources Needed for Breeding**

Adult: Insect pollinators, possibly scarification/fire (NatureServe, 2015)

**Other Reproductive Information**

Adult: The longevity of prairie bush-clover seeds in the soil is relatively unknown; however, a study examining seed germination and the seed bank of prairie bush-clover found that the large majority (about 95%) of seeds germinated during the second year. Individual prairie bush-clover plants have been documented entering a period of dormancy that may last 1-2 years. Individual plants may enter dormancy in response to increased competition and/or lack of disturbance (grazing) (Bockenstedt 2002, p. 45). (USFWS, 2021)

**Reproduction Narrative**

Adult: Blooms mainly in mid-July. Lespedeza species produce both larger, showy chasmogamous flowers and greatly reduced cleistogamous flowers. The cleistogamous flowers are obligately self-pollinated. Clewell (1966a) demonstrated that the chasmogamous flowers of other members of the genus are more often self- pollinated than cross-pollinated, thus Lespedeza has a strong tendency towards autogamy. In one study, only 20% of pods contained seeds (Baskin pers. comm.). Pollinators for some other Lespedeza species are known: Bombus fraternus (L. capitata and L. virginica), Xylocopa micans (L. steuvei, L. angustifolia), Campsomeris plumipes (same species), and Epargyreus clarus (same species). Haugen and Fitch (1955) have suggested that surface fire might cause scarification in Lespedeza bicolor. Clewell (1966a) found that germination success of L. cuneata increased following heating in an oven 90C for 30 minutes. On the other hand, L. leptostachya has been germinated in both Illinois and Kentucky without scarification (Kurz and Bowles 1981, Baskin pers. comm.). Smith (pers. comm.) has observed germination in the absence of fire every year for four years at one site in Minnesota (NatureServe, 2015). Plants under cultivation have been observed to flower the same year they germinated, whereas wild plants may require 5 or more years to reach maturity. Mature plants have been observed to flower repeatedly over four sequential sampling seasons. It is estimated that individual plants frequently live ten years or more. Growth and development of terminal inflorescences continues into early September (USFWS, 1988).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Dry to mesic gravel and sandy prairie (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Possibly a disturbance regime (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: 0.3 - 1.9 per sq. m (USFWS, 1988)

**Tolerance Ranges/Thresholds**

Adult: Moderate (NatureServe, 2015)

**Habitat Narrative**

Adult: Inhabits dry gravel prairies and dry-mesic prairies in Illinois (Steyermark and Swink 1955, Kurz and Bowles 1981), dry-mesic prairies in Minnesota (Smith 1981) and Iowa (Huston 1981), dry prairie and sandy prairie in Wisconsin (Tans and Read 1975). Characteristics of dry gravel and dry-mesic prairies in Illinois include steep, well-drained, usually calcareous soil sites (White and Madany 1978). Smith (1981) noted that five of six Minnesota sites are north or northwest-facing slopes of 10 to 15 degrees, all well drained (the sixth site was on level ground). Apparently withstands moderate grazing. May require disturbance for reproduction and to reduce competition (NatureServe, 2015). Estimates of density in 1986 range from 0.3 to 1.9 plants per square meter (USFWS, 1988). Prairie bush-clover is endemic to Midwestern prairies in Illinois, Iowa, Minnesota, and Wisconsin. The majority of populations at the time of listing were found on gentle, north-facing slopes of 10-15 degrees. Surveys conducted over the last thirty years have found that the species can occur on north, west, and east-facing slopes. Plants are usually found around the edges of slopes or within barely concave areas that are not subject to nutrient or herbicide input from drain-tile discharge (Nancy Sather, Minnesota Department of Natural Resources (MNDNR), retired, pers. comm, June 30, 2021). Soil types include, but are not limited to fine silty loam, sand, fine sandy loam, or clay loam (USFWS 1988, p. 2; Cole and Biesboer 1992, p. 567). Prairie bush-clover also occurs at bedrock outcrop sites interspersed with upland prairie (USFWS 1988, p. 8). The species occurs on disturbed sites or prairie habitats that have been previously mowed, burned, cultivated, or grazed, in addition to undisturbed remnant prairie sites (USFWS 1988, p. 7, Nancy Sather, MNDNR, retired, pers. comm., June 30, 2021). Prairie bush-clover can thrive in great numbers on actively grazed sites (Nancy Sather, MNDNR, retired, pers. comm., June 30, 2021). The known range of prairie bush-clover overlapped with the bison (Bison bison) range and, as a result, the species co-evolved with grazing (Todd Bittner, Cornell Botanical Garden, pers. comm., June 22, 2021). Many sites that are currently protected in Minnesota are former pastures where the species was discovered only when systematic grassland surveys targeted them as potential habitat. At one heavily grazed pasture site in Minnesota, 1,117 prairie bush-clover plants shorter than 10 cm (3.9 inches) were discovered. The population was similar to other formerly grazed sites where flowering prairie bush-clover plants are visible approximately three years after the cessation of grazing (Nancy Sather, MNDNR, retired, pers. comm., June 30, 2021). At formerly cultivated sites, the species was visible and widely dispersed across the site, rather than the patchy distribution common at southwestern Minnesota sites, a few years after cultivation ended. It is likely that prairie bush-clover seeds in the seed bank were spread across the site due to cultivation practices (Nancy Sather, MNDNR, retired, pers. comm., June 30, 2021) (USFWS, 2021).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Within the genus there are no special structures to aid in seed dispersal, and seed dispersal is probably via animals consuming the fruits and passing the seeds. Clewell (1966a) tested 108 seeds of other members of the genus that were consumed by bobwhite quail (Colinus virginianus) and obtained 100% germination success. He also tested 16 seeds that were consumed by small mammals, and obtained 89% germination success (NatureServe, 2015). Seed dispersal mechanisms for prairie bush-clover are largely unknown; however, seeds are thought to be dispersed by either gravity or animal activity (for example, voles, small rodents) (Bockenstedt 2002, p. 4). (USFWS, 2021)

***Population Information and Trends***

**Population Trends:**

Increasing (USFWS, 2021a)

**Resiliency:**

Thirty-seven prairie bush-clover populations or 33% currently exhibit excellent or good resiliency across all four states in the geographic range. The 12 populations that are in excellent condition all have over 1000 individual prairie bush-clover plants and no evidence of significant and recent (defined as occurring over the last 20 years) decline. The majority (8 or 67%) of the populations ranked as excellent are composed of high-quality prairie with minimal threats due to persistent management and 10 or more acres of contiguous suitable habitat. Ten populations with excellent resiliency are owned by a conservation organization or are permanently protected for purposes of conservation. One population is owned privately or by an organization that is currently interested in conservation and one population is currently not protected. The 25 prairie bush-clover populations currently ranked as having good resiliency all have at least 10 individual plants, with the majority of those populations having 100 or more. All but two of these populations occur in areas with high or fair quality prairie habitat with minimal threats and/or persistent management. Two populations occur at sites with degraded prairie habitat and inconsistent management. The amount of suitable contiguous habitat at populations with good resiliency varies from less than 1 acre to 10 or more acres. The majority (18 or 72%) of prairie bush-clover populations exhibiting good resiliency are owned by a conservation organization and are permanently protected for purposes of conservation. Five populations are currently unprotected with no informal agreement in place. One population is owned privately or by an organization that is currently interested in conservation and one population has an informal agreement in place. The majority, 76 populations or 67%, of prairie bush-clover populations rangewide currently exhibit fair or poor resiliency. Populations with fair resiliency have 99 or fewer plants or have shown significant recent decline (as determined by state biologists and species experts), degraded habitat due to high impact grazing, brush encroachment and/or non-native, invasive species, with inconsistent management. These populations are generally characterized as having one to four acres of contiguous suitable habitat and the landowner has an informal conservation agreement in place. Thirty-five populations currently have poor resiliency. Populations exhibiting poor resiliency generally have fewer than 10 plants or have shown significant recent decline and are present in low quality habitat with no management. Non-native, invasive species are the dominant vegetation at these sites and suitable contiguous habitat is less than one acre. The sites are not protected from future land conversion. In addition, 12 populations are currently considered extirpated. (USFWS, 2021).

**Representation:**

The distribution of extant prairie bush-clover (Lespedeza leptostachya) by representative category. Representative Category. Dry Prairie. Number of Extant Populations: 52. Percent of Populations 46%. Representative Category. Dry-Mesic Prairie. Number of Extant Populations: 41. Percent of Populations 36%. Representative Category. Mesic Prairie. Number of Extant

Populations: 14. Percent of Populations 12%. Representative Category. Bedrock Prairie. Number of Extant Populations: 6. Percent of Populations 5%. (USFWS, 2021).

**Redundancy:**

Redundancy describes the ability of a species to withstand catastrophic events by maintaining multiple, resilient populations across the species' geographic range. The redundancy of prairie bush-clover is based on its 113 extant populations distributed across Illinois, Iowa, Minnesota, and Wisconsin and the four prairie habitat types that we define as representative categories. Individual populations in each of the four prairie habitat types (representative categories) are dispersed throughout the species' overall range, and, therefore, are distributed geographically. Thus, the number and resiliency of populations in each representative category also characterizes current distribution (redundancy) in terms of the spatial impact of a catastrophic event. (USFWS, 2021).

**Number of Populations:**

113 (USFWS, 2021)

**Population Size:**

24,530 (USFWS, 1998)

**Population Narrative:**

There are about 32 extant populations, and many of these are small (<150 stems) (NatureServe, 2015). Total population size in peripheral populations is 1,923 and 22,607 in core populations (USFWS, 1988). As of 2020 (over 30 years later), there are 113 known extant populations across the four states (USFWS, 2021). The number of known populations of prairie bush-clover has increased from 36 populations at the time of listing in 1987 (52 FR 783) to 113 populations today. The number of known extant populations has increased in Iowa, Minnesota, and Wisconsin. Additional populations were found in all four states as a result of increased survey effort post-listing. For instance, seven new prairie bush-clover populations were discovered in Minnesota in 1990 (Sather 1991, p. 1) (USFWS, 2021a).

***Threats and Stressors***

**Stressor:** Habitat loss and degradation (USFWS, 1988)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Threatened by loss of habitat due to agriculture and urbanization, may be threatened by plant succession, lack of natural disturbance (which prevents shrub invasion) at individual sites, and slow germination and seedling establishment rates. Specific threats to occurrences include use of herbicides or run-off containing herbicides at Cihak Prairie (Jackson Co., Minnesota; Smith 1981). Quarry operations threaten the Morton Outcrop (Renville Co., Minnesota; Smith 1981) site and the Winnebago Co. (IL) site (Kurz and Bowles 1981). At least four sites are presently being grazed (USFWS 1987). Woody species invasion threatens two sites in Wisconsin and two in Minnesota (USFWS 1987). Roadside mowing and weedy vegetation is threatening a site near a housing development in Wisconsin (Richardson pers. comm.) (USFWS, 1988).

**Stressor:** Herbivory (USFWS, 1988)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbivory by both insects and mammals may contribute to mortality. Insect herbivory has been reported for Illinois, Minnesota and Iowa populations. Young leaves and growing tips of young plants are damaged by insects throughout the summer. There is evidence of infestation by Cuculionid or Brucid beetles in Minnesota populations. At time, damage by mammals may reach significant proportions in localized areas (USFWS, 1988).

**Stressor:** Succession (USFWS, 1988)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Tentative evidence suggest that L. leptostachya is detrimentally affected by woody invasion but no data are available adequately to evaluate the threats (USFWS, 1988).

**Stressor:** Hybridization (NatureServe, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Hybridization with L. capitata is known to have occurred at two sites in Minnesota, one in Iowa, and one in Illinois (USFWS 1988).

**Stressor:** Herbicide Use
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Incompatible use of herbicides at known population sites would directly impact an individual plant’s ability to produce seeds and may disrupt connectivity across microhabitats. Seed dispersal may also be impacted due to a decline in pollinators, which are largely unknown for prairie bush-clover. Prairie bush-clover populations located near agricultural fields or adjacent to existing roadways may be at increased risk of exposure to herbicide use (USFWS 1988, p. 15). (USFWS, 2021).

**Stressor:** Habitat Conservation
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Conversion of documented prairie bush-clover sites to row crops and gravel quarries has destroyed at least two sites in Wisconsin and Illinois (USFWS 1988, p. 14). Agricultural activity resulting in a direct conversion to row-crops destroyed at least one known prairie bush-clover site in Wisconsin (USFWS 1988, p. 14). Conversion of documented populations to rock or gravel quarries has occurred at least once in Illinois (USFWS 1988, p. 15). One unprotected Illinois population was lost due to commercial development (Todd Bittner, Cornell Botanic Garden, pers. comm., June 22, 2021). Extant prairie bush-clover populations located on private land are at risk of conversion to row crop or rural residential development (USFWS 1988, p. 14), and populations located adjacent to existing rights of way are at risk due to potential roadway expansion in the

future (USFWS 1988, p. 15). (USFWS, 2021).

**Stressor:** Climate Change
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change may act as a stressor on the species by promoting non-native vegetation growth and exacerbating drought conditions. Changes in precipitation regimes are anticipated with fewer, but larger events followed by prolonged dry periods and drought stress (Knapp et al. 2008, p. 816). These alterations may create novel ecosystems that suppress native plant species and promote expansion of invasive, non-native species into prairie bush-clover habitat (Knapp et al. 2008, p. 817). Climate change may also promote dominant, non-native vegetation growth and encroachment with the increase in $CO_2$ and subsequent increase in plant biomass (Blumenthal et al. 2013, p. 1161). Increased biomass at sites with prairie bush-clover populations may lead to increases in thatch, or layer of organic plant matter, which makes seed germination increasingly difficult. Altered precipitation and temperature regimes may influence when management activities in prairie habitat can occur by increasing or reducing opportunities for the use of prescribed fire. Prolonged periods of warmer temperatures may allow for more opportunities for prescribed burning, while increased precipitation in the spring or early summer may constrain when prescribed burns may occur. Ultimately, the timing of prescribed burns may become increasingly unpredictable due to variable temperatures and changes in precipitation regimes (Wisconsin Initiative on Climate Change Impacts 2017). (USFWS, 2021).

**Stressor:** Dominant Vegetation Encroachment
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Prairie systems are reliant on natural disturbance regimes to maintain the structure of the prairie. Without fire, grazing, or other natural disturbances, prairie communities may transition to scrubshrub or early successional habitat types. Mature prairie bush-clover plants can succumb to prolonged competition with woody vegetation encroachment. This has been documented at populations in Wisconsin and Minnesota (Nancy Sather, MN DNR retired, pers. comm., June 30, 2021). There are a number of invasive, non-native plant species, including buckthorn, that currently pose a threat to prairie bush-clover populations with no active management or management plans in place. Native dominant woody plant species documented at sites include: Buckthorn species (Ceanothus species), Hawthorn species (Crataegus species), eastern red cedar (Juniperus virginiana), quaking aspen (Populus tremuloides), cherry species (Prunus species), burr oak (Quercus macrocarpa), black oak (Quercus velutina), smooth sumac (Rhus glabra), staghorn sumac (Rhus typhina), western snowberry (Symphoricarpos occidentalis), and riverbank grape (Vitis riparia) (USFWS 1988, p. 10). (USFWS, 2021).

**Stressor:** Drought
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Prairie bush-clover predominantly occurs in habitats with dry soil types (dry prairie, bedrock prairie) or characteristics (dry-mesic prairie), which makes the species relatively droughttolerant; however, populations at sites with mesic soil types (mesic prairie) may be

subjected to additional stress from prolonged drought periods (Knapp et al. 2008, p. 816). Prolonged drought events lasting multiple consecutive growing seasons may have long lasting impacts on populations. If conditions are not favorable, the prairie bush-clover may enter a state of dormancy for a year; however, if unfavorable conditions persist for two or more years, dormant plants may not survive. Non-dormant plants may produce fewer chasmogamous flowers which may further impact the genetic diversity of a population. A prolonged drought may also have a significant impact on seedling survival (Kevin Doyle, Wisconsin Department of Natural Resources, pers. comm., June 22, 2021). (USFWS, 2021).

**Stressor:** Hybridization
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** There have been numerous documented reports of hybridization between prairie bush-clover and round-headed bush clover (Lespedeza capitata) in all four states (Fant et al. 2010, p. 2197). Both species are found in remnant prairie habitats and have overlapping flowering periods (USFWS 1988, p. 16). Hybrids have been documented at Minnesota sites since the early 1980s (Nancy Sather, MNDNR, retired, pers. comm., June 30, 2021). Numerous hybrid plants were observed at Jeffers Petroglyphs National Monument in 1995 (MN Natural Heritage Program 1995, p. 4). The number of prairie bush-clover populations with hybrids and the number of hybrid plants within populations has steadily increased since 1987, when only two Minnesota populations had documented hybrids (Nancy Sather, MNDNR, retired, pers. comm., June 30, 2021). Now hybrids are present in all four states in the prairie bush-clover range (Fant et al. 2010, p. 2197). No systematic documentation of hybrids has been conducted in Minnesota; however, biologists recently discovered that one of the first populations to support hybrids had been completely swamped by morphological hybrids (Nancy Sather, MNDNR, retired, pers. comm., June 30, 2021). Hybrid plants have vegetative traits (stem circumference, leaf width, and petiole length) that often are intermediate between the round-headed bush clover and the prairie bush-clover. Genetic testing indicated that prairie bush-clover acts as the seed-bearing parent (Fant et al. 2010, p. 2202). The hybrid plants may also be capable of self-fertilization, as both parent species produce cleistogamous flowers. At least one instance of back-crossing has been observed at a site in Minnesota. This occurs when a hybrid individual crosses with one of the hybridizing species (round-headed bush clover or prairie bush-clover) and produces an offspring that is morphologically and genetically similar to the parent, in this case, prairie bush-clover (Nancy Sather, MNDNR, retired, pers. comm., June 30, 2021). Prairie bush-clover is not a genetically diverse species, so genetic assimilation to round-headed bush clover may serve as a threat to the genetic diversity of prairie bush-clover (Fant et al. 2010, pp. 2203). For this report, we considered the potential impacts of hybridization qualitatively, rather than quantitatively as it's unclear how many populations have documented hybrid plants. (USFWS, 2021).

***Recovery***

**Reclassification Criteria:**
Not available

**Delisting Criteria:**
1. Protect and bring under appropriate management a minimum of twenty viable naturally-occurring populations of prairie bush-clover within the core habitat area (USFWS, 1988).

2. Protect and manage a minimum of fifteen viable naturally-occurring populations (representing the full range of habitat types) outside the core habitat area (USFWS, 1988).

**Recovery Actions:**

- Protect selected viable populations and their habitat. Initiate landowner awareness and permanent portection activities. Stabilize protection with long-term management plans and agreements (USFWS, 1988).
- Provide appropriate management at each protected site (USFWS, 1988).
- Inventory to locate additional populations. Search historical sites where prairie bush clover has been found and habitat is still present. Identify and search potential new sites (USFWS, 1988).
- Monitor population trends at known sites (USFWS, 1988).
- Establish artificial seed banks for selected populations (USFWS, 1988).
- Provide appropriate public information (USFWS, 1988).
- Conduct appropriate research. Determine important habitat parameters, including characterization of soils. Increase knowledge of species and population biology (life history, population structure and dynamics, competition, predation). Determine natural seed bank (USFWS, 1988).
- Study the response of populations to a variety of potential management techniques (fire, grazing, mowing, pesticides, shrub and tree removal) (USFWS, 1988).
- Determine genetic diversity within and between populations (USFWS, 1988).
- Management objectives should include maintaining population size in good condition occurrences and increasing population size in degraded occurrences. Monitoring should be used to track the accomplishment of these objectives. Monitoring will be critical at Anderson Prairie, Iowa, where the herbicides Banvel and 2,4,D were applied to an area with two stands of L. leptostachya in June 1985 (Roosa pers. comm.) (NatureServe, 2015).
- In Minnesota, Smith (pers. comm.) has been monitoring one population using a bi-coordinate system that enables workers to map and relocate individual plants and to record demographic data each year. Smith's method has also been adapted for use at another site in Minnesota (Sather 1987) and one in Iowa (Nekola 1985) (NatureServe, 2015).
- In Illinois, yearly stem counts are taken at sites being monitored for management response (Schwegman pers. comm., Packard pers. comm.) (NatureServe, 2015).
- In Wisconsin, stem counts are made each year (Martin, Richardson, pers. comm.) (NatureServe, 2015).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Over the next five-years, the following conservation actions are recommended to directly benefit and assist in the continued recovery of prairie bush-clover. • Coordinate survey efforts across the geographic range of the species and assess the status of populations that have not been monitored for over 10 years (2011 or earlier) with an emphasis on populations characterized as having excellent or good resiliency. • Increase the number of protected populations across representative categories. This may include implementing and/or increasing outreach efforts with private landowners. • Manage habitat to support prairie bush-clover populations through practices that duplicate the natural processes of the prairie ecosystem (prescribed burns, grazing, or other methods to manage non-native, invasive species and/or encroaching woody vegetation). • Encourage and support research focused on identifying and documenting prairie bushclover pollinators, their abundance, and life histories. (USFWS, 2021a).

# SPECIES ACCOUNT: *Lesquerella lyrata* (Lyrate bladderpod)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 9/29/1990; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

An annual made up of one to several, usually simple and erect stems of 1 to 3 decimeters (din) (4 to 12 inches) (in.) in length. Leaves and stems are shortly pubescent. The outer stems are usually decumbent at the base. Basal leaves are stalked and lyrate-shaped, 2 to 7 centimeters (cm). (0.8 to 2.8 in.) long and 6 to 15 millimeters (mm) (0.2 to 0.6 in.) wide. The terminal lobes are large and orbicular to elliptic in shape. The stem leaves are ovate to broadly oblong and obtuse, 5 to 20 mm (0.2 to 0.8 in.) long and 4 to 10 mm (0.2 to 0.4 in.) wide, and sessile with prominent ear-like projections (auricles) at the bases. The margins of the stems are nearly smooth to coarsely toothed. Inflorescences are dense. The flowers are ascending on densely pubescent stalks 1 to 1.5 cm (0.4 to 0.6 in.) long. Sepals are pubescent, yellowish, oblong, 3 to 4 mm (0.1 to 0.2 in.) long and 1.2 to 1.5 mm (0.1 in.) wide. Petals are yellow, broadly ovate, 5 to 7 mm (0.2 to 0.3 in.) long and 3.5 to 4 mm (0.1 to 0.2 in.) wide, and slightly rounded. The fruits are siliques, which are glabrous, globose in shape, 2.5 to 3.5 mm (0.1 in.) high and 3 to 4 mm (0.1 to 0.2 in.) broad. Seeds are flattened, brown, oval to nearly orbicular in outline, and margined, and range from 1.5 to 2.5 mm (0.1 in.) on the longest dimension (USFWS, 1996).

**Taxonomy**

Rollins (1955) considered L. lyrata to be an evolutionary link between L. densipila and L. auriculata, the somewhat closer relationship being with the former. Kral (1983) noted the close resemblance of L. lyrata and L. densipila, that the fruits of D. lyrata were slightly smaller and that both the fruit and the persistent styles are perfectly glabrous. McDaniel (1987) suggested that this difference, while consistent, was insufficient to justify recognition at the species level, and stated that assignment to varietal rank would be more appropriate. However, no worker has formally provided data to support such a change in taxonomic status (USFWS, 1996).

**Historical Range**

The current and historical distribution of D. lyrata is confined to parts of Franklin, Colbert, and Lawrence counties in Alabama. (USFWS, 1996)

**Current Range**

The current and historical distribution of D. lyrata is confined to parts of Franklin, Colbert, and Lawrence counties in Alabama. (USFWS, 1996)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

<u>Adult:</u> ~1 year (USFWS, 2009)

**Breeding Season**

Adult: March - April (USFWS, 2009)

**Reproduction Narrative**

Adult: The lyrate bladderpod is a winter annual with a long-lived seed bank. Flowering takes place usually from mid-March to April (USFWS, 2009).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Limestone outcropping/hill, glades (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Early successional habitats, disturbance (USFWS, 2009)

**Geographic or Habitat Restraints or Barriers**

Adult: Shading (USFWS, 2009)

**Environmental Specificity**

Adult: Moderate (NatureServe, 2015)

**Habitat Narrative**

Adult: Inhabits red soils, limestone outcroppings and hills, disturbed cedar glades and glade-like areas (open pastures, cultivated fields, bottomlands, and roadsides in calcareous areas) (FNA 2010) (NatureServe, 2015). The lyrate bladderpod appears to be an early successional species that historically colonized the shallow soils on or adjacent to cedar glade habitats. This species slowly disappears as the soil layer develops and other competing plants establish themselves (U.S. Fish and Wildlife Service 1996). Shading causes decreased vigor and death and decreases the number of seeds at the site (Baskin and Baskin 1998, 2000). Disturbance is needed primarily to remove competing vegetation and also to bring seeds to the soil surface for germination (Baskin and Baskin 2000, U.S. Fish and Wildlife Service 1990, 1996; Webb and Kral 1986). The need for ground disturbance to maintain populations is evidenced in the fact that the best populations are those that are subject to some type of recurring disturbance such as grazing, plowing, and mowing (USFWS, 2009).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2024)

**Number of Populations:**

3 (USFWS, 2019)

**Population Narrative:**

Currently, there are three sites in three different counties known for this species (USFWS, 2019). The species is limited to three populations in three counties in northwest Alabama. Two of the three populations are not protected and appear to be declining. The unprotected populations are located on disturbed remnants of cedar glades. Cedar glades have been fragmented by agriculture and development and mostly exist as remnants today (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Herbicide Use (USFWS, 1996)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat/Loss of individual plants
**Narrative:** The use of pre-emergent herbicides on agricultural crops as well as the use of herbicides as part of road side/easement maintenance is listed as threat to this species (USFWS, 1996).

**Stressor:** Road improvement (USFWS, 1996)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Road improvement is listed a s a threat to this species (USFWS, 1996)

**Stressor:** Proposed rock quarry (USFWS, 1996)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** At the time of the 1996 Recovery Plan a proposed rock quarry was threatening the habitat of this species. It is unclear whether this quarry was ever developed (USFWS, 1996).

**Stressor:** Development/Urbanization (USFWS, 1996)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Development for commercial, industrial and housing are listed as a threat to this species (USFWS, 1996)

**Stressor:** Trash dumping (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Trash dumping has destroyed or negatively impacted this species habitat (USFWS, 2009).

**Stressor:** Woody succession (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat

**Narrative:** Lack of disturbance can result in competition (and shade) from invading perennials (USFWS, 2009).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat/Loss of individual plants
**Narrative:** There are no State laws in Alabama protecting the lyrate bladderpod and its habitat. Otherwise, protection is afforded to this species under Section 7 and Section 9 of the ESA. The majority of one of the populations is permanently protected and consistently managed due to its location in a Nature Conservancy preserve. An adjacent portion of this population is currently being managed for the lyrate bladderpod under a voluntary Wildlife Cooperative Extension Agreement (WCEA) until the year 2017 (Hurt 2008a). The management outlined in the WCEA has been beneficial for the species, however, it does not provide for the permanent protection and management of this site (USFWS, 2009).

***Recovery***

**Reclassification Criteria:**
Not available

Recovery Priority Number: 8

**Delisting Criteria:**
Species will be considered for delisting when nine demonstrably secure and self-sustaining populations exist. A demonstrably secure population is defined as one for which legal protection and active, successful management have been established. A self-sustaining population is defined as a population that is shown by monitoring data to be reproducing and relatively stable for at least a 10-year period (USFWS, 1996).

**Recovery Actions:**

- Protect and manage known populations. Negotiate with State and local highway departments and landowners. Develop management plans for each population and site (USFWS, 1996).
- Search for new populations. Conduct searches for additional populations. Continue to re-examine historic occurrence localities. Search for potential relocation/establishment sites for possible use in the future (USFWS, 1996)
- Conduct ecological research. Conduct hybridization studies, studies on seedbank size and seed viability. Study germination relative to natural conditions and agicuultural practices (1996).
- Conduct long-term site and population monitoring. Implement population monitoring. Monitor management techniques and results (USFWS, 1996).
- Maintain seeds and plants ex situ. Maintain seeds and plants (USFWS, 1996).
- Provide information to the public. Conservation efforts with the greatest successes are those with the greatest amount of public support. Plans should be developed to disperse information on D. lyrata to the local public, particularly to agricultural landowners (USFWS, 1996).

- Continue management and monitoring on Lawrence County population (USFWS, 2009).
- Work to secure protection and implement appropriate management for all other populations, most likely through conservation easements (USFWS, 2009).
- Renew contact with State and county highway department to ensure proper protective measures are implemented for those areas where plants occur onto roadside rights-of-way (USFWS, 2009).
- Survey in vicinity of known populations and revisit all known historical sites regularly (USFWS, 2009).
- Work with landowners to reintroduce some type of ground disturbance activity at historical sites during appropriate time of year and follow with survey of sites next flowering season (USFWS, 2009).
- Gather base-line data on all populations and initiate long-term monitoring as means to track population trends and evaluate management efforts (USFWS, 2009).
- Expand species' biology studies to include field experiments (USFWS, 2009).
- Ensure preservation of genetic material from all populations through long-term seed storage through coordination with USDA Seed Storage Laboratory in Fort Collins, Colorado (USFWS, 2009).
- Implement all other tasks identified in the recovery plan, as appropriate (USFWS, 2009).
- Update recovery plan (USFWS, 2009).
- Recovery Priority Number: 8

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES A detailed discussion of recovery actions and criteria are presented in the Recovery Plan (Service 1996). In the course of this status review new and/or targeted potential recovery activities were identified and are included below. These activities are recommended to support and promote recovery of lyrate bladderpod. Recovery Activities • Pursue protection of currently unprotected populations. o Work to renew landowner agreement for property adjacent to Prairie Grove Glade Preserve. o Work to renew contact with State and county highway departments to ensure proper protective measures are implemented for those areas where plants occur within roadside rights-of-way. • Conduct habitat management to control competing vegetation and promote population growth. • Work with landowners to reintroduce some type of ground disturbance activity at historical sites during appropriate time of year and follow with survey of sites next flowering season. • Continue surveys to locate additional populations. • Work with cooperators to expand ex situ (off-site) preservation of genetic material and produce plants for potential outplantings. • Create a management manual for landowners, farmers, and the local transportation departments. Monitoring and Research Activities • Gather baseline data on all populations and implement consistent and long-term monitoring of all populations to track population trends and evaluate management efforts. • Study efficacy and optimal application of various habitat management practices (e.g., mowing, herbicide, prescribed fire). • Define self-sustaining population (USFWS, 2024).

# SPECIES ACCOUNT: *Lesquerella pallida* (White bladderpod)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 03/11/1987; Southwest Region (R2) (USFWS, 2016)

**Physical Description**

White bladderpod is an annual member of the Brassicaceae or Mustard Family. The plant overwinters as a tap-rooted, leafy rosette, reaching a maximum height of two feet as an erect plant or may be spreading. The white flowers appear in April and May and are composed of four one-half inch long petals. It produces pea shaped "bladderpods" that enclose the seeds before dying as its harsh habitat dries in the summer heat. Seed set occurs from late May to early June and the dormant stage begins in July and usually last until October.

**Current Range**

White bladderpods are known to occur only on the Weches Outcrops of San Augustine County, Texas.

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Habitat Type**

Adult: Glades within pine-oak forests

**Environmental Specificity**

Adult: Very Narrow (inferred from NatureServe, 2015))

**Habitat Narrative**

Adult: The white bladderpod occurs in natural openings or glades within pine-oak forests on shallow, stony, calcareous sandy loam or sandy clay loam over glauconite or ironstone of the Weches Formation; in addition, these glades are seep-moistened during the winter and spring but become desiccated during the summer (Poole et al. 2007, p. 378). White bladderpod population numbers are heavily influenced by local environmental conditions, such as winter or spring moisture and spring frost, as well as invasion of woody and herbaceous plants that tend to out-compete the white bladderpod.

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

Six extant or unknown abundance populations (USFWS, 2023).

**Population Size:**

112 - 10,000

**Population Narrative:**

Currently, there are eight known populations of the white bladderpod. Seven of the sites are located on private property, and the eighth site is located on private property and the adjacent road ROW of SH 21. Three of the populations were last surveyed in 2001 and found to have an extant population, four other populations were last surveyed in 2006 with extant populations, and the remaining population was surveyed in 2009 and found to have an extant population. White bladderpod population size varies drastically from year-to-year and appears to be due to differences in winter and spring moisture and spring frost or grazing by animals (Service 1992). The population numbers vary from 10,000 to 112 individual plants (see Table 1. for the most recent survey results for the known extant populations of the white bladderpod). Six extant or unknown abundance populations (USFWS, 2023).

***Threats and Stressors***

**Stressor:**
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The primary threats to white bladderpod are the invasion of woody and herbaceous plants into their limited habitat as well as overgrazing (Service 1992). Pasture improvement through the use of herbicides, plowing, and the introduction of non-native pasture grasses can destroy white bladderpod populations and habitat. Since all populations occur partly or wholly on private property, any major changes in land use are detrimental. In addition to home or other building construction, road construction is a threat to the populations of white bladderpod that occur within road ROWs. Rock quarrying poses a significant threat to the species since crushed rock from the Weches formation is used for gravel roads. Areas of suitable habitat within San Augustine County have already been lost to quarrying. Small populations could be prone to extirpation if a series of unfavorable years greatly reduces seed production and depletes the soil seed bank. Recolonization after a population has been lost would require long distance seed dispersal, which appears to be poor in white bladderpod (Service, 1992). )

**Stressor:** Surface Mining (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Mining of glauconite minerals may continue to threaten the white bladderpod within its range. As described in the species 2014 5-year status review, “two EO IDs are located adjacent to a glauconite mine. There has not been an opportunity to survey the sites and therefore it is unknown whether or not these two populations have been impacted by the mining activities.” New glauconite mines in the area have not been developed, however glauconite mining is unregulated and therefore forecasting when and/or where these activities will appear on the landscape is extremely difficult. Mining of glauconite in the vicinity of occupied and suitable moist, alkaline habitat remains a potential threat to the white bladderpod (USFWS, 2023).

**Stressor:** Oil and Gas (USFWS, 2023)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Oil and gas development diminishes habitat quality and quantity through direct loss of habitat, introduction of nonnative species into modified areas of habitat, and an altered site hydrology. The white bladderpod is found atop glade habitats of East Texas's Hayensville Shale; since the white bladderpod can co-occur with the L. texana, (see the Texas golden gladecress SSA (Service 2022, pp. 41-44) for more detail). In San Augustine County in general, the majority of existing pipelines are located in the area north of State Highway (SH) 21 and west of the town of San Augustine. To the east of San Augustine, there are fewer pipelines, but of those that are located in this area, several are large gas transmission lines. The Railroad Commission of Texas (RRC) regulates the oil and natural gas industry in the state of Texas. The RRC has detailed information on all existing pipelines, but the agency has no way to predict future routes for new pipelines or wells. New pipelines and their routes are not displayed on the RRC website and although impacts from pipelines excavations could have an effect on the white bladderpod, specific locations of any future pipeline and any effects on the species and its suitable habitat are unknown. In addition to pipelines, associated oil and gas activities such as drilling and/or maintenance could also affect the white bladderpod and its habitat. Pipeline and well pad construction will continue to be a threat to the species as the demands for oil and gas production within San Augustine County continue. Since 2017, drilling permits issued by the RRC have generally increased over time and permits for 2023 are increasing (Figure 1; RRC 2023). In addition, projects that do not require consultation under Section 7 of the Act including maintenance and expansion associated with oil and gas wells, pads, roadways, etc. are occurring within existing known occupied sites of the white bladderpod. Since a federal nexus is often lacking in these cases, any coordination with the Service is not required (USFWS, 2023)

**Stressor:** Development – Transportation Projects (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** ROW that is managed by TxDOT. Observations from past site visits and TxDOT's online Project Tracker application as of April 2023, show resurfacing projects "underway or beginning soon" along SH 21 both east and west of the towns of San Augustine. On the west side of this town in the stretch of SH 21 where EO ID 12396 is located, the project is marked as ongoing. TxDOT is aware of the plants' presence and is avoiding the EO ID. Additional areas of exposed Weches glades occur within the ROWs within San Augustine County, but as of August 2023 none have been occupied by the white bladderpod (USFWS, 2023).

**Stressor:** Climate Change (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** It is anticipated that effects from climate change could impact white bladderpod. The species is known from a single county known for its climatic extremes of temperature and precipitation (TNC 2003, ii; Diggs et al. 2006, p. 80) and native flora are well adapted to the region. White bladderpod is an edaphic (soil) specialist, restricted to soils with alkaline sediments with unique mineral and water retention properties described as seepy and saturated during the cool moist winter and spring months and dry during the summer (USFWS 1992, p. 4). These features may restrict the plant's capacity to spatially shift into surrounding habitat in response to

a changing climate (USFWS 2014, p. 15). Warnock (1992) documented the effects of its restricted nature with a high variability in population counts, attributing fluctuations to early year frosts and dry springs. The localized effects of climate change on white bladderpod are unknown, however The Intergovernmental Panel on Climate Change (2014, p. 26) projects that temperatures and the intensity and duration of heat waves will increase, which could make these populations less stable and persistent into the future (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 2

**Recovery Actions:**

- The Recovery Plan requires the establishment of 12 self-sustaining populations of white bladderpod and the establishment of agreements for the protection and management of these populations in order to downlist the species from endangered to threatened. The Recovery Plan calls for the protection and management of the populations and habitat, the gathering of biological information necessary for management, establishing a botanical garden population, the search for new populations, and the establishment of new populations as necessary to meet downlisting criteria (Service, 1992). For more detailed information regarding recovery actions for the white bladderpod, please refer to White Bladderpod (Lesquerella pallida) Recovery Plan (Service 1992) (Recovery Plan). Shrub removal from three privately owned white bladderpod sites in 1995 proved to be beneficial, resulting in more plants being present the following spring. However, ongoing brush control is necessary to maintain suitable habitat at these sites. Three seed propagation facilities have been established and maintained, and the Nature Conservancy of Texas has developed a "Conservation Area Plan for the San Augustine Glades" under a Cooperative Agreement with the Service.

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Future actions to aid in the recovery of the white bladderpod should focus on the implementation of the following actions: • Contact the land stewards and managers of all white bladderpod sites. • Work with land stewards to develop and implement management beneficial for the bladderpod. • Continue monitoring and surveys of known populations. • Implement projects and agreements through the Traditional Section 6 program with TPWD, the Service's PFW Program, as well as cooperative agreements with state and federal agencies. • Continue to search for additional populations. • Continue reintroduction efforts. Implement a reintroduction program, adhering to the Service's Controlled Propagation and Reintroduction Policy. • Acquire new conservation agreements with interested parties. • Continue conservation and recovery awareness through public and land steward outreach (USFWS, 2023).

# SPECIES ACCOUNT: *Lesquerella perforata* (Spring Creek bladderpod)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 12/23/1996; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

A herbaceous annual, stems several to many, outer ones usually decumbent (a plant that has its base lying on the ground and a stern that grows upward) at base, inner ones erect, simple or branched, 10 to 15 cm tall, stems and leaves are covered with fine or coarse hairs. Leaves at the base (rosette) have a petiole (leafstalk) and are lyrately (several lobes, which increase in size toward one large terminal lobe) lobed with pointed teeth on the margins. The stem leaves are sessile (stalkless and attached directly at the base), auriculate (ear shaped), oblong to obovate (egg shaped), with few to many teeth on the margins. The cross-shaped flowers are arranged in a raceme (stalked flowers arranged singly along an elongated unbranched axis), have white to pale lavender petals with a yellow base, and are 7 to 9 mm long. The fruits, or pods, are broadly obovoid (egg shaped) to pear-shaped, very inflated, 4 to 7 mm long, and divided into two halves. The outer surface of the pod is papery with very sparse hairs and the inside is densely hairy. The septum (the internal partition between the two halves) is perforated or nearly absent with only a small portion attached to the fruit wall. There are up to 10 round seeds in a pod measuring 1.5 to 2.5 mm long, strongly flattened and surrounded by a thin margin (USFWS, 2006)..

**Taxonomy**

Lesquerella is a genus of the Brassicaceae, the mustard family, named for the seventeenth century Swiss and American botanist Leo Lesquereux. There are approximately 75 taxa of Lesquerella with the majority occurring in the western states; only a few taxa are found in the Interior Low Plateau of Tennessee, Alabama, and Kentucky (Al-Shehbaz 1987). Only one species, Lesquerella lescurii (Nashville mustard), had been described in the eastern states prior to the 1950's work of Dr. Reed C. Rollins, a Harvard University expert on the Brassicaceae. From 1952 to 1955, Rollins described three new species of Lesquerella endemic to the Central Basin of Tennessee, L. densipila (Duck River bladderpod), L. stonensis (Stones River bladderpod), and L. perforata (Spring Creek bladderpod) (USFWS, 2006).

**Historical Range**

See current range/distribution.

**Current Range**

Known only from Wilson County, Tennessee (USFWS, 2006).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Flowering usually occurs in March and April. The fruit splits open upon maturity in late April and early May, and the enclosed seeds are dispersed and lie dormant until autumn. The plant dies back soon after the fruits mature (USFWS, 2006).

**Reproduction Narrative**

Adult: Lesquerella perforata is an annual that germinates between September and early October, overwinters as a small rosette of leaves, and fully develops and flowers the following spring. Full sunlight is required for optimum growth. Flowering usually occurs in March and April. The fruit splits open upon maturity in late April and early May, and the enclosed seeds are dispersed and lie dormant until autumn. The plant dies back soon after the fruits mature. Germination can only occur when the correct temperature coincides with adequate moisture (Pearson 1967). Upon germination, the cycle starts over again. The seeds of L. stonensis can remain viable in the seed bank for at least 6 years, and perhaps those of L. perforata can do the same (Rollins 1955, Kral 1983, Baskin & Baskin 1990, Fitch 2004) (USFWS, 2006).

**Habitat Type**

Adult: Limestone outcrops (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: This species is found mainly where sites have been disturbed by flooding or by cultivation, and tends to occur in areas of full sun on well-drained soils, as well as (rarely) on limestone rock outcrops. Most historic and current occurrences are on flood plains, where periodic flooding removes encroaching grasses and woody plants. Also occurs in places where other types of disturbances "substitute," such as on annually cultivated bottom land fields (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species and the low number of known populations.

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: No information found.

***Population Information and Trends***

**Number of Populations:**

23 (USFWS, 2024)

**Population Size:**

Fluctuates widely from year to year (USFWS, 2006)

**Population Narrative:**

Known from four populations consisting of 13 extant sites in Wilson County, Tennessee. Three additional sites no longer support the species. (U.S. Fish and Wildlife Service 1996) (NatureServe, 2015). Low resiliency, representation and redundancy are inferred by the low number of knownm populations and the specifici habitat requirements of this species. As of 2019, there are 23 extant occurrences of Spring Creek bladderpod. Of the extant occurrences, 8 are located within the Spring Creek watershed, 11 within the Barton's Creek watershed, and 4 within the Cedar Creek watershed. One occurrence (EO 35) was discovered on USACE lands in 2015. All other occurrences are located on privately or municipally owned land. Land management activities, compatible and otherwise, are a primary driver of trends in the species' distribution and abundance. Maintenance of fescue pasture or lawns and applications of winter cover crops and pre-emergent herbicides to agricultural fields are not conducive to annual germination, growth, and reproduction of Spring Creek bladderpod, but are prevalent land uses within the species' geographic range. Fragmentation is not known to be affecting the extant occurrences, but could become a significant threat if occurrences are extirpated as a result of development or changes in management of agricultural lands. (USFWS, 2019). The Spring Creek bladderpod is an annual plant endemic to Tennessee. The species currently occurs in only three HUC 12 watersheds in Wilson County, TN: Spring Creek, Barton's Creek, and Cedar Creek. Since the last status review, one additional occurrence of the species was discovered in the Spring Creek watershed, and one occurrence was designated as extirpated in the Barton's Creek watershed, resulting in a total of 23 extant populations across the range. The species primarily occurs on private land, with no management agreements currently in place (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Cropland conversion to pasture (USFWS, 2006)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The conversion of cropland to pastures that contain grasses (e.g.) fescue poses a threat because of competition and lack of annual disturbance (USFWS, 2006).

**Stressor:** Urbanization/Development (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Those sites on private lands in the City of Lebanon, primarily in Barton's Creek drainage, remain at high risk of loss to urbanization (USFWS, 2011). This includes placing fill material on this species habitat and road building.

***Recovery***

**Reclassification Criteria:**

Spring Creek bladderpod will be considered for reclassification to threatened status when there are 15 protected occurrences, five of which are located within the floodplain of each of three creeks (Spring Creek, Barton's Creek, and Cedar Creek). These occurrences, located on either public or private land, must be protected by a permanent conservation easement with a management agreement. Each occurrence must consist of an average of 500 plants over a five-year period, with no less than 100 plants in any given year (USFWS, 2011).

Recovery Priority Number: 5.

**Delisting Criteria:**
Spring Creek bladderpod will be considered for delisting when there are 25 protected occurrences, with at minimum five occurrences located within the floodplain of each of the three creeks (Spring Creek, Barton’s Creek, and Cedar Creek). Each occurrence located on either public or private land must be protected by a permanent conservation easement with a management agreement. Each occurrence must consist of an average of 500 plants over a ten-year period, with no less than 100 plants in any given year (USFWS, 2011).

**Recovery Actions:**
- We have not met the criteria for reclassifying Spring Creek bladderpod to threatened. No occurrences are protected by conservation easement; though three are protected by non-binding cooperative management agreements. Spring Creek bladderpod abundance fluctuates considerably over time (Table 1). While 500 or more plants have been observed at most of the occurrences at some point in time, fewer than 100 have also been observed at most occurrences at some point in time (USFWS, 2011).
- Continued efforts to implement recovery actions identified in the species’ recovery plan, improve monitoring techniques, and refine guidance for managing Spring Creek bladderpod are necessary. Specific emphasis should be placed on determining whether additional occurrences exist in the Cedar Creek drainage, and efforts should be redoubled to work with private and municipal landowners to ensure long-term protection of known occurrences through conservation easements (USFWS, 2011).

***Conservation Measures and Best Management Practices:***
- Recommendations for Future Actions The Service should continue working with partners to implement recovery actions identified in the species’ recovery plan; in particular, attempts should be made to improve monitoring techniques and mapping of occurrences, search for new occurrences, protect habitat that can be owned or managed by a public entity in perpetuity, and work cooperatively with private and municipal land owners to manage habitat for the species. Emphasis should be placed on determining the current status of occurrences lacking current data, surveying for additional occurrences, establishing conservation easements with private and municipal landowners to ensure long-term protection of known occurrences, and cooperatively managing habitat with private and municipal land owners. The Service recommends carrying out the actions below in an attempt to achieve the recovery criteria for Spring Creek bladderpod: 1. Determine whether EOs 18, 24, and 25 are extant. If Spring Creek bladderpod is not found at these sites, they should be evaluated to determine whether habitat has been destroyed or could be restored by working cooperatively with willing land owners. Sites with restoration potential should be prioritized for determining whether landowners would be willing to cooperatively manage habitat for the species. Additional sites to prioritize for cooperative habitat management include EOs 17, 19, 20, 28, and 34. 2. Conduct annual monitoring, collecting data that can be used to determine whether the recovery standard (i.e., 5-year average of at least 500 plants with no less than 100 in any given year) has been met at a given EO. Sites that meet this standard should be prioritized for protection via land purchase, conservation easement, or cooperative management

agreement. 3. Protect extant occurrences by acquiring occupied parcels or establishing conservation easements or agreements with private, state, and federal partners. The site on USACE lands should be a priority for establishing a cooperative agreement, to ensure appropriate management and monitoring of Spring Creek bladderpod on federal lands. 4. Due to the difficulty of accessing private property, where occurrences are predominantly located, surveys to locate new occurrences should combine use of aerial imagery flown during the species' flowering period, drone surveys, and ground-based surveys (where landowner permission is granted) to accurately determine the extent of populations. Survey effort should be focused in the Cedar Creek watershed, the only watershed within the range of Spring Creek bladderpod where fewer than five occurrences, as required by recovery criteria, are known to exist. Where possible, surveys should target federal or state-owned properties. 5. Conduct experiments to determine whether removing and relocating topsoil containing the seed bank to a secure, protected location is an effective method for minimizing adverse effects of site destruction for development or other purposes. This practice should not at this time be considered avoidance of an adverse effect for purposes of Section 7 consultation, as this is an unproven method. If this practice is determined to be effective, prioritize the identification of watershed-based recipient sites for populations facing extirpation and proactively acquire lands in extant watersheds with this priority. (USFWS, 2019)

- RECOMMENDED FUTURE ACTIVITIES A detailed discussion of recovery actions and criteria are presented in the Spring Creek Bladderpod Recovery Plan (Service 2006). Renewing recently expired conservation agreements and/or identifying landowners with which to develop new management agreements would be supportive of recovery criteria and recovery actions identified in the recovery plan. The priority 1 actions identified in the recovery plan (e.g. establishing protection goals for EOs, pursuing easement or conservation agreements with landowners, developing management plans for EOs, etc.) are still very relevant. Actively engaging partners, and exploring opportunities for new partnerships, to implement these actions could be helpful in reinvigorating conservation efforts. Implementing these actions may also be facilitated by working proactively with landowners to balance the needs of the species within a sustainable working landscape and/or in the context of increased development pressures (USFWS, 2024).

# SPECIES ACCOUNT: *Lesquerella thamnophila* (Zapata bladderpod)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 12/22/1999; Southwest Region (R2)

**Physical Description**

Zapata bladderpod is a pubescent, silvery-green, herbaceous perennial of the Brassicacea family, with sprawling stems 17 to 34 inches long. Basal leaves are narrowly elliptical to oblanceolate and acute, 1.5 to 4.8 inches long, and 0.3 to 0.6 inch wide, with entirely or slightly-toothed margins. Stems leaves are linear to narrowly elliptical and acute, 1 to 1.5 inches long and 0.1 to 0.3 wide, and have entire or slightly toothed margins. Cauline or stem leaves are linear to narrowly elliptical and acute, 3 to 4 cm (1 to 1.5 in) long and 2 to 8 mm (0.1 to 0.3 in) wide, with margins similar to basal leaves. The presence of stellate trichomes (small hair-like structures) on the leaves produces the plant's appearance of a whitish or silvery-green color. The inflorescence is a loose raceme of bright, yellow-petaled flowers. The flowers appear throughout the year depending upon temperature and rainfall, and are arranged along an axis with the lower flowers maturing first. Fruits are round and 4.5 to 6.5 mm (0.2 to 0.8 in) in diameter on short, downward curving pedicels (Poole 1989). (USFWS, 2004)

**Taxonomy**

Zapata bladderpod was first described as Lesquerella thamnophila Rollins and Shaw, based on specimens collected in Starr and Zapata counties (now EOs 1, 2, and 3) (Rollins and Shaw 1973). Al-Shehbaz and O'Kane (2002), citing molecular, morphological, cytological, biogeographic, and ecological data, transferred 91 taxa of Lesquerella to Physaria, including P. thamnophila. Genetic analyses, based on DNA sequences of the internal transcribed spacer of nuclear ribosomal DNA and length variation of inter-simple sequence repeat regions, revealed that Physaria, as previously recognized, was nested within and evolved more than once from Lesquerella. The former genus was polyphyletic, and the latter was paraphyletic. These authors united the two into a single monophyletic genus, conserving the earlier-published name of Physaria. This taxonomic revision is supported by the Flora of North America (O'Kane 2015), the Integrated Taxonomic Information Service (2015), Poole et al. (2007), and the Tropicos database (Tropicos 2015). (USFWS, 2015)

**Historical Range**

Starr and Zapata Counties, Texas.

**Current Range**

Starr and Zapata Counties, Texas. (USFWS, 2015)

**Critical Habitat Designated**

Yes; 1/22/2001.

**Legal Description**

On December 22, 2000, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective January 22, 2001) for Lesquerella thamnophila (Zapata bladderpod) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes eight critical habitat units (CHUs), in Texas (65 FR 81182-81212).

**Critical Habitat Designation**

The critical habitat designation for Lesquerella thamnophila includes eight CHUs in Starr County, Texas. This species critical habitat encompasses approximately 5,158 acres (ac) (2,088 hectares (ha)). Legal descriptions are presented below. Maps for general information purposes depicting the CH units are available in the Final Rule (65 FR 81182-81212).

Unit 1, Cuellar Tract (18 hectares (ha); 45 acres (ac))—(Segment 669). Note: All bearings are based on the Texas State Plane Coordinate System, South Zone, as referenced by the National Geodetic Survey Triangulation Station ‘‘LABRA’’ (not found) having State plane coordinates of N = 331,881.065, E = 1,794,777.75. The scale factor used is 0.9999252, and the theta angle is ¥00° 37' 32?. All areas and distances are true surface measurements. Beginning at a standard U.S. Fish and Wildlife Service (FWS) aluminum monument set for corner on the southeasterly line of Porcion No. 59 and the northeast corner of Share 35 and stamped ‘‘Tract 669, COR. No. 1, R.P.L.S. #4303’’ and having a State plane coordinate value of N = 320,083.51, E = 1,799,578.77, from which triangulation station ‘‘LABRA’’, bears N 22° 08' 38?W, 12,737.98 feet; thence, in a southwesterly direction along the common line of Porcion 59 and 60, S 54° 32' 24?W, 2,290.19 feet, to a standard FWS aluminum monument set for corner, being the common corner of Shares 35 and 26 and stamped ‘‘Tract 669, COR. No. 2, R.P.L.S. No. 4303; thence, in a northwesterly direction along the common line of Share 35 with Shares 26 and 27, N 35° 27' 36?W, 640.00 feet to a standard FWS aluminum monument set for corner, being the most southerly common corner of Shares 35 and 34 and stamped ‘‘Tract 669, COR. No. 3, R.P.L.S. No. 4303’’; thence, in a northeasterly direction along the common line of Shares 35 and 34; N 54° 32' 24?E, 2,290.19 feet to a standard FWS aluminum monument set for corner, being the most northerly common corner of shares 35 and 34 and stamped ‘‘Tract 669, COR. No. 4, R.P.L.S. No. 4303; thence, in a southeasterly direction along the common line of Shares 35 and 36 Parcel–A; S 35° 27' 36? E, 640.00 feet to the point of beginning and containing 33.648 acres of land. (Cuellar Tract—Segment 672). Note: All bearings are based on the Texas State Plane Coordinate System, South Zone, as referenced by U.S. Fish and Wildlife Service GPS Monument No. 105 having State plane coordinates (NAD 27) of N = 311,099.90, E = 1,799,824.45. The scale factor used is 0.9999252, and the theta angle is ¥00° 37' 32?. All areas and distances are true surface measurements. Beginning at a standard FWS aluminum monument set for corner on the common line between Porcions 59 and 60, and being the northeast corner of Share 26 and stamped ‘‘Tract 672, COR. No. 1, R.P.L.S. No. 3680’’ and having a State plane coordinate value of N = 318,737.64, E = 1,797,725.36, from which FWS GPS Monument No. 105 bears S 15° 22' 02? E, 7,920.94 feet; thence, in a southeasterly direction along the common line of Porcion 59 and 60, S 54° 27' 12?W, 806.50 feet to a standard FWS aluminum monument set for corner, being the southeast corner of said north one-half (1/2) of Share 26, same being the northeast corner of the south one-half (1/2) of Share 26 and stamped ‘‘Tract 672, COR. No. 2, R.P.L.S. No. 3680’’; thence, in a northwesterly direction along the common line of said north and south one-half (1/2) of Share 26; N 35° 27' 36? W, 463.31 feet to a standard FWS aluminum monument set for corner in the common line between Shares 26 and 27 and stamped ‘‘Tract 672, COR. No. 3, R.P.L.S. No. 3680’’; thence, in a northeast direction along the common line of Shares 26 and 27; N 54° 32Prime;; 24? E, 806.50 feet to a standard FWS aluminum monument set for corner, being the most northerly common corner of Shares 26 and 27 in the south line of Share 35 and stamped ‘‘Tract 672, COR. No. 4, R.P.L.S. No. 3680’’; thence, in a southeasterly direction along the common line of Shares 35 and 26; S 35° 27' 36? E, 462.09 feet to the point of beginning and containing 8.567 acres of land. (Cuellar Tract—Segment 673). Note: All bearings are based on the

Texas State Plane Coordinate System, South Zone, as referenced by FWS GPS Monument No. 105 having State plane coordinates (NAD 27) of N = 311,099.90, E = 1,799,824.45. The scale factor used is 0.9999252, and the theta angle is ¥00° 37' 32?. All areas and distances are true surface measurements. Beginning at a standard FWS aluminum monument set for the common north corner of Shares 26 and 27, in the south line of Share 35 and stamped ‘‘Tract 672, COR. No. 4, R.P.L.S. No. 3680’’ and having a state plane coordinate value of N = 319,114.02, E = 1,797,457.29, from which FWS GPS Monument No. 105 bears S 16° 27' 21? E, 8,356.40 feet; thence, in a southwesterly direction along the common line of Shares 26 and 27, S 54° 32' 24? N, 806.50 feet to a standard FWS aluminum monument set for corner, being the southeast corner of said north one-half (1/2) of Share 27, same being the northeast corner of the south one-half (1/2) of Share 27 and stamped ‘‘Tract 672, COR. No. 3, R.P.L.S. No. 3680’’; thence, in a northwesterly direction along the common line of said north and south one-half (1/2) of Share 27; N 35° 27' 36? W, 592.30 feet to a standard FWS aluminum monument set for corner in the common line between Shares 27 and 28 and stamped ‘‘Tract 674, COR. No. 3, R.P.L.S. No. 3680’’; thence, in a northeasterly direction along the common line of Shares 27 and 28, N 54° 32' 24? E, 806.50 feet to a standard FWS aluminum monument set for corner, being the most northerly common corner of Shares 27 and 28 in the south line of Share 34 and stamped ‘‘Tract 674, COR. No. 2, R.P.L.S. No. 3680’’; thence, in a southeasterly direction along the common line of Shares 34 and 27, S 35° 27' 36? E, 592.30 feet to the point of beginning and containing 10.966 acres of land. (Cuellar Tract—Segment 672). Note: All bearings are based on the Texas State Plane Coordinate System, South Zone, as referenced by FWS GPS Monument No. 105 having State plane coordinates (NAD 27) of N = 311,099.90, E = 1,799,824.45. The scale factor used is 0.9999252, and the theta angle is ¥00° 37' 32?. All areas and distances are true surface measurements. Beginning at a standard FWS aluminum monument set replacing a 1–inch iron pipe found for the common north corner of Shares 28 and 29, in the south line of Share 33 and stamped ‘‘Tract 674, COR. No. 1, R.P.L.S. No. 3680’’; and having a state plane coordinate value of N = 320,078.90, E = 1,796,770.06, from which FWS GPS Monument No. 105 bears S 18° 47' 11? E, 9,484.36 feet; thence, in a southeasterly direction along the common line of Share 28 and Shares 33 and 34, S 35° 27' 36? E, 592.30 feet to a standard FWS aluminum monument set for corner, being the common northerly corner of Shares 28 and 27 and stamped ‘‘Tract 674, COR. No. 2, R.P.L.S. No. 3680’’; thence, in a southwesterly direction along the common line of said Share 28 and 27; S 54° 32' 24? W, 806.50 feet to a standard FWS aluminum monument set for the southeasterly corner of said north one-half (1/2) of Share 28, same being the northeasterly corner of the south one-half (1/2) of Share 28 and stamped ‘‘Tract 674, COR. No. 3, R.P.L.S. No. 3680’’; thence, in a northwesterly direction along the common line of the north and south one-half (1/2) of Share 28, N 35° 27' 36? W, 592.30 feet to a standard FWS aluminum monument set for corner in the common line between Shares 28 and 29 and stamped ‘‘Tract 674, COR. No. 4, R.P.S. No. 3680’’; thence, in a northeasterly direction along the common line of Shares 28 and 29; N 54° 32' 24? E, 806.50 feet to the point of beginning and containing 10.966 acres of land.

Unit 2, Chapeno Tract (28 ha; 69 ac)— (Chapeno Tract—Segment 660). Note: All bearings and distances are based on the International Boundary Commission Monuments as referenced by the U.S.C. & G.S. Triangulation Station ‘‘LABRA.’’ The scale factor used is 0.9999252, and the theta angle is ¥00° 37' 32? (NAD 1927). All areas shown are true ground areas. Commencing for reference at the U.S.C. & G.S. triangulation station ‘‘LABRA,’’ having coordinate values: x = 1,794,777.75, y = 331,881.06; thence, S 02° 08' 43? W, a distance of 9,020.47 feet to the northwesterly boundary line of said 44.900-acre tract for the northmost corner of said Share No. 17 and being corner No. 1 and the northernmost corner and place of beginning of the tract herein-described; thence, along the northeasterly boundary line of Share No. 17 and the southwesterly boundary line of a 35-foot perpetual easement, S 32° 11' 36? E, 840.62 feet to the easternmost corner of said Share No. 17 and being corner No. 2 of this tract; thence, along the southeasterly boundary line of Share No. 17 and the northwesterly boundary line of Share No. 18, S 47° 29' 30? W, 293.59 feet to a said point on a fence line along the southwesterly boundary line of said 44.900-acre tract for the southernmost corner of said Share No. 17 and being corner No. 3 of this tract; thence, following said fence line along the southwesterly boundary line of Share No. 17 and the southwesterly boundary line of said 44.900-acre tract, N 30° 16' 28? W, 166.16 feet to a standard FWS aluminum monument stamped ‘‘Tract (660), R.P.S. No. 4731’’ set for a corner of said 44.900-acre tract and being corner No. 4 of this tract; thence, continuing along said fence line along the southwesterly boundary line of Share No. 17 and the southwesterly boundary line of said 44.900-acre tract, N 31° 04' 59? W, 684.02 feet to a standard FWS aluminum monument stamped ‘‘Tract (660), R. P. S. No. 4731’’ set for the westernmost corner of said 44.900-acre tract and being corner No. 5 of this tract, thence, following a fence line along the northwesterly boundary line of Share No. 17 and the northwesterly boundary line of said 44.900-acre tract, N 48° 42' 36? E, 273.46 feet to the place of beginning and containing 5.396 acres of land. (Chapeno Tract—Segment 661). Note: All bearings and distances are based on the International Boundary Commission Monuments as referenced by the U.S.C. & G.S. triangulation station ‘‘LABRA.’’ The scale factor used is 00.9999252, and the theta angle is ¥00° 37' 32? (NAD 1927). All areas shown are true ground areas. E, 941.54 feet to a point on a fence line along the southeasterly boundary line of said 44.900-acre tract for the easternmost corner of said Share No. 19 and being corner No. 2 of this tract; thence, following said fence line along the southeasterly boundary line of Share No. 19 and the southeasterly boundary line of said 44.900-acre tract, S 55° 22' 51? W, 8.49 feet to a standard FWS aluminum monument stamped ‘‘Tract (662), R. P. S. No. 4731’’ set for a corner of said 44.900-acre tract and being corner No. 3 of this tract; thence, continuing along said fence line along the southeasterly boundary line of Share No. 19 and the southeasterly boundary line of said 44.900-acre tract, S 54° 58' 43? W, 243.72 feet to the southernmost corner of Share No. 19 and being corner No. 4 of this tract; thence, along the northeasterly boundary line of Share No. 18 and the southwesterly boundary line of Share No. 19, N 42° 40' 05 W, 623.01 feet to a corner of Share No. 19 and being corner No. 5 of this tract; thence, along the northeasterly boundary line of a 35-foot perpetual easement and the southwesterly boundary line of Share No. 19, N 32° 08' 41? W, 293.64 feet to the westernmost corner of said Share No. 19 and being corner No. 6 of this tract; thence, along the southeasterly boundary line of a 35- ft. perpetual easement and the northwesterly boundary line of Share No. 19, N 48° 23' 35? E, 219.73 feet to the place of beginning and containing 5.396 acres of land. (Chapeno Tract—Segment 663). Note: All bearings and distances are based on the International Boundary Commission Monuments as referenced by the U.S.C. & G.S. triangulation station ‘‘LABRA.’’ The scale factor used is 00.9999252, and the theta angle is ¥00° 37' 32? (NAD 1927). All areas shown are true ground areas. Commencing for reference at the U. S. C. & G. S. triangulation station ‘‘LABRA,’’ having coordinate values: x = 1,794,777.75, y = 331,881.06; thence, S 01° 55' 50? E, a distance of 9,166.26 feet to the northernmost corner of said share No 20, and being corner No. 1, and the northernmost corner and place of beginning of the tract herein-described; thence, along the northeasterly boundary line of Share No. 20 and the southwesterly boundary line of Share No. 21, S 44° 17' 45? E, 975.87 feet to a point on a fence line along the southeasterly boundary line of said 44.900-acre tract for the easternmost corner of said Share No. 20 and being corner No. 2 of this tract; thence, following said fence line along the southeasterly boundary line of Share No. 20 and the southeasterly boundary line of said 44.900-acre tract; S 55° 22' 51? W, 273.48 feet to the southernmost corner of Share No. 20 and being corner No. 3 of this tract; thence, along the northeasterly boundary line of Share No. 19 and the southwesterly boundary line of Share No. 20, N 41° 14’ 45’’ W, 941.54 feet to the westernmost corner of Share No. 20 and being corner No. 4 of this tract; thence, along the southeasterly boundary line of a 35-ft. perpetual easement and the northwesterly boundary line of Share No. 20, N 48° 23' 35? E, 219.73 feet to the place of beginning and containing 5.396 acres of land. (Chapeno Tract—Segment 664). Note: All bearings and distances are based on the International Boundary Commission Monuments as referenced by the U.S.C. & G.S. triangulation station ‘‘LABRA.’’ The scale factor used is 00.9999252, and the theta angle is ¥00° 37' 32? (NAD 1927). All areas shown are true ground areas. Commencing for reference at the U.S.C. & G.S. triangulation station ‘‘LABRA,’’ having coordinate values: x = 1,794,777.75, y = 331,881.06; thence, S 03° 00' 15? E, a distance of 9,027.56 feet to the northernmost corner of said Share No. 21 and being corner No. 1 and the northernmost corner and place of beginning of the tract herein-described; thence, along the northeasterly boundary line of Share No. 21 and the southwesterly boundary line of Share No 22, S 46 ° 18' 57’’ E, 1,008.60 feet to a point on a fence line along the southeasterly boundary line of said 44.900-acre tract for the easternmost corner of Share No. 21 and being corner No. 2 of this tract; thence, following said fence line along the southeasterly boundary line of Share No. 21 and the southeasterly boundary line of said 44.900-acre tract, S 54° 17' 59? W, 56.04 feet to a standard FWS aluminum monument stamped ‘‘Tract (664), R. P. S. No. 4731’’ set for a corner of said 44.900-acre tract and being corner No. 3 of this tract; thence, continuing along said fence line along the southeasterly boundary line of Share No. 21 and the southeasterly boundary line of said 44.900-acre tract, S 55° 22' 51? W, 202.51 feet to the southernmost corner of Share No. 21 and being corner No. 4 of this tract; thence, along the northeasterly boundary line of Share No. 20 and the southwesterly boundary line of Share No. 21, N 44° 17' 45? W, 975.87 feet to the westernmost corner of Share No. 21 and being corner No. 5 of this tract; thence, along the southeasterly boundary line of a 35-foot perpetual easement and the northwesterly boundary line of Share No. 21, N 48° 23' 35? E, 219.73 feet to the place of beginning and containing 5.396 acres of land. (Chapeno Tract—Segment 665). Note: All bearings and distances are based on the International Boundary Commission Monuments as referenced by the U.S.C. & G.S. Triangulation station ‘‘LABRA.’’ The scale factor used is 00.9999252, and the theta angle is ¥00° 37' 32? (NAD 1927). All areas shown are true ground areas. Commencing for reference at the U.S.C. & G.S. Triangulation station ‘‘LABRA,’’ having coordinate values: x = 1794,777.75, y = 331,881.06; thence, S 04° 06' 38? E, a distance of 8,892.12 feet to the northernmost corner of said Share No. 22 and being corner No. 1 and the northernmost corner and place of beginning of the tract herein-described; thence, following a fence line along the northeasterly boundary line of Share No. 22 and the southwesterly boundary line of Share No. 23, S 47° 33' 31? E, 1,036.06 feet to a point on a fence line along the southeasterly boundary line of said 44.900-acre tract for the easternmost corner of said Share No. 22 and being corner No. 2 of this tract; thence, following said fence line along the southeasterly boundary line of Share No. 22 and the southeasterly boundary line of said 44.900-acre tract, S 54° 17' 59? W, 245.67 feet to the southernmost corner of Share No. 22 and being corner No. 3 of this tract; thence, along the northeasterly boundary line of Share No. 21 and the southwesterly boundary line of Share No. 22, N 46° 18' 57? W, 1,008.60 feet to the westernmost corner of Share No. 22 and being corner No. 4 of this tract; thence, along the southeasterly boundary line of a 35-foot perpetual easement and the northwesterly boundary line of Share No. 22, N 48° 23' 35? E, 219.73 feet to the place of beginning and containing 5.396 acres of land. (Chapeno Tract—Segment 666). Note: All bearings and distances are based on the International Boundary Commission Monuments as referenced by the U.S.C. & G.S. triangulation station ‘‘LABRA.’’ The scale factor used is 00.9999252, and the theta angle is ¥00° 37' 32? (NAD 1927). All areas shown are true ground areas. Commencing for reference at the U.S.C. & G.S. Triangulation station ‘‘LABRA,’’ having coordinate values: x = 1,794,777.75, y =331,881.06; thence, S 05° 15' 03? E, a distance of 8,710.10 feet to the northernmost corner of said Share No. 23 and being corner No. 1 and the northernmost corner and place of beginning of the tract herein-described; thence, following a fence line along the northeasterly boundary line of Share No. 23 and the southwesterly boundary line of said Share No. 24, S 48 ° 10' 23? E, 1,061.62 feet to a point on a fence line along the southeasterly boundary line of said 44.900-acre tract for the easternmost corner of Share No.23 and being corner No. 2 of this tract; thence, following said fence line along the southeasterly boundary line of Share No. 23 and the southeasterly boundary line of said 44.900-acre tract, S 54° 17' 59? W, 234.95 feet to the southernmost corner of Share No.23 and being corner No. 3 of this tract; thence, along the northeasterly boundary line of Share No. 22 and the southwesterly boundary line of Share No. 23, N 47° 33' 31? W, 1,036.06 feet to the westernmost corner of Share No. 23 and being corner No. 4 of this tract; thence, along the southeasterly boundary line of a 35-ft. perpetual easement and the northwesterly boundary line of Share No. 23, N 48° 23' 35? E, 219.73 feet to the place of beginning and containing 5.396 acres of land. (Chapeno Tract—Segment 667). Note: All bearings and distances are based on the International Boundary Commission Monuments as referenced by the U.S.C. & G.S. Triangulation station ‘‘LABRA.’’ The scale factor used is 00.9999252, and the theta angle is ¥00° 37' 32? (NAD 1927). All areas shown are true ground areas. Commencing for reference at the U.S.C. & G.S. Triangulation station ‘‘LABRA,’’ having coordinate values: x = 1,794,777.75, y = 331,881.06; thence, S 06° 25' 32? E, a distance of 8,631.65 feet to the northeasterly boundary line of said 44.900-acre tract for corner No. 1 and the place of beginning of the tract herein-described; thence, following a fence line along the northeasterly boundary line of share No. 24 and the northeasterly boundary line of said 44.900-acre tract, S 51° 42' 47? E, 679.97 feet to a standard FWS aluminum monument stamped ‘‘Tract (667), R. P. S. No. 4731’’ set for a corner of said 44.900-acre tract and being corner No. 2 of this tract; thence, continuing along the fence line along the northeasterly boundary line of Share No. 24 and the northeasterly boundary line of said 44.900-acre tract, S 01° 11' 48? E, 136.46 feet to a standard FWS aluminum monument stamped ‘‘Tract (667), R. P. S. No. 4731’’ set for a corner of said 44.900-acre tract and being corner No. 3 of this tract; thence, continuing along the fence line along the northeasterly boundary line of Share No. 24 and the northeasterly boundary line of said 44.900-acre tract, S 54° 15' 17? E, 309.21 feet to a standard FWS aluminum monument stamped ‘‘Tract (667), R. P. S. No. 4731’’ set on a fence line for the easternmost corner of Share No. 24 and being on the southeasterly boundary line of said 44.900-acre tract and being corner No. 4 of this tract; thence, following said fence line along the southeasterly boundary line of share No. 24 and the southeasterly boundary line of said 44.900-acre tract, S 54° 17' 59? W, 197.94 feet to the southernmost corner of Share No. 24 and being corner No. 5 of this tract; thence, following said fence line along the southwesterly boundary line of Share No. 24 and the northeasterly boundary line of Share No. 23, N 48° 10' 23? W, 1,061.62 feet to the westernmost corner of Share No. 24 and northernmost corner of Share No. 23 and being corner No. 6 of this tract; thence, along the southeasterly boundary line of a 35-ft. perpetual easement and the northwesterly boundary line of Share No. 24, N 48° 23' 35? E, 219.73 feet to the place of beginning and containing 5.396 acres of land.

Unit 3, Arroyo Morteros Tract (41 ha; 102 ac)—Note: All bearings are based on the Texas State Plane Coordinate System, South Zone, (NAD 27), as referenced by FWS GPS Monument No. 105 having State plane coordinates of N = 311,099.90, E = 1,799,824.45. The scale factor used is 0.9999252, and the theta angle is ¥00° 37' 32?. All areas and distances are true surface measurements. Beginning at a 1/2-inch iron rod found for corner No. 1 on the common line between Porcions 59 and 60, and being the northwest corner of that certain 127.71-acre tract and having a State plane coordinate value of N = 315,746.07, E = 1,793,538.58, from which FWS GPS monument No. 105 bears S 53° 31' 49? E, 7,816.59 feet; thence, in a northeasterly direction along the common line of Porcion 59 and 60; N 54° 27' 12? E, 510.43 feet to a standard FWS aluminum monument set for corner replacing a 1/2-inch iron rod found, being the northwest corner of the herein described tract and stamped ‘‘Tract 670, Cor. No. 2, R. P. L. S. No. 3680’’; thence, in a easterly direction through the interior of said 536.485 acre tract; S 35° 20' 27? E, 3,621.01 feet to a standard FWS aluminum monument set for corner replacing a 1/2-inch iron rod found, being the northeast corner of the herein-described tract and stamped ‘‘Tract 670, Cor. No. 3, R.P.L.S. No. 3680’’; thence, in a southerly direction continuing through the interior of said 536.485 acre tract; S 61° 18' 54? W, 219.24 feet to a fence corner post found for a northwesterly corner of that certain 17.408 acre tract and being corner No. 4; thence, in a easterly direction along the common line between said 17.408 acre tract and the herein described tract; S 88° 47' 16? W, 110.41 feet to a fence post found for angle point and corner No. 5; thence, in a easterly direction continuing along said common line between a 17.408 acre tract and herein described tract; N 79° 11' 33? W, 67.63 feet to a fence post found for angle point and corner No. 6; thence, in a easterly direction continuing along said common line between a 17.408 acre tract and herein described tract; S 71° 49' 04? W, 50.57 feet to a fence post found for angle point and corner No. 7; thence, in a southerly direction continuing along said common line between a 17.408 acre tract and herein described tract; S 15° 40' 49? W, 44.43 feet to a fence post found for angle point and corner No. 8; thence, in a southerly direction continuing along said common line between a 17.408 acre tract and herein described tract; S 00° 18' 59? E, 253.83 feet to a fence post found for angle point and corner No. 9; thence, in a southerly direction continuing along said common line between a 17.408 acre tract and herein described tract; S 06° 36' 21? W, 182.88 feet to a fence post found for angle point and corner No. 10; thence, in a southerly direction continuing along said common line between a 17.408 acre tract and herein described tract; S 26° 38' 19? W, 125.18 feet to a fence post found for angle point and corner No. 11; thence, in a southerly direction continuing along said common line between a 17.408 acre tract and herein described tract; S 67° 33' 26? W, 129.76 feet to a fence post found for angle point and corner No. 12; thence, in a southerly direction continuing along said common line between a 17.408-acre tract and herein described tract; S 45° 58' 19? W, 73.00 feet to a fence post found for angle point and corner No. 13; thence, in a southerly direction continuing along said common line between a 17.408 acre tract and herein described tract; S 35° 10' 19? W, 113.60 feet to a fence post found for angle point and corner No. 14; thence, in a southerly direction continuing along said common line between a 17.408 acre tract and herein described tract; S 19° 34' 19? W, 42.80 feet to a fence post found for angle point and corner No. 15; thence, in a southerly direction continuing along said common line between a 17.408-acre tract and herein described tract; S 15° 23' 41? W, 28.84 feet to a 1/2-inch iron rod found on the apparent gradient boundary of the Rio Grande for the southeast corner hereof and corner No. 16; thence, in a westerly direction along said apparent gradient boundary of the Rio Grande; N 62° 26' 09? W, 81.47 feet to a point on said apparent gradient boundary of the Rio Grande for corner No. 7; thence, in a northwesterly direction continuing along said apparent gradient boundary of the Rio Grande; N 36° 34' 14? W, 122.63 feet to a point on said apparent gradient boundary of the Rio Grande for corner No. 18; thence, in a northerly direction continuing along said apparent gradient boundary of the Rio Grande; N 20° 15' 10? W, 58.91 feet to a point on said apparent gradient boundary of the Rio Grande for corner No. 19; thence, in a northwesterly direction continuing along said apparent gradient boundary of the Rio Grande; N 34° 02' 20? W, 118.95 feet to a point on said apparent gradient boundary of the Rio Grande for Corner No. 20; thence, in a westerly direction continuing along said apparent gradient boundary of the Rio Grande; S 73° 36' 56? W, 17.73 feet to a point on said apparent gradient boundary of the Rio Grande for corner No. 21; thence, in a northwesterly direction continuing along said apparent gradient boundary of the Rio Grande; N 43° 36' 30? W, 118.21 feet to a point on said apparent gradient boundary of the Rio Grande corner No. 22; thence, in a northerly direction continuing along said apparent gradient boundary of the Rio Grande; N 28°12' 58? W, 168.21 feet to a point on said apparent gradient boundary of the Rio Grande for corner No. 23; thence, in a northwesterly direction continuing along said apparent gradient boundary of the Rio Grande; N 49° 09' 29? W, 149.82 feet to a point on said apparent gradient boundary of the Rio Grande for corner No. 24; thence, in a westerly direction continuing along said apparent gradient boundary of the Rio Grande; N 66° 23' 26? W, 123.27 feet to a point on said apparent gradient boundary of the Rio Grande for corner No. 25; thence, in a westerly direction continuing along said apparent gradient boundary of the Rio Grande; N 77° 18' 49? W, 240.49 feet to a point on said apparent gradient boundary of the Rio Grande for corner No. 26; thence, in a westerly direction continuing along said apparent gradient boundary of the Rio Grande; S 80° 06' 32? W, 129.98 feet to a point on said apparent gradient boundary of the Rio Grande for corner No. 27; thence, in a westerly direction continuing along said apparent gradient boundary of the Rio Grande; N 79° 54' 48? W, 218.17 feet to a point on said apparent gradient boundary of the Rio Grande for corner No. 28; thence, in a westerly direction continuing along said apparent gradient boundary of the Rio Grande; S 81° 13' 28? W, 136.03 feet to a 1/2-inch iron rod found on said apparent gradient boundary of the Rio Grande for the southeast corner of the aforementioned 127.71 acre tract, same being the southwest corner hereof and corner No. 29; thence, in a northerly direction along the common line between said 127.71-acre tract and the herein described tract; N 06° 09' 33? W, 237.00 feet to a fence post found for angle point and corner No. 30; thence, in a northerly direction continuing along the common line between said 127.71-acre tract and the herein described tract; N 05° 51' 34? W, 198.49 feet to a fence post found for angle point and corner No. 31; thence, in a Northerly direction continuing along the common line between said 127.71-acre tract and the herein described tract; N 07° 49' 27? E, 161.97 feet to a fence post found for angle point and corner No. 32; thence, in a Northerly direction continuing along the common line between said 127.71-acre tract and the herein described tract; N 07° 47' 00? E, 302.39 feet to a fence post found for angle point and corner No. 33; thence, in a northerly direction continuing along the common line between said 127.71 acre tract and the herein described tract; N 07° 17' 37? E, 493.82 feet to a fence post found for angle point and corner No. 34; thence, in a northeasterly direction continuing along the common line between said 127.71-acre tract and the herein described tract, as fenced; N 46° 28' 41? E, 643.50 feet to a fence post found for angle point and corner No. 35; thence, in a northwesterly direction continuing along the common line between said 127.71 acre tract and the herein described tract; N 47° 51' 47? W, 1,087.49 feet to a fence post found for angle point and corner No. 36; thence, in a northerly direction continuing along the common line between said 127.71-acre tract and the herein described tract; N 21° 22' 25? W, 375.05 feet to the point of beginning and containing 89.90 acres of land.

Unit 4, Las Ruinas Tract (104 ha; 256 ac)—Note: All bearings are based on the Texas State Plane Coordinate System, South Zone, as referenced by National Geodetic Survey (NGS.) Triangulation Station ‘‘GORGORA’’ having State plane coordinates (NAD 27) of N = 275,335.73, E = 1.833,217.01. The scale factor used is 0.9999421, and the theta angle is -00° 16' 22?. All areas and distances are true surface measurements. Beginning at a 2- inch iron pipe having State plane coordinates of N = 280,488.40, E = 1,804,584.01 for the northerly southeast corner of the herein described tract, from which said triangulation station ‘‘GORGORA’’ bears S 79° 47' 55? E, a distance of 29,092.93 feet, same being the southwest corner of Share 96, of said Porcion 66, and the southwest corner of a 1455.52-acre tract of land as described, same being in the north line of Share 94, of said Porcion 66, same being in the north line of Tract ‘‘K’’, a 26.82-acre tract of land as described, for corner No. 1 and point of beginning of the herein described tract of land. Thence, westerly along the common line between said northerly line of tract ‘‘K’’ and the southerly line hereof N 80° 30' 29? W, 871.09 feet to a 6? iron pipe found for corner No. 2, same being the northwest corner of said Tract ‘‘K’’; thence, southerly along the common line between the westerly line of said Tract ‘‘K’’ and the easterly line hereof S 09° 22' 35? W, 837.18 feet, to a 13/4? iron pipe found for the southwest corner of said tract ‘‘K’’ and the northwest corner of a 23.5131-acre tract of land at corner No. 3, thence, southerly along the common line between said 23.5131-acre tract and the most southerly easterly line hereof, S 09° 22' 35? W, 540.00 feet to a standard FWS aluminum monument set, said monument being in the north line of a 56.82-acre tract of land as described for corner No. 4 and stamped ‘‘Tract 630, Ref. No. 4, RPLS 3680’’; thence, westerly along the common northerly line between said 56.82 acre tract and the southerly line hereof, N 80° 31' 16? W, 3295.18 feet to the apparent gradient boundary of the Rio Grande, and passing a standard FWS aluminum monument set for reference at a distance of 3,210.08 feet and stamped ‘‘Tract 630, Ref. No. 5, RPLS 3680’’; thence, northerly along the apparent gradient boundary of the Rio Grande N 63° 00' 17? E, 192.97 feet to a point on the apparent gradient boundary of the Rio Grande for Corner No. 6; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 62° 39' 49? E, 398.99 feet to a point on the apparent gradient boundary of the Rio Grande for Corner No. 7; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 60° 14' 39? E, 722.34 feet to a point on the apparent gradient boundary of the Rio Grande for corner No. 8; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 57° 28' 43? E, 416.75 feet to a point on the apparent gradient boundary of the Rio Grande for corner No. 9; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 57° 55' 40? E, 171.44 feet to a point on the apparent gradient boundary of the Rio Grande for corner No. 10; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 47° 49' 48? E, 287.44 feet to a point on the apparent gradient boundary of the Rio Grande for corner No. 11; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 43° 00' 00? E, 246.79 feet to a point on the apparent gradient boundary of the Rio Grande for corner No. 12; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 39° 40' 14? E, 295.08 feet to a point on the apparent gradient boundary of the Rio Grande for corner No. 13; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 35° 41' 43? E, 380.79 feet to a point on the apparent gradient boundary of the Rio Grande for corner No. 14; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 31° 28' 24? E, 370.58 feet to a point on the apparent gradient boundary of the Rio Grande for corner No. 15; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 33° 19' 15? E, 293.00 feet to a point on the apparent gradient boundary of the Rio Grande for corner No. 16; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 13° 43' 08? E, 146.31 feet to a point on the apparent gradient boundary of the Rio Grande for corner No. 17; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 11° 00' 57? E, 189.14 feet to a point on the apparent gradient boundary of the Rio Grande for corner No. 18; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 02° 10' 54? W, 305.51 feet to a point on the apparent gradient boundary of the Rio Grande for corner No. 19; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 01° 31' 51? W, 416.25 feet to a point on the apparent gradient boundary of the Rio Grande for corner No. 20; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 00° 01' 29? W, 441.45 feet to a point on the apparent gradient boundary of the Rio Grande for corner No. 21; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 03° 29' 26? E, 405.03 feet to a point on the apparent gradient boundary of the Rio Grande for corner No. 22; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 08° 08' 02? E, 308.09 feet to a point on the apparent gradient boundary of the Rio Grande for corner No. 23; thence, northerly continuing along said apparent gradient boundary of the Rio Grande N 39° 03' 01? E, 218.95 feet to a point on the apparent gradient boundary line of the Rio Grande, for corner No. 24 and northwest corner of this tract, same being the southwest corner of a 60.77-acre tract of land; thence, easterly along the common line between the south line of said 60.77- acre tract and the northerly line hereof S 80° 31' 16? E, 1942.92 feet to a standard FWS aluminum monument set and stamped ‘‘Tract 630, Ref. No. 25, RPLS 3680’’ for corner No. 25, same being the southeast corner of said 60.77- acre tract, same being in the west line of Share 339 of said Porcion 66, same being in the west line of said 1,455.52- acre tract of land, and passing a standard FWS aluminum monument set for Reference at a distance of 38.95 feet and stamped ‘‘Tract 630, Ref. No. 24, RPLS 3680’’; thence, southerly along the common line between the west line of said Share 339, Share 319, Share 227, Share 231, Share 230, Share 229, Share 518, Share 226, Share 225, Share 224, and said Share 96, same being the west line of said 1,455.52-acre tract and the east line hereof S 09° 28' 44? W, 3,845.12 feet and passing a 2-inch iron pipe found for the southwest corner of Share 339, same being the northwest corner of Share

319 at a distance of 315.48 feet, and being 0.46 feet easterly of and perpendicular to this line, and also passing a 1-1/2 inch iron pipe found for the southwest corner of Share 319, same being the northwest corner of Share 227 at a distance of 711.48 feet, and being 0.39 feet easterly of and perpendicular to this line, and also passing a 2-inch iron pipe found for the southwest corner of Share 231, same being the northwest corner of Share 230 at a distance of 1,320.71 feet, and being 0.09 feet easterly of and perpendicular to this line, to the point of beginning of the herein described tract and containing 254.42 acres of land.

Unit 5, Arroyo Ramirez Tract (273 ha; 675 ac)—Formal surveying of the tract has not been performed. Described as, ‘‘All of Share 79, Porcion 68, Abstract 191, Former Jurisdiction of Mier, Mexico, now Starr County, Texas, and all of Share 166, Porcion 69, Abstract No. 160, Former Jurisdiction of Mier, Mexico, now Starr County, Texas. Description by approximated latitude/ longitude coordinates (attached maps): Beginning at Latitude/Longitude 26° 24 00.9?N/099° 03' 23.9?W, westward to Latitude/Longitude 026° 24' 04.7?N/ 099° 03' 46.5?W, northward to Lat/Long 026° 24' 25.2?N/099° 03' 43.3? W, westward to Lat/Long 026° 24' 26.0? N/ 099° 03' 49.8? W, northward to Lat/Long 026° 25' 05.5? N/099° 03' 42.6? W, eastward to Lat/Long 026° 24' 56.6? N/ 099° 02' 40.3? W to the apparent gradient boundary of the Rio Grande River.

Unit 6, Los Negros Creek Tract (47 ha; 116 ac)—The following described tract of land is located in Starr County, Texas, about 1 mile northwest of the town of Roma, being 111.67 acres out of Share 13, Porcion 70, and being more particularly described as follows: Beginning at Cor. No. 1, an iron pin set for the northeast corner of Share No. 13 of Porcion No. 70 ; thence, along an old fence line and the dividing line between Share Nos. 13, 1–B and 12–A, S 09° 15' W, 2,694.00 feet to Cor. No. 2 an iron pin set on the Old High Bank of the Rio Grande and the southeast corner of this tract; thence leaving said fence line and along said Old High Bank with the following two courses, N 63° 17' 27? W, 1,161.54 feet to Cor. No. 3 and N 87° 10' 00? W, 612.00 feet to Cor. No. 4, a set iron pin and the southwest corner of this tract; thence leaving said Old High Bank and along the dividing line of Tract 2 and 3 of said Share 13 and an old fence line with the following three courses, N 09° 15' E, 841.30 feet to Cor. No. 5, a set iron pin; N 80° 45' W, 397.50 feet to Cor. No. 6, a set iron pin; and N 09° 15' E, 1,572.60 feet to Cor. No. 7 & iron pin set for the northwest corner of this tract; thence leaving said dividing line and along the north line of this tract and an old fence line, S 80° 45' E, 2,113.70 feet to Cor. No. 1 and the true place of beginning, containing 111.67 acres of land bounded on the West, North, and East by lands of unknown owner and on the South by the Rio Grande.

Unit 7, La Puerta Tract (1,577 ha; 3,895 ac) (Segment 590). Note: All bearings and distances are based on the Texas State Plane Coordinate System, South Zone, as referenced by National Geodetic Survey (NGS) triangulation station ‘‘Fordyce 2’’ and NGS triangulation station ‘‘Monument’’. Scale factor used was 0.99993949; theta angle used was ¥00° 06' 15?. All areas are true ground measured areas. Beginning at corner No. 1, a standard U.S. Fish and Wildlife Service (FWS) aluminum monument stamped ‘‘TR 590 COR 1’’ set in the west boundary of Porcion 86, said point being at the southwest corner of the aforementioned 8,061-acre tract, and also being the northeast corner of a 160-acre tract recorded in volume 60, pages 47–48, Deed Records, Starr County, Texas, from which NGS triangulation station ‘‘Monument’’ bears N. 68° 59' 27? W, 8,477.20 feet; thence, from corner No. 1, along the western boundary line of said 8,061-acre tract and Porcion 86, N 09° 02' 27? E, 25,125.17 feet to corner No. 2, a standard FWS aluminum monument stamped ‘‘TR 590 COR 2’’, set at a fence corner from which NGS triangulation station ‘‘Monument’’ bears S 28° 34' 49? W, 24,795.18 feet; said corner No. 2 also being the northwest corner of the herein described tract, thence, from corner No. 2, departing said western boundary line, with fence, S. 78° 52' 36? E, 1,889.04 feet, to corner No. 3, a standard FWS aluminum monument stamped ''TR 590 COR 3'' set at fence corner; thence, from corner No. 3, continuing with fence, N 06° 16' 07? E, 1,007.99 feet to corner No. 4, a standard FWS aluminum monument stamped ''TR 590 COR 4'' set at fence corner; thence, from corner No. 4, continuing with fence, S 78° 42' 12? E, 2,691.33 feet to corner No. 5, a standard FWS aluminum monument stamped ''TR 590 COR 5'' set for angle; thence from corner No. 5, continuing with fence, S 72° 35' 38? E, 2,000.57 feet to corner No. 6, a standard FWS aluminum monument stamped ''TR 590 COR 6'' set at fence corner, said point being a perpendicular distance of 20.20 feet from the eastern boundary line of Porcion 87, said point also being the Northeast corner of the herein described tract; thence, from corner No. 6, continuing with fence, S 09° 01' 08? W, 10,831.38 feet to corner No. 7, a standard FWS aluminum monument stamped ''TR 590 COR 7'' set for angle adjacent to a found 5/8-inch iron pin; thence, from corner No. 7, continuing with fence, S 08° 56' 57? W, 10,030.04 feet, to corner No. 8, a standard FWS aluminum monument stamped ''TR 590 COR 8'' set for angle point, said point being at the intersection of said fence with the east boundary line of Porcion 87; thence, from corner No. 8, departing said fence, along the east boundary line of Porcion 87, S 09° 02' 27? W, 4,824.69 feet to corner No. 9, a standard FWS aluminum monument stamped ''TR 590 COR 9'' set for corner; thence, from corner No. 9, departing said east line, N 80° 47' 09? W, 6,527.80 feet to the place of beginning and containing 3,844.674 acres. (La Puerta 590a). Note: All bearings and distances are based on the Texas State Plane Coordinate System, South Zone, (NAD 27), as referenced by the National Geodetic Survey (NGS) Triangulation Station ''Monument'' having a coordinate value of N = 250,167.56; E = 1,912,489.81. Scale factor applied equals 0.99993949; theta angle equals ¥00° 06' 15?. All areas are based on true ground measurements. Beginning at corner No. 1, a standard FWS aluminum monument stamped ''TR 590A COR 1'' set over a 2-inch iron pipe found in the west boundary line of Porcion 87, east boundary line of Porcion 86, at the northwest corner of said Lot 22, also being the northeast corner of a 2.83-acre tract as described by deed recorded in Volume 516, Page 62, Official Records, Starr County, Texas and being in the south boundary line of USA Tract (590) as described by deed recorded in Volume 608, Page 309, Official Records, Starr County, Texas said point having a coordinate value of N = 246,550.96; E = 1,923,962.74 and bearing S 72° 30' 13? E, 12,029.47 feet from NGS Triangulation Station ''Monument''; thence from corner No. 1, with south boundary line of said USA Tract (590), the north boundary line of said Lot 22, S 80° 47' 09? E, 2,922.00 feet to corner No. 2, a standard FWS aluminum monument stamped ''TR 590 COR 9'' found at the southeast corner of said USA Tract (590), also being the northeast corner of said Lot 21, and being in the east boundary line of Porcion 87, west boundary line of Porcion 88 for the northeast corner of the herein-described tract of land; thence, from Corner No. 2, with the said east boundary line of Porcion 87, west boundary line of Porcion 88, and also being the east boundary line of said Lot 21, S 08° 18' 30? W, 1,130.60 feet to corner No. 3, a standard FWS aluminum monument stamped ''TR 590A COR 3'' set in the existing north right-of-way line of U.S. Highway 83 with the intersection of said east boundary line of Porcion 87, west boundary line of Porcion 88 for the southeast corner of the herein described tract of land; thence, from corner No. 3, with and along the said existing north right-ofway line of U.S. Highway 83, N 66° 14' 23? W, 18.20 feet to corner No. 4, a standard FWS aluminum monument stamped ''TR 590A COR 4'' set for an angle point; thence, from corner No. 4, continuing along said existing north right-of-way line, N 60° 31' 23? W, 100.39 feet to corner No. 5, a standard FWS aluminum monument stamped ''TR 590A COR 5'' set for an angle point; thence, from corner 5, continuing along said existing north right-of-way line, N 66° 14' 23? W, 499.97 feet to corner No. 6, a standard FWS aluminum monument stamped ''TR 590A COR 6'' set for an angle point; thence, from corner No.

6, continuing along said existing north right-of-way line, N 71° 57' 23? W, 100.39 feet to a corner No. 7, a standard FWS aluminum monument stamped ‘‘TR 590A COR 7’’ set for an angle point; thence, from corner No. 7, continuing along said existing north right-of-way line, N 66° 14' 14? W, 1,084.94 feet to corner No. 8, a 5/8-inch iron rod found at the intersection of the said existing north right-of-way line with the proposed north right-of-way line of U.S. Highway 83; thence, from corner No. 8, departing said existing north right-of-way line with and along the proposed north right-of-way line of U.S. Highway 83, N 60° 43' 04? W, 200.90 feet to corner No. 9, a 5/8-inch iron rod found for an angle point; thence, from corner No. 9, continuing along said proposed north right-of-way line, N 69° 54' 31? W, 300.83 feet to corner No. 10, a 5/8-inch iron rod found at the intersection of said proposed north right-of-way line with the existing north right-of-way line of U.S. Highway 83; thence, from corner No. 10, with the said existing north right-of-way line of U.S. Highway 83, N 66° 16' 51? W, 399.70 feet to corner No.11, a standard FWS aluminum monument stamped ‘‘TR 590A COR 11’’ set over a 1/2-inch iron rod found for an angle point; thence, from corner No. 11, continuing along said existing North right-of-way line, N 64° 31' 54? W, 335.45 feet to corner No.12, a standard FWS aluminum monument stamped ‘‘TR 590A COR 12’’ set at the intersection of said existing north rightof-way line with the west boundary line of Porcion 87, east boundary line of Porcion 86; thence, from corner No. 12, departing said existing north right-ofway line with the said west boundary line of Porcion 87, east boundary line of Porcion 86, N 08° 56' 59? E, 357.90 feet to corner No.1, the point of beginning and containing 50.033 acres of land. (La Puerta Tract—Segment 590b). Note: All bearings and distances are based on the Texas State Plane Coordinate System, South Zone, (NAD 27), as referenced by the National Geodetic Survey (NGS) Triangulation Station ‘‘Monument’’ having a coordinate value of N = 250,167.56' E = 1,912,489.81. Scale factor applied equals 0.00003040; theta angle equals ¥00° 06' 15?. All areas are based on true ground measurements. Beginning at corner No. 1, a 5/8-inch iron rod found at the intersection of the west boundary line of Porcion 87, east boundary line of Porcion 86 with the proposed south right-of-way line of U.S. Highway 83, said point bears S 08° 57' 33? W, 139.55 feet from a 5/8-inch iron rod found in the existing south right-of-way line of U.S. Highway 83, said point having a coordinate value of N = 245,880.85, E = 1,923,857.21 and bearing S 69° 20' 18? E, 12,148.81 feet from NGS Triangulation Station ‘‘Monument’’; thence, from corner No. 1, with the said proposed south right-of-way line, S 66° 14' 23? E, 3,043.33 feet to corner No. 2, a 5/8-inch iron rod found at the intersection of the east boundary line of Porcion 87, the west boundary line of Porcion 88 and the said proposed south right-of-way line, thence, from corner No. 2, with the said east boundary line of Porcion 87, west boundary line of Porcion 88, S 08° 59' 29? W, 2,925.70 feet to corner No. 3, a standard FWS aluminum monument stamped ‘‘TR 590B COR 3’’ set over a 1/2-inch iron rod found at the intersection of said east boundary line of Porcion 87, west boundary line of Porcion 88 with the north right-of-way line of the MissouriPacific Railroad; thence, from corner No. 3, with the said north right-of-way line of the Missouri-Pacific Railroad, N 52° 58' 07? W, 3,333.49 feet to corner No. 4, a standard FWS aluminum monument stamped ‘‘TR 590B COR 4’’ set over a 3/8-inch iron rod found at the intersection of the said north right-ofway line with the said west boundary line of Porcion 87, the east boundary line of Porcion 86, said point also being the southeast corner of a 39.492-acre tract, thence from corner No. 4, with the said west boundary line of Porcion 87, east boundary line of Porcion 86, N 08° 56' 13? E, 1,715.55 feet to corner No. 5, a standard FWS aluminum monument stamped ‘‘TR 590B COR 5’’ set over a 1/2- inch iron rod found at the southeast corner of a 2.0-acre tract, thence, from corner No. 5, continuing along said west boundary line of Porcion 87, east boundary line of Porcion 86, N 09° 08' 05? E, 418.93 feet to corner No. 1, the point of beginning and containing 170.950 acres of land.

Unit 8-Private ranch site comprises 0.552 hectares (1.36 acres) within the Universal Transverse Mercator, Zone 14 and begins at UTM 490706 E, 2929709 N; thence to 490729 E, 2929706 N; to 490748 E, 2929720 N; to 490762 E, 2929722 N; to 490767 E, 2929704 N; to 490767 E, 2929679 N; to 490769 E, 2929654 N; to 490770 E, 2929637 N; to 490770 E, 2929629 N; to 490760 E, 2929619 N; to 490743 E, 2929614 N; to 490732 E, 2929612 N; to 490720 E, 2929614 N; to 490709 E, 2929670 N; and thence to point of beginning.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Lesquerella thamnophila critical habitat consists of three components (65 FR 81182-81212):

(a) Arid upland habitats of various soil types, including highly calcareous sandy loam to loamy sand, with low to moderate salinity levels on low sloping hills;

(b) Absence of substantial previous soil disturbance and seeding or sodding of exotic grasses; and

(c) A sparse overstory of shrub species typical of the Tamaulipan biotic province, but lacking a complete canopy as might be provided by a continuous overstory dominated by mesquite (Prosopis glandulosa).

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Flowers February - April, peaks in March (USFWS, 2024)

**Key Resources Needed for Breeding**

Adult: Insect pollinated

**Other Reproductive Information**

Adult: Zapata bladderpod receives a range of pollinator visitors such as beetles, various flies, bees, and wasps. Rainfall in this hot, semi-arid region occurs most reliably from September through November. Seed germination and the emergence of basal rosettes from dormant caudices probably occur in the fall and early winter in response to rain, cooler weather, and shorter day lengths (Service 2015, p. 6). Flowering occurs mainly from February to April, with a peak in March; flowering has occasionally been observed as late as October and as early as January (Middleton et al. 2024, p. 250). Most fruiting has been observed in March and April (Service 2015, p. 5). Usually, there are four seeds in each of the two chambers (8 seeds per capsule) but there are sometimes as many as 10–11 seeds per capsule (USFWS, 2024)

**Reproduction Narrative**

Adult: Zapata bladderpod blooms from April through September and produces bright yellow flowers. Plants will bloom throughout most of the year with adequate temperature and rainfall. Fruits are round, 0.2 to 0.8 inch in diameter, and are on short, downward curving pedicels (Poole 1989). Zapata bladderpod is known to be opportunistic, with the density of Zapata bladderpod plants and size of populations fluctuating with temperature levels and amount of rainfall. Zapata bladderpod is a perennial plant that sprouts above ground levels and produces stems more readily during periods of favorable weather. It can respond dramatically to rainfall events and increase from small, barely-detectable above-ground plants, to thousands of plants (USFWS 2004).

**Habitat Type**

Adult: Shrublands

**Environmental Specificity**

Adult: Moderate (inferred from USFWS, 2004)

**Habitat Narrative**

Adult: Zapata bladderpod is endemic to South Texas, where it occupies cenizo and/or guajillo (Acacia berlandieri) shrublands. It can occur on graveled to sandy-loam, upland terraces above the Rio Grande flood plain. The soils on which the species is known to occur vary depending on location. In Starr County, documented populations occur within the Jimenez-Quemado soil association and on Catarina series soils. In Zapata County, they occur within the Zapata-Maverick soil association and may also occur within the Copita-Zapata soils (USFWS 2004). Zapata bladderpod may occur within areas of sparse vegetation or under canopy of associated shrub species. The shrub species may serve as nurse plants for Zapata bladderpod, potentially reducing the amount of sunlight on the soil surface and helping to maintain moisture in the root area. Adjacent shrubs also provide protection from soil erosion and may serve as a deterrent to browsing animals. Associated plants include mesquite, granjeno, Spanish dagger (Yucca treculeana), lotebush, guayacan (Guaiacum angustifolium), cenizo (Leucophyllum frutescens), and blackbrush (Acacia ridgula) (USFWS 2004).

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

12 populations, 19,770 total acres.

**Population Size:**

>200,000 total

**Additional Population-level Information:**

a total of 12 known populations monitored within Starr and Zapata counties, estimated population sizes collected from 2022-2024-indicate that most populations have experienced declines (see Table 1). Of the six populations with confirmed population declines, five have experienced substantial reductions (31 to 99%) in the number of individuals documented compared to the high ever documented, and only two populations currently meet the MVP of at least 2,000 individuals. (USFWS, 2024)

**Population Narrative:**

The recovery plan stated that there are 7 extant populations, while the TXNDD now lists 8 extant populations and two of unknown status. Of the latter, EO 2 is a historic record north of Roma for which the precise location is unknown. EO17 was detected during a survey of private land in 1994, also north of Roma, and the site has not since been re-visited. The recovery plan also states that there are 11 documented occurrences, but this figure confounds known populations and designated areas of critical habitat. We believe the EOs reported by TXNDD correctly represent our current knowledge of the populations and distribution of Zapata bladderpod. (USFWS, 2015) Four of the seven populations known historically to occur in Starr County still support Zapata bladderpod plants (USFWS 2004). Two of these seven are in the highway ROWs between Zapata and Falcon, and one on private property in Siesta Shores subdivision. The populations that occur on the LRGV NWR tracts in Starr County continue to maintain the largest number of plants (USFWS 2004). Three refuge tracts and the private ranch have fairly large populations. These populations number in the thousands of individuals in rainy years but occur within a very restricted area covering only a few acres (Best 2006, personal comm.). In Zapata County, three of the four historically documented sites still support Zapata bladderpod. The predominance of private lands in South Texas limits access for surveys, therefore the species range may be more extensive than what is currently known. The size of populations fluctuates depending on rainfall and weather cycles increasing the difficulty in locating the plants (USFWS 2004).

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** • Buffelgrass is more prevalent in disturbed soils; not highly competitive in Zapata bladderpod habitat. • Soils are extremely prone to erosion. Root- plowing and other forms of soil disturbance exacerbate erosion. • Overgrazing increases soil erosion. • Foot and ATV traffic associated with border security destroys plants by trampling and leads to soil erosion. • Rapid local population growth, highway construction between Laredo and Rio Grande City. • Petroleum development and pipeline construction continues at rapid pace. (USFWS, 2015)

**Stressor:** The inadequacy of existing regulatory mechanisms (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Endangered Species Act (ESA) does provide some legal protection for federally-listed plants on land under federal jurisdiction, including the three populations on tracts of Lower Rio Grande Valley NWR. However, as described above, Endangered Species Act provisions, including section 7 consultation, can be waived by DHS to expedite construction of border barriers. Federally-listed plants occurring on private lands have very limited protection under the ESA, unless also protected by State laws; the State of Texas also provides very little protection to listed plant species on private lands. Therefore, Zapata bladderpod populations and habitats on private land are not subject to federal or state protection unless there is a federal nexus, such as provisions of the Clean Water Act or a federally-funded project. (USFWS, 2015)

**Stressor:** Other natural or man-made factors affecting its continued existence (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** • Some EOs within developed areas or along highway ROWs are vulnerable. • Periodic vegetation shredding along utility ROWs may have beneficial effect, provided that soil is not disturbed. • Small isolated populations subject to genetic drift and inbreeding. • Historic conversion of shrub savanna to dense shrubs and cessation of wildfire may have affected populations. • Potential impacts of climate changes. (USFWS, 2015)

***Recovery***

**Reclassification Criteria:**
1. Maintain or establish 12 geographically distinct, self-sustaining populations located within the species' historical range in the United States, with at least one population in each of the 3 geologic formations from which the species is currently known to occur. Each population should consist of at least 2,000 reproductive individuals (have flowered at least once or are capable of flowering) as determined during years when precipitation patterns have stimulated growth and reproduction. The numbers of reproductive individuals at each of the 12 population sites must be stable or increasing. (USFWS, 2019)

2. To count toward reclassification, all populations must be appropriately protected and actively managed to reduce or eliminate threats to the species. Agreements for the protection and appropriate management of the 12 self-sustaining populations must be in place. Perpetual protection on public land will be assured via Service-approved management plans (e.g. National Wildlife Refuge Comprehensive Conservation Plans). Formal stewardship agreements (e.g. conservation easements or similar instruments) must be in place to ensure perpetual long-term, species-appropriate management on privately-owned land. (USFWS, 2019)

Recovery Priority Number: 8C

**Delisting Criteria:**
1. Over a 30-year period following reclassification of the species to threatened, monitoring of 12 fully protected, self-sustaining populations consisting of at least 2,000 reproductive individuals per population shows that the populations are stable or increasing. These populations will be located within the species' historical range in the United States, with at least one population in each of the three geologic formations from which the species is currently known to occur.

2. Populations continue to be protected through perpetual management agreements. Threats to each population have been reduced or eliminated through appropriate site management that may include such actions as limiting erosion by excluding vehicles, foot traffic, and/or overgrazing by livestock, diminishing woody vegetation using means that do not disturb the soil, or potentially controlling invasion by non-native grasses. The effectiveness of this management would be determined by monitoring the condition of habitat and the status of the species' such that it is stable or increasing in number

**Recovery Actions:**
- 1. Protect known bladderpod populations in the United States. The known populations of Zapata bladderpod must be protected from habitat destruction or degradation and other relevant threats. Relationships with private landowners, soil conservation district agencies, roadway construction agencies, oil and gas exploration/production agencies, and rural development agencies should be developed to raise awareness of and conserve the habitat

where bladderpod populations are located. (USFWS, 2004)

- 2. Search for new populations. Surveys should be conducted to locate Zapata bladderpod populations in the United States and Mexico. Many areas of native habitat have not been surveyed for this species due to lack of access. This species is difficult to detect without an intensive search due to its ephemeral tendencies during drought conditions. Information on the Zapata bladderpod's appearance, rarity, and vulnerability should be provided to Federal, State, and private landowners. To ensure accuracy, surveys should be conducted at favorable times to locate the plants, (e.g., after rainfall) focusing on associated soil types. Federal (i.e. USFWS, USDA, etc.) and State (TPWD, TDA, etc.) agencies as well as non-governmental organizations (TNC) should increase efforts to form relationships with private landowners to search for and protect populations. (USFWS, 2004)
- 3. Conduct studies to gather information about Zapata bladderpod for management and recovery in the wild. Information on the ecology, life history, population biology, and pollination for the Zapata bladderpod in its native habitat is lacking. Efforts to understand and manage the species are therefore hindered. Studies conducted to gather basic biological information on the species should focus on factors that will enable a better understanding of habitat and provide insight into effective management for the species. Information obtained from the studies should be incorporated into management plans as appropriate to assist recovery of the species. New information should be incorporated into future recovery plan revisions. (USFWS, 2004)
- 4. Establish a botanical garden population and seed bank. Specimens from the known population(s) should be maintained at different institutions. A seed bank should be established for the species and maintained at the National Seed Storage Laboratory in Fort Collins, Colorado. The San Antonio Botanical Garden has indicated an interest in conducting research on propagation techniques and seedling production for the Zapata bladderpod, and to establish an educational botanical garden population (Cox 2002 pers. comm.). At least two refugia collections and seed bank reserves should be established and maintained to provide assurance against extinction if a loss of natural populations should occur. Cultivated plants could provide individual plants for research and provide a plant source for possible reintroductions. (USFWS, 2004)
- 5. Establish new populations as necessary to meet downlisting criteria. Due to the apparent rarity of the Zapata bladderpod within its range, reintroductions of the species may be necessary to aid recovery. The Service defines reintroduction as placing species in its historic range. As some of the collection data for this species is ambiguous, any reintroduction will need to be undertaken in areas of appropriate habitat within the historic range of the species. Reintroduction efforts could be implemented on Federal lands such as those within the LRGV Refuge Complex or on State or private lands volunteered for use. Any reintroduction efforts will follow Service policy on controlled propagation of endangered and threatened species, and incorporate the most recent reintroduction guidelines available (Falk et al. 1996). (USFWS, 2004)
- 6. Develop a public information and awareness program. Public awareness and cooperation are essential for the success of the Zapata bladderpod recovery program. An informative program about the Zapata bladderpod, threats to the species, the Recovery Plan, and the Endangered Species Act in general, should be developed for presentation to private landowners, agency personnel, and other interested groups. The program should include the identification of recovery tasks that the individuals or groups being addressed can accomplish to participate in recovery of the species. Additionally, information on the Zapata bladderpod should be included within any Lower Rio Grande or Mexico/United States Bi-

national Ecosystem program so that a coordinated approach to recovery can be implemented. (USFWS, 2004)

- 7. Develop delisting criteria and a post-recovery monitoring plan. Once the needed information on distribution, life history, ecology, and genetics are obtained, delisting criteria and a post-delisting monitoring plan can be developed. Future criteria should be developed that incorporate measures to alleviate threats identified under the five listing factors and identify when the species will no longer be threatened with endangerment. All information needs for Zapata bladderpod that have been determined as critical during the course of recovery-oriented research must be evaluated prior to delisting. If the downlisting criteria are no longer being met, the species should be returned to the status of endangered. Post-delisting monitoring for a minimum of five years is required by the ESA. (USFWS, 2004)
- Revise the recovery plan and recovery criteria to define both down-listing and de-listing criteria. (USFWS, 2015)
- Consider revising criteria to allow larger numbers of smaller populations to contribute to recovery; use frequency of recruitment as a measure of demographic trends. • Conduct public outreach in Starr and Zapata counties to raise local awareness of Zapata bladderpod. Support conservation of wild populations on private lands with willing landowners through the USFWS Partners for Fish and Wildlife Program, section 6funded grants, cooperative efforts with Natural Resources Conservation Service, or nongovernmental partners. Establish a private landowner support group for conservation of Zapata bladderpod (and perhaps other plant species of concern known from that region), similar to the group now actively working to conserve Texas snowbells (Styrax platanifolius ssp. texanus). (USFWS, 2015)
- Support scientific investigation of the reproductive biology and pollination, genetic structure of the wild populations, response to shrub cutting and prescribed burning, and degree of tolerance or requirement for gypsum (gypsovagy versus gypsophily). (USFWS, 2015)
- Prohibit vehicle traffic, including ATVs, from Zapata bladderpod occupied habitats at LRGV NWR, and limit foot traffic to the greatest extent possible. (USFWS, 2015)
- Develop a potential habitat model based on geological and soil factors. Conduct expanded surveys based on this model on private lands (with landowner permission) in Texas as well as Tamaulipas and Nuevo León (pending the resolution of security issues on the Mexican side of the border). (USFWS, 2015)
- Collect seeds from the most vulnerable populations, develop propagation methods, and reintroduce the propagated Zapata bladderpod plants into suitable protected habitats to create refugia for the vulnerable populations.

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Continue public outreach in Starr and Zapata counties to raise local awareness of Zapata bladderpod and other listed plants, such as prostrate milkweed. Support conservation of wild populations on private lands with willing landowners through the Service's Partners for Fish and Wildlife Program, section 6 grants, cooperative efforts with Natural Resources Conservation Service, or non-governmental partners. Complete in-progress scientific investigations of the reproductive biology, seed ecology, and pollination of Zapata bladderpod. Implement findings from propagation experiments to repopulate priority areas using results from best management practices currently in development to increase germination and reduce seedling transplant mortality. Prohibit vehicle traffic, including ATVs, from Zapata bladderpod occupied habitats at National Wildlife Refuge tracts, and limit foot traffic to the greatest extent possible.

Continue to work with U.S. Customs and Border Protection and Texas Department of Transportation to avoid, minimize, and mitigate impacts. When possible, prioritize habitat protection and avoidance of impacts, rather than translocation of individuals from established populations. Relocation efforts and plant survival have so far had minimal success; therefore, until better methods are developed for translocation of plants, this practice should be used with caution and only as a last resort. (USFWS, 2024)

# SPECIES ACCOUNT: *Lessingia germanorum (=L.g. var. germanorum)* (San Francisco lessingia)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A slender annual herb, mostly 1-3 dm tall. The flower heads have bright yellow disk flowers; they lack rays (NatureServe, 2015).

**Taxonomy**

Lessingia germanorum is the type species for its genus (the first plant selected by taxonomists to represent the group; the exemplar for all related species). San Francisco lessingia is currently considered a distinct species, it was formerly thought to be most closely related to Lessingia glandulifera A. Gray var. pectinata Jeps. (Howell 1929, S. Markos, pers. comm. 1998) (USFWS, 2003). It is a member of the aster family (Asteraceae) (USFWS, 2012).

**Historical Range**

Historically, L. germanorum occurred within central dune scrub habitats throughout the San Francisco peninsula. At the time of listing in 1997, Lessingia germanorum was restricted to the Presidio area of the San Francisco peninsula (five occurrences), and the Hillside Park occurrence in Daly City near the base of San Bruno Mountain (one occurrence) (USFWS, 2012).

**Current Range**

Currently the species is known to occur at seven locations in the Presidio (M. Chassé, National Park Service, in litt., October 26, 2011, p. 1;M. Chassé in litt., September 29, 2011) and at one occurrence near Hillside Park in Daly City (USFWS, 2012).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: cross-pollination (USFWS, 2012)

**Lifespan**

Adult: 1 year (USFWS, 2012)

**Breeding Season**

Adult: August - November (USFWS, 2012)

**Key Resources Needed for Breeding**

Adult: Insect pollinators (USFWS, 2012); wind (USFWS, 2003)

**Reproduction Narrative**

Adult: L. germanorum is an annual plant typically flowers between August and November. Spence (1964) determined that Lessingia species are generally self-incompatible (infertile when restricted to self-fertilization) making the presence of appropriate pollinators necessary for seed production. Information on California pollinators which was published in 1979 (Krombein et al. 1979), lists five species of native bees that visit the Lessingia germanorum. They include Andrena baeriae, Hoplitis productus gracilis, Anthophora urbana urbana, Exomalopsis nitens, and Ashmeadiella californica californica (Krombein et al. 1979, pp. 1799, 2018, 2026, 2118, and 2164) (USFWS, 2012). Reproductive output of individual plants is highly variable. Pogge (1998) found a range from 1 to over 1,400 flowerheads per plant, depending on plant size. Large plants in sparsely vegetated areas may produce many hundreds of flowerheads, each bearing up to 40 florets (potential seeds; Lane 1993), but actual average number of seeds per flowerhead is about 26 (Pogge 1998), implying that the largest individuals may produce up to 36,400 seeds. Pollination is possibly achieved by wind as well (Spence 1964) (USFWS, 2003).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Dune scrub (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Natural disturbance (USFWS, 2003)

**Geographic or Habitat Restraints or Barriers**

Adult: 80 - 300 ft. elevation (USFWS, 2012); dense vegeation (USFWS, 2003)

**Spatial Arrangements of the Population**

Adult: Clumped (USFWS, 2003)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2012)

**Tolerance Ranges/Thresholds**

Adult: Moderate (inferred from USFWS, 2003)

**Habitat Narrative**

Adult: Inhabits dune scrub habitats; now restricted to remnant sand dunes and terraces (NatureServe, 2015). It grows in open areas with blowing sand at an elevation range between 24 to 91 m (80 to 300 ft). Most populations are found in vegetation gaps in stabilized old sand dunes or sandy soils derived from ancient sandy coastal deposits (USFWS, 2012). Spence (1964) observed that annual Lessingia species were typical of dry, open, and somewhat disturbed habitats, occurring in small, dense, disjunct populations. Nearly all historic collections of San Francisco lessingia with specific locality and habitat information have been made in areas with disturbed dune deposits. Undisturbed areas of dune scrub or nonnative grassland with high density and cover of vegetation show little tendency to become invaded by San Francisco lessingia, even when they are adjacent to source populations of this species (P. Baye, pers.

observ. 1997 to 1998). In contrast, San Francisco lessingia can spread vigorously under favorable climate conditions when extensive substrate disturbance occurs (USFWS, 2003).

***Dispersal/Migration***

**Dispersal**

Adult: Low (inferred from USFWS, 2003)

**Dispersal/Migration Narrative**

Adult: The seeds, which are attached to a crown of hairlike bristles, are light and easily carried by the wind (USFWS, 2012). Seed dispersal distance has not been studied, but seedling distribution tends to be contagious around parent plants. Landscape barriers to dispersal, such as tree plantations, may be more significant barriers to dispersal than inherent dispersal ability of achenes. Seeds may also possibly be passively dispersed by humans, by adherence of seed to footwear or clothing (J. Cannon, pers. comm. 1997) (USFWS, 2003).

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

3 (USFWS, 2024)

**Population Size:**

Variable depending on year; 500,000 - 2,000,000 overall range (USFWS, 2003)

**Population Narrative:**

Currently, there are seven known occurrences at the Presidio and one population near Hillside Park. The occurrences on the Presidio occupy 2.4 ha (6 ac) and consist of an estimated mean of 129,133 plants (M. Chassé, in. litt., October 18, 2011, p. 2). In any given year, however, the area occupied and the numbers of plants will vary due to factors such as vegetation changes and levels of stewardship (M. Chassé, in. litt., October 18, 2011, p. 2). Approximately 300 plants were found in a portion of the Hillside Park occurrence in 2011 (T. Corelli, in litt., September 14, 2011). Research by Markos and Baldwin (2002) indicates that there is distinct genetic variation between the Presidio populations and the Hillside Park population (USFWS, 2012). The overall rangewide number of San Francisco lessingia plants, though highly fluctuating and quantified with variable accuracy and precision, ranges over a magnitude around 500,000 to 2,000,000 plants (USFWS, 2003). At the time of listing, San Francisco lessingia was known from the Presidio population (Occurrence 1) in San Francisco County and the San Bruno Mountain population (Occurrence 7) in San Mateo County (Service 1997, pp. 33368–33369; Diversity Database 2023, pp. 1, 6). Additionally, a population in the general vicinity of Lake Merced (Occurrence 4) had not been seen since 1947 and was considered “possibly extirpated” (Diversity Database 2023, p. 5). A population in the vicinity of Fulton Street (Occurrence 3) had not been observed since 1927 and was considered extirpated due to extensive development in the area (Diversity Database 2023, p. 4). The Crissy Field population (Occurrence 8) had been introduced to restored habitat in Crissy Field by unintentional seeding during the winter of 1999–2000 (Diversity Database 2023, p. 7). Unfortunately, reports from site managers over a nine-year period have consistently indicated the Crissy Field population has not persisted (Chassé and Forrestel 2014, p. 27; Chassé 2016, p. 31; Chassé undated (c), p. 21). Survey data for this population is included in Appendix 1, Table 2d. The Diversity Database currently categorizes the occurrence as “presumed extant” (Diversity Database 2023, p. 7). Currently, San Francisco lessingia occurs in three populations: Presidio, San Bruno Mountain, and Fort Funston (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Nonntaive plants and succession (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Currently, nonnative annual grasses and forbs are still a threat to Lessingia germanorum on the Presidio; the most dominant nonnative grass within L. germanorum habitat is Bromus diandrus (M. Chassé, in. litt., October 18, 2011, p. 2). In the absence of disturbance, back dunes on the Presidio that are capable of supporting Lessingia germanorum go through a succession to stable dune scrub which does not support the species. Large scale projects that result in the removal of dune scrub will need to be considered to maintain the L. germanorum over time (M. Chassé, in. litt., October 18, 2011, p 3) (USFWS, 2012).

**Stressor:** Urbanization (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The threats to L. germanorum from pedestrians, and hikers are considered to be low; digging dogs are a moderate threat. Since the time of listing, 0.3 acre of Lessingia germanorum habitat on the Presidio in the Lobos Dunes occurrence was adversely affected at the base of Landfill 10. Landfill 10 was in the process of remediation by the Presidio Trust when heavy rain storms in late 2009 and early 2010, eroded loose soil from the landfill, burying L. germanorum plants and habitat downslope. The owner of two parcels that support part of the Hillside Park occurrence recently submitted plans to the City of Daly City for development of a nine-lot subdivision, known as the Hillside Park Court Subdivision, on these parcels (J. Naughton, City of Daly City Planning and Zoning Department, pers. comm., December 6, 2011; K. McIntire, San Bruno Mountain Watch, in litt., November 29, 2011). In addition, a road to access the development is proposed to be constructed through a third parcel that is part of Hillside Park and is also occupied by L. germanorum (K. McIntire, in litt., November 29, 2011) (USFWS, 2012).

**Stressor:** Climate change (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects. Although there is uncertainty on the effects of climate change on this species, the vulnerability of the species to significant shifts in climate is increased by the natural and artificial barriers to dispersal (M. Chassé, in. litt., October 18, 2011, p 3) (USFWS, 2012).

**Stressor:** Loss of pollinators (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat fragmentation increases the risk at all occurrences to reduced seedset from loss of pollinators. Two recent studies of bee diversity have been conducted at several sites in the Presidio (Wood et al. 2005, Van Den Berg et al. 2010). The study conducted in 2004 (Wood et al, 2005) established a baseline of species and numbers of bees found at nine sites on the Presidio. The study conducted in 2008 (Van Den Berg et al. 2010) resampled three of these sites and added a new previously unsampled site. A comparison of the results of the two studies at the three sites in common, Thompson Reach, Lobos Dunes (the site of a L. germanorum occurrence), and the World War II Memorial, revealed a number of differences between the studies. Overall, the average bee species richness and abundance at the three previously samples sites were greater in 2004 with 47 species and 1,283 individuals compared to 36 species and 878 individuals in 2008 (Van Den Berg et al. 2010, p. 4). At the World War II Memorial site; however, a different trend was observed in 2008. Bee diversity increased from 15 species in 2004 to 26 species in 2008 although five species including the common bumblebee, Bombus vosnesenskii, had declined dramatically. Abundance of bees at this site more than doubled from 192 individuals in 2004 to 391 in 2008 (Van Den Berg et al. 2010, p. 5). The identity of the plants being visited by the pollinators monitored in these studies was not recorded (USFWS, 2012).

***Recovery***

**Reclassification Criteria:**
1. Long-term expansion of existing populations and reduction of nonnative vegetation occurs in dune reserves in the Presidio Recovery Unit (Lobos Creek, Battery Caulfield, Wherry, Rob Hill, and Public Health Services Hospital sites). The populations in these reserves are expected to fluctuate but should not decline below 50,000, 1,000, 5,000, 5,000, and 5,000, respectively. Cover of nonnative vegetation in these reserves should be less than 5 percent, 20 percent, 5 percent, 20 percent, and 20 percent, respectively. Research and monitoring are expected to determine the most efficient methods for control of nonnative vegetation and may result in modification of these recovery criteria (USFWS, 2003).

2. The population of the Daly City reserve shows no net long-term decrease. Populations are expected to fluctuate but should not decline below 50,000 plants. Cover of nonnative vegetation should show no progressive increase over more than 2 years (USFWS, 2012).

3. Recreation management needs for maintenance of a dune scrub community in the Fort Funston Reserve are established through sitespecific studies, and a reintroduced population has persisted over a full precipitation cycle. The population is expected to fluctuate but should achieve a minimum self-sustaining population size of approximately 500,000 plants within the first ten years after founders are transplanted (USFWS, 2012).

4. At least 1,000 seeds representing both the existing Presidio and Daly City populations are stored and maintained in qualified botanical gardens as insurance against extinction in the wild (USFWS, 2012).

5. The Lobos Dunes unit has expanded to Battery Caulfield Road and upper Baker Beach (USFWS, 2012).

Recovery Priority Number: 2C

**Delisting Criteria:**
1. Expanded, restored reserves with natural vegetation and dune dynamics are established in the Presidio Recovery Unit. The area including Baker Beach dunes, Lobos Dunes and nearby conifer groves, Wherry Dunes and Housing sites, and the Battery Caulfield Road site must be restored to a contiguous dune field (approximately 44 hectares [110 acres]) with unobstructed wind fetch to the Golden Gate, locally steep dune slopes, and a natural successional mosaic of active and stabilizing dune blowouts (population at least 500,000 plants; nonnative vegetative cover must not exceed 5 percent during the first 10 years of restoration and must decline over the first 15 years). Dune habitat at the Rob Hill reserve area must increase to 2 hectares (5 acres) and the southwest slope of Rob Hill must be restored to dune scrub (population at least 100,000 plants; nonnative vegetative cover must not exceed 5 percent). At least 3 hectares (7 acres) of the Public Health Services Hospital dune area above the slope must be restored to native dune vegetation (population at least 50,000 plants; nonnative vegetative cover must not exceed 5 percent). Research and monitoring are expected to determine the most efficient methods for control of nonnative vegetation and may result in modification of these recovery criteria (USFWS, 2003).

2. At least 1.2 hectares (3 acres) of Daly City Reserve in the Southern Recovery Unit are cleared of nonnative vegetation and intensively managed (population at least 50,000 plants; no increases in nonnative vegetation (USFWS, 2003).

3. Dune restoration and vegetation management should be done on 30 hectares (75 acres) at Fort Funston Reserve in the Southern Recovery Unit sufficient to establish ecosystem function and support a self-sustaining population of San Francisco lessingia. Site-specific studies of recreational use management compatible with maintenance of a dune scrub community must be completed to further define the restoration and management strategies. Buffers of landscape vegetation around all historic structures and buffer management needs will also need to be identified. A population should be reintroduced from the Daly City seed source (population at least 10,000 plants after 5 years; must reach 500,000 plants after 10 years; new colonies must spontaneously establish within 10 years). Nonnative woody vegetative cover must be below 1 percent; iceplant and European beachgrass cover must decline and be below 10 percent after 10 years. Research and monitoring are expected to determine the most efficient methods for control of nonnative vegetation and may result in modification of these recovery criteria (USFWS, 2003).

4. Populations must be introduced in the Satellite Recovery Unit (should reach 100,000 plants within 10 years, with minimum size of 5,000 plants). This criterion is preliminary subject to additional information. The locations of dune areas suitable for management within this Recovery Unit are scattered around the western half of San Francisco County. The specific size, number, and configuration of reserves needs to be determined on the basis of more detailed site-specific information (USFWS, 2003).

**Recovery Actions:**

- Protect and restore a series of ecological urban wildland reserves (USFWS, 2003).
- Promote population increases of target species within urban wildland reserves and reintroduce target species to restored habitat (USFWS, 2003).
- Long-term removal (local eradication) or suppression of invasive, nonnative vegetation within and around all reserves and subsequent reestablishment of native communities compatible with endangered species within the ecological reserves (USFWS, 2003).
- Identify a lead organization to monitor and manage the Hillside Park occurrence in Daly City. Encourage a volunteer weeding program at this site with coordination and assistance from City of Daly City, San Bruno Mountain Watch, California Native Plant Society, other environmental groups, landowners, and school groups (USFWS, 2012).
- Continue control of invasive plants, particularly annual grasses and forbs, through ongoing stewardship on the Presidio (USFWS, 2012).
- Expand Lessingia germanorum habitat in the Presidio through implementation of the Presidio Vegetation Management Plan objectives, particularly in the Wherry Reserve area (USFWS, 2012).
- Collect seed from all populations for accession at approved seed banking facilities and for outplanting within the Presidio and at other suitable habitat within the historic range of the species (USFWS, 2012).
- Formulate adaptive management strategies for native dune scrub succession that would mimic natural disturbance where such natural processes have been reduced or eliminated entirely (USFWS, 2012).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Develop site-specific management plans for occupied areas in the Presidio and Fort Funston populations (Service 2003, p. 207), and implement habitat management and population monitoring in accordance with the plans. Establish monitoring and management goals commensurate with available funding. 2. Include removal of non-native shading trees at Battery Caulfield in management plan for that site. Seek funding to remove trees. 3. Collect seeds at all occupied locations and for storage at facilities approved by the Center for Plant Conservation. 4. Conduct research into how long San Francisco lessingia seeds can remain viable in the soil. 5. Survey the San Bruno population (USFWS, 2024).

# SPECIES ACCOUNT: *Liatris ohlingerae* (Scrub blazingstar)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 8/28/1989; Southeast Region (R4)

**Physical Description**

The scrub blazing star (Liatris ohlingerae), a member of the aster family, is a long-lived perennial herb having a thickened, cylindric root. Its stems are erect, usually unbranched, and it can grow up to 1 m tall. Its leaves are fleshy and narrow (1 to 2.5 mm), and generally 3 to 8 cm long (Wunderlin et al. 1980). Flower heads are well separated on the stem with individual disc flowers up to 1 cm broad; the inflorescences are up to 3 cm across. The corollas are bright purplish-pink in color. The broad flower heads and narrow leaves distinguish L. ohlingerae from the eight other Liatris species in central Florida. (USFWS, 1999)

**Taxonomy**

Blake (1923) placed L. ohlingerae in the blazing star genus, naming it Lacinaria ohlingerae. Small (1924) created a new genus for this plant, which became Ammopursus ohlingeri. Robinson (1934) reinstated the scrub blazing star in the large genus of the blazing stars as Liatris ohlingerae. Gaiser's (1946) treatment of Liatris, and Cronquist's (1980) floristic treatment of the aster family in the Southeast retains this plant in the genus Liatris, although Lakela (1964) argued in favor of reinstating Ammopursus as a genus containing only one species. (USFWS, 1999)

**Historical Range**

Highlands and Polk Counties, Florida (USFWS, 1999)

**Current Range**

Southern Lake Wales Ridge of southern Polk and Highlands Counties, Florida (USFWS, 2019)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Dependency on Other Individuals or Species**

Adult: pollinators

**Breeding Season**

Adult: Peak flowering of scrub blazing star is from June through August.

**Other Reproductive Information**

Adult: The growth of new basal leaves begins in March and the elongation of stems begins in April. Flowering and fruiting occurs from summer through fall. Flowering begins in May and June, but the peak occurs in August with a rapid decline toward the middle of September. The seeds start to disperse in August and peak in October. Each plant produces approximately eight filled (presumably viable) seeds a year. The plant's above ground parts die back in October to November or by the first freeze. Liatis ohlingerae can remain in a dormant state through at least one growing season. The seedling growth rate for L. ohlingerae is slow compared to most other scrub endemics. Many others grow to reproductive maturity in only one season, while the juvenile stage for L. ohlingerae was found to be at least 2 years. Interestingly, cultivated L. ohlingerae mature to flowering in 8 months. Limited water and nutrients are believed to be responsible for the difference between wild populations and cultivated plants. (USFWS, 1999)

**Reproduction Narrative**

Adult: Liatris ohlingerae requires cross-pollination to reproduce. Butterflies, especially skippers (Hesperiidae), are thought to be the primary pollinators, although other insects may also contribute to pollination (FWS 1996). Flowering and fruiting in this species all more abundant in shaded microhabitats. Individuals in open and edge habitats only produce one-quarter as many mature flower heads (Herndon 1996). The seeds of this species are short-distance wind dispersers, with bristles and hairs that assist in "planting" the seeds correctly. Low germination on leaf litter-covered soil suggests that many seeds in shade (the favored microhabitat) may get trapped in the leaf litter and fail to sprout or die shortly after sprouting (Herndon 1996). (USFWS, 1999)

**Habitat Type**

Adult: Rosemary bald habitats and adjoining scrubby flatwoods

**Environmental Specificity**

Adult: Narrow (USFWS, 2019)

**Habitat Narrative**

Adult: The species is found in rosemary scrub and also along the ecotone between rosemary scrub and scrubby flatwoods. It can also be found scattered in surrounding scrub. Scrub blazing star has important microhabitat requirements, particularly its preference for shade. Unlike most other scrub endemics, scrub blazing star appears to thrive in lightly shaded areas and does not specialize in open microsites (Herndon 1999, Weekley et al. 2008b). Both rosemary scrub and scrubby flatwoods are pyrogenic (fire-maintained) communities. Historical FRIs in rosemary scrub ranged from 20 to 100 years, while scrubby flatwoods have a 5 to 20 year average FRI. (USFWS, 2019)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: No information available.

***Population Information and Trends***

**Population Trends:**

Only 6 populations are considered stable, 7 are estimated to be declining, and 32 have an unknown status mostly due to lack of recent surveys (USFWS, 2021)

**Number of Populations:**

~45 extant (USFWS, 2021)

**Population Narrative:**

Scrub blazing star is extant on the Lake Wales Ridge (roughly 90 to 100 occurrences) and Winter Haven Ridge (one occurrence) in Highlands and Polk Counties. Its range extends from Lake Blue in Polk County south along the Lake Wales Ridge to ABS at the south end of the Ridge in Highlands County (FNAI 2009a). The last FNAI Element Tracking Summary (FNAI 2015) reported 70 extant occurrences, 45 of which were on managed areas. This was a significant decrease (approximately 23 percent) from the last 5-year status review (Service 2010a), which reported 91 extant occurrences. (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species is restricted to xeric scrub habitats in one or more of the interior Central Florida counties of Polk, Highlands, Hendry, Osceola, and Lake, where habitat destruction from development continues to occur and development pressure remains high. Areal extent of post-Columbian xeric upland habitat loss on the Lake Wales Ridge is estimated to exceed 85 percent (Weekley et al. 2008a). Increasing pressure from population growth is likely to result in further loss of these habitats going forward. Carr and Zwick (2016) analyzed existing land use and landscape patterns to identify areas (including central Florida) most likely for development to accommodate a growing human population. They suggests that Florida's 2070 population will be early 15 millionpersons greater than in 2010, for an estimated total of 33,721,828. Using these figures, they estimated relative losses to agriculture, open space, and conservation to other land uses. If trends continue, they estimate 34 percent of land will be developed by 2070, up from 19 percent in 2010. At the same time, conservation lands will increase less than 1 percent (from 9,269,000 acres in 2010 to 9,525,000 acres by 2070). Overall, loss of habitat to development, primarily on private lands, will likely continue in Central Florida, eliminating populations and reducing the area of suitable habitat for these species. Therefore, habitat on protected lands are critical for the recovery of this scrub plants. (USFWS, 2019)

**Stressor:** Lack of adequate fire management
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire is necessary to maintain the scrub habitats upon which this species depends. Historically, lightning-induced fires were a vital component in maintaining native vegetation within the scrub community. Fire suppression started on a regional scale on the Central Florida ridges about 80 years ago. Due to the extent of residential and agricultural development throughout Central Florida, fire has all but disappeared from the region as a widespread, natural phenomenon. Prescribed fire is a crucial management component for maintenance of all scrub habitats. Because of the difficulties of applying prescribed fire on an ever-increasing urban landscape, imperiled species on unmanaged sites will almost certainly disappear over time (Turner et al. 2006). In managed areas, prescribed fire is essential to manage habitats and restore or maintain suitable conditions for scrub species. (USFWS, 2019)

**Stressor:** Limited geographic range
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species occurs occur within a relatively limited geographic range in Central Florida. The limited geographic range in combination with the loss of habitat has resulted in a highly fragmented landscape where the remaining scrub areas and their residing species have become more and more isolated from each other, thereby making resiliency, redundancy, and representation more challenging to achieve. The effects of habitat fragmentation on species richness have been exhaustively studied (MacArthur and Wilson 1967, Diamond 1975, 1978; Simberloff and Abele 1976, 1982; Zimmerman and Bierregaard 1986). For most taxonomic groups, large habitat patches in close proximity to each other provide for the greatest species diversity and minimize extinction probabilities. On the contrary, small patches that are isolated are less likely to preserve species that would otherwise be common in the mosaic of communities that existed before isolation. Since at least the Pleistocene, Florida scrub has been characterized by an insular, discontinuous distribution, but the degree of habitat fragmentation seen today is unprecedented and certainly will contribute to increases in extinction rates among scrub-dependent plants and animals. (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**
1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations and sites needed to assure 20 to 90 percent probability of persistence for 100 years (USFWS, 1999)

2. When these sites, within the historic range of L. ohlingerae, are adequately protected from further habitat loss, degradation, and fragmentation (USFWS, 1999)

3. When these sites are managed to maintain the rosemary bald of the xeric oak scrub community to support L. ohlingerae (USFWS, 1999)

4. When monitoring programs demonstrate that these sites support the appropriate numbers of self-sustaining populations, and those populations are stable throughout the historic range of the species (USFWS, 1999)

Recovery Priority Number: 2

**Delisting Criteria:**
1. At least 40 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)

2. Populations (as defined in criterion 1) in rosemary scrub or scrubby flatwoods habitats are distributed across the known range of the species. (USFWS, 2019)

3. Populations are protected and managed via a conservation mechanism to a degree that enough suitable habitat is present for the species to remain viable for the foreseeable future. (USFWS, 2019)

**Recovery Actions:**

- Determine current distribution of L. ohlingerae. This species is difficult to survey. It is easily overlooked when not in bloom and does not grow in the typical open gaps of scrub. A thorough survey is needed to determine the distribution for this species. Survey efforts should be focused from August through October. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection. (USFWS, 1999)
- Conduct research on life history characteristics. Though recent work has greatly increased the base of knowledge for this species, more work on its basic biology and ecology is necessary for effective recovery. (USFWS, 1999)
- Monitor existing populations of L. ohlingerae. (USFWS, 1999)
- Provide public information about L. ohlingerae. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. Care is needed, though, to avoid revealing specific location information. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of L. ohlingerae and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)
- Develop delisting criteria. Once reclassification is achieved, research and monitoring results may provide data necessary to develop delisting criteria. (USFWS, 1999)
- Habitat-Level Recovery Actions: Prevent degradation of existing habitat. Restore areas to suitable habitat. Conduct habitat-level research projects. Monitor habitat/ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS A detailed discussion of recovery actions and criteria are presented in the Recovery Plan and amendment (Service 1999 and 2019, respectively). During this status review, new and/or targeted potential recovery activities were identified and are included below. Recovery Activities • Work with State, Federal, and non-profit partners to ensure adequate fire management is achieved at sites that support scrub blazing star. • Work with private landowners to acquire or conserve extant populations and restore scrub habitat on these sites. • Ensure representation of scrub blazing star at the National Center for Genetic Resources Preservation in Fort Collins, Colorado. Monitoring/Research Activities • Determine the condition of populations on private land whose status is currently unknown. • Continue demographic monitoring at ABS and LWRSF and expand to additional populations throughout the range to evaluate population trends. • Conduct monitoring to document presence on protected lands at least every five years (Menges et al. 2019). • Conduct presence/absence surveys in areas of suitable habitat within and north of the current range to discover new populations, expand extent of known populations, or to verify the species is not likely present. • Determine the factors responsible for low seedling recruitment. Specifically, examine potential impacts from changes in the timing and amount of precipitation expected with climate change. • Evaluate the overall threat posed by herbivory across the range and at various life stages. (USFWS, 2021)

# SPECIES ACCOUNT: *Lilaeopsis schaffneriana var. recurva* (Huachuca water-umbel)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 1997, Southwest Region (R2)

**Physical Description**

Lilaeopsis schaffneriana ssp. recurva is a semi-aquatic to fully aquatic herbaceous perennial in the carrot family (Apiaceae). The root system is comprised of both long horizontal rhizomes and connected shorter vertical rhizomes. Hollow linear leaves that taper to a point are produced singly or in clusters at the top of short rhizomes. The leaves vary greatly in length from 2.5 to 33 centimeters (cm) (0.98 to 12.99 inches (in)) depending on their habitat, with shorter leaves typically found in dryer environments and longer when submerged in water. Umbels (umbrella-like flower structures) are born on stalks shorter than the leaves and contain three to ten 1.0 to 2.0 mm (0.04 to 0.08 in) wide perfect flowers with five white to slightly maroon tinted petals and maroon anthers. Fruits are spherical and dry, 1.6 to 2.3 mm (0.6 to 0.09 in) long by 1.2 to 2.0 mm (0.04 to 0.08 in) broad, with five distinct spongy ribs that make the seed buoyant and easily dispersed by water.

**Taxonomy**

Lilaeopsis schaffneriana ssp. recurva is a member of the carrot family (Apiaceae). Within the Apiaceae, Lilaeopsis is in tribe Oenantheae and subfamily Apioideae. In general, researchers consider plants west of the Continental Divide in Sonora to be ssp. recurva and those to the east, ssp. schaffneriana (64 FR 37441, p. 37442). Genetic analysis is warranted to better understand the relationship of occurrences within and between localities in southeastern Arizona, northern Sonora, and northwestern Chihuahua, Mexico (USFWS, 2017).

**Historical Range**

The type specimen of L. schaffneriana ssp. recurva was collected in the Santa Cruz Valley of southern Arizona near Tucson on May 19, 1881, in an area that is now encompassed by the City of Tucson and no longer provides suitable habitat for the species.

**Current Range**

Within the Santa Cruz, San Pedro, and Rio Yaqui watersheds in southern Arizona, we are aware of 17 locations supporting extant occurrences of L. schaffneriana ssp. recurva, 8 locations where all L. schaffneriana ssp. recurva occurrences are considered extirpated, and 6 locations where historical occurrences have not been seen in recent years. Within the Santa Cruz, San Pedro, Rio Yaqui, Rio Sonora, and Rio Concepcion watersheds in Sonora, Mexico, we are aware of 21 locations supporting L. schaffneriana ssp. recurva occurrences, though most of these locations have not been revisited in recent years (USFWS, 2017).

**Critical Habitat Designated**

Yes; 7/12/1999.

**Legal Description**

On July 12, 1999, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Lilaeopsis schaffneriana var. recurva (Huachuca water-umbel) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes seven critical habitat units (CHUs), in Arizona(64 FR 37441-37453).

**Critical Habitat Designation**

The critical habitat designation for Lilaeopsis schaffneriana var. recurva includes seven CHUs in Cochise and Santa Cruz counties, Arizona.  Designated habitat includes a total of 83.2 kilometers (km) (51.7 miles (mi)) of streams or rivers (64 FR 37441-37453).

Unit 1. Santa Cruz County, Arizona. From USGS 7.5' quadrangle map Sonoita, Arizona. Gila and Salt Principal Meridian, Arizona: T. 20 S., R. 16 E., beginning at a point on Sonoita Creek in sec. 34 at approx. 31°39'19'' N latitude and 110°41'52'' W longitude proceeding downstream (westerly) to a point in sec. 33 at approx. 31°39'07'' N latitude and 110°42'46'' W longitude covering approx. 2 km (1.25 mi.).

Unit 2. Santa Cruz County, Arizona. From USGS 7.5' quadrangle map Lochiel, Arizona. That portion of the Santa Cruz River beginning in the San Rafael De La Zanja Grant approx. at 31°22'30'' N latitude and 110°35'45'' W longitude downstream (southerly) to Gila and Salt Principal Meridian, Arizona, T. 24 S., R. 17 E., through secs. 11 and 14, to the south boundary of sec. 14 covering approx. 4.4 km (2.7 mi.). Also, a tributary that begins in T. 24 S., R. 17 E., sec. 13 at approx. 31°21'10'' N latitude and 110°34'16'' W longitude downstream (southwesterly) to its confluence with the Santa Cruz River covering approx. 3 km (1.9 mi.).

Unit 3. Cochise County, Arizona. From USGS 7.5' quadrangle map Huachuca Peak, Arizona. Gila and Salt Principal Meridian, Arizona: That portion of Scotia Canyon beginning in T. 23 S., R. 19 E., sec. 3 at approx. 31°27'19'' N latitude and 110°23'44'' W longitude downstream (southwesterly) through secs. 10, 9, 16 and to approx. 31°25'22'' N latitude and 110°25'22'' W longitude in sec. 21 covering approx. 5.4 km (3.4 mi.).

Unit 4. Cochise County, Arizona. From USGS 7.5' quadrangle map Huachuca Peak, Arizona. Gila and Salt Principal Meridian, Arizona: That portion of Sunnyside Canyon beginning in T. 23 S., R. 19 E., on the east boundary of sec. 10 downstream (southwesterly) to the south boundary of sec. 10 covering approx. 1.1 km (0.7 mi.).

Unit 5. Cochise County, Arizona. From USGS 7.5' quadrangle map Miller Peak, Arizona. That portion of Garden Canyon in the Fort Huachuca Military Reservation beginning at approx. 31°27'13'' N latitude and 110°22'33'' W longitude downstream (northwesterly) to approx. 31°28'45'' N latitude and 110°20'11'' W longitude covering approx. 6.1 km (3.8 mi.).

Unit 6. Cochise County, Arizona. From USGS 7.5' quadrangle map Miller Peak, Arizona. Gila and Salt Principal Meridian, Arizona: That portion of Bear Canyon beginning at a point in T. 24 S., R. 19 E., sec. 1 at approx. 31°22'30'' N latitude and 110°21'47'' W longitude upstream through T. 23 S., R. 19 E., sec. 36 to a point in sec. 31 at approx. 31°23'18'' N latitude and 110°21'22'' W longitude covering approx. 1.7 km (1.0 mi.). Also, continuing up an unnamed tributary beginning at a point in T. 23 S., R. 19 E., sec. 31 at approx. 31°23'18'' N latitude and 110°21'22'' W longitude upstream (northerly) to a point in T. 23 S., R. 19 E., sec. 30 at approx. 31°23'44'' N latitude and 110°21'14'' W longitude covering approx. 0.9 km (0.5 mi.). Also, that portion of Lone Mountain

Canyon beginning at its confluence with Bear Creek at a point in T. 23 S., R. 19 E., sec. 36 at approx. 31°22'54'' N latitude and 110°21'43'' W longitude to a point in sec. 36 at approx. 31°23'26'' N latitude and 110°21'58'' W longitude, thence up an unnamed tributary northwesterly into sec. 25 thence northerly to a point at approx. 31°24'13'' N latitude and 110°21'54'' W longitude covering approx. 2.7 km (1.7 mi.). Also that portion of Rattlesnake Canyon beginning at its confluence with Lone Mountain Canyon in T. 23 S., R. 19 E., sec. 36 upstream northeasterly into sec. 25 to a point at approx. 31°22'08'' N latitude and 110°21'31'' W longitude covering approx. 1.5 km (1.0 mi.).

Unit 7. Cochise County, Arizona. From USGS 7.5' quadrangle maps: Hereford, Ariz.; Tombstone SE, Ariz.; Nicksville, Ariz.; Lewis Springs, Ariz.; Fairbank, Ariz.; Land, Ariz. Gila and Salt Principal Meridian, Arizona: That portion of the San Pedro River beginning in the San Rafael Del Valle Grant at a point approx. 200 meters upstream (south) of the Hereford Road bridge at approx. 31°26'16'' N latitude and 110°06'24'' W longitude continuing downstream (northerly) through the San Rafael Del Valle Grant; T. 21 S., R. 22 E.; T. 21 S., R 21 S.; through the San Juan De Las Boquilla y Nogales Grant to a point at approx. 31°48'28'' N latitude and 110°12'32'' W longitude covering approx. 54.2 km (33.7 mi.).

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation.  The PCEs of Lilaeopsis schaffneriana var. recurva critical habitat consists of four components (64 FR 37441-37453):

(1) Sufficient perennial base flows to provide a permanently or nearly permanently wetted substrate for growth and reproduction of Lilaeopsis;

(2) A stream channel that is relatively stable, but subject to periodic flooding that provides for rejuvenation of the riparian plant community and produces open microsites for Lilaeopsis expansion;

(3) A riparian plant community that is relatively stable over time and in which nonnative species do not exist or are at a density that has little or no adverse effect on resources available for Lilaeopsis growth and reproduction; and

(4) In streams and rivers, refugial sites in each watershed and in each reach, including but not limited to springs or backwaters of mainstem rivers, that allow each population to survive catastrophic floods and recolonize larger areas.

***Life History***

**Food/Nutrient Resources**

**Food Source**

Adult: Substrate nutrients

**Food/Nutrient Narrative**

Adult: Organic, perenially wet (or nearly so) soils comprised of silt or clay (Titus and Titus 2008) provide the nutrients needed for growth.

**Reproductive Strategy**

Adult: Vegetative (clonal), experiments suggest that most if not all Lilaeopsis spp. are self-compatible.

**Dependency on Other Individuals or Species**

Adult: Although the pollinator(s) of this taxon is unknown, Radke (pers. comm. April 22, 2014) documented a formica ant species feeding on the nectar of Lilaeopsis schaffneriana ssp. recurva flowers along the San Pedro River in both 2012 and 2013; he believes this may be an important pollinator for the taxon.

**Breeding Season**

Adult: Flowering has been observed episodically between March and October, peaking in July and occurring with abundance irregularly (Warren et al. 1991, p. 15). Germination occurs one to two weeks after seeds disperse (Gori 1995, p. 3) and flowering can begin within three months of germination.

**Key Resources Needed for Breeding**

Adult: Hydrologic regime; intermediate level of flooding (not scouring)

**Reproduction Narrative**

Adult: Although Lilaeopsis schaffneriana ssp. recurva is capable of reproducing both sexually, through seed, and asexually, through rhizomes, vegetative reproduction is likely the primary form of reproduction. Never-the-less, natural seed banks are important for the persistence of rare species and observations in the field suggest L. schaffneriana ssp. recurva seed may remain viable for 5 to 10 years, an important survival strategy during times of drought. Another important survival strategy of L. schaffneriana ssp. recurva are its rhizomes, which enable occurrences to rapidly expand or contract in size between years, seasons, or both, in response to local environmental conditions including temperature and water availability. The taxon can re-root if clumps of rhizomes are dispersed via floods to new habitats. Periodic low to moderate flooding provides disturbed open space for re-colonization, reduces competition (FWS 1999), and acts as a dispersal mechanism for seeds and dislodged clumps (Titus and Titus 2008, FWS 1997). Dislodged clumps only survive if they are deposited in sites that provide the necessary habitat (see sheltering) (Titus and Titus 2008). Flowering has been observed episodically between March and October, peaking in July and occurring with abundance irregularly (Warren et al. 1991, p. 15). Germination occurs one to two weeks after seeds disperse (Gori 1995, p. 3). Although the pollinator(s) of this taxon is unknown, Radke (pers. comm. April 22, 2014) documented a formica ant species feeding on the nectar of Lilaeopsis schaffneriana ssp. recurva flowers along the San Pedro River in both 2012 and 2013; it is believed this may be an important pollinator for the taxon (USFWS, 2017).

**Habitat Type**

Adult: Cienegas (marshes), rivers, streams, and springs in permanently wet (or nearly so) muddy or silty substrates with some organic content; generally found in shallow and slow-flowing waters that are relatively stable, or in active stream channels containing refugial sites where the plants can escape the effect of scouring floods. The taxon occurs in both full sun and understory shade of Fremont cottonwood-Goodding willow forests. Found between 610 to 2,170 m (2,001-7,060 ft) elevation in the US, the range of the taxon crosses the Sierra Madrean Region of southeastern Arizona and adjacent portions of Sonora, Mexico (USFWS, 2017).

**Habitat Vegetation or Surface Water Classification**

Adult: (1) Forest & Woodland, (2) Shrubland & Grassland, (3) Semi-desert, (5) Aquatic Vegetation

**Dependencies on Specific Environmental Elements**

Adult: Yes; see key resources needed

**Environmental Specificity**

Adult: High

**Tolerance Ranges/Thresholds**

Adult: Low

**Site Fidelity**

Adult: None

**Habitat Narrative**

Adult: The Huachuca water umbel is found between 610 and 2,170 m (2,001 and 7,060 ft) elevation in the Sky Island Region of southeastern Arizona and as high as 2,240 m (7,349 ft) elevation in adjacent portions of Sonora, Mexico (Titus & Titus 2008 p. 459; Vernadero Group 2011 p. 3; Vernadero Group & Desert Botanical Garden 2012 p. A-16). The taxon is found in deep riparian soils along the margins of flood plains, stream terraces, cienegas, and alluvial fans in 0 to 15 cm of water (USFWS, 2024).

***Dispersal/Migration***

**Motility/Mobility**

Adult: Low

**Dispersal**

Adult: Usually through flood waters, but long-distance despersal of seeds or rhizonmes by birds or other vectors might be responsible for geographically distant occurrences.

**Dispersal/Migration Narrative**

Adult: Surface and groundwater development has disrupted aquatic habitat connectivity that once provided opportunities for expansion of the population into new, downstream habitats after flood events. After a flood, Lilaeopsis can rapidly expand its population and occupy disturbed habitat until interspecific competition exceeds its tolerance. In rivers and streams, the expansion and contraction of Lilaeopsis populations appears to depend on the presence of ‘‘refugia’’ where the species can escape the effects of scouring floods, a watershed that has an unaltered flow regime, and a healthy riparian community that stabilizes the channel. (USFWS 1999). At present, the known populations are largely isolated from other waterways. Long-distance despersal of seeds or rhizonmes by birds or other vectors might be responsible for geographically distant occurrences.

***Population Information and Trends***

**Population Trends:**

Declining

**Species Trends:**

Stable or declining across range

**Number of Populations:**

30 naturally-occurring locations in the U.S. and 21 in Sonora, Mexico.

**Population Size:**

Individual L. schaffneriana ssp. recurva plants are difficult to identify due to their clonal reproduction and clustered growth habit. In addition, the taxon is difficult to detect due to its diminutive size.

**Additional Population-level Information:**

The clonal nature of the taxon may also reduce genetic diversity, increasing vulnerability to extinction. Occurrences are in many cases isolated which makes the chance of natural recolonization after extirpation less likely (USFWS, 2017).

**Population Narrative:**

Within the Santa Cruz, San Pedro, and Rio Yaqui watersheds in southern Arizona, we are aware of 17 locations supporting extant occurrences of L. schaffneriana ssp. recurva, 8 locations where all L. schaffneriana ssp. recurva occurrences are considered extirpated, and 6 locations where historical occurrences have not been seen in recent years. Within the Santa Cruz, San Pedro, Rio Yaqui, Rio Sonora, and Rio Concepcion watersheds in Sonora, Mexico, we are aware of 21 locations supporting L. schaffneriana ssp. recurva occurrences, though most of these locations have not been revisited in recent years. The greatest quantities of L. schaffneriana ssp. recurva are found within the San Pedro River, the western Huachuca Mountains and Cienega Creek (USFWS, 2017).

***Threats and Stressors***

**Stressor:** Aquatic habitat degradation
**Exposure:** Not assessed; see narrative
**Response:** Not assessed; see narrative
**Consequence:** Not assessed; see narrative
**Narrative:** Human activities that contribute to aquatic habitat loss and degradation within the historical range of L. schaffneriana ssp. recurva include: groundwater overdrafts, surface water diversions, impoundments, channelization, improper livestock grazing, agriculture, mining, sand and gravel operations, road building, non-native species introductions, urbanization, wood cutting, wildfires, and recreation (Hendrickson and Minckley 1984, p. 161; Bahre 1991, pp. 177-178; Hereford 1993, p. 2). Flood control projects that permanently alter stream flow characteristics may reduce or eliminate stream sinuosity and associated pool and backwater habitats that are critical to L. schaffneriana ssp. recurva. Ground water pumping may lead to perennial reaches becoming intermittent or ephemeral and to springs drying out, resulting in the loss of L. schaffneriana ssp. recurva occurrences (Warren et al. 1991, p. 7; 60FR 16836, p. 16838; Service 2014b, pp. 148-149). Such activities are widespread in Arizona.

**Stressor:** Wildfire and associated sedimentation and scouring
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire would generally not burn the wetland habitat of L. schaffneriana ssp. recurva due to high humidity; however it has the potential to burn adjacent upland habitats causing indirect effects on L. schaffneriana ssp. recurva and its habitat throughout the range of the taxon (Service 2009a, p. 21). Effects include increased runoff of floodwaters, deposition of debris and sediment originating in the burned area, and potential for scouring of L. schaffneriana ssp. recurva individuals and habitat (Service 2014b, p. 145). Since the mid-1980s, wildfire frequency in western forests has nearly quadrupled compared to the average of the period 1970 to 1986 (Westerling et al. 2006, p. 941). The timing, frequency, extent, and destructiveness of wildfires are likely to increase (Westerling et al. 2006, p. 943) and with them changes in vegetation community composition and structure, increased presence of invasive exotic plants, and alterations in the hydrologic and nutrient cycles (Griffis et al. 2000, p. 243; Crawford et al. 2001, p. 265; Hart et al. 2005, p. 167; Smithwick et al. 2005, p. 165; Stephens et al. 2014, p. 42). Post-fire flooding and associated sedimentation can strip out, bury, or stunt growth of L. schaffneriana ssp. recurva patches, or transform habitat from wet or marshy to dry, sandy, or gravelly (Service 2009a, p. 24; Service 2013a, p. 4). At lower elevations, the spread of non-native invasive grasses has been increasing in recent decades and these non-native grasses not only out-compete native grassland species, but they have a completely different fire regime than the native grasses, tending to form dense stands that promote higher intensity fires more frequently (USFWS, 2017).

**Stressor:** invasive, non-native plant competition
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Lilaeopsis schaffneriana ssp. recurva are most abundant in areas with ample sunlight and low competition with other native and non-native species (Titus and Titus 2008c, p. 459). The best available scientific and commercial information indicates that invasive exotic plants have increased their presence within aquatic habitat of southeastern Arizona, and this invasion and expansion of infestations are expected to continue. Because L. schaffneriana ssp. recurva is sensitive to competition from both native and non-native herbaceous plants, the continued increase in such species as S. halepense, C. dactylon, N. officinale, and R. discolor can only lead to a decrease in the presence of L. schaffneriana ssp. recurva throughout the range of the taxon (USFWS, 2017).

**Stressor:** Livestock grazing
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Lilaeopsis schaffneriana ssp. recurva are affected by livestock grazing in the following ways: 1) trampling, 2) direct impacts from construction of range improvement projects, 3) changes in stream geomorphology that lead to erosion, sedimentation, and downcutting, 4) watershed degradation and resulting adverse effects to stream hydrology, and 5) consumption (Service 1999, p. 237; Anderson 2006, p. 28). Observations of L. schaffneriana ssp. recurva response to grazing indicate the taxon is capable of experiencing light to moderate grazing with

negligible impact (Simms pers. comm. October 26, 2011; Anderson 2006, pp. 22, 31; Edwards pers. comm. February 21, 2001; Rorabaugh 2013, entire). However, grazing during dry periods when cattle spend a disproportionate amount of their time, if not controlled, in riparian areas, may result in harmful effects to L. schaffneriana ssp. recurva and other riparian obligates (Edwards pers. comm. February 21, 2001; Service 2002a, pp. 76-77; Krueper 1996, p. 287; Malcom and Radke 2008, p. 81; Service 2014a, pp. 3, 6-7). In such instances, severe and widespread trampling may occur; roots and soil structure can be damaged; vegetation species composition and structure can shift; soil can become compacted; stream banks can be degraded; runoff and soil erosion from storm events may increase with higher peak flows; and stream entrenchment may occur; all of which would have harmful effects on L. schaffneriana ssp. recurva habitat and existing occurrences (Service 2002a, p. 138; Krueper 1996, pp. 287-288; Simms pers. comm. October 26, 2011). In instances where natural disturbance is low or infrequent, occasional trampling and grazing by domestic livestock could improve habitat for L. schaffneriana ssp. recurva; poorly managed livestock use, however, can be detrimental to the taxon and its habitat (USFWS, 2017).

**Stressor:** Dought and climate change
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Lilaeopsis schaffneriana ssp. recurva evolved in the Southwest and has persisted in many locations throughout its range through historical droughts such as those of the 1950s. However, given the severity and persistence of the present multi-year drought, it is unknown how long L. schaffneriana ssp. recurva will maintain viability in de-watered habitat. It has been suggested that seed from this taxon may persist for 5 to 10 years in such situations (Titus and Titus 2008a, p. 319; Titus and Titus 2008b, p. 398; Titus and Titus 2008c, p. 463). There is a reasonable likelihood that the current drought and rise in temperatures will continue for many more years throughout the range of L. schaffneriana ssp. recurva. It is unknown how long L. schaffneriana ssp. recurva can remain dormant during an extended drought. The projected drought will likely contain periods of high year-to-year precipitation variability characteristic of Southwest climate. Rise in temperature is also likely to continue for many more years. Whether this variability will be enough to preserve occurrences L. schaffneriana ssp. recurva remains unknown.

**Stressor:** Recreation
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Recreational activities, such as hiking and camping, if poorly managed, can result in soil compaction, streambank destabilization, erosion and sedimentation, increases in the presence of invasive non-native plant species, and trampling of L. schaffneriana ssp. recurva and other riparian plant species, thus reducing habitat quality (USFWS 2017).

### *Recovery*

**Reclassification Criteria:**
A minimum cumulative extent of 2,000 square meters (0.2 ha / 0.5 ac) of naturally occupied habitat exists in the San Pedro Watershed, 20 percent of which occurs in tributary streams,

springs, or cienegas; and a minimum of 2,000 square meters (0.2 ha /0.5 ac) in the Santa Cruz Watershed, 90 percent of which occurs in tributary streams, springs, or cienegas, distributed among the areas of Cienega Creek (35 percent), Sonoita Creek (10 percent), the San Rafael Valley uplands and mainstem (10 percent), and the western Huachuca Mountains (35 percent); and a minimum of 125 square meters (0.01 ha / 0.03 ac) exists in the Rio Yaqui Watershed; this level of occupancy is sustained or improved for a minimum of 10 years over a 15 year period. (USFWS, 2017)

At least 3 separate introduced occurrences with a minimum cumulative extent of 150 square meters (0.015 ha / 0.037 ac) of occupied habitat are placed in each of the three United States watersheds and are stable or increasing over a 10 year period (USFWS, 2017).

Threats to the taxon and its habitat have been managed and reduced, and management is in place for a minimum of 20 years to ensure the persistence of occurrences with minimum cumulative extent (as reflected by the achievement and maintenance of downlisting criteria 1 and 2) in each of the three United States watersheds (USFWS, 2017).

A living collection of as many plugs as resources allows, collected from genetically distinct regions (e.g. Fort Huachuca / SPRNCA north; San Rafael / Las Cienegas / Sonoita; SPRNCA south / San Bernardino), from both the San Pedro and the Santa Cruz watersheds is maintained in at least one botanical garden in southern Arizona for recovery and educational purposes (USFWS, 2017).

Seeds of L. schaffneriana ssp. recurva are collected following Center For Plant Conservation guidelines, which include collecting from no more than 10 percent of the standing seed crop from 50 individual seed bearing plants per population (if the population size permits), and collecting from a variety of microsites and physical characteristics within the stand of plants. These seeds are stored at both the Agricultural Research Service National Center for Genetic Resources Preservation in Fort Collins, Colorado and stored according to protocols at a local facility such as the Desert Botanical Gardens in Phoenix, Arizona, for long-term conservation and recovery purposes (USFWS, 2017).

Recovery Priority Number: 3C

**Delisting Criteria:**
To delist L. schaffneriana ssp. recurva, the criteria for down-listing must be met and the level of occupancy in the downlisting criteria is sustained or increasing for a minimum of 20 years over a 30 year period (USFWS, 2017).

**Recovery Actions:**
- Maintain or enhance groundwater hydrography, as measured by both well observations and stream gages, by reducing water withdrawal and increasing water conservation and recharge (USFWS, 2017).
- Conserve historical, existing, newly discovered, and newly established L. schaffneriana ssp. recurva occurrences and their seedbanks through the protection of occupied habitat, unoccupied corridors, and habitat quality; augment existing and establish new L. schaffneriana ssp. recurva occurrences in appropriate habitat using appropriate genetic stock to increase the redundancy (number of occurrences) and resiliency (size of

occurrences) of the taxon to help ensure the long-term survival of the taxon in southern Arizona; establish plants at botanical gardens and other Service approved facilities for research, recovery, and educational purposes; and maintain seeds for conservation and recovery at seed storage facilities (USFWS, 2017).

- Remove stressors related to invasive plants and poorly managed livestock grazing to historical, existing, newly discovered, and newly established L. schaffneriana ssp. recurva occurrences and their habitats (USFWS, 2017).
- Work toward a standardized monitoring technique and continue monitoring occurrences (USFWS, 2017).
- Conduct research and monitoring that will facilitate better understanding of: a) the distribution and genetics of the taxon in both the United States and Mexico, b) population and metapopulation dynamics and trends, c) life history, d) response to threats, and e) other relationships key to recovery of the species (USFWS, 2017).
- Develop collaborative partnerships with Federal and State land managers, private landowners, museums and botanical gardens, seed storage facilities, and others; provide outreach to the public as needed to accomplish recovery; promote the achievement of conservation and recovery in Mexico, resulting in long-term protection of L. schaffneriana ssp. recurva and its habitat; in coordination with stakeholders, revise this plan as needed as new information comes to light so that the recovery strategy and actions implement recovery in as efficient a manner as possible (USFWS, 2017).
- The principal recovery strategy is to conserve the habitat of L. schaffneriana ssp. recurva by decreasing groundwater pumping, increasing water conservation and recharge, and protecting L. schaffneriana ssp. recurva occurrences and their seed banks (USFWS, 2018).
- Monitoring, surveying, scientific study, outreach and partnership development, augmentation and introduction, and reduction or removal of stressors (USFWS, 2018).
- Introduction and Augmentation of occurrences: There has been success in establishing L. schaffneriana ssp. recurva into locations with suitable habitat within the historical range of the taxon (e.g. Audubon Research Ranch, Las Cienegas National Conservation Area, Fort Huachuca, and on the San Pedro Riparian National Conservation Area). Other attempts to establish this taxon have ultimately failed (e.g. Leslie Canyon National Wildlife Refuge and Sonoita Creek). Still other attempts have had mixed results (e.g. San Bernardino National Wildlife Refuge).
- Easements: Since 1990, the Nature Conservancy has held a conservation easement on one private property on Sonoita Creek which supports L. schaffneriana ssp. recurva (Killeen pers. comm. April 29, 2014). Although the easement was created for a purpose other than the protection of L. schaffneriana ssp. recurva, the taxon benefits from this land protection. Several additional conservation easements on the Babacomari River are held by The Nature Conservancy, Fort Huachuca, and the Bureau of Land Management; collectively these easements protect several miles of perennial water in the Babocomari River (Duncan pers. comm. April 29, 2014).
- In 1999, Arizona State Parks purchased 1,440 ha (3,557 ac) of land in the San Rafael Valley including the Santa Cruz River which supports small occurrences of L. schaffneriana ssp. recurva. The land is rested from livestock grazing, protected from development through an easement, and is managed to minimize the impacts of non-native species. In 2013, the Arizona Land Trust protected 3.2 km (2 mi) of Sonoita Creek on the Circle Z Ranch, including perennial stretches.

- In Sonora, Mexico, Rancho El Aribabi is a federally designated private reserve, which recognizes ecological values and also precludes mineral entry. The Ranch, which contains L. schaffneriana ssp. recurva, is managed for its ecological values and ecotourism. Similarly, Rancho los Fresnos, which also supports an occurrence of L. schaffneriana ssp. recurva, is owned and managed for its ecological values by the conservation organization Naturalia. Livestock have been removed from the property and management includes the use of prescribed burning. At Rancho San Bernardino, in Sonora, the Cuenca los Ojos Foundation actively manages lands known to have historically supported and may currently support L. schaffneriana ssp. recurva. Management includes extensive restoration of grasslands and waterways, resulting in the many-fold increase in extent of perennial water in Rio San Bernardino creating habitat for the taxon.
- Conservation and Management Plans: There are three conservation plans currently in place that provide some benefit to L. schaffneriana ssp. recurva. First, the 2008 Malpai Borderlands Habitat Conservation Plan ensures that no cattle grazing occurs within San Bernardino National Wildlife Refuge, thereby protecting L. schaffneriana ssp. recurva from trampling and overgrazing impacts (MBHCPTWG and Lehman 2008, p. 105). Second, the 2009 Leslie Canyon Watershed Safe Harbor Agreement incorporates management actions related to the recovery of the taxon, including its propagation and establishment in existing aquatic habitats, the maintenance of wetland levels, and the exclusion of humans and livestock that may excessively trample the taxon (Service 2009b, p. 7). Lastly, although most L. schaffneriana ssp. recurva occur outside of Pima County, the Draft Pima County Multi-Species Conservation Plan includes monitoring of a) L. schaffneriana ssp. recurva every 2 to 3 years, b) habitat conditions at Bingham Cienega, and c) post restoration efforts (Pima County 2012, pp. 70, 81).
- Fort Huachuca participates in water conservation efforts, effluent reuse or recharge, the purchase of conservation easements, and storm water recharge; all which benefit L. schaffneriana ssp. recurva and its habitat (Service 2014b, p. 21). In addition, Fort Huachuca personnel monitor L. schaffneriana ssp. recurva both on the Fort and on the San Pedro National Conservation Area regularly (Service 2014b, p. 20). There is no livestock grazing allowed on Fort Huachuca, eliminating the threat L. schaffneriana ssp. recurva of overgrazing and measures are taken to ensure recreational trampling does not occur (Service 2014b, p. 21). In addition, transplanting of plugs has occurred in the past and may continue in the future (Service 2014b, p. 21).
- Conservation Areas: The Bureau of Land Management manages the Las Cienegas National Conservation Area which encompasses much of the upper Cienega Creek watershed, an area supporting multiple patches of L. schaffneriana ssp. recurva. The area was set aside to conserve, protect, and enhance this resource and is managed under a comprehensive management plan which includes assurance that riparian and wetland sites are properly functioning (Bureau of Land Management 2003, pp. 7-9). The Bureau of Land Management also conducts periodic monitoring of L. schaffneriana ssp. recurva along upper Cienega Creek and has plans for introducing plugs at up to 11 locations over a 10 year period (Service 2008, p. 3). In addition, to protect these sensitive riparian and wetland habitats, the Bureau of Land Management designated this area as the Empire-Cienega Area of Critical Environmental Concern. The goal of the designation is to protect and enhance watershed, grassland, and threatened/endangered wildlife resources, emphasizing total ecosystem management (Bureau of Land Management 2003, p. A6-1).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The principal recovery strategy for the Huachuca water umbel is to conserve the habitat by decreasing groundwater pumping, increasing water conservation and recharge, and protecting occurrences and their seedbanks. Providing conservation and restoration of the taxon and its habitat will allow stable, self-sustaining occurrences to persist with some level of connectivity and opportunity for expansion and dispersal. Additional actions needed include monitoring, surveying, scientific study, outreach and partnership development, augmentation and introduction, and reduction or removal of stressors. Several recovery actions listed in the Recovery Plan are already under way, including water use reduction and effluent recharge. Also, some introductions have been made with varying success and more introductions are anticipated (USFWS, 2024).

# SPECIES ACCOUNT: *Limnanthes floccosa ssp. californica* (Butte County meadowfoam)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 06/08/1992; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A densely pubescent, winter annual herb. Stems from 3-25 cm in length, generally prostrate with tips curved upward. Flowers are white with dark yellow veins at the base of each of 5 petals (Fish and Wildlife Service 1992) (NatureServe, 2015).

**Taxonomy**

Before 1973, Butte County meadowfoam was not differentiated from the more widespread woolly meadowfoam (Limnanthes floccosa ssp. floccosa). An alternative common name, Shippee meadowfoam, is derived from the type locality (California Department of Fish and Game 1987a, Ornduff 1993c). Limnanthes floccosa ssp. californica is a member of the meadowfoam or false mermaid family (Limnanthaceae), which is a small family comprising only 2 genera and 10 species (Ornduff 1993c) (USFWS, 2005).

**Historical Range**

Endemic to California, only known from Butte County (Skinner 1997) (NatureServe, 2015). Known historically and currently to occur only in Butte County within the Northeast Sacramento Valley Vernal Pool Region (USFWS, 2008).

**Current Range**

At least eight new occurrences of Limnanthes floccosa ssp. californica have been discovered since 1988 (USFWS, 2005). The range of Butte County meadowfoam lies entirely within Butte County, California. Butte County meadowfoam is found primarily on the margins of vernal swales and to a lesser extent on the margins of vernal pools located on alluvial terraces in annual grasslands and mima mound topography. Mima mounds are soil mounds of unknown origin that are a few feet in height. The species is restricted to a narrow 28-mile strip along the eastern flank of the Sacramento Valley from northwestern to central Butte County and occurrences are found at 120 to 1,200 feet in elevation (USFWS, 2023).

**Critical Habitat Designated**

Yes; 2/10/2006.

**Legal Description**

On August 11, 2005, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Limnanthes floccosa ssp. californica (Butte County meadowfoam) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes four critical habitat units (CHUs), in California (70 FR 46924-46999).

**Critical Habitat Designation**

The critical habitat designation for Limnanthes floccosa ssp. californica includes four CHUs in Tehama and Butte Counties, California. This species critical habitat encompasses approximately

16,363 acres (71 FR 7118-7316).

Unit 1: Tehama and Butte Counties. (i) Unit 1A: Tehama and Butte Counties, California. From USGS 1:24,000 scale quadrangles Richardson Springs NW, Campbell Mound, Richardson Springs. (ii) Unit 1B: Butte County, California. From USGS 1:24,000 scale quadrangle Richardson Springs.

Unit 2: Butte County, California. From USGS 1:24,000 scale quadrangle Richardson Springs.

Unit 3: Butte County, California. From USGS 1:24,000 scale quadrangle Richardson Springs, Paradise West, Chico.

Unit 4: Butte County, California. From USGS 1:24,000 scale quadrangles Oroville, Shippee.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Limnanthes floccosa ssp. californica critical habitat consists of two components (70 FR 46924-46999):

(i) Topographic features characterized by isolated mound and intermound complex within a matrix of surrounding uplands that result in continuously, or intermittently, flowing surface water in the depressional features including swales connecting the pools described in PCE (ii), providing for dispersal and promoting hydroperiods of adequate length in the pools.

(ii) Depressional features including isolated vernal pools with underlying restrictive soil layers that become inundated during winter rains and that continuously hold water or whose soils are saturated for a period long enough to promote germination, flowering, and seed production of predominantly annual native wetland species and typically exclude both native and nonnative upland plant species in all but the driest years. As these features are inundated on a seasonal basis, they do not promote the development of obligate wetland vegetation habitats typical of permanently flooded emergent wetlands.

**Special Management Considerations or Protections**

Existing manmade features and structures, such as buildings, roads, railroads, airports, runways, other paved areas, lawns, and other urban landscaped areas do not contain one or more of the primary constituent elements. Federal actions limited to those areas, therefore, would not trigger a consultation under section 7 of the Act unless they may affect the species and/ or primary constituent elements in adjacent critical habitat.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: cross-pollination, self-pollination (USFWS, 2008)

**Lifespan**

Adult: One year (USFWS, 2008)

**Breeding Season**

Adult: February - April (USFWS, 2008)

**Key Resources Needed for Breeding**

Adult: Insect pollinators, based on closely related species (USFWS, 2008)

**Reproduction Narrative**

Adult: This is an annual plant. Limnanthes floccosa ssp. californica typically begins flowering in February, reaches peak flowering in March, and may continue into April if conditions are suitable. Nutlets are produced in March and April, and the plants die back by early May (Jokerst 1989, Dole and Sun 1992). Limnanthes floccosa ssp. californica has floral adaptations that allow for cross-pollination by insects, but self-pollination mechanisms take over to ensure seed set if insect pollination is unsuccessful. The particular pollinators of L. floccosa ssp. californica have not been identified; however, other meadowfoam species are pollinated by the native burrowing bees Andrena limnanthis and Panurginus occidentalis (Thorp and Leong 1998) and by honeybees (Kesseli and Jain 1984), beetles, flies, true bugs (order Hemiptera), butterflies, and moths (Mason 1952, Thorp and Leong 1998) (USFWS, 2008).

**Habitat Type**

Adult: Wetland (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Valley and foothill grasslands, ephemeral drainages, vernal pool depressions (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Mima mound topography (USFWS, 2008)

**Geographic or Habitat Restraints or Barriers**

Adult: 165 - 1,167 ft. elevation (USFWS, 2008)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Moderate (inferred from USFWS, 2008)

**Habitat Narrative**

Adult: Inhabits valley and foothill grasslands (mesic soils) (Skinner 1997). Associates are Limnanthes alba ssp. alba, L. douglasii var. rosea, and L. floccosa ssp. floccosa. Grows in three types of seasonal wetlands: ephemeral drainages, vernal pool depressions in ephemeral drainages, and occasionally around the edges of isolated vernal pools (Fish and Wildlife Service 1992) (NatureServe, 2015). This species occurs on alluvial terraces in annual grasslands with mima mound topography. The occurrences are found at 165 to 1,167 feet in elevation (McNeill and Brown 1979, CNDDB 2007). Limnanthes floccosa ssp. californica occurs in different soils on Tuscan-Igo-Anita Complex Fan terraces of 0-3 percent slope, 0-50 percent rock cobble with an underlying clay durapan. According to the 2006 Butte Area Soil Survey, L. floccosa ssp. californica is found on 32 different "Musym" classes of soil, but always with an underlying durapan, rock cobble and common hydrological factors (J. Marr, CDFG, in litt. January 2007, Natural Resource Conservation Service 2006). Limnanthes floccosa ssp. californica has also been found occasionally in disturbed areas, such as drainage ditches, firebreaks, and graded sites (McNeill and Brown 1979, Jokerst 1989, Kelley and Associates Environmental Sciences 1992b, BioSystems Analysis, Inc. 1993, Kelley and Associates Environmental Sciences 1993a) (USFWS, 2008).

***Dispersal/Migration***

**Dispersal**

Adult: Low (USFWS, 2008)

**Dispersal/Migration Narrative**

Adult: Nutlets of L. floccosa ssp. californica are apparently dispersed by water and can remain afloat for up to 3 days (Hauptli et al. 1978). Most meadowfoam nutlets are dispersed only short distances. Birds and livestock are potential sources of long distance seed dispersal, but specific instances of such dispersal have not been documented (Jain 1978) (USFWS, 2008).

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2008)

**Number of Populations:**

20 (USFWS, 2023)

**Population Narrative:**

In 1989, less than 200,000 plants likely existed in the censused populations (Fish and Wildlife Service 1992) (NatureServe, 2015). There are 20 total extant natural occurrences. Quantitative information on the numbers of plants and area occupied by Limnanthes floccosa ssp. californica has not been collected in a consistent and systematic manner at all occurrences since the time of listing; therefore, definitive range-wide abundance and population trend information is not yet available (USFWS, 2008). At the time of listing in 1992, the species was known from 18 extant populations and 3 extirpated populations within a narrow 25-mile strip along the eastern flank of the Sacramento Valley from central Butte County to the northern portion of the city of Chico (Service 1992, p. 24193). The 2005 Recovery Plan and the 2008 status review reported 21 natural occurrences (20 extant and 1 extirpated prior to listing) and 1 introduced occurrence (Service 2005, p. II-34; Service 2008, p. 2). Sixteen of these occurrences were reported in the Diversity Database in 2007 when the occurrence records were reviewed for the 2008 status review (Service 2008, p. 1). Seven of the natural occurrences were discovered after the 1992 listing (North Table Mountain, Upper Rock Creek, and the five localities on Dove Ridge Conservation Bank that were recorded as one occurrence in the Diversity Database) (Service 2008, p. 2–7), but the range of the species remained largely unchanged. The 2005 Recovery Plan also reported that many of the occurrences revisited since listing had been reduced in extent while the boundaries of other occurrences had expanded due to identification of additional occupied habitat (Service 2005, p. II-34). The introduced experimental population on the Tuscan Preserve in northwestern Butte County was established just outside of the historical range of the taxon using seed from the Doe Mill occurrence (occurrence number 20) and thus marginally increased the range of the species (Service 2005, p. II-36). The Shippee (occurrence number 6) and the North of Skyway/Bruce Road (occurrence number 20) occurrences, which were presumed extirpated at listing (Service 1997, p. 24193), were considered extant at the time of the 2008 status review as the species had been rediscovered at both locations following listing (Service 2008, pp. 6, 8). The current distribution of Butte County meadowfoam is similar to that described in the 2005 Recovery Plan (Service 2005, pp. II-34–36) and 2008 status review (Service 2008, pp. 5–7). The Diversity Database currently reports a total of 20 occurrences including 19 natural occurrences and the introduced occurrence at the Tuscan Preserve (Table 1; Diversity Database 2023, entire). All occurrences of the species are currently presumed extant. The Diesel occurrence (occurrence 39), which was thought to be extirpated prior to listing, is now presumed extant as 16 individuals were observed at the site in 2010 (Diversity Database 2023, entire). Seven occurrences (occurrence numbers 44, 45, 46, 47, 48, 50, and 51) have been added to the Diversity Database since the 2008 status review. Two of these occurrences (occurrence numbers 50 and 51) were discovered after 2008, while the other five occurrences were known prior to 2008 but were not added to the Diversity Database until recently (Diversity Database 2023). Occurrence number 50 is located in proximity to the North Table Mountain Ecological Reserve and occurrence number 42, and the occurrence expands the eastern extent of the species' range by 0.3 miles (Diversity Database 2023). Occurrence number 51 is located within the previously known range of the species in proximity to occurrence number 20. Additionally, three occurrence records (occurrence numbers 34, 41, and 43) have been combined in the Diversity Database with other previously known occurrences. Furthermore, an additional occurrence south of Chico Regional Airport was identified by Sloop et al. (2011), but this occurrence has not yet been added to the Diversity Database (Sloop et al. 2011, p. 315; Diversity Database 2023, entire). Overall, the distribution of Butte County Meadowfoam remains largely unchanged since the 2005 Recovery Plan and the 2008 status review (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Development (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** 11 occurrences are located on privately owned land and are unprotected. Habitat loss or degradation from urbanization continues to be the greatest threat to all occurrences of the subspecies, even to those that are protected from development. Habitat degradation results from changes in the amount of surface and subsurface water hydrology, introduction of invasive plants, and in areas adjacent to agricultural or residential uses, introduction of pesticides and herbicides. In addition to the threats from development projects that have already been proposed, rapid population growth is predicted for all of Butte County and its urban areas. The City of Chico predicts the construction of approximately 20,000 new housing units and a 61 percent increase in population by 2030 (Butte County Association of Governments 2006). The population of Butte County is expected to increase by 48 percent by 2030 (Butte County Association of Governments 2006). The need for additional housing and associated development will likely threaten the remaining unprotected occurrences of Limnanthes floccosa ssp. californica which are mostly located in or near existing urban areas or roads (USFWS, 2008).

**Stressor:** Nonnative plants (USFWS, 2008)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** he Draft Land Management Plan for the Doe Mill Preserve (Center for Natural Lands Management 1996) noted that the occurrence of Limnanthes floccosa ssp. californica was "healthy" in 1991 but was reduced in numbers in 1996 and stressed from competition with the nonnative grass, Taeniatherum caput-medusae (medusa-head). Glyceria declinata (waxy manna grass) is a nonnative, perennial grass which may become a threat to Limnanthes floccosa ssp. californica. Glyceria declinata forms dense stands and is able to invade vernal pool habitat and displace native plants (The Nature Conservancy 2006) (USFWS, 2008).

**Stressor:** Drought and climate change (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Maintenance of the natural hydrology of these wetlands is necessary for the survival and recovery of this subspecies. Drought or flood conditions will place additional strains on the vernal pool ecosystems supporting L. floccosa ssp. californica occurrences. Climate is predicted to change in California during the 21st century (Lenihan et al. 2006, Cayan et al. 2005, Field et al. 1999). Even modest changes in warming could result in a reduction of the spring snowpack, earlier snowmelt, and more runoff in winter with less runoff in spring and summer, more winter flooding, and drier summer soils (Cayan et al. 2005, Field et al. 1999). Although the specific effects of climate change on L. floccosa ssp. californica are not yet known, the predicted shift in precipitation of increased winter runoff and reduced spring and summer rainfall have the potential to adversely affect this subspecies (USFWS, 2008).

**Stressor:** Off-road vehicles (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Impacts from off-road vehicles continue to threaten to the subspecies. In 2006, a vehicle driving off-road in Bidwell Ranch became stuck in the mud near an area supporting L. floccosa ssp. californica (B. Vlamis, pers. comm., 2007). Vehicles can crush the plants and seeds, and compact the soil, thus making germination more difficult, and alter the hydrology of the habitat. Portions of many L. floccosa ssp. californica occurrences are located adjacent to roads and are unfenced thereby exposing them to potential damage from off-road driving (USFWS, 2008).

***Recovery***

**Reclassification Criteria:**
See delisting criteria.

Recovery Priority Number: 3C

**Delisting Criteria:**
1. Suitable vernal pool habitat within each prioritized core area for the species is protected (USFWS, 2008).

2. Species occurrences distributed across the species geographic range and genetic range are protected. Protection of extreme edges of populations protects the genetic differences that occur there (USFWS, 2008).

3. Reintroductions must be carried out and meet success criteria established in the recovery plan (USFWS, 2008).

4. Additional occurrences identified through future site assessments, GIS and other analyses, and status surveys that are determined essential to recovery are protected. Any newly found occurrences may count towards recovery goals if the occurrences are permanently protected as described in the recovery plan (USFWS, 2008).

5. Habitat protection results in protection of hydrology essential to vernal pool ecosystem function, and monitoring indicates that hydrology that contributes to population viability has been maintained through at least one multi-year period that includes above average, average, and below average local rainfall as defined above, a multi-year drought, and a minimum of 5 years of post-drought monitoring (USFWS, 2008).

6. Habitat management and monitoring plans that facilitate maintenance of vernal pool ecosystem function and population viability have been developed and implemented for all habitat protected (USFWS, 2008).

7. Mechanisms are in place to provide for management in perpetuity and long-term monitoring of criterion 1 - 5 (USFWS, 2008).

8. Monitoring indicates that ecosystem function has been maintained in the areas protected under criterion 1 - 4 for at least one multi-year period that includes above average, average, and below average local rainfall, a multi-year drought, and a minimum of 5 years of post-drought monitoring (USFWS, 2008).

9. Seed banking actions have been completed for species that would require it as insurance against risk of stochastic extirpations or that will require reintroductions or introductions to contribute to meeting recovery criteria (USFWS, 2008).

10. Status surveys, 5-year status reviews, and population monitoring show populations within each vernal pool region where the species occur are viable (e.g., evidence of reproduction and recruitment) and have been maintained (stable or increasing) for at least one multi-year period that includes above average, average, and below average local rainfall, a multi-year drought, and a minimum of 5 years of post-drought monitoring (USFWS, 2008).

11. Status surveys, status reviews, and habitat monitoring show that threats identified during and since the listing process have been ameliorated or eliminated. Site-specific threats identified through standardized site assessments and habitat management planning also must be ameliorated or eliminated (USFWS, 2008).

12. Research actions necessary for recovery and conservation of the covered species have been identified (these are research actions that have not been specifically identified in the recovery actions but for which a process to develop them has been identified). Research actions (both

specifically identified in the recovery actions and determined through the process) on species biology and ecology, habitat management and restoration, and methods to eliminate or ameliorate threats have been completed and incorporated into habitat protection, habitat management and monitoring, and species monitoring plans, and refinement of recovery criteria and actions (USFWS, 2008).

13. Research on genetic structure has been completed (for species where necessary – for reintroduction and introduction, seed banking) and results incorporated into habitat protection plans to ensure that within and among population genetic variation is fully representative by populations protected in the Habitat Protection section of this document, described previously in criterion 1 - 5 (USFWS, 2008).

14. Research necessary to determine appropriate parameters to measure population viability for each species have been completed (USFWS, 2008).

15. Recovery Implementation Team is established and functioning to oversee rangewide recovery efforts (USFWS, 2008).

16. Vernal pool regional working groups are established and functioning to oversee regional recovery efforts (USFWS, 2008).

17. Vernal pool region working groups have developed and implemented outreach and incentive programs that develop partnerships contributing to achieving recovery criteria (USFWS, 2008).

**Recovery Actions:**

- Establish a range-wide recovery implementation team (USFWS, 2005).
- Establish working groups and develop participation plans for each vernal pool region (USFWS, 2005).
- Develop and implement adaptive management plans based on monitoring data and best available science (USFWS, 2005).
- Assist local governments in developing habitat conservation plans and developing land use protection measures (USFWS, 2005).
- Assist private landowners in developing landowner agreements (USFWS, 2005).
- Acquire habitat, where necessary (USFWS, 2005).
- Track losses and protection of suitable habitat and occurrences within core areas (USFWS, 2005).
- Ensure mechanisms are in place to provide for the perpetual management and monitoring of core areas, vernal pool regions, or for each management unit within a vernal pool region, as appropriate (USFWS, 2005).
- Permanently protect remaining occurrences through conservation easements, fee title, or other protective methods. Implement existing approved management plans for Limnanthes floccosa ssp. californica. Develop and implement management plans for all occurrences for which management plans have not yet been developed (USFWS, 2008).
- Conduct a status survey of all recorded locations of Limnanthes floccosa ssp. californica to verify the identity of the plants and determine the status, area occupied, micro-site and hydrology analysis, pollinators, and threats of plants present. Many of the occurrences in CNDDB have not been thoroughly surveyed for over 15 years. The one presumed extirpated

site should also be revisited and surveyed (USFWS, 2008).
- Conduct surveys on potential Limnanthes floccosa ssp. californica habitat in Butte County for additional occurrences, including the area northeast of Highway 99 between the City of Chico and the intersection of Highways 70 and 149 (USFWS, 2008).
- Conduct studies to determine the effects of grazing and burning on Limnanthes floccosa ssp. californica and appropriate management at each L. floccosa ssp. californica occurrence based on individual conditions of each location such as soil type and grass species present (USFWS, 2008).
- Conduct a study to determine the effects of nonnative, invasive plants on Limnanthes floccosa ssp. californica and appropriate management at L. floccosa ssp. californica occurrences (USFWS, 2008).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations that will aid in the recovery and conservation of Butte County meadowfoam. These recommendations have been previously discussed in the 2008 status review (Service 2008, p. 21) and remain valid. 1. Permanently protect remaining occurrences through conservation easements, fee title, or other protective methods. Implement existing approved management plans for Butte County meadowfoam. Develop and implement management plans for all occurrences for which management plans have not yet developed. 2. Conduct a status survey of all recorded locations of Butte County meadowfoam to verify the identity of the plants and determine the status, area occupied, micro-site and hydrology analysis, pollinators, and threats of plants present. Many of the occurrences in the Diversity Database have not been thoroughly surveyed in recent years. 3. Conduct surveys on potential Butte County meadowfoam habitat in Butte County for additional occurrences, including the area northeast of Highway 99 between the City of Chico and the intersection of Highways 70 and 149. 4. Conduct studies to determine the effects of grazing and burning on Butte County meadowfoam and appropriate management at each Butte County meadowfoam occurrence based on individual conditions of each location such as soil type and grass species present. 5. Conduct studies to determine the effectiveness and survival rates of transplanted Butte County meadowfoam. 6. Conduct studies to learn more about seed bank dynamics and length of time that seeds can survive in the soil before germination for Butte County meadowfoam. 7. The Recovery Plan describes both down- and de-listing criteria as preliminary that will need periodic reassessment because data was lacking at the time the Recovery Plan was developed. Therefore, reassess both down- and de-listing criteria for the Butte County meadowfoam and develop stepdown success parameters, if appropriate, that reflect the species' life history and narrow range (USFWS, 2023).

# SPECIES ACCOUNT: *Limnanthes floccosa ssp. grandiflora* (Large-flowered woolly Meadowfoam)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 12/9/2002; Pacific Region (R1)

**Physical Description**

an upright annual herb with simple stems that occasionally branch near the base. The plants reach 5 to 10 centimeters (2 to 4 inches) high, are mostly glabrous throughout, and have pinnate leaves which are divided into five to nine divisions. The plant's petals are 7.5 to 8 millimeters (0.30 to 0.31 inches) long and equal the sepal length (Figure II-10). The petals are glabrous with the exception of two rows of inside hairs. Each flower produces three to five nutlets. The flowers are white in color with an occasional slight yellow tinge at the base of the petals. (USFWS, 2010)

**Taxonomy**

Limnanthes pumila ssp. pumila, a member of the false mermaid family (Limnanthaceae), was first collected from the top of Table Rock, Jackson County, Oregon, and then described by Howell in 1897 as Limnanthes pumila. M.E. Peck revised the name to Limnanthes bellingeriana in 1937 (Abrams 1951), but C. T. Mason reassigned the name to Limnanthes pumila (Mason 1952). Arroyo (1973) treated the taxon as a subspecies within Limnanthes floccosa, but it is currently assigned to Limnanthes pumila ssp. pumila based on hybridization trials and molecular data (Chambers and Meyers 2011) (USFWS, 2010). In recognition of recent taxonomic changes, on June 23, 2015, we published a technical correction in the Federal Register officially changing the name of the species from Limnanthesfioccosa ssp. grandiflora to Limnanthes pumila ssp. grandijiora (80 FR 35860, p. 35863) (USFWS, 2019).

**Historical Range**

Endemic to the Middle Rogue River of Jackson County, Oregon. (USFWS, 2010)

**Current Range**

Endemic to the Middle Rogue River of Jackson County, Oregon. (USFWS, 2019)

**Critical Habitat Designated**

Yes; 8/20/2010.

**Legal Description**

On July 21, 2010, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective August 20, 2010) for Limnanthes floccosa ssp. grandiflora (Large-flowered woolly Meadowfoam) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes eight critical habitat units (CHUs), in Oregon (75 FR 42490-42570).

**Critical Habitat Designation**

The critical habitat designation for Limnanthes floccosa ssp. grandiflora includes eight CHUs in Jackson County, Oregon. This species critical habitat encompasses approximately 5,840 acres (ac) (2,363 hectares (ha)). All critical habitat units in Jackson County are located within the Middle

Rogue River Basin or “Agate Desert.” Brief descriptions are presented below. Detailed coordinates of and maps depicting the CH units are available in the Final Rule (USFWS, 2010).

Unit RV1 for Limnanthes floccosa ssp. grandiflora: Shady Cove, Jackson County, Oregon. (i) Unit RV1 consists of approximately 8 ha (20 ha) of intact vernal pool– mounded prairie habitat. The unit is located 460 m (1,500 ft) west of Highway 62 and parallels a 430-m (1,411-ft) stretch of the highway. The unit is 0.8 km (0.5 mi) south of Shady Cove, 1.3 km (0.8 mi) northeast of Takelma Park, and 122 m (400 ft) east of the Rogue River.

Unit RV2 for Limnanthes floccosa ssp. grandiflora: Hammel Road, Jackson County, Oregon. (i) Unit RV2 is composed of four subunits and comprises approximately 69 ha (169 ac) of vernal pool–mounded prairie. The unit is located 1.2 km (0.75 mi) northeast of the confluence of Reese Creek and the Rogue River, 1.3 km (0.8 mi) west of Highway 62, and 430 m (1,400 ft) east of the Rogue River.

Unit RV3 for Limnanthes floccosa ssp. grandiflora: North Eagle Point, Jackson County, Oregon. (i) Unit RV3 is composed of four subunits and totals 490 ha (1,210 ac) of intact vernal pool habitat. The unit is located southwest of Mosser Mountain and northeast of Long Mountain. The four subunits loosely follow a 6.9-km (4.3-mi) stretch of Hog Creek beginning at its origin. Originating 3.8 km (2.4 mi) east of Highway 62 in subunit RV3D, Hog Creek runs through RV3C, crosses Highway 62, flows between RV3B (located 100 m (328 ft) west of Highway 62) and RV3A (located 600 m (1,970 ft) west of Highway 62), before emptying into the Rogue River after 2.4 km (1.5 mi). Subunit RV3A is located 560 m (1,837 ft) southeast of the confluence of Reese Creek and the Rogue River. Subunit RV3B is located 100 m (328 ft) west of Highway 62 at the intersection of Ball Road and extends along an 835- m (2,740-ft) stretch of Hog Creek. Subunit RV3C is located 2 km (1.2 mi) north of Eagle Point (see Index map) and extends 2.6 km (1.6 mi) south of the junction of Ball Road and Reese Creek Road. Subunit RV3D is located 3.2 km (2 mi) east of Long Mountain and is 2.4 km (1.5 mi) southeast of the junction of Highway 62 and Ball Road. It extends along a 1.8-km (1.1-mi) stretch of Hog Creek.

Unit RV4 for Limnanthes floccosa ssp. grandiflora: Rogue Plains, Jackson County, Oregon. (i) Unit RV4 consists of 243 ha (600 ac) of partially intact vernal pool– mounded prairie habitat. The unit is located 122 m (400 ft) southeast of the junction of Highway 234 and Modoc Road. It extends 2 km (1.2 mi) south along Modoc Road from the intersection, is located 1.4 km (0.87 mi) southwest of Dodge Bridge, and is 1.0 km (0.6 mi) northwest of Rattlesnake Rapids on the Rogue River.

Unit RV5 for Limnanthes floccosa ssp. grandiflora: Table Rock Terrace, Jackson County, Oregon. (i) Unit RV5 includes 49 ha (122 ac) of intact vernal pool–mounded prairie habitat. The unit is located on privately owned land 670 m (2,200 ft) north of the junction of Modoc and Antioc Roads, is 1.4 km (0.9 mi) east of Upper Table Rock, and is 650 m (2,300 ft) west of the Rogue River. This unit follows along an 800-m (2,600-ft) stretch of Modoc Road to the east of the unit and along a 700- m (2,300-ft) stretch of Antioc Road to the west of the unit.

Unit RV6 for Limnanthes floccosa ssp. grandiflora: White City, Jackson County, Oregon. (i) Unit RV6 for Limnanthes floccosa ssp. grandiflora consists of eight subunits totaling 740 ha (1,829 ac) in size and includes intact vernal pool– mounded prairie and swale habitats. The unit is located around White City, is 1.6 km (1.0 mi) southwest of Eagle Point, and is 440 m (1,444 ft) southeast of the confluence of the Rogue River and Little Butte Creek. Subunit RV6A is located north of

Whetstone Creek and is 500 m (1,200 ft) west of the junction of Highway 62 and Antelope Road. Subunits RV6B, RV6C, RV6D, and RV6E are located north of Avenue G in White City, south of Little Butte Creek, and 670 m (2,200 ft) southwest of Antelope Creek. Subunits RV6F and RV6G are located approximately 500 feet west of Dry Creek and are east of Highway 62 in White City. Subunit RV6H is located north of Whetstone Creek and south of Antelope Road. Subunit RV6H roughly encircles the Hoover Ponds, east of Highway 62, and is 850 m (2,790 ft) east of subunit RV6A.

Unit RV7 for Limnanthes floccosa spp. grandiflora: Agate Lake, Jackson County, Oregon. (i) Unit RV7 consists of 421 ha (1,039 ac) of intact vernal pool–mounded prairie and swale habitat. The unit is located 500 m (1,640 ft) east of the Agate Reservoir, lies along a 5.4-km (3.4-mi) stretch roughly parallel and between Dry Creek and Antelope Creek, is 330 m (1,080 ft) north of Tater Hill, and is 1.4 km (0.9 mi) southeast of the confluence of Dry Creek and Antelope Creek.

Unit RV8 for Limnanthes floccosa ssp. grandiflora: Whetstone Creek, Jackson County, Oregon. (i) Unit RV8 consists of 344 ha (850 ac) of intact vernal pool–mounded prairie and swale habitat. The unit is located approximately 1.4 km (0.9 mi) southeast of the confluence of the Rogue River and Whetstone Creek, 2.2 km (1.4 mi) southwest of Tou Velle State Park, and 2.9 km southeast of the confluence of Bear Creek and the Rogue River. The unit roughly parallels a 2.6-km (1.6-mi) stretch of Whetstone Creek to the south.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Limnanthes floccosa ssp. grandiflora critical habitat consists of the following habitat components (75 FR 42490-42570):

(i) Vernal pools or ephemeral wetlands and the adjacent upland margins of these depressions that hold water for a sufficient length of time to sustain Limnanthes floccosa ssp. grandiflora germination, growth, and reproduction, occurring in the Rogue River Valley vernal pool landscape. These vernal pools or ephemeral wetlands are seasonally inundated during wet years but do not necessarily fill with water every year due to natural variability in rainfall, and support native plant populations. Areas of sufficient size and quality are likely to have the following characteristics: (A) Elevations from 372 to 469 m (1,220 to 1,540 ft); (B) Associated dominant native plants including, but not limited to: Alopecurus saccatus, Deschampsia danthonioides, Eryngium petiolatum, Lasthenia californica, Myosurus minimus, Navarretia leucocephala ssp. leucocephala, Phlox gracilis, Plagiobothrys bracteatus, Trifolium depauperatum, and Triteleia hyacinthina. (C) A minimum area of 8 ha (20 ac) to provide intact hydrology and protection from development and weed sources.

(ii) The hydrologically and ecologically functional system of interconnected pools, ephemeral wetlands, or depressions within a matrix of surrounding uplands that together form vernal pool complexes within the greater watershed. The associated features may include the pool basin or depressions; an intact hardpan subsoil underlying the surface soils up to 0.75 m (2.5 ft) in depth; and surrounding uplands, including mound topography and other geographic and edaphic features, that support these systems of hydrologically interconnected pools and other ephemeral wetlands (which may vary in extent depending on site-specific characteristics of pool size and depth, soil type, and hardpan depth).

(iii) Silt, loam, and clay soils that are of alluvial origin, with a 0 to 3 percent slope, primarily classified as Agate– Winlo complex soils, but also including Coker clay, Carney clay, Provig–Agate complex soils, and Winlo very gravelly loam soils.

(iv) No or negligible presence of competitive, nonnative, invasive plant species. Negligible is defined for the purpose of this rule as a minimal level of nonnative plant species that will still allow Limnanthes floccosa ssp. grandiflora to continue to survive and recover.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain the features that are essential to the conservation of the species and that may require special management considerations or protection. All areas we are designating as critical habitat require some level of management to address current and future threats to Limnanthes floccosa ssp. grandiflora, to maintain or enhance the physical or biological features essential to their conservation, and to ensure the recovery and survival of these species. The major threats to the PCEs in the areas identified as critical habitat for Limnanthes floccosa ssp. grandiflora include: development on private lands; mining activities; ground disturbance that affects surface hydrology, including ORV use and road construction or maintenance activities; incompatible agricultural and grazing practices; garbage dumping; the succession of meadow habitat to forested habitat due to fire suppression; and encroachment and displacement by nonnative plants. In all of the units in Jackson County, special management is needed to reduce or eradicate the threats posed by development, habitat fragmentation, ground disturbance that affects surface hydrology, and incompatible grazing practices. In all of the units in Josephine County, special management is needed to reduce or eradicate the threats posed by development, ORV use, mining activities, garbage dumping, and woody vegetative succession. Please refer to the unit descriptions in the Critical Habitat Designation section for further discussion of special management considerations or protection of the PCEs related to geographically specific threats to Limnanthes floccosa ssp. grandiflora. In addition, for all units, special management is needed to control and monitor the encroachment of nonnative, invasive plant species to maintain intact vernal pool–mounded prairies and wet meadow ecosystems such that they can continue to support populations of Limnanthes floccosa ssp. grandiflora. Special management considerations or protection of the vernal pool– mounded prairies and wet meadow habitats that may be needed to support reproduction and growth of Limnanthes floccosa ssp. grandiflora include: controlled burning and vegetation clearing to maintain early seral stages (early stages of plant succession in the progression toward a climax community); control of nonnative, invasive plant species; grazing management; the reestablishment of hydrology; re-seeding with native plants; monitoring; and protection from development (Borgias 2004, pp. 47–53; ONHDB 1994, pp. 13– 20). (USFWS, 2010)

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Meadowfoam typically begins flowering in March, reaches peak flowering in April, and may continue into May if conditions are suitable (USFWS, 2016).

**Reproduction Narrative**

Adult: Meadowfoam produces one to three flowers per flower stalk; each flower will produce a cluster of 1 to 5 hard nutlets by mid-May that will quickly drop in the drying mud. Over much of its range, meadowfoam is restricted to the relatively wetter, inner fringe of vernal pools in the Rogue Valley plains. Meadowfoam typically begins flowering in March, reaches peak flowering in April, and may continue into May if conditions are suitable. Nutlets are produced in late April, and the plants begin to die back by mid-May or when the soil becomes dry (Borgias 2004). Nutlets of meadowfoam apparently are dispersed by water; they can remain afloat for up to three days (USFWS 2012). However, the nutlets of the plant are normally dispersed only short distances. Thus, meadowfoam nutlets would not be expected to disperse beyond their pool or swale of origin. Birds and livestock are potential sources of long-distance seed dispersal, but specific instances of dispersal have not been documented (Jain 1978) (USFWS, 2016).

**Habitat Type**

Adult: Vernal pools (USFWS, 2016)

**Environmental Specificity**

Adult: Very narrow. Specialist or community with key requirements scarce. (Natureserve, 2015)

**Habitat Narrative**

Adult: Meadowfoam is endemic to vernal pool habitats within Jackson County, Oregon. The majority of the extant and historical sites for meadowfoam in the Rogue Valley occur on soil formations characterized by Agate-Winlo silty clay loam series (deep, poorly drained soils present in depressions in alluvial stream terraces) at elevations of 366 to 400 m (1,200 to 1,310 feet) (USFWS 2012). According to Arroyo (1973), the plant occurs generally near the wetter, inner edges of pools, as opposed to the drier outer fringes, which harbor the slightly more common L. floccosa ssp. floccosa (USFWS 2012). However, meadowfoam has been observed on the outside edges of vernal pools, sympatric with L. floccosa ssp. floccosa, and has even been observed in some areas on low upland mounds. The deeper basins are dominated by Plagiobothrys stipitatus, Eryngium petiolatum, Navarretia leucocephala ssp. leucocephala, and Myosurus minimus. Alopecurus saccatus (Pacific foxtail), and Deschampsia danthonioides are also common plant associates. The inner vernal pool edges occupied by meadowfoam often have up to 10 to 15% exposed soil, due partly to gopher or vole foraging activity (USFWS< 2016).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Birds and livestock are potential sources of long-distance seed dispersal, but specific instances of dispersal have not been documented (Jain 1978) (USFWS, 2016).

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2016)

**Population Growth Rate:**

Suspected. Decline of 30-50% (NatureServe, 2015)

**Number of Populations:**

23 (USFWS, 2024)

**Population Size:**

10,000 - 100,000 individuals  (NatureServe, 2015; USFWS, 2016))

**Additional Population-level Information:**

A total of 23 large-flowered woolly meadowfoam populations across the range of the species are documented as extant (ORBIC 2023, entire; USFWS 2024, entire). Of the 23 documented populations, 18 occur on property that can be accessed and monitored but 5 occur on private land that is inaccessible. Because of the inaccessibility of 5 populations, we cannot determine their status; however, based on recent aerial photography, the landscape appears intact, so we have no reason to believe the populations are extirpated. The 18 meadowfoam populations with consistent monitoring show that 13 populations are stable or increasing and 5 populations appear to be declining. For more detail on the population trend please see Appendix A. (USFWS, 2024)

**Population Narrative:**

Since the adoption of the 20 12 recovery plan, Limnanthes pumila ssp. grandiflora remains at 18 known populations (or occurrences) with two new populations documented and one population (Eagle Point) lost since 201 1 (Table 1) (Figure 1). In addition, a new population of 160 individual plants  t the PacificCorps Substation was discovered on City of Medford owned land, but also quickly became  extirpated during this period. The east Agate Desert, Whetstone Savannah, Highway 140, ODOT Dutton Road site, and Jackson Sports Park populations previously considered separate are combined herein due to their close proximity. (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Habitat degradation (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Nearly 50% of Limnanthes pumila ssp. grandiflora sites have been severely altered (Meyers 2008). In 1999, a function and value assessment of vernal pool quality, abundance, and distribution determined that habitat with intact hydrology and only moderately altered vegetation accounted for just 3,600 acres or 17.6% of the original landform; approximately 2,104 acres of this contained well-distributed and abundant vernal pools (Oregon Natural Heritage Program 1999) (USFWS, 2016).

**Stressor:** Development (USFS, 2016).
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Road construction, housing, industrial and commercial development are listed as threats to this species. Other development in Medford, occurring in 2006, resulted in the loss of habitat (USFWS, 2016).

**Stressor:** ORV use (USFWS, 2016)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Off-road vehicle use is listed as a threat to this species. Recreational off-road vehicle activities have also impacted two meadowfoam populations in the White City area (USFWS, 2016).

**Stressor:** Dumping (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fill and contaminant dumping are listed as threats to this species (USFWS, 2016). Since 2002, a known meadowfoam population in the Agate Desert near Table Rocks Road was partially impacted due to disposal of contaminants (perhaps herbicide) that removed native vegetation from a 0.75 acre portion of vernal pools. The source of the spill was not determined (USFWS, 2016).

**Stressor:** Non-native plants (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasion of non-native annual grasses and herbs is listed as a threat to this species (USFWS, 2016).

**Stressor:** Herbicide spraying (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbicide spraying is listed as a threat to this species (USFWS, 2016).

**Stressor:** Livestock grazing (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Poorly managed livestock grazing is listed as a threat to this species (USFWS, 2016).

**Stressor:** Predation (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** There is a potential threat of predation by meadowfoam fly (Scaptomyza apicalis) larvae (USFWS 2012). The meadowfoam fly, which occurs in northern California and Southern Oregon, is the only insect pest of significance on species of meadowfoam. The larvae of the meadowfoam fly have been known to cause severe damage to both vegetative and reproductive tissue in Limnanthes alba and may be present on meadowfoam in the Agate Desert, though the fly has not been observed (USFWS 2012) (USFWS, 2016).

***Recovery***

**Reclassification Criteria:**
Reclassification from Endangered to Threatened status may be considered for Limnanthes pumila ssp. grandiflora when the following criteria are met: a. At least 16 of the 18 documented and extant occurrences (approximately 90 percent) have been protected from development. If extant occurrences become extirpated, protection of reintroduced or introduced occurrences may be substituted. Introduced or newly discovered populations outside of currently known core areas may be substituted if deemed equivalent in their contribution to recovery. (USFWS, 2010)

b. At least 90 percent of suitable vernal pool habitat acreage within the four Rogue Valley Priority 1 core areas has been protected, and at least 85 percent of suitable vernal pool habitat acreage within the five Rogue Valley Priority 2 core areas has been protected (see Tables IV-2 and IV-4 of the Recovery Plan). All suitable vernal pool habitat must include soils and hydrology that support Limnanthes pumila ssp. grandiflora. This habitat includes both occupied and suitable habitat. Suitable habitat that is not currently known to be occupied must be protected to provide for corridors and dispersal habitat, restoration dynamics, provide for reintroduction/introduction sites, and to protect currently undiscovered populations. (USFWS, 2010)

c. Management plans for each protected area are developed for species protection and conservation and implemented as soon as feasible. The management plans should address vegetation control, include a set of methods to reduce thatch buildup and noxious weed control, set a monitoring schedule to assess population levels to quantitatively determine trends, include a set of methods to maintain hydrological functions, outline an outreach plan for neighboring landowners, and set a plan to deter garbage dumping. Management plans should take an ecosystem approach to management, conserving associated wetland and upland species. (USFWS, 2010)

d. Additional Limnanthes pumila ssp. grandiflora occurrences identified through future site assessments, GIS and other analyses, and status surveys that are determined necessary to recovery are protected. (USFWS, 2010)

e. Achievement of self-sustaining Limnanthes pumila ssp. grandiflora populations within core areas will be determined through species monitoring and status surveys in each protected occurrence. In order to be considered self-sustaining, populations should demonstrate evidence of reproduction by seed set or presence of seedlings and exhibit population trends that are stable, increasing or show only minor declines from high population levels for 10 years prior to consideration for reclassification. (USFWS, 2010)

f. Seed collection is accomplished within each core area as insurance against the risk of stochastic extirpations and to ensure that genetic variation can be restored if extirpations occur. Seed banking may also be necessary in order to complete the reintroductions or introductions required to meet recovery criteria (see Table IV-4 of the Recovery Plan). (USFWS, 2010)

Recovery Priority Number: 3C

**Delisting Criteria:**

Delisting may be considered for Limnanthes pumila ssp. grandiflora when all downlisting criteria plus the following criteria are met: (USFWS, 2010)

a. Status surveys, status reviews, and population monitoring show the populations are self-sustaining. Population trends must be shown to be stable, increasing or exhibiting only slight declines from high population levels during a 10-year period prior to consideration following downlisting (e.g., evidence of reproduction and recruitment) and have been determined to be stable, increasing or showing only minor declines from high population levels, and implementation of management plans is effectively managing or eliminating threats. (USFWS, 2010)

b. At least 17 of 18 Limnanthes pumila ssp. grandiflora occurrences (approximately 95 percent of documented/extant occurrences) have been protected from development. If extant occurrences become extirpated, protection of reintroduced or introduced occurrences may be substituted. Introduced or newly discovered populations outside of currently known core areas may be substituted if deemed equivalent in their contribution to recovery. (USFWS, 2010)

c. At least 95 percent of suitable vernal pool habitat acreage within each Priority 1 core area and 90 percent of suitable vernal pool habitat acreage within Priority 2 core areas has been protected from development. All suitable vernal pool and wet meadow habitat must include soils and hydrology that support Limnanthes pumila ssp. grandiflora. Reintroductions and introductions are accomplished, as necessary and applicable, to replace populations where status surveys indicate the species has been extirpated (Table IV-4). (USFWS, 2010)

d. A post-delisting monitoring plan has been developed for Limnanthes pumila ssp. grandiflora . (USFWS, 2010)

**Recovery Actions:**

- 1. Protect vernal pool and wet meadow habitat from loss, fragmentation, degradation, and incompatible uses. Protection of vernal pool and wet meadow habitat is the broader objective of this recovery plan, because listed species addressed in the plan are now found in mostly fragmented habitat remnants. The first step is to identify and protect remaining relatively higher quality habitat. Although we have identified core areas of suitable habitat for listed species largely based on aerial photo interpretation, Geographic Information Systems soil data layers, topographic maps, historic species occurrence data, and species population mapping, there are uncertainties that can only be resolved by conducting ground level surveys. Complementary actions (1.1 and 1.2) may be necessary steps prior to actual habitat protection actions and are presented sequentially in order as Priority 2 actions. Priority 1 actions will focus habitat protection within identified Priority 1 and 2 recovery core areas, while lower priority actions may include actions outside of core areas. In general, actions which address the most critical threats (loss, fragmentation, or degradation of habitat) are the highest priority actions. (USFWS, 2010)
- 2. Manage, monitor, and restore vernal pool and wet meadow habitat. Management plans are encouraged to be developed to conserve the listed species occurring at each site. Elements of plans may include: restriction of off-road vehicle use by fencing access roads into preserves using proper signage to restrict vehicle access and avoid inadvertent habitat destruction; habitat restoration and noxious weed prevention programs; use of mowing, burning, or managed grazing to reduce density of native and nonnative vegetation;

monitoring effects of management actions for effectiveness, employing adaptive modification; continued monitoring of known Limnanthes pumila ssp. grandiflora populations on extant sites; surveys for new sites in appropriate habitat; or population introductions into unoccupied habitat. Management plans should identify responsibilities of the management agency or organization to protect species. (USFWS, 2010)

- 3. Conduct rangewide population status surveys. A status survey is a process comprising literature review, examination of herbarium or museum specimens, and a series of surveys conducted throughout a species' range. Historical localities of a species are identified, potential locations where the species may occur are predicted based on distributional and ecological data, and historical and potential locations are surveyed for presence of a species. Ground surveys may be a follow-up to determine if species still occur at site. (USFWS, 2010)
- 4. Conduct research essential to the conservation of these species. In addition to or in conjunction with current monitoring efforts, provide opportunities for further research with schools, State and local governments, or private endeavors. Study pollination vectors between and among populations. Research role of mammals, insects, birds, and wind as cyst and seed dispersal vectors. Evaluate techniques to reduce impacts from encroachment of native woody plant succession. Conduct research on prescribed burning, mowing, and native planting on introduced annual grasses. Refine research on appropriate grazing practices. Research genetic and morphologic traits among individuals and populations. Investigate restoration and recovery methods of historical vernal pool ecosystems that were degraded due to biosolid fill, and log debris fill. Determine incidence of herbivory or predation on Limnanthes pumila ssp. grandiflora populations. Develop offsite and onsite cultivation and propagation techniques for Limnanthes pumila ssp. grandiflora. Research associated soil crusts as indicators for vernal pool health and function. (USFWS, 2010)
- 5. Enhance public awareness and participation in recovery of the species. Seek to involve stakeholders in the recovery implementation process. Stakeholders are those parties that may be affected by proposed recovery actions, and may include, but are not limited to, Federal and State agencies, Tribal governments, county and city governments, nongovernmental organizations, and private landowners. Through schools, local community meetings, recovery team meetings, county, city, and State fairs, or other venues, we seek to establish contacts with private landowners to provide information about the species. (USFWS, 2010)
- 6. Develop post-delisting monitoring plans. Prior to delisting, a 5-year post-delisting monitoring plan should be developed and in effect. Monitoring and research results should be used to guide the long-term conservation of the species. These tasks are considered a lower priority until more significant and urgent conservation actions can be achieved. Complete post-delisting monitoring plan for Limnanthes pumila ssp. grandiflora. (USFWS, 2010)
- Recommended Future Actions: Develop conservation easements or conservation programs for existing occurrences on private lands . Assist Jackson County School District #9 with habitat management for Limnanthes pumila ssp. grandiflora . Augment Limnanthes pumila ssp. grandiflora on protected habitat in the Rogue Airfield and North Eagle Point core areas • Assist the Bureau of Reclamation with Limnanthes pumila ssp. grandiflora habitat restoration • Conduct best management practices studies for Limnanthes pumila ssp. grandiflora. (USFWS, 2019)
- All of the General Plant Conservation Measures (Section 3.13.1) apply for meadowfoam. In additional, livestock grazing will not be used to control or remove invasive and non-native

vegetation at project sites occupied by large-flowered meadowfoam, unless approved by the local Service office. Also, this plant can be associated with vernal pool habitats, which can support Cook's desert parsley and vernal pool fairy shrimp (other listed species), and additional PDC, restrictions, and conservation measures may apply for vernal pool fairy shrimp (USFWS, 2016).

***Conservation Measures and Best Management Practices:***

- Recommendations for Future Actions: • While the majority of known large-flowered woolly meadowfoam populations have been protected, future conservation will need to continue to be reliant on private lands. For this reason, enhanced and targeted outreach to private landowners is needed for conservation partnership in key areas leading to protected areas contributing to recovery. Protection tools include conservation easements or conservation programs. • Augment large-flowered woolly meadowfoam on protected habitat in BOR's Agate Lake Reservoir property, Denman Wildlife Area, and protected habitat in the North Eagle Point core area. • Develop and implement surveillance for hybridization between white meadowfoam and large-flowered woolly meadowfoam. • Conduct best management practices studies such as grazing, seeding, mowing, and prescribed fire to improve resilience of large-flowered woolly meadowfoam populations (USFWS<, 2024)

# SPECIES ACCOUNT: *Limnanthes vinculans* (Sebastopol meadowfoam)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 01/02/1992; Pacific Southwest (R8)

**Physical Description**

An annual herb of the false meadowfoam family (Limnanthaceae) with weak, somewhat fleshy, decumbent stems up to 30 cm (11.8 in) long (stems grow longest when the plant is submerged while actively growing). The seedlings are unusual among Limnanthes species in that they have entire leaves. Leaves of mature plants are up to 10 cm (3.9 in) long and have 3 to 5 leaflets that are narrow and unlobed with rounded tips. Although the first leaves are narrow and undivided, leaves on the mature plant have three to five undivided leaflets along each side of a long stalk (petiole). The length of the petiole also appears to be promoted by submergence. The shape of the leaves distinguishes L. vinculans from other members of the Limnanthes genus. Limnanthes vinculans has fragrant, white flowers during April and May. The flowers are borne in the leaf axils (upper angle between leaf and stem), are bell- or dishshaped, with petals 12 to 18 mm (0.47 to 0.71 in) long. The sepals (green outermost whorl of flower parts that enclose the bud) are shorter than the petals, which turn outward as the nutlets (small, dry nuts) mature. The nutlets are dark brown, 3 to 4 mm (0.12 to 0.16 in) long, and covered with knobby pinkish tubercles (small wartlike projections) (Ornduff 1969a, Brown and Jain 1977, Hauptli et al. 1978, Wainwright 1984, Patterson et al. 1994, Ornduff and Morin 2012). The seeds of L. vinculans germinate after the first significant rains in fall. Repeated drying and filling of pools in the spring favors development of large plants with many branches and long stems. (USFWS< 2016)

**Taxonomy**

The earliest collection of Limnanthes vinculans was made in 1946 “between Bodega and Petaluma, south of Sebastopol” but this record most likely represents a site near Sebastopol (Wainwright 1984). The species was not described until 1969, when Ornduff (1969a) officially published the name L. vinculans. Another common name for this species is Cunningham Marsh meadowfoam (Wainwright 1984, Patterson et al. 1994). The type locality for L. vinculans is Todd Road, just west of the intersection with Llano Road, which is near Sebastopol in Sonoma County (Ornduff 1969a). Limnanthes vinculans is similar to L. douglasii var. nivea (snowy meadowfoam) and L. alba (white meadowfoam) in flower characteristics, and to L. bakeri (Baker’s meadowfoam) in leaf characteristics. However, seedlings of L. douglasii and L. alba have lobed leaves and the mature leaves have more, deeper lobes called leaflets (5 to 13 leaflets as compared to 3 to 5 leaflets in L. vinculans). In addition, the petals of white meadowfoam curve inward as the nutlets mature. L. bakeri has smaller flowers than L. vinculans, occasionally has two or three lobes on the leaflets, and occurs only in Mendocino County (Ornduff and Crovello 1968, Ornduff 1969a, Brown and Jain 1977, Wainwright 1984, Ornduff and Morin 2013). (USFWS, 2016)

**Historical Range**

In California, in Sonoma and Napa Counties. (USFWS, 2016)

**Current Range**

In California, in Sonoma, Napa, and Lake Counties. (USFWS, 2019)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: self-pollination, cross-pollination (USFWS, 2016)

**Lifespan**

Adult: One year (USFWS, 2016)

**Dependency on Other Individuals or Species**

Adult: Pollinators such as Conophorus flies and Limnanthes bees (USFWS, 2016)

**Key Resources Needed for Breeding**

Adult: Seed bank (USFWS, 2008); fall rains, insect pollinators (USFWS, 2016)

**Reproduction Narrative**

Adult: According to Patterson et al. (1994), the seeds of Limnanthes vinculans germinate after the first significant rains in fall, although late initiation of rains may delay seed germination. L. vinculans plants grow slowly underwater during the winter, and growth rates increase as the pools dry. Repeated drying and filling of pools in the spring favors development of large plants with many branches and long stems. L. vinculans begins flowering as the pools dry, typically in March or April. The largest plants can produce 20 or more flowers. Flowering may continue as late as mid-June, although in most years the plants have set seed and died back by then. Each plant can produce up to 100 nutlets. Nutlets of Limnanthes vinculans likely remain dormant in the soil, as has been noted in other species of Limnanthes (Patterson et al. 1994). For example, in the late 1980s and early 1990s, a site in Cotati remote from other L. vinculans occurrences was surveyed for several years by independent qualified botanists. None of these botanists identified flowering occurrences of L. vinculans on the project site. Conditions of the pools on the site were highly degraded by wallowing hogs (Sus scrofa) and subsequent eutrophication (over enrichment by nutrients) of the pools. Following several years of negative surveys, 12 plants of Sebastopol meadowfoam emerged simultaneously in one pool in the first year following removal of hogs. (USFWS, 2016)

**Habitat Type**

Adult: Wetland (USFWS, 2016)

**Habitat Vegetation or Surface Water Classification**

Adult: Northern Basalt Flow and Northern Hardpan vernal pools (USFWS, 2016)

**Geographic or Habitat Restraints or Barriers**

Adult: 50 - 380 ft. elevation (USFWS, 2016)

**Spatial Arrangements of the Population**

Adult: Linear, patchy (NatureServe, 2015)

**Environmental Specificity**

Adult: Very narrow (NatureServe, 2015)

**Dependency on Other Individuals or Species for Habitat**

Adult: Wetland obligate

**Habitat Narrative**

Adult: This species grows in northern basalt flow and northern hardpan vernal pools (Sawyer and Keeler-Wolf 1995), wet swales and meadows, on the banks of streams, and in artificial habitats such as ditches (Wainwright 1984; CNDDB 2002). Limnanthes vinculans grows in both shallow and deep areas, but is most frequent in pools 25 to 51 cm (10 to 20 in) deep (Patterson et al. 1994). The species is most abundant in the margin habitat at the edge of vernal pools or swales (Pavlik et al. 2000, 2001). Most confirmed occurrences of L. vinculans on the Plain grow on Wright loam or Clear Lake clay soils (Patterson et al. 1994, CNDDB 2002). A few occurrences are on other soil types, including Pajaro clay loam, Cotati fine sandy loam, Haire clay loam (Patterson et al. 1994) and Blucher fine sandy loam (Wainwright 1984). (USFWS, 2016)

***Dispersal/Migration***

**Dispersal**

Adult: Low, based on closely related species (USFWS, 2016)

**Dispersal/Migration Narrative**

Adult: Mechanisms for dispersal of nutlets in this species have not been studied. Likely dispersal agents include water (Wainwright 1984), birds, and livestock (Jain 1978). Jain (1978) studied dispersal of nutlets similar to those of L. vinculans in two species of meadowfoam, L. bakeri (Baker's meadowfoam) and L. striata (striped meadowfoam). Nutlets of L. bakeri did not disperse beyond the point where they were placed. Nutlets of L. striata moved a short distance within the same pool where they were placed but did not disperse to other pools (Hauptli et al. 1978, Jain 1978). (USFWS, 2016)

***Population Information and Trends***

**Population Trends:**

90% of vernal pool habitat destroyed (NatureServe, 2015)

**Species Trends:**

Primarily unknown or decreasing (USFWS, 2008)

**Number of Populations:**

38 presumed extant (USFWS, 2024)

**Population Size:**

1,000's (USFWS, 2024)

**Additional Population-level Information:**

At the time of listing in 1991, Sebastopol meadowfoam was documented in 29 locations in the southwestern portion of the Santa Rosa Plain, previously referred to as the Cotati Valley, in Sonoma County (B. Guggolz, California Native Plant Society, pers. comm. 1990, as cited in Service 1991, p. 61174). The 2008 status review defined distribution according to the Diversity Database, in which Sebastopol meadowfoam was known from 40 occurrences in Sonoma County and one occurrence (#39) in Napa County at the Napa River Ecological Reserve (Service 2008, p. 4). The Napa County occurrence was discovered in 1993, after publication of the final listing rule in Service 1991 (Diversity Database 2024, p. 39). In Sonoma County, 38 occurrences were in central and southern Santa Rosa Plain, while the other two were in Atascadero Creek Marsh west of Sebastopol (#20) and in Knights Valley northeast of Windsor (#40) (Diversity Database 2001, as cited in Service 2008, p. 4). As noted in the 2019 status review, one additional occurrence (#53) was found in Napa County, southeast of the City of Calistoga, and two occurrences were found in Sonoma County near the City of Sebastopol (#54) and the City of Rohnert Park (#55) (Service 2019, p. 4). Two additional occurrences (#56 and #57) were introduced in Sonoma County during mitigation activities or to establish conservation banks. Another change made to the Diversity Database is the removal of occurrence #55 in June 2020 due to misidentification (K. Ferguson, California Department of Fish and Wildlife, in litt. 2024). The occurrence was observed in 2012 and identified as Sebastopol meadowfoam based on early blooming plants (M. Lang, Dudek, in litt. 2020). Verification later in the blooming period revealed that the plants were misidentified and were Douglas' meadowfoam; however, the occurrence was not removed from the Diversity Database until 2020 (Lang in litt. 2020). The final change in distribution since the previous status review is the status change of occurrence #35 from "possibly extirpated" to "extirpated". The occurrence was last observed in 1998 and is presumed to be extirpated by development, based on aerial imagery (Diversity Database 2024, p. 35). Seeds were collected from this occurrence in 1993, 1994, 1997, and 1998 and sown at occurrence #34 (Diversity Database 2024, p. 35). Of the 46 occurrence records currently described in the Diversity Database, three are considered "extirpated", five are "possibly extirpated", and the remaining 38 are "presumed extant" (USFWS, 2024)

**Population Narrative:**

The available vernal pool habitat is limited as 90% of the vernal pool habitat has been destroyed by urbanization or agricultural development (CPC 2006) (NatureServe, 2015). Populations can vary greatly in size from year to year. Patterson et al. (1994) estimated only 10 hydrologically separate populations of L. vinculans exist. The CNDDB (2008) reports 32 extant occurrences, with the trend for most occurrences either unknown or decreasing. The genetic variability of Limnanthes vinculans is low compared to other Limnanthes species (Jain 1984). However, populations of this species do differ in genetic makeup (Jain in litt. 1980) (USFWS, 2008). The current status of numerous Limnanthes vinculans occurrences is unknown; however, the most current information from CNDDB, from survey data collected by the Adopt-a-Vernal Pool program, and from species experts indicates that there are 37 occurrences of L. vinculans that are presumed extant of which at least three have been introduced (USFWS, 2016).

***Threats and Stressors***

**Stressor:** Development and conversion to agriculture (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Today, the largest continuing threats to this species are urban development and land conversion to agriculture (such as vineyards) and associated agricultural activities and wastewater irrigation. The most recent estimates from the California Department of Conservation (2002) are that about 71,000 acres of Sonoma County have been converted to urban uses (Sonoma County Permit and Resource Management Department 2014). The threat of urban development to these species in the Santa Rosa Plain is expected to continue. In addition to urban development, land conversion to agriculture and associated agricultural activities has reduced occurrences of these plants (CNDDB 2014). In 1991, at the time of the listing, approximately 34,500 acres of land were in wine grape production in Sonoma County (Sonoma County Agricultural Commissioner 1991). As of 2012, the acreage of wine grapes in Sonoma County had increased to approximately 58,400 acres (Sonoma County Agricultural Commissioner 2013). Additionally, irrigation with recycled water, a practice that began in the Santa Rosa Plain in the 1970s, has emerged as a major threat. Although the California Regional Water Quality Control Board regulations (Water Quality Control Plan for the North Coast Region) prohibit discharge of recycled water to surface waters during the summer, the regulations did not contemplate that recycled water would be used to irrigate vernal pools and other types of seasonal wetlands (J. Short, pers. comm., 2007). Recycled water, as opposed to wastewater, is tertiary-treated (City of Santa Rosa, in litt. 2015** [comment letter]). Wastewater, however, can come from many sources including livestock waste ponds and runoff from agricultural fields (City of Santa Rosa, in litt. 2015** [comment letter]). (USFWS, 2016)

**Stressor:** Alteration of hydrology (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Some actions, such as runoff from irrigation or irrigation with recycled water, can result in increased water on the landscape. The vernal pool habitat may receive more water than it normally would or receive it at an inappropriate time, resulting in flooding and death of listed plant seedlings. If water from urban or agricultural runoff continues to fill pools during spring and summer months, the listed plants will disappear because they cannot tolerate permanent inundation; invasion by plant species adapted to permanent inundation will occur. Additionally, irrigation with recycled water and runoff from irrigation can contain chemicals, such as herbicides, and other nutrients (Pereira et al. 1996) that can alter the vernal pool plant community, prevent germination, or kill seedlings. Nitrogen deposition from automobile traffic may also modify habitat by increasing soil nutrients, thus posing a continuing threat to remnant habitat that might otherwise be suitable for these species. Weiss and Luth (2003, p. 1) conducted research on the effects of nitrogen deposition along a highway south of the San Franciscan peninsula in San Francisco County. They found that nitrogen deposition within 100 m to 400 m from the highway was correlated with increased nonnative grass cover within these areas, resulting in competition for space with native plants. An increase in nonnative grass cover through changed habitat conditions could threaten the three plant species by competing for soil moisture and nutrients and inhibiting successful germination. (USFWS, 2016)

**Stressor:** Off-highway vehicles (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Damage by off-highway vehicles was noted as a threat to this species. Currently, on Department-owned properties that support the listed plants, some damage to preserves from vehicle trespass does occur, but without damage to the vernal pools. The most significant damage to vernal pools from vehicles has resulted from a Mosquito Vector Control vehicle driving through the vernal pools to spray for mosquitoes during the time when the pools were wet in 2014. Disturbance to the pools included physical damage to the pools and swales from tire ruts and crushing and uprooting the plants (S. Martinelli, CDFW, in litt. 2014). The level of this threat is likely to be variable and is difficult to predict or monitor. (USFWS, 2016)

**Stressor:** Grazing managment and thatch accumulation (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Appropriate levels of grazing may provide some control of weedy plants, reduce competition between native plants and invasive plants, and can provide some bare soil for germination of native plants, all of which may provide opportunities for native plants to germinate. Cessation of cattle grazing has been found to exacerbate the negative effects of invasive nonnative plants on vernal pool inundation period. If grazing is removed, areas of bare soil can be quickly occupied by nonnative, invasive plants. Removal of grazing from vernal pool grasslands where grazing is the traditional land use practice may have devastating impacts on vernal pool habitat, particularly on upland habitat surrounding vernal pools (G. Cooley, in litt., 2014). For example, non-native grasses increased and native grasses decreased in vernal pools when grazing was discontinued at a site in the Southeastern Sacramento Valley, resulting in a 50 to 80 percent reduction in vernal pool inundation (Marty 2005). Since the time of listing, grazing has been removed at many locations and has resulted in thatch build-up. Anecdotal evidence supports the theory that thatch build-up of nonnative vegetation has caused a reduction in the size of extant populations of the listed plants. The Department is re-establishing appropriate grazing practices on some Department-owned lands to reduce thatch build-up and nonnative competitors to the three listed plants (e.g., Todd Road Unit Ecological Preserve). However, reintroduction of grazing may not return a site to its former condition because nonnative plants may continue to occupy the once-vacant niches. For example, harding grass (Phalaris aquatica), a robust, invasive perennial grass, can be present in a grazed field, and not be obvious. If grazing is removed, however, the suppressed harding grass can become vigorous and dominate the entire field within a year or two and grazing will not remove this species once it is established (G. Cooley, in litt. 2014). We recognize that there is disagreement among biologists as to the extent of the threat of inappropriate grazing on the three species. As the final rule concluded, we believe that although the effect of well-managed livestock grazing may be beneficial to vernal pool ecosystem. (USFWS, 2016)

**Stressor:** Loss of Genetic Diversity / Inappropriate Mixing of Populations(USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** An additional potential threat to these three plants is the disruption of normal gene flow due to population restoration efforts that may mix populations, which may cause unanticipated adverse effects such as disruption of locally adapted gene complexes and outbreeding depression (when offspring from individuals from different populations have lower health/fitness than progeny from individuals from the same population). Several sites are

proposed as Preserves in the Santa Rosa Plain and include proposals to seed/inoculate created or restored vernal pools. Seed from a limited number of donor occurrences has already been used for several years to inoculate multiple created or restored sites, creating a risk of overrepresentation of a small gene pool (swamping). The threat level of this activity is unknown; however, the 2007 Programmatic Biological Opinion (Service 2007) includes measures to reduce this potential threat as well as the requirement to obtain a collection permit from the Department. (USFWS, 2016)

**Stressor:** Climate change (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Narrative: Since the 1950s, the Northern Hemisphere has experienced warmer air temperatures and decreased snowfall (Ackerly et al. 2010, IPCC 2013). By the end of the 21st century, climate change is predicted to result in more intense precipitation events in the form of rain, increased summer continental drying, extreme weather events, and increased wildfire (Ackerly et al. 2010, IPCC 2013). However, current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2013). Climate simulations have shown that California temperatures are likely to increase by 2.7 degrees Fahrenheit (1.5 degrees Celsius) to 8.1 degrees Fahrenheit (4.5 degrees Celsius) depending on the emissions scenario (Cayan et al. 2008). The predicted impacts on California's ecosystems projected with a high certainty include (1) higher sea level and (2) decreased suitable habitat for many terrestrial species as climate change intensifies human impacts [for example isolated patches of vernal pools can be so poorly connected with other patches that migrations required by climate change may be difficult or impossible without human intervention (Field et al. 1999)]. Climate change threatens to increase the loss of pollinators if the abundance of flowers preferred by pollinators decreases. Pollinator emergence times may also be altered by a warming climate. If this occurs, the synchrony of bloom periods and pollinator emergence could be disrupted. The loss of pollinators would further reduce the amount of seed produced by the listed plants because of the plants' limited ability to self-pollinate. Although there currently are no data available regarding changes in plant bloom periods or emergence dates of pollinators in the Santa Rosa Plain in response to climate change, Forister and Shapiro (2003) found that over a period of 31 years, warmer and drier winter conditions were associated with earlier butterfly appearance in the Central Valley of California. Although the loss of seed produced in a single year would not likely lead to the extirpation of the species, the continued reduction of the seed crop or dependence on self-pollination would reduce the seedbank, genetic variation, and the potential for population expansion. Monitoring of vernal pool ecosystems to determine effects from climate change is necessary to determine what adaptive land management practices would be the most appropriate to ensure the sustainability of vernal pool species (Pyke and Marty 2005), including B. bakeri, L. burkei, and L. vinculans. (USFWS< 2016)

**Stressor:** Extirpation due to Stochastic Events, Isolated Occurrences, and Small Size of Occurrences (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Chance events constitute a serious threat to Blennosperma bakeri. Because the known occurrences of B. bakeri are limited in number and in range, the species are vulnerable to stochastic (random) events—natural but damaging environmental perturbations and catastrophes such as droughts, storm damage, disease outbreaks, and fires, from which large wide-ranging populations can generally recover, but may lead to extirpation of small isolated populations (Gilpin and Soule 1986). The majority of the remaining habitat associated with the three species is vernal pools and swales in the Santa Rosa Plain. The nature of the vernal pool and swale habitat associated with the three plants may also increase the effects of drought. Vernal pools and swales are inundated only briefly and may not fill during dry years. As a result, we consider stochastic events to be of significant concern for these species. Isolated, small occurrences may also be at risk from a decrease in reproductive rate resulting from decreasing population density. The correlation of reproductive rate with population density, called the Allee effect, may be the result of either increased density or quality of compatible mates, or increased pollination, or both (Stephens et al. 1999). In small populations, if either the plants or their pollinators decline, consequences on the reproductive output of the other may result in an extinction vortex in which each generation is more likely to go extinct (Gilpin and Soulé 1986, Soulé and Mills1998). (USFWS, 2016)

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Service found that many existing regulatory mechanisms were not sufficient to protect plants, including section 404 of the Clean Water Act, the protections of the California Endangered Species Act, and the California Environmental Quality Act. The 1991 final rule also found that listing the plants under the Federal Endangered Species Act would provide better protection by requiring the Army Corps of Engineers (and other Federal agencies) to consult with the Service prior to final determinations on a proposed activity. (USFWS, 2016)

**Stressor:** Non-native invasive species (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Creating a drier habitat and facilitating the invasion of non-native upland species, may permanently change the plant community and the non-native plants may outcompete the listed species (Bauder 2000, Marty 2005, competition discussed further below). With insufficient water, the distribution of plant species that are normally found higher on the edge of the vernal pools may shift downward along the moisture gradient in response to the introduction of invasive plants that now flourish at pool edges. Non-native grasses maintain dominance at pool edges, sequestering light and soil moisture, promoting thatch build-up, and shortening inundation periods. Species strongly associated with vernal pools may disappear from shallow pools as a result of invasion by upland non-native plants. In addition, the invasive species can further alter the hydrology of the site by reducing the inundation period (Marty 2005). Reduction in inundation period is thought to be due to increased evapo-transpiration associated with dense cover of nonnative plants at the vernal pools (Marty 2005). Once non-native, invasive plants are introduced to vernal pools, competition with native species can come from several interactions including root competition (roots of one species are more efficient at absorbing moisture and nutrients from the soil) and pollination success (one species will set more seed and produce

more plants). Plant size can also confer superiority when competing with smaller plants. A larger plant can shade smaller or shorter plants and seedlings, depriving them of adequate sunlight which is necessary for plant and seedling growth and survival, and in some cases necessary for seed germination (Barbour et al. 1987). (USFWS, 2016)

**Stressor:** Pesticides (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Environmental Protection Agency (Agency) recently released final biological evaluations assessing the effects of labeled uses of three neonicotinoid pesticides on listed species (Agency 2022a, entire; Agency 2022b, entire; Agency 2022c, entire). The three pesticides (clothianidin, imidacloprid, and thiamethoxam) are registered for use on a variety of agricultural crops; there are also some non-agricultural applications. The three pesticides target insect species by acting on their neurotransmitters to cause excessive nervous stimulation, paralysis, and death. Sebastopol meadowfoam is primarily pollinated by its specialist bee, Andrena pulvera, but it is also visited by a diversity of other bees and syrphid flies (Gilmore 2018, pp. 4, 54–57). The Agency's final biological evaluations determined that all three pesticides are highly toxic to bees, have the potential to result in bee brood and colony reductions, and if affected bee colonies decline near Sebastopol meadowfoam, there is a potential for the three pesticides to indirectly adversely affect the species (Agency 2022a, p. 4; Agency 2022b, p. 2; Agency 2022c, p. 3). The Agency anticipates releasing amended proposed interim decisions and a national consultation with the Agency is currently pending (USFWS, 2024).

**Stressor:** Genetics (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Historically, the species' gene flow was disrupted by habitat fragmentation. Now, gene flow is altered by mitigation activities and human-facilitated movement of seeds among populations. The 2019 status review confirms the threat of disruption of gene flow and change in flow patterns due to habitat restoration activities, based on new information from Halbur et al. (2014) (Service 2019, p. 4). Mitigation activities for Sebastopol meadowfoam, including vernal pool creation with seed inoculation, is concentrated in the center of the species range (Halbur et al. 2014, p. 681). Halbur et al. (2014) found enhanced gene flow at the center of the range due to establishment of new habitat and occurrences (p. 691). As a result, individuals in created pools are more genetically similar than individuals in natural pools separated by similar distances (Halbur et al. 2014, p. 691). In contrast, the population at a particular mitigation site known as Slippery Rock exhibits the opposite genetic dynamics (i.e., more genetic differentiation from surrounding sites), as the seeds were translocated from the northern range boundary to the center of the range (Halbur et al. 2014, p. 692). This is a potential barrier to gene flow due to outbreeding depression (USFWS, 2024)

***Recovery***

**Reclassification Criteria:**
A/1: Of all extant, native occurrences in the Plain not protected as of December 2014, 75 percent of the Limnanthes vinculans Northern Core Area occurrences, and 80 percent of the

Limnanthes vinculans Southern Core Area occurrences are permanently protected to maintain the current geographic, elevational, and ecological distribution of the species. Priority should be given to occurrences that have been shown to be isolated and/or genetically unique. (USFWS, 2016)

A/2: New preserves protect a total of 500 ac in two general areas: 200 ac in the Limnanthes vinculans Northern Core Area and 300 ac in the Limnanthes vinculans Southern Core Area. These preserves consist of occupied habitat that was not protected as of December 2014. The ecological integrity (e.g., water quality, hydrology, and uplands condition) of these areas is not threatened by adverse habitat modification. Buffers between the protected habitat and incompatible land uses is sufficient to ensure that there are no significant adverse effects to Limnanthes vinculans, such as changes in hydrology or contamination by pesticides or herbicides, currently and into the foreseeable future (USFWS, 2016).

A/3: New preserves (comprised of restored or created habitat) must be 10 ac or greater; however, preserves with existing native occurrences may be less than 10 ac. The preserves should be as near to new or existing preserves as possible. (USFWS, 2016)

A/4: The total new preserve acreage among all core areas consists of a minimum of 70 ac of vernal pools and swales (40 ac in the Limnanthes vinculans Northern Core Area and 30 ac in the Limnanthes vinculans Southern Core Area). However, new preserves are no more than 35 percent wetland which is based on general wetland to upland percentages. (USFWS, 2016)

A/5: Service-approved conservation and management plans that protect vernal pool habitat and upland habitat and address effects of invasive plants are developed and are being effectively implemented. (USFWS, 2016)

A/6: Service shall work with Mosquito Abatement Districts so that their practices in the core and management areas are implemented to avoid impacts to the species. (USFWS, 2016)

E/1: All native occurrences, extant as of December 2014, in the Limnanthes vinculans Northern Core Area as well as the Theiller (owned by CDFW) and Haroutounian (owned by Sonoma County Open Space) sites in the southern portion of the Limnanthes vinculans Southern Core Area, are replicated at 1:3 (quadrupled in numbers of occurrences) in permanently protected appropriate sites. The remaining occurrences in Limnanthes vinculans Southern Core Area are replicated at 1:1 because they are genetically similar. Replication is accomplished by collecting seed or inoculum from a natural occurrence and planting it at additional sites. For example: collecting seed or inoculum at one site and planting it at two additional sites increases the original single occurrence to 3 occurrences (1:2); planting it at three additional sites increases the original occurrence to 4 occurrences (1:3). (USFWS, 2016).

E/2: The preserves noted in Factor A are occupied by Limnanthes vinculans at a density of 1,500 seeds per square meter when measured on a 25-year moving average which includes at least one above average and one average rainfall year, and a multi-year drought. A multi-year drought is defined as a period of 3 or more years of below average local rainfall. (USFWS, 2016)

E/3: Service-approved conservation and management plans that protect vernal pool habitat and upland habitat and address effects of small occurrences of the listed plants and climate change, are developed and are being effectively implemented. (USFWS, 2016)

Recovery Priority Number: 2C

**Delisting Criteria:**
A/1: At least ninety percent of all known occurrences of Limnanthes vinculans that are extant as of December 2014, have been protected in perpetuity. (USFWS, 2016)

E/1: In addition to replication noted in criterion 7 of the downlisting criteria for Limnanthes vinculans, all occurrences in management areas have been replicated at 1:2 at permanently protected at appropriate locations. (USFWS, 2016)

E/2: All replicate occurrences in management areas have achieved the same density (1,500 seeds per square meter) as the core area occurrences. (USFWS, 2016)

E/3: If Limnanthes vinculans is found at the Knights Valley site, the northernmost location, this occurrence should be replicated at 1:2 in permanently protected appropriate locations. (USFWS, 2016)

E/4: All genetically unique and isolated unprotected sites in management areas are permanently protected in situ. Identification of some genetically unique occurrences is not yet known but will be determined during research listed in Table 6 of the Recovery Plan. (USFWS, 2016)

**Recovery Actions:**
- 1. Protect extant occurrences and potential habitat for Limnanthes vinculans. Natural areas that are known to contain species covered in this recovery plan should be protected in perpetuity through land acquisition, conservation easements, or other means. Protection of these areas will need to be followed by identification of threats and application of appropriate and adaptive management to ensure abatement of these threats. In addition to areas that currently support the species, two other types of natural areas also need to be protected or secured: areas where the endangered plants have been found in the past but not been seen recently, and that retain habitat that can be readily restored so that plants can be reintroduced successfully; and areas where the plants have not been found but are appropriate for vernal pool creation, and subsequent introduction of the endangered plants. (USFWS, 2016)
- 2. Develop a central database for survey data from all natural and created occurrences of Limnanthes vinculans including information on protection status. Data should include numbers of plants; area occupied by the species; presence of invasive species; site condition; land ownership; level of management; disturbance; whether the site is natural, restored, or created; and degree of genetic uniqueness. If the site has been seeded, the origin of the seed should be identified by name and location of parcel where seed was collected, location of specific pools where seed was collected, and date of seed collection. Any observations of pollinators, such as species or type of pollinator, should also be recorded. This information will serve as the current baseline for evaluating progress of the Factor A and Factor E comparative downlisting and delisting recovery criteria for each of the three plant species. This database should be updated regularly and should be available to all management agencies (USFWS, 2016). In addition, the database should track the location of source seed for sites with created occurrences (USFWS, 2019).

- 3. Collect and store seed from all occurrences of Limnanthes vinculans. Seed collections for each plant taxon should be representative of both population- and species-level genetic diversity; seeds should be collected from multiple plants at each occurrence. Seed collection guidelines published by the Center for Plant Conservation (1991) should be followed. Seed collection should be conducted with caution to ensure that donor populations are not adversely affected by the collection. No more than 5 percent of the reproductive output should be removed from donor populations. Store seeds at two storage facilities certified by the Center for Plant Conservation. Seeds should be collected every 5 years to ensure that seeds in storage are viable. Permits will be required for collecting federally-listed plant seed on federal lands. (USFWS, 2016)
- 4. Survey historical locations and other potential habitat (not previously surveyed) where Limnanthes vinculans may occur. (USFWS, 2016)
- 5. Conduct research necessary to develop a population viability analysis for Limnanthes vinculans. Table 2 of the Recovery Plan lists research tasks needed for the development of a population viability analysis for all three species in the Recovery Plan. All research tasks need to be performed for each of the three species. To maximize efficiency, it may be possible to study the effects of an experimental factor on all three species in the Recovery Plan via the same experiment. (USFWS, 2016)
- 6. Conduct necessary biological research on Limnanthes vinculans and use results to guide recovery efforts. Table 6 of the Recovery Plan the needed research tasks for the recovery of Blennosperma bakeri, Lasthenia burkei, and Limnanthes vinculans. All research tasks need to be performed for each of the three species. To maximize efficiency, it may be possible to study the effects of an experimental factor on all three species via the same experiment. (USFWS, 2016)
- 7. Habitat management for Limnanthes vinculans. Develop adaptive management plans and implement appropriate management actions for all protected sites. Work with local agricultural commissions to track conversion of agricultural uses to vineyards or other non-suitable agricultural uses. Decrease acreage of vernal pool habitat within priority preservation and restoration areas that are subjected to altered hydrologic regimes through irrigation practices. Develop treatment protocol with mosquito abatement district to avoid impacts to listed species and vernal pool habitat during treatment. (USFWS, 2016)
- 8. Restore or create vernal wetlands, followed by reintroduction of the species per a restoration techniques white paper and a Reintroduction and Genetic Management Plan. As noted in the Factor A discussion, much of the habitat and occurrences of the three listed plants has been destroyed or fragmented by urban development and conversion to agricultural use. Restoration or creation of habitat, when appropriate, will be necessary to maintain the numbers of plants and occurrences at levels sufficient for survival of the species. Restoration and creation of vernal pool habitat has been conducted for many years in the Santa Rosa Plain for the three plants. To better understand these processes and their rates of success, a white paper and a Reintroduction and Genetic Management Plan should be developed. (USFWS, 2016)
- 9. Monitor all protected occurrences. Monitoring plans should be developed and implemented for all protected natural and replicated occurrences. Protected occurrences should be monitored annually for plant density, area occupied by the listed species, site condition, changes in hydrology, application of recycled water and wastewater, effects of grazing, invasive species, vandalism, and whether management is appropriate for the listed species' needs. The responsible party for monitoring should also keep an ongoing record of

management activities and precipitation on the site, so that changes in rare plant populations can be related to changes in management activities. Monitoring efforts for co-occurring species (e.g. Blennosperma bakeri and Limnanthes vinculans at Wright Mitigation Bank) should be coordinated to increase efficiency and reduce costs. (USFWS, 2016)

- 10. Engage and educate the public about Limnanthes vinculans recovery. Public education and outreach is important to inform residents and land managers in the Santa Rosa Plain and other areas that support habitat for the species about the significance of the plants and the importance of management and protection of habitat for their persistence. Education and outreach activities should include: (1) develop a public outreach plan, (2) outreach to enhance public understanding of vernal wetlands in general and of imperiled vernal wetland species in particular, (3) information on regulatory responsibilities with regard to endangered species, (4) programs to encourage local interest and involvement in site stewardship, and (5) programs including conservation easements and incentive programs that are available to landowners who may have the vernal pool species on their land. (USFWS, 2016)
- 13. Agency coordination. Partner with California Department of Fish and Wildlife, Army Corps of Engineers, Regional Water Quality Control Board, Sonoma County, Marin/Sonoma Mosquito and Vector Control District, and Cities of Santa Rosa, Cotati, Rohnert Park, and Windsor to ensure resource management practices are aligned with species conservation needs. Resource management practices to be addressed include: irrigation of vernal pool habitat with recycled water and wastewater within priority preservation and restoration areas; protection of habitat buffers; stream ordinances, grading ordinances, and water quality regulations; and vineyard conversion or other agricultural conversion of areas adjacent to vernal pool habitat that contribute to hydrologic regime and/or provide upland habitat for sustaining the Sonoma County California tiger salamander. Provide legal assurances to willing landowners who implement projects that provide a net conservation benefit. (USFWS, 2016)

# SPECIES ACCOUNT: *Linum arenicola* (Sand flax)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/31/2016; Southeast Region (R4)(USFWS, 2017)

**Physical Description**

Linum arenicola is a small, perennial herb that is 35 to 53 cm (14 to 21 in) tall with yellow flowers that are similar in appearance those of a buttercup (Ranunculus spp.). When not in flower, it resembles a short, wiry grass. Plants have one to several stems arising from their base. Leaves are linear in shape, 7– 10 millimeters (mm) (0.3–0.4 in) long, 0.6–1 mm (0.02–0.04 in) wide, and arranged alternately along stems, and they have glands scattered along their edges. Flowers are produced on stems consisting of a few slender, spreading branches. The individual flowers are on small stalks 2 mm (0.08 in) long or shorter. The flowers have five yellow, egg-shaped petals that are 4.5–5.5 mm (0.18–0.22 in) long, and five green, lance-shaped to egg-shaped sepals that are 2.4–3.2 mm (0.09–0.13 in) long. The seeds are ovate, 1.2– 1.4 mm (0.05–0.06 in) long, and 0.7- 0.8 mm (0.027–0.031 in) wide (Rogers 1963, pp. 103–104) (USFWS, 2015). The fruit is an elongate pod, roughly similar to that of a pea, 33–45 millimeters (mm) (1.3–1.8 inches (in)) long and 4.5–5.0 mm (0.19–0.17 in) wide, with a soft fuzzy texture, which turns gray with age and eventually splits open to release seeds (Irwin and Barneby 1982, p. 757; Small 1933, pp. 662–663) (USFWS, 2016).

**Taxonomy**

Linum arenicola was first described by Small in 1907 as Cathartolinum arenicola from plants he collected in Miami-Dade County in 1904. This treatment was consistently followed by Small (1913a, p. 69; 1913b, p. 96; 1933, p. 752). In 1931, Winkler included Cathartolinum within the genus Linum, renaming the plants Linum arenicola (Winkler 1931, p. 30). Others have followed this treatment, including Rogers (1963, p. 103), Long and Lakela (1971, p. 505), Robertson (1971, p. 649), Wunderlin (1998, p. 100), and Wunderlin & Hansen (2003, p. 100) (Hodges and Bradley 2006, p. 37). Synonyms include Cathartolinum arenicola Small (Wunderlin and Hansen 2004, p. 5). The Integrated Taxonomic Information System (2015, p. 1) uses the name Linum arenicola and indicates that this species' taxonomic standing is accepted. The online Atlas of Florida Vascular Plants (Wunderlin and Hansen 2008, p. 1) uses the name L. arenicola. There is consensus that L. arenicola is a distinct taxon. We have carefully reviewed the available taxonomic information to reach the conclusion that the species is a valid taxon (USFWS, 2015).

**Historical Range**

The historical range of Linum arenicola consists of central and southern Miami-Dade County and Monroe County in the lower Florida Keys (Bradley and Gann 1999, p. 61). In Miami-Dade County, records for the species were widespread from the Coconut Grove area to the southern part of the County, close to what is now the main entrance to Everglades National Park and Turkey Point (Bradley and Gann 1999, p. 61). In the Florida Keys (Monroe County), there are records of the species from Big Pine Key, Ramrod Key, Upper and Lower Sugarloaf Keys, Park Key, Boca Chica Key, Middle Torch Key (Bradley and Gann 1999, p. 61), and Big Torch Key (Hodges 2010, p. 10) (USFWS, 2015).

**Current Range**

The current range of Linum arenicola consists of eight extant populations in Miami-Dade County and four islands in the Florida Keys: Big Pine Key, Upper and Lower Sugarloaf Keys, and Big Torch Key (USFWS, 2015).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual

**Breeding Season**

Adult: Flowers are produced from February to September, with a peak around March and April

**Reproduction Narrative**

Adult: Little is known about the life history of Linum arenicola, including pollination biology, seed production, or dispersal. Reproduction is sexual, with new plants generated from seeds. The species produces flowers from February to September, with a peak around March and April. L. arenicola population demographics or longevity have not been studied (Bradley and Gann, 1999, p. 65; Hodges and Bradley 2006, p. 41; Hodges 2007, p. 2).

**Habitat Type**

Adult: Temporary pools; Forest/Woodland, Old field, Woodland - Conifer, Woodland - Mixed

**Environmental Specificity**

Adult: Moderate (inferred from USFWS, 2015)

**Habitat Narrative**

Adult: Pine Rocklands: Linum arenicola occurs in pine rocklands, disturbed pine rocklands, dry marl prairie, and disturbed areas on rocky soils adjacent to these habitats (Bradley and Gann 1999, p. 61; Hodges and Bradley 2006, p. 37). L. arenicola grows in thin soil over limestone or in small soil patches caught in surface irregularities of exposed limestone (Kernan and Bradley, 1996, p. 2). Sites most likely to support L. arenicola have a grass- and herbdominated understory, abundant pine regeneration, and high cover of exposed rock (Ross and Ruiz 1996, pp. 5–6). The pine rocklands and marl prairies where this species occurs require periodic fire to maintain an open, shrub-free subcanopy, and to reduce litter levels (Bradley and Saha 2009, p. 4). Pine rocklands habitat is described in detail for Chamaecrista lineata var. keyensis, above. Roadsides and Other Disturbed Sites: While pine rocklands historically were the primary habitat of Linum arenicola, the species is currently rare in relatively undisturbed pine rocklands, with the exception of plants on Big Pine Key. Several occurrences are in scraped (scarified) pine rocklands remnants that are dominated by native pine rocklands species, but have little or no pine canopy or subcanopy (Bradley and Van Der Heiden 2013, pp. 9–12). Two populations in Miami-Dade County occur entirely on levees composed of crushed oolitic limestone that are surrounded by sawgrass marsh (Bradley and Gann 1999, p. 61; Bradley and Van Der Heiden 2013, pp. 7–9). Roadsides and other disturbed sites are important habitat for L. arenicola because they imitate upland herbaceous habitat (Hodges and Bradley 2006, p. 40). The most robust roadside populations occur in areas adjacent to pine rocklands or rockland hammocks (Hodges 2010, p. 3). Where L. arenicola is found on roadsides, the ground cover is dominated mostly by native herbs and grasses where exotic lawn grasses have not been planted (Bradley 2006, p. 37). Infrequent mowing of some roadsides, and of disturbed sites such as Homestead Air Reserve Base (HARB) and U.S. Special Operations Command South Headquarters (SOCSOUTH), a unified command of all four services in the Department of Defense (DOD) has likely allowed the species to persist by preventing these sites from being taken over by hardwoods. Because Linum arenicola seems to only rarely occur within intact pine rocklands, but more frequently adjacent to this habitat, developing conservation and management plans for this species is exceptionally difficult. Its persistence on roadsides is not fully understood. L. arenicola was at one time more common in pine rocklands in Miami-Dade County, but a lack of periodic fires in most pine rocklands fragments over the last century have pushed this species into more sunny, artificial environments (Bradley and Gann 1999, p. 61). It is also possible that the species has evolved to persist along roadsides as fire regimes and natural areas were altered and destroyed over the last century (Hodges and Bradley 2006, p. 41). Dry Marl Prairie: Marl prairie is a sparsely vegetated, grass-dominated community found on marl substrates in South Florida. Marls are fine, white, calcareous muds formed from calcite precipitated by a mixture of green algae, blue green algae, and diatoms, known as periphyton. It is seasonally inundated (2 to 4 months) to a shallow depth averaging about 20 cm (8 in). Marl prairie is a diverse community that may contain over 100 species. Marl prairie normally dries out during the winter and is subject to fires at the end of the dry season (FNAI 2010, p. 1). Occurrences reported from marl prairie are at sites that have been artificially drained (Bradley and Van Der Heiden 2013, p. 11), or are scraped pine rocklands that function more like marl prairie (Kernan and Bradley 1996, p. 11). As with roadside populations of Linum arenicola, it is possible that dry marl prairies have become refugia for the species as fire regimes and natural areas were altered and destroyed over the last century. Accordingly, the Service does not consider marl prairie to be a primary habitat for L. arenicola (USFWS, 2015).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

In the 5 populations where data are sufficient to assess trend, 3 appear stable and 2 appear declining

**Number of Populations:**

15 extant; 14 presumed extant (USFWS, 2024)

**Population Narrative:**

The large area of potential habitat and scarcity and diminutive size of L. arenicola make thorough surveys for this species difficult (Hodges and Bradley 2006, p. 37). Based on a compilation of all survey work through 2013, including Austin (1980), Kernan and Bradley (1996, pp.1– 30), Bradley and Gann (1999, pp. 61– 65), Hodges and Bradley (2006, pp. 37– 41), Bradley and Saha (2009, p. 10), Bradley (2009, p. 3), Hodges (2010, pp. 4–5, 15), Bradley and van der Heiden (2013, pp. 6–12,19), and Bradley et al. (2015, pp. 28–29), of 26 historical population records for Linum arenicola, 12 populations are extant and 14 are extirpated, a loss of roughly

54 percent of known populations, from the early 1900s to the present. reliable population trends can be derived from past surveys for 5 of the 12 extant populations. Populations on Big Pine Key and Big Torch Key have shown clear declines. Three populations appear to be stable (data suggest they have not declined appreciably). Data are insufficient to determine trends for the remaining seven populations. The data also show that 5 of the 12 extant populations are rather small, having fewer than 100 plants. Currently there are 15 extant populations and 14 presumed extirpated populations (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Habitat loss, fragmentation, and degradation (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat loss, fragmentation, and degradation, and associated pressures from increased human population, are major threats; these threats are expected to continue, placing these plants at greater risk. The species may be impacted when pine rocklands are converted to other uses or when lack of fire causes the conversion to hardwood hammocks or other unsuitable habitat conditions. Any populations of this species found on private property could be destroyed by development; the limited pine rocklands, rockland hammock, and coastal berm habitat on public lands can also be affected by development of recreational facilities or infrastructure projects. Although efforts are being made to conserve publicly and privately owned natural areas and apply prescribed fire, the long-term effects of large-scale and wide-ranging habitat modification, destruction, and curtailment will last into the future, while ongoing habitat loss due to population growth, development, and agricultural conversion continues to pose a threat. Therefore, based on the best information available, we have determined that the threats to the species from habitat destruction, modification, or curtailment are occurring throughout the entire range of the species and are expected to continue into the future (USFWS, 2015).

**Stressor:** Disease or Predation (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** No diseases or incidences of predation have been reported for Chamaesyce deltoidea ssp. serpyllum or Argythamnia blodgettii. Key deer are known to occasional browse plants indiscriminately, including Chamaecrista lineata var. keyensis and Linum arenicola. Key deer do not appear to feed on Argythamnia blodgettii, probably due to potential toxicity (Hodges and Bradley 2006, p. 19). Seed predation by an insect occurs in Chamaecrista lineata var. keyensis, and seems to be exacerbated by habitat fragmentation. Individuals at the urban edge suffer higher insect seed predation than those inside the forest (Liu and Koptur 2003, p. 1184). While seed predation and occasional Key deer browsing may be a stressor, they do not appear to rise to the level of threat at this time. Therefore, the best available data do not indicate that disease or predation is a threat to Chamaecrista lineata var. keyensis or Linum arenicola (USFWS, 2015).

**Stressor:** The Inadequacy of Existing Regulatory Mechanisms (USFWS, 2015)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** Currently, Chamaecrista lineata var. keyensis, Chamaesyce deltoidea ssp. serpyllum, Linum arenicola, and Argythamnia blodgettii are found on Federal, State, and County lands; however, there is no regulatory mechanism in place that provides substantive protection of habitat or protection of potentially suitable habitat at this time. NPS and USFWS Refuge regulations provide protection at ENP and the Florida Keys Wildife Refuge Complex, respectively. The Act provides some protection for candidate species on NWRs and during intraService section 7 consultations. State regulations provide protection against trade, but allow private landowners or their agents to clear or remove species on the Florida Regulated Plant Index. State Park regulations provide protection for plants within Florida State Parks. The NFC program in Miami is designed to protect rare and important upland (non-wetlands) habitats in south Florida; however, this regulatory strategy has several limitations (as described above) that reduce its ability to protect the four plants and their habitats. Although many populations of the four plants are afforded some level of protection because they are on public conservation lands, existing regulatory mechanisms have not led to a reduction or removal of threats posed to these plants by a wide array of sources (see discussions under Factor A, above, and Factor E, below) (USFWS, 2015).

**Stressor:** Other Natural or Manmade Factors Affecting Its Continued Existence (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** We have analyzed threats from other natural or manmade factors including: nonnative, invasive plants; management practices used on roadsides and disturbed sites (such as mowing, sodding, and herbicide use); pesticide spraying and its effects on pollinators; environmental stochasticity; effects from small population size and isolation; and the effects of climate change, including SLR. The related risks from hurricanes and storm surge act together to impact populations of all four plants. Some of these threats (e.g., nonnative species) may be reduced on public lands due to active programs by Federal, State, and county land managers. Many of the remaining populations of these plants are small and geographically isolated, and genetic variability is likely low, increasing the inherent risk due to overall low resilience of these plants (USFWS, 2015).

***Recovery***

**Reclassification Criteria:**
Not available- this species does not have a recovery plan.

Recovery Priority Number: 5

***Conservation Measures and Best Management Practices:***

- Recovery Activities • Work with land managers to incorporate conservation mowing regimes beneficial to the species. • Conduct or continue to conduct habitat restoration on all occupied sites, including (a) removal of native hardwoods and non-native invasive plants and (b) establish a prescribed burn or mowing regimen. • Coordinate with the South Florida Water Management District (SFWMD) and other partners conducting Everglades restoration projects in and around the L-31E and nearby intersecting canals to ensure that sand flax is not impacted or that mitigation occurs. • Develop a captive propagation and reintroduction plan for the species that assesses risks and guides future introductions. o Determine if translocations may be beneficial to occupy suitable habitat. o Assess reintroduction locations where sand flax has been extirpated. o Consider prioritizing augmenting populations that have less than ten plants to ensure population survival and genetic exchange. o Assess collections currently in seed banks and prioritize new locations for collection for seed banking with a focus on those that are not yet represented or are under-represented in storage. • Establish best horticultural practices for ex situ cultivation. • Acquire land or develop conservation agreements in occupied habitat or unoccupied suitable habitat. • Rescue sand flax in cases where development is scheduled. • Discuss potential for reducing pesticides use in and around areas with this species with local mosquito control districts. Monitoring and Research Activities • For all populations with fewer than 100 individuals, monitor at least once per year. • Research the possibility of hybridization with other species of Linum, namely L. medium and L. floridanum before reintroduction to northern portions of the range. • Conduct genetic research to determine the amount of genetic variation between and within populations. • To determine how long viability is retained in storage, re-test seeds that Fairchild has banked at 5 years and repeat tests every 5 years thereafter. • Further investigate impacts of pesticides on pollination rates. Outreach Activities • Increase public awareness and appreciation for native plants and habitats. o Attend public events when appropriate to improve community understanding of management techniques and policies, such as prescribed fire, in pine rockland habitats (USFWS, 2024).

# SPECIES ACCOUNT: *Linum carteri carteri* (Carter's small-flowered flax)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/06/2014; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

Annual or short-lived perennial herb with an erect stem, 230–360 millimeters (mm) (9.0–14.2 inches (in)) tall, commonly branched near the base and puberulent (covered with minute hairs). Its leaves are slender (18–26 mm (0.7–1.0 in) long and 0.8–1.2 mm (0.03– 0.05 in) wide), entire, alternate, and closely overlap at the base of the plant. This variety has stipules with paired dark glands. Its inflorescence is an ascending or spreading cyme (usually flat-topped or convex flower cluster in which the main axis and each branch end in a flower that opens before the flowers below or to the side of it), with yellow petals that are broadly obovate (egg-shaped), 9–17 mm (0.35– 0.67 in) long, and quickly deciduous. The fruit is straw-colored, ovoid, 4.1– 4.6 mm (0.16–0.18 in) long, 3.4–3.7 mm (0.13–0.15 in) in diameter, and dehisces (opens spontaneously at defined places) into five two-seeded segments; seeds are narrowly ovoid-elliptic, 2.3–2.8 mm (0.09–0.11 in) long, 1.0–1.3 mm (0.04– 0.05 in) wide. In habit and flower, the plant closely resembles Piriqueta cistoides ssp. caroliniana (pitted stripeseed) in the family Turneraceae (USFWS, 2014).

**Taxonomy**

In the order Laurales, family Lauraceae (Flax family). Linum carteri was named by Small in 1905; in 1907, he put it in a segregate genus, calling it Cathartolinum carteri. In 1963, Rogers renamed the plants as a variety of Linum rigidum, noting the close relationship of Florida plants to those in the Western United States. In 1968, he split the taxon into two varieties, calling pubescent plants Linum carteri var. carteri, and segregating the glabrous plants as Linum carteri var. smallii, basing the division on new genetic data from Mosquin and Hayley (1967) and his own morphological data (Bradley and Gann 1999). L. c. var. carteri was treated as endemic to Miami-Dade County, while L. c. var. smallii was slightly more widespread in southern Florida . ITIS (2013) uses the name Linum carteri var. carteri and indicates that this species' taxonomic standing is accepted. Based upon the best available scientific information, Linum carteri var. carteri is a distinct taxon, endemic to Miami-Dade County in Florida. (USFWS, 2013)

**Historical Range**

First collected in 1903 between the Coconut Grove and Cutler areas of Miami, Florida, and since that time, it has been found in pine rocklands from as far north as the Brickell Hammock area to as far south as the Naranja area (USFWS, 2013).

**Current Range**

Currently found in eastern Miami-Dade County, Florida, from R. Hardy Matheson Preserve (near Pinecrest) southwest to Naranja/ Modello, with a distance of approximately 27.3 km (17 mi) between the farthest locations (USFWS, 2013).

**Critical Habitat Designated**

Yes; 9/16/2015.

**Legal Description**

On August 17, 2015, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective September 16, 2015) for Linum carteri carteri (Carter's small-flowered flax) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes seven critical habitat units (CHUs), in Florida (80 FR 49846-49886).

**Critical Habitat Designation**

The critical habitat designation for Linum carteri carteri includes seven CHUs (49 sub-units) in Miami-Dade County, Florida. This species critical habitat encompasses approximately 2,706 acres (ac) (1,095 hectares (ha)). Brief descriptions are presented below. Maps depicting the CH units are available in the Final Rule. (80 FR 49846-49886)

Unit LCC1: Trinity Pineland and Surrounding Areas, Miami-Dade County, Florida: Unit LCC1 consists of 19 ac (48 ha) in Miami-Dade County. Within Unit LCC1, there are three subunits—LCC1A and LCC1B (primarily County-owned), and LCC1C (combination of State lands and private ownership). The unit is comprised of State lands within Trinity Pineland County Park (4 ac (10 ha)); County lands primarily within Tropical Park and A. D. ‘‘Doug’’ Barnes Park (7 ha (18 ac)); and parcels in private ownership (8 ha (19 ac)). This unit is bordered on the north by SW 24 Street, on the south by the Snapper Creek Expressway (State Road (SR) 878), on the east by SW 67 Avenue, and on the west by SW 87 Avenue.

Unit LCC2: Nixon Smiley Pineland Preserve and Surrounding Areas, Miami-Dade County, Florida: Unit LCC2 consists of approximately 113 ha (278 ac) of habitat in MiamiDade County. Within Unit LCC2, there are six subunits (LCC2A–LCC2F) comprising primarily conservation lands and including four larger areas plus two smaller areas. The unit is comprised of State lands within Camp Matecumbe, Tamiami Pineland Complex Addition, and Rockdale Pineland (53 ha (131 ac); County/local lands within Nixon Smiley Pineland Preserve, Tamiami #8 (Nixon Smiley Addition) Pineland, Pine Shore Pineland Preserve, Ron Ehman Park, and Rockdale Pineland Addition (59 ha (147 ac)); and parcels in private or other ownership (<1 ha (<1 ac)). This unit is bordered on the north by SW 104 Street, on the south by SW 152 Street (Coral Reef Drive), on the east by U.S. 1 (South Dixie Highway), and on the west by SW 177 Avenue (Krome Avenue).

Unit LCC3: USDA Subtropical Horticultural Research Station and Surrounding Areas, Miami-Dade County, Florida: Unit LCC3 consists of approximately 128 ha (316 ac) of habitat in MiamiDade County. Within Unit LCC3, there are nine subunits (LCC3A–LCC3I), including two larger areas (USDA and Deering Estate at Cutler) plus seven smaller areas surrounding these. The unit is comprised of Federal lands within the USDA Subtropical Horticultural Research Station (59 ha (145 ac)); State lands within the R. Hardy Matheson Preserve, Ludlam Pineland, Deering Estate at Cutler, and Deering Estate South Addition (45 ha (112 ac)); County/local lands within Coral Reef Park, Ned Glenn Nature Preserve, and Bill Sadowski Park (15 ha (38 ac)); and parcels in private ownership (8 ha (21 ac)). This unit is bordered on the north by SW 112 Street, on the south by the intersection of Old Cutler Road and Franjo Road (County Road (CR) 977), on the east by the Atlantic Ocean, and on the west by U.S. 1 (South Dixie Highway).

Unit LCC4: Richmond Pinelands and Surrounding Areas, Miami-Dade County, Florida: Unit LCC4 consists of approximately 386 ha (952 ac) in Miami-Dade County. Within Unit LCC4, there are four subunits (LCC4A–LCC4D), primarily within the Richmond Pinelands complex (made up of Federal and County-owned lands, as well as land owned by the University of Miami). The unit is comprised of Federal lands owned by USCG, ACOE, U.S. Prison Bureau, and NOAA (75 ha (185 ac)); County/local lands within and adjacent to Larry and Penny Thompson Park, Martinez Pineland, Zoo Miami, and Eachus Pineland (240 ha (592 ac)); and parcels in private or other ownership (71 ha (175 ac)). This unit is bordered on the north by SW 152 Street (Coral Reef Drive), on the south by SW 200 St (Quail Drive/SR 994), on the east by U.S. 1 (South Dixie Highway), and on the west by SW 177 Avenue (Krome Avenue).

Unit LCC5: Quail Roost Pineland and Surrounding Areas, Miami-Dade County, Florida: Unit LCC5 consists of approximately 98 ha (242 ac) in Miami-Dade County. Within Unit LCC5, there are 10 subunits (LCC5A–LCC5J), including 4 larger areas plus 6 smaller areas surrounding these. The unit is comprised of State lands within Quail Roost Pineland, Goulds Pineland and Addition, and Silver Palm Groves Pineland (39 ha (97 ac)); County/ local lands including Medsouth Park, Black Creek Forest, Rock Pit #46, and lands owned by the School Board of Miami-Dade County (18 ha (44 ac)); and parcels in private ownership (41 ha (101 ac)), including Porter-Russell Pineland owned by the Tropical Audubon Society. This unit is bordered on the north by SW 200 St (Quail Drive/SR 994), on the south by SW 248 Street, on the east by the Florida Turnpike, and on the west by SW 194 Avenue.

Unit LCC6: Camp Owaissa Bauer and Surrounding Areas, Miami-Dade County, Florida: Unit LCC6 consists of approximately 128 ha (315 ac) of habitat in MiamiDade County. Within Unit LCC6, there are 21 subunits (LCC6A–LCC6U), composed of 1 larger area (Camp Owaissa Bauer and its addition) and 20 smaller areas surrounding it. The unit is comprised of State lands within Owaissa Bauer Pineland Addition, Ingram Pineland, West Biscayne Pineland, and Fuchs Hammock Addition (20 ha (51 ac)); County/local lands including Camp Owaissa Bauer, Pine Island Lake Park, Seminole Wayside Park, and Northrop Pineland (63 ha (156 ac)); and parcels in private ownership (44 ha (109 ac)), including the private conservation area, Pine Ridge Sanctuary. This unit is bordered on the north by SW 248 Street, on the south by SW 312 Street, on the east by SW 112 Avenue, and on the west by SW 217 Avenue.

Unit LCC7: Navy Wells Pineland Preserve and Surrounding Areas, Miami-Dade County, Florida: Unit LCC7 consists of approximately 201 ha (497 ac) of habitat in MiamiDade County. Within Unit LCC7, there are seven subunits (LCC7A–LCC7G), including one larger area (Navy Wells Pineland Preserve) and six smaller outlying areas. The unit is comprised of State lands within Palm Drive Pineland, Navy Wells Pineland #39, Navy Wells Pineland Preserve (portion), and Florida City Pineland (53 ha (132 ac)); County/ local lands including primarily Sunny Palms Pineland and Navy Wells Pineland Preserve (portion) (125 ha (309 ac)); and parcels in private ownership (23 ha (56 ac)). This unit is bordered on the north by SW 320 Street, on the south by SW 368 Street, on the east by U.S. 1 (South Dixie Highway), and on the west by SW 217 Avenue.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Linum carteri carteri critical habitat consists of three components (80 FR 49846-49886):

(i) Areas of pine rockland habitat that contain: (A) Open canopy, semi-open subcanopy, and understory; (B) Substrate of oolitic limestone rock; and (C) A plant community of predominately native vegetation that may include, but is not limited to: (1) Canopy vegetation dominated by Pinus elliottii var. densa (South Florida slash pine); (2) Subcanopy vegetation that may include, but is not limited to, Serenoa repens (saw palmetto), Sabal palmetto (cabbage palm), Coccothrinax argentata (silver palm), Myrica cerifera (wax myrtle), Myrsine floridana (myrsine), Metopium toxiferum (poisonwood), Byrsonima lucida (locustberry), Tetrazygia bicolor (tetrazygia), Guettarda scabra (rough velvetseed), Ardisia escallonioides (marlberry), Psidium longipes (mangroveberry), Sideroxylon salicifolium (willow bustic), and Rhus copallinum (winged sumac); (3) Short-statured shrubs that may include, but are not limited to, Quercus pumila (running oak), Randia aculeata (white indigoberry), Crossopetalum ilicifolium (Christmas berry), Morinda royoc (redgal), and Chiococca alba (snowberry); and (4) Understory vegetation that may include, but is not limited to: Andropogon spp.; Schizachyrium gracile, S. rhizomatum, and S. sanguineum (bluestems); Aristida purpurascens (arrowfeather threeawn); Sorghastrum secundum (lopsided Indiangrass); Muhlenbergia capillaris (hairawn muhly); Rhynchospora floridensis (Florida white-top sedge); Tragia saxicola (pineland noseburn); Echites umbellata (devil's potato); Croton linearis (pineland croton); Chamaesyce spp. (sandmats); Chamaecrista deeringiania (partridge pea); Zamia integrifolia (coontie); and Anemia adiantifolia (maidenhair pineland fern).

(ii) A disturbance regime that naturally or artificially duplicates natural ecological processes (e.g., fire, hurricanes, or other weather events) and that maintains the pine rockland habitat described in paragraph (2)(i) of this entry.

(iii) Habitats that are connected and of sufficient area to sustain viable populations of Linum carteri var. carteri in the pine rockland habitat described in paragraph (2)(i) of this entry.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the specific areas within the geographic area occupied by the species at the time of listing contain features which are essential to the conservation of the species and which may require special management considerations or protection. The features essential to the conservation of Linum carteri var. carteri may require special management considerations or protection to reduce threats related to habitat loss, fragmentation, and modification primarily due to development; inadequate fire management; nonnative, invasive plants; and sea level rise. Destruction of the pinelands for economic development has reduced pine rockland habitat on the Miami Rock Ridge outside of ENP by over 98 percent, and remaining habitat in this area is highly fragmented. Linum carteri var. carteri occurs on a mix of private and publicly owned lands, only some of which are managed for conservation. Populations of the plants that occur on private land or non-conservation public land are vulnerable to habitat loss, while populations on conservation lands are vulnerable to the effects of habitat degradation if natural disturbance regimes are disrupted (e.g., through inadequate fire management). Prolonged lack of fire in pine rockland typically results in succession to rockland hammock, and displacement of native species by invasive, nonnative plants often occurs. Further development and degradation of pine rocklands increase fragmentation and decrease the conservation value of the remaining functioning pine rockland habitat. In addition, pine rocklands are expected to be further degraded and fragmented due to anticipated sea level rise, which would fully or partially inundate some pine rocklands along the coast and in the southern portion of Miami-Dade County (near Navy Wells Pineland Preserve), and cause increases in the salinity of the water table and soils resulting in vegetation shifts in additional pine rocklands across the Miami Rock Ridge. Many existing pine rockland fragments are also projected to be developed for housing as the human population grows and adjusts to changing sea levels. Special management considerations and protections that will address these threats include increased coordination and conservation of these plants and their habitat on

Federal lands, and improved habitat restoration and management efforts (including fire management and nonnative plant treatments) of high-priority and high-elevation sites. (USFWS, 2013)

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 2013)

**Lifespan**

Adult: 1 - 2 years (USFWS, 2013)

**Breeding Season**

Adult: Flowers year-round (USFWS, 2013)

**Key Resources Needed for Breeding**

Adult: May be pollinated by Insects (USFWS, 2013)

**Reproduction Narrative**

Adult: The reproductive ecology and biology of Linum carteri var. carteri is not well understood, but reproduction is sexual. This species is capable of flowering throughout the year, but tends to have most abundant flowering and fruiting following rain. While specific pollinators are unknown, flower morphology suggests this variety may be pollinated by butterflies, bees, or both; self-pollination has also been suggested. For adult reproductive plants, average plant growth was fairly constant from July through October, flowering and fruit production were most abundant in July, and plant mortality increased during the fall months (USFWS, 2013).

**Habitat Type**

Adult: Terrestrial (USFWS, 2013)

**Habitat Vegetation or Surface Water Classification**

Adult: Pine rocklands that have undergone some sort of substrate disturbance (USFWS, 2013)

**Dependencies on Specific Environmental Elements**

Adult: Disturbed areas (e.g. firebreaks, canal banks, edges of railway beds) (USFWS, 2013)

**Geographic or Habitat Restraints or Barriers**

Adult: Elevations of approximately 1.6–4.8 m (USFWS, 2013)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2013)

**Habitat Narrative**

Adult: Linum carteri var. carteri habitat are areas of pine rockland habitat that contain open canopy, semi-open subcanopy, and understory, a substrate of oolitic limestone rock, and a plant community of predominately native vegetation. A disturbance regime is also present that naturally or artificially duplicates natural ecological processes (e.g., fire, hurricanes, or other weather events) and that maintains the pine rockland habitat (USFWS, 2014). Its known populations are found at elevations ranging from approximately 1.6–4.8 m (5.2 - 15.9 ft) (USFWS, 2013).

***Dispersal/Migration***

**Dependency on Other Individuals or Species for Dispersal**

Adult: Unknown (USFWS, 2013)

**Dispersal/Migration Narrative**

Adult: Dispersers are unknown, although historically water may have played a role in dispersal when summer high- water conditions in adjacent wet prairies may have inundated portions of pine rocklands (USFWS, 2013).

***Population Information and Trends***

**Population Trends:**

Not available.

**Species Trends:**

Declining (USFWS, 2014)

**Population Growth Rate:**

Low (inferred from USFWS, 2014)

**Number of Populations:**

6 (USFWS, 2023)

**Population Size:**

~2000 individuals (USFWS, 2023)

**Population Narrative:**

Only small and fragmented occurrences of L. c. var. carteri remain. Four of the seven remaining populations have fewer than 20 individual plants. There are great differences in plant numbers from year to year, probably because individuals typically live 1–2 years and grow from seed. This trait makes them more vulnerable than perennials to changes in environment. Viable plant populations for small, short-lived herbs may consist of tens of thousands of plants. Indications are that most existing populations are at best marginal (USFWS, 2014). Carter’s small-flowered flax is currently known from six occurrences in Miami-Dade County (Table 1). The total number of individual plants during peak months (spring/summer) is approximately 2000 (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Habitat loss, fragmentation, and degradation (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Habitat modification caused by development (i.e., conversion to both urban and agricultural land uses) is a primary threat, in addition to habitat modification and degradation through inadequate fire management, which includes both the lack of prescribed fire and suppression of natural fires. Habitat fragmentation reduces the size of plant populations, and increases spatial isolation of remnants (USFWS, 2013)

**Stressor:** Competition from nonnative invasive plants (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Nonnative plants have significantly affected pine rocklands, and threaten all occurrences of Linum carteri var. carteri to some degree. Nonnative invasive plants compete with native plants for space, light, water, and nutrients, and make habitat conditions unsuitable for this species, which responds positively to open conditions; the invasive plants also affect the characteristics of a fire when it does occur (USFWS, 2013).

**Stressor:** Climate change (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Extreme weather events could be catastrophic on isolated, small populations. The narrow distribution makes them more susceptible to extirpation from a single catastrophic event (USFWS, 2013).

**Stressor:** Incompatible management practices (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Incompatible management practices (such as no mowing or too-frequent mowing), fire suppression, accidental impacts to populations that grow along preserve edges, illegal dumping, invasive non-native plants, factors stemming from small population sizes, and climate change (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
Not available.

Recovery Priority Number: 6

**Delisting Criteria:**
Not available.

**Recovery Actions:**
- Not available.
- Not available

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIVITIES In additional to standard monitoring and assessment of the species' status, the highest priority actions recommended for Carter's small-flowered flax are: • Conduct or continue to conduct habitat restoration on all occupied sites, including (a) removal of native hardwoods and non-native invasive plants and (b) establish a prescribed burn regimen. • Acquire and restore habitat at Old Dixie Pineland. • Restore habitat at the Montgomery Botanical Center pineland and the Gifford Arboretum pineland sites. Monitor whether plants emerge from the soil seed bank, and if so, develop a long-term management plan for the sites. • Convert the portion of the USDA Chapman Field Station where the species is found into a managed nature preserve. • Work with land managers to incorporate conservation mowing regimes beneficial to the species • Ensure that populations which are maintained through mowing are not mowed between January and July but are mowed between August and December. • Bank seeds from wild populations, with a focus on those whose seeds were last banked over a decade ago. Additional recommended actions are: • Conduct studies to determine whether Manila grass has negative effects on the species' reproduction or growth. • Conduct additional studies (following Maschinski and Walters 2008) to determine optimal mowing regimes. • Fine-tune horticultural methods for ex situ cultivation. • Research the pollination biology of the species. • Conduct genetic research to determine the amount of genetic variation between and within populations. • Introduce additional metapopulations to suitable habitat at the Deering Estate. • Introduce plants to suitable habitat at Camp Owaissa Bauer. • Determine whether there is potential for additional reintroductions or augmentations (USFWS, 2023).

# SPECIES ACCOUNT: *Lomatium cookii* (Cook's lomatium)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 12/9/2002; Pacific Region (R1)

**Physical Description**

A perennial herb that grows 15 to 50 centimeters (6 to 20 inches) tall with a slender, twisted taproot (Figure II-3). The base often branches at or below ground level, forming multiple stems. The leaves are glossy bluish-green, minutely interdivided, and strictly basal (growing directly from the root crown, out of the ground, not along the stems). The pale yellow flowers are clustered into 5- centimeter (2-inch) umbels (umbrella-like formation of flower clusters). Each flowering stalk produces either primarily male or female umbels. Through one flowering season, L. cookii may produce up to eight male or female (sometimes both) flowering stalks. The bracts found below the umbels are thin, lance-shaped and have an entire margin. An umbel of female flowers will develop boat-shaped fruits 8 to 13 millimeters (0.3 to 0.5 inch) long with thickened margins. The flowering stalk very rarely forms leaves, unlike the closely associated L. utriculatum (foothills desert parsley). The single umbel bracts best distinguish L. cookii from L. bradshawii (Bradshaw's lomatium), indigenous to wet prairies from the southern Willamette Valley in Oregon to southwest Washington, and L. humile (alkali desert parsley), found in vernal pools in northern California (Kagan 1986). The umbel bracts can be used to distinguish L. cookii from the much wider, toothed, and overlapping umbel bracts of L. utriculatum. (USFWS, 2010)

**Taxonomy**

In the parsley family (Apiaceae). Lomatium cookii was first collected in 1981 and subsequently described from vernal pools in the Agate Desert, Jackson County, Oregon (Kagan 1986). Additional populations were found at French Flat in the Illinois Valley, Josephine County, Oregon in 1988 (Oregon Natural Heritage Information Center 2008). Slight morphological differences exist between L. cookii populations in the Agate Desert and French Flat, but these differences are not considered significant enough to separate the species into subspecies (M. Gitzendanner, pers. comm. 2002). (USFWS, 2010)

**Historical Range**

In southwestern Oregon, in Jackson and Josephine Counties. (USFWS, 2010)

**Current Range**

In Oregon, known from the Agate Desert, just north of the City of Medford in Jackson County's Rogue Valley, and from the French Flat or Illinois Valley sites in Josephine County. (USFWS, 2019)

**Critical Habitat Designated**

Yes; 8/20/2010.

**Legal Description**

On July 21, 2010, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective August 20, 2010) for Lomatium cookii (Cook's lomatium) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes sixteen critical habitat units (CHUs), in Oregon (75 FR 42490-42570).

**Critical Habitat Designation**

The critical habitat designation for Lomatium cookii includes sixteen CHUs in Jackson and Josephine Counties, Oregon. This species critical habitat encompasses approximately 6,289 acres (ac) (2,545 hectares (ha)) (75 FR 42490-42570). All critical habitat units in Jackson County are located within the Middle Rogue River Basin or “Agate Desert.” Brief descriptions are presented below. Detailed coordinates of and maps depicting the CH units are available in the Final Rule (USFWS, 2010).

Unit RV6, subunits A, F, G, and H, for Lomatium cookii: White City, Jackson County, Oregon. (i) Unit RV6, subunits A, F, G, and H for Lomatium cookii comprises 546 ha (1,349 ac) of vernal pool–mounded prairie and swale habitats. RV6 is located around White City, is 1.6 km (1.0 mi) southwest of Eagle Point, and is 440 m (1,444 ft) southeast of the confluence of the Rogue River and Little Butte Creek. Subunit RV6A is located north of Whetstone Creek and is 500 m (1,200 ft) west of the junction of Highway 62 and Antelope Road. Subunits RV6F and RV6G are located approximately 500 feet west of Dry Creek and are east of Highway 62 in White City. Subunit RV6H is located north of Whetstone Creek and south of Antelope Road. Subunit RV6H roughly encircles the Hoover Ponds, east of Highway 62, and is 850 m (2790 ft) east of subunit RV6A.

Unit RV8 for Lomatium cookii: Whetstone Creek, Jackson County, Oregon. (i) Unit RV8 for Lomatium cookii consists of 344 ha (850 ac) of vernal pool–mounded prairie and swale habitat. Unit RV8 is located approximately 1.4 km (0.9 mi) southeast of the confluence of the Rogue River and Whetstone Creek, 2.2 km (1.4 mi) southwest of Tou Velle State Park, and 2.9 km southeast of the confluence of Bear Creek and the Rogue River. The unit roughly parallels a 2.6-km (1.6-mi) stretch of Whetstone Creek to the south.

Unit RV9, subunits A, B, C, D and E, for Lomatium cookii: Medford Airport, Jackson County, Oregon. (i) Unit RV9, subunits A through E, consists of 34 ha (83 ac) of slightly degraded vernal pool–mounded prairie habitat. The five subunits of RV9 are located mostly within the Rogue Valley International–Medford Airport, approximately 2 km (1.2 mi) west of Coker Butte and 1.5 km (0.9 mi) northeast of Bear Creek. Subunit RV9A is located 1.4 km (0.9 mi) north of the Rogue Valley International–Medford Airport and is 300 m (980 ft) east of the junction of Vilas Road and Table Rock Road. Subunits RV9B through E are located between Upton Slough and Bear Creek, 2 mi (1.2 km) southeast of the junction of Vilas Road and Table Rock Road, and 1.7 km northeast of the junction of Interstate 5 and Highway 62.

Unit IV1 for Lomatium cookii: Anderson Creek, Josephine County, Oregon. (i) Units IV1A and B comprise 35 ha (85 ac) of wet meadow and sloped mixed conifer habitat. Unit IV1A is located 3.5 km (2.2 mi) north of Selma, and 14 km (8.8 mi) north of Cave Junction; it is along a 1.0-km (0.6-mi) stretch of Anderson Creek and Highway 199, 2.0 km (1.2 mi) southwest of Hays Hill Summit. It is also 1.7 km (1.0 mi) northwest of the junction of Draper Valley Road and Indian Creek Road. Unit IV1B is located 3.5 km (2.2 mi) north of Selma, 3.4 km (2.1 mi) southwest of Hays Hill Summit, and 0.8 km (0.5 mi) west of the junction of Draper Valley Road and Highway 199.

Unit IV2 for Lomatium cookii: Draper Creek, Josephine County, Oregon. (i) Unit IV2 is composed of 28 ha (70 ac) of intact wet meadow habitat. It is located 2.7 km (1.7 mi) northeast of Selma and 13.5 km (8.4 mi) north of Cave Junction; it is along a 900-m (2,900-ft) stretch of Draper Creek, and is located 800 m (2,600 ft) east of Anderson Creek. The unit is 800 m (2,600 ft) north-

northwest of the confluence of Draper Creek and Davis Creek and is 200 m (650 ft) southeast of the junction of Draper Valley Road and Indian Creek Road.

Unit IV3 for Lomatium cookii: Reeves Creek North, Josephine County, Oregon. (i) Unit IV3 consists of 152 ha (374 ac) of sloped, mixed-conifer and shrubby habitat. The unit is located 1.4 km (0.9 mi) east of the confluence between Reeves Creek and the Illinois River and extends along a 2.0-km (1.2-mi) stretch of Reeves Creek, beginning 800 m (2,600 ft) northeast of the junction of Highway 199 and Reeves Creek Road.

Unit IV4 for Lomatium cookii: Reeves Creek East, Josephine County, Oregon. (i) Unit IV4 consists of 83 ha (204 ac) of sloped, partially open, mixed-conifer and shrubby habitat. It is located 6.2 km (3.9 mi) south of Selma and 5.3 km (3.3 mi) northwest of Cave Junction. It occurs along a 500-m (1,640-ft) stretch of Reeves Creek located 700 m (2,300 ft) southeast of Unit IV3.

Unit IV5 for Lomatium cookii: Reeves Creek South, Josephine County, Oregon. (i) Unit IV5 consists of 165 ha (407 ac) of sloped, partially open, mixed-conifer and understory shrub habitat. The unit is roughly parallel to Highway 199 for 2.5 km (1.6 mi), which is 500 m (1,640 ft) west of the unit. The unit is located 1.6 km (1.0 mi) north of Cave Junction, 1 km (0.6 mi) southeast of Sauers Flat, 800 m (2,600 ft) east of Kerby, and 1.2 km (0.7 mi) east of the confluence between Holton Creek and the Illinois River.

Unit IV6 for Lomatium cookii: Laurel Road, Josephine County, Oregon. (i) Unit IV6 totals 182 ha (449 ac) of intact wet meadow habitat. It is located west and alongside of the base of Lime Rock, 1.2 km (0.7 mi) east of the city of Cave Junction; it follows along Highway 46 for 1.5 km (0.9 mi). Subunit IV6A is located 1.2 km (0.7 mi) west of Lime Rock summit, 1.0 km east of the junction of Laurel Road and Highway 199; it is also roughly parallel to Highway 199 for 1.3 km (0.8 mi). Highway 199 lies approximately 1.0 km (0.6 mi) west of the subunit. Subunit IV6B is 2.7 km (1.7 mi) east of the confluence of the east and west forks of the Illinois River and from the intersection of Holland Loop Road and Highway 46; it extends approximately 1.8 km (1.1 mi) to the northeast and 2.7 km (1.7 mi) to the north.

Unit IV7 for Lomatium cookii: Illinois River Forks State Park, Josephine County, Oregon. (i) Unit IV7 consists of 55 ha (136 ac) of intact wet meadow habitat. The unit is located 500 m (1,640 ft) west of the city of Cave Junction and 600 m (1,970 ft) southeast of Pomeroy Dam; it is also 230 m (750 ft) east of the confluence of the east and west forks of the Illinois River. The unit occurs along a 2.8-km (1.7-mi) stretch of the West Fork Illinois River.

Unit IV8 for Lomatium cookii: Woodcock Mountain, Josephine County, Oregon. (i) Unit IV8 consists of 234 ha (579 ac) of wet meadow and shrubby habitat. The unit is located 2.4 km (1.5 mi) southwest of the city of Cave Junction, 5.3 km (3.3 mi) north of O’Brien, and 140 m (ft) west of the confluence of Woodcock Creek and the West Fork Illinois River. It occurs along a 3.3-km (2.0-mi) stretch of West Side Road. Unit IV7 is 400 m (ft) west of Highway 199 and roughly parallels the highway for 5.0 km (3.1 mi).

Unit IV9 for Lomatium cookii: Riverwash, Josephine County, Oregon. (i) Unit IV9 consists of 12 ha (30 ac) of intact wet meadow and streambank habitat. It is located 4.2 km (2.6 mi) south of Cave Junction and 6.1 km (3.8 mi) north-northeast of O’Brien. It is located along the east bend of the West Fork Illinois River, 700 m (2,300 ft) south (upstream) of the confluence between Woodcock

Creek and the West Fork Illinois River.

Unit IV10 for Lomatium cookii: French Flat North, Josephine County, Oregon. (i) Unit IV10 consists of 45 ha (110 ac) of intact wet meadow habitat. The unit is located 3.7 km (2.3 mi) south of Cave Junction, 900 m (2,950 ft) north of the intersection of Sherrier Drive and Raintree Drive, and 1.7 km (1.1 mi) southwest of the confluence of Althouse Creek and the East Fork Illinois River. It parallels a 300-m (980-ft) stretch of Rockydale Road.

Unit IV11 for Lomatium cookii: Rough and Ready Creek, Josephine County, Oregon. (i) Unit IV11 consists of 118 ha (292 ac) of intact wet meadow habitat. The unit roughly follows along and is adjacent to a 1.9-km (1.2-mi) stretch of Airport Drive. It is located 3 km (1.9 mi) north of O'Brien, 900 m (2,950 ft) west of the Rough and Ready Forest Wayside State Park, and 122 m (400 ft) east of the confluence with the Illinois River and Rough and Ready Creek.

Unit IV12 for Lomatium cookii: French Flat Middle, Josephine County, Oregon. (i) Unit IV12 consists of 492 ha (1,216 ac) of intact wet meadow habitat. The unit is located 4.5 km (2.8 mi) east of Cave Junction, 3.7 km (2.3 mi) northeast of O'Brien, 140 m (460 ft) north and 560 m (1,830 ft) west of Esterly Lakes, 1.4 km (0.9 mi) northeast of Indian Hill, and 300 m (960 ft) east of the confluence of Rough and Ready Creek and the West Fork Illinois River. It also follows along a 1.6-km (1.0-mi) stretch of Rockydale Road until the junction with Waldo Road.

Unit IV13 for Lomatium cookii: Indian Hill, Josephine County, Oregon. (i) Unit IV13 consists of 22 ha (54 ac) of intact wet meadow habitat. The unit is located adjacent to and lies east of a 900-m (2,950-ft) stretch of the West Fork Illinois River. It is located approximately 300 m south (upstream) of the confluence of Rough and Ready Creek and the West Fork Illinois River. The unit is 1.8 km (1.1 mi) northeast of O'Brien and 350 m (1,150 ft) northwest of Indian Hill.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Lomatium cookii critical habitat consists of the following components (75 FR 42490-42570): (USFWS, 2010)

(i) In the Rogue River Valley: (A) Vernal pools and ephemeral wetlands and depths and the adjacent upland margins of these depressions that hold water for a sufficient length of time to sustain Lomatium cookii germination, growth, and reproduction. These vernal pools or ephemeral wetlands support native plant populations and are seasonally inundated during wet years but do not necessarily fill with water every year due to natural variability in rainfall. Areas of sufficient size and quality are likely to have the following characteristics: (1) Elevations from 372 to 411 m (1,220 to 1,350 ft); (2) Associated dominant native plants including, but not limited to: Alopecurus saccatus, Achnatherum lemmonii, Deschampsia danthonioides, Eryngium petiolatum, Lasthenia californica, Myosurus minimus, Navarretia leucocephala ssp. leucocephala, Phlox gracilis, Plagiobothrys bracteatus, Trifolium depauperatum, and Triteleia hyacinthina; and (3) A minimum area of 8 ha (20 ac) to provide intact hydrology and protection from development and weed sources.

(B) The hydrologically and ecologically functional system of interconnected pools or ephemeral wetlands or depressions within a matrix of surrounding uplands that together form vernal pool complexes within the greater watershed. The associated features may include the pool basin and ephemeral wetlands; an intact hardpan subsoil underlying the surface soils up to 0.75 m (2.5 ft) in depth; and surrounding uplands, including mound topography and other geographic and edaphic features that support systems of hydrologically interconnected pools and other ephemeral wetlands (which may vary in extent depending on sitespecific characteristics of pool size and depth, soil type, and hardpan depth).

(C) Silt, loam, and clay soils that are of ultramafic and nonultramafic alluvial origin, with a 0 to 3 percent slope, classified as Agate–Winlo or Provig– Agate soils.

(D) No or negligible presence of competitive, nonnative invasive plant species. Negligible is defined for the purpose of this rule as a minimal level of nonnative plant species that will still allow Lomatium cookii to continue to survive and recover.
(ii) In the Illinois River Valley: (A) Wet meadows in oak and pine forests, sloped mixed-conifer openings, and shrubby plant communities that are seasonally inundated and support native plant populations. Areas of sufficient size and quality are likely to have the following characteristics: (1) Elevations from 383 to 488 m (1,256 to 1,600 ft); (2) Associated dominant native plants including, but not limited to: Achnatherum lemmonii, Arbutus menziesii, Arctostaphylos viscida, Camassia spp., Ceanothus cuneatus, Danthonia californica, Deschampsia cespitosa, Festuca roemeri var. klamathensis, Poa secunda, Ranunculus occidentalis, and Limnanthes gracilis var. gracilis; (3) Occurrence primarily in bottomland Quercus garryana–Quercus kelloggii–Pinus ponderosa (Oregon white oak–California black oak– ponderosa pine) forest openings along seasonal creeks; and (4) A minimum area of 8 ha (20 ac) to provide intact hydrology and protection from development and weed sources.

(B) The hydrologically and ecologically functional system of streams, slopes, and wooded systems that surround and maintain seasonally wet alluvial meadows underlain by relatively undisturbed ultramafic soils within the greater watershed.

(C) Silt, loam, and clay soils that are of ultramafic and nonultramafic alluvial origin, with a 0 to 40 percent slope, classified as Abegg gravelly loam, Brockman clay loam, Copsey clay, Cornutt–Dubakel complex, Dumps, Eightlar extremely stony clay, Evans loam, Foehlin gravelly loam, Josephine gravelly loam, Kerby loam, Newberg fine sandy loam, Pearsoll–Rock outcrop complex, Pollard loam, Riverwash, Speaker–Josephine gravelly loam, Takilma cobbly loam, or Takilma Variant extremely cobbly loam.

(D) No or negligible presence of competitive, nonnative invasive plant species. Negligible is defined for the purpose of this rule as a minimal level of nonnative plant species that will still allow Lomatium cookii to continue to survive and recover.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain the features that are essential to the conservation of the species and that may require special management considerations or protection. All areas we are designating as critical habitat require some level of management to address current and future threats to Lomatium cookii, to maintain or enhance the physical or biological features essential to their conservation, and to ensure the recovery and survival of these species. The major threats to the PCEs in the areas identified as critical habitat for Lomatium cookii include: development on private lands; mining activities; ground disturbance that affects surface hydrology, including ORV use and road construction or maintenance activities; incompatible agricultural and grazing practices; garbage dumping; the succession of meadow habitat to forested habitat due to fire suppression; and encroachment and displacement by nonnative plants. Herbivory by voles may also affect Lomatium cookii in the Illinois River Valley. In all of the units in Jackson County, special management is needed to reduce or eradicate the threats posed by development, habitat fragmentation, ground disturbance that affects surface hydrology, and incompatible grazing practices. In all of the units in Josephine County, special management is needed to reduce or eradicate the threats posed by development, ORV use, mining activities, garbage dumping, and woody vegetative succession. Please refer to the unit descriptions in the Critical Habitat Designation section for further discussion of special management considerations or protection of the PCEs related to geographically specific threats to Limnanthes floccosa ssp. grandiflora and Lomatium cookii. In addition, for all units, special management is needed to control and monitor the encroachment of nonnative, invasive plant species to maintain intact vernal pool–mounded prairies and wet meadow ecosystems such that they can continue to support populations of Lomatium cookii. Special management considerations or protection of the vernal pool– mounded prairies and wet meadow habitats that may be needed to support reproduction and growth of Lomatium cookii include: controlled burning and vegetation clearing to maintain early seral stages (early stages of plant succession in the progression toward a climax community); control of nonnative, invasive plant species; grazing management; the reestablishment of hydrology; re-seeding with native plants; monitoring; and protection from development (Borgias 2004, pp. 47–53; ONHDB 1994, pp. 13– 20). (USFWS, 2010)

***Life History***

**Food/Nutrient Resources**

**Habitat Type**

Adult: Seasonally wet (vernal soil) (USFWS, 2016)

**Environmental Specificity**

Adult: Very Narrow (USFWS, 2016)

**Habitat Narrative**

Adult: Desert parsley in the Illinois Valley grows on seasonally wet soils. For much of its range in the Rogue River Valley, the plant occurs on upland mounds, at the bottom of rocky vernal pools, and on vernal pools flanks. It occurs in either strongly expressed or weakly expressed vernal pool formations and appears to tolerate various types of disturbance. In the Rogue River Valley, populations of desert parsley are found in shallow Agate-Winlo complex in sparse prairie vegetation. Common plant associates include Lupinus bicolor (bicolor lupine), Colinsia sparsiflora (sparse-flowered collinsia), Clarkia purpurea (purple clarkia), Erodium cicutarium (filaree), foothills desert-parsely, Achnatherum lemmonii (Lemmon’s needlegrass), Poa bulbosa (bulbous bluegrass), Brodiaea elegans (elegant brodiaea), Madia spp (tarweed), Lasthenia californica (goldfields), Hemizonia fitchii (Fitch’s tarweed), and Plagiobothrys spp (popcornflower). In the Illinois Valley, desert parsley occurs in open wet meadows and along roadsides adjacent to meadows on Brockman clay loam, Josephine gravelly loam, Pollard loam, Eightlar extremely stony clay, Takilma cobbly loam, Abegg clay loam, and Newberg loam soils. Brockman clay loam soils in the French Flat area average 61 to 89 cm (24 to 35 inches) in depth.

These seasonally wet soils have the ability to block water permeability through the soil, similar to the Agate Desert vernal pools, but lack that region's distinctive mound and swale topography. Soils in the Illinois Valley are partially derived from serpentine formations that occur on surrounding slopes and hilltops. Common species in the Illinois Valley associated with desert parsley include Danthonia californica (California oatgrass), Chlorogalum pomeridianum (soap plant), Plagiobothrys bracteatus (bracted popcornflower), Hesperichiron californica (hesperichiron), Horkelia californica (California horkelia), Calochortus uniflorus (short-stemmed mariposa lily), and wedge-leaved buckbrush. Two rare plants that may occasionally occur with desert parsley in the Illinois Valley are Senecio hesparius (western senecio) and Microseris howellii (Howell's microseris) (USFWS, 2016).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2019)

**Number of Populations:**

23 extant (USFWS, 2024)

**Population Size:**

10,000 - 1,000,000 individuals (NatureServe, 2024)

**Additional Population-level Information:**

Based on representative population assessments at the monitored locations provided in the 2019 5-Year Review, as well as assuming the other known populations are still occupied by Lomatium cookii, we conclude the overall distribution remains unchanged. Lomatium cookii remains concentrated within the Illinois and Rogue River Valleys of southwestern Oregon and within its known historical range. Even with the extirpation of one population and the addition of one populations, range contraction or expansion of the species has not occurred. (USFWS, 2019)

**Population Narrative:**

There are a total of 36 populations of Lomatium cookii, 11 in the Rogue Valley and 25 in the Illinois Valley. Here we present the most recent information available through the individual monitoring programs for most of the 36 sites that have been assessed since the last census. This includes information for one new population record of Lomatium cookii (Waldo Road in the Illinois Valley). Information is not available for 15 known occurrences of the species (Table 1). It should be noted that L. cookii population parameters fluctuate annually depending on seasonal precipitation and temperature; therefore, it is not unexpected that the species population size estimate will vary from year to year. (USFWS, 2019). Geographically, the overall population is distributed into two areas, the Rogue and Illinois Valleys. In the Rogue Valley, the 14 known Cook's lomatium populations consist of 7 recently monitored (or extant) and 7 unknown populations (Table 1 and Figure 1). Of the 7 known populations, abundance in 6 populations is increasing or stable and 1 is in decline. In the Illinois Valley we have documented 16 extant populations and 6 unknown populations (Table 2 and Figure 2). Of the 16 extant populations, abundance in 11 populations is increasing or stable and 5 are in decline. Overall, both areas combined, a total of 23 populations are documented as extant and 13 are considered unknown (ORBIC 2023, entire; ODA 2021, p. 6, USFWS 2024, entire). Unknown populations have had no documentation in the last 10 years, mostly due to inaccessibility. An additional 5 population have been determined to be extirpated. The previous 5-year review in 2019, documented a total of 10 Rogue Valley and 25 Illinois Valley populations. Of these, 20 were documented as extant and 15 were considered unknown (USFWS 2019a). At that time, we only knew of a single extirpated population (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Habitat or population loss due to development (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Factor A listing threats include habitat or population loss due to development, either through present or threatened destruction, modification or curtailment of habitat or range (USFWS 2002). Factor A threats to Lomatium cookii in the Rogue and Illinois River valleys include habitat impacts resulting from residential, urban, and commercial development; aggregate and mineral mining; agricultural development (including leveling, ditching, tilling, and stock pond construction or water impoundments); road construction and maintenance; off-road vehicle (ORV) use that affects surface hydrology; incompatible grazing practices; and encroachment by nonnative plants (ONHDB 1994; USFWS 2002). The adverse effects of residential, urban, and commercial development are more evident in the Rogue River Valley while the threat of mining is a more conspicuous threat in the Illinois River Valley (USFWS 2002; USFWS 2010). Factor A impacts resulting from residential, urban, agricultural, industrial, and commercial development between 1940 to present, resulted in over 60 percent loss of the vernal pool landscape in the Rogue River Valley due to removal of habitat, altered hydrology, or altered topography (ONHP 1997; Wille and Petersen 2006). (USFWS, 2011)

**Stressor:** Vandalism (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Vandalism are Factor A threats in the form of intentional disregard or dismantling of signage or fencing intended to protect certain wetland areas from unauthorized ORV use, and subsequent damage resulting from that use, has resulted in negative effects on the hydrology of the habitat for Lomatium cookii (for example, by altering the surface hydrology, resulting in excess or a lack of hydrology in otherwise suitable habitat). (USFWS, 2011)

**Stressor:** Grazing (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The effect of grazing on suitable habitat depends on how the grazing is managed. There are various reports showing how grazing practices can positively or negatively affect native plant species’ richness (Marty 2005). Marty’s (2005) study indicates that wet season grazing resulted in a decrease of native forb species at vernal pool edge habitat, but year-round grazing actually improved species’ richness (Factor A listing threats). (USFWS, 2011)

**Stressor:** Non-native plants and small population size (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Lomatium cookii is also threatened by encroachment of nonnative plants and small population size (Factor E listing threats). Nonnative plants that can outcompete L. cookii include annual grasses and herbs. Nonnative grasses, namely Hordeum marinum ssp. gussoneanum (Mediterranean barley), Lolium spp. (perennial and annual rye), and Taeniantherum caput-medusae (medusahead), form a dense thatch layer that inhibits plant growth (USFWS 2010). (USFWS, 2011)

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Depending on whether intentions were deliberate or inadvertent, Factor D, the lack of legal protection for all federally or state listed plants on privately owned property could be partially responsible for much habitat loss in recent years due to development in areas that were incorrectly assumed to be outside of jurisdictional wetlands (USFWS 2006). (USFWS, 2011)

**Stressor:** Herbicide spraying, mowing, grading, and other road maintenance activities (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbicide spraying, mowing, grading, and other road maintenance activities may threaten small Cook's lomatium sites adjacent to roads on private lands in the range of the species. However, this threat is unknown but considered relatively insignificant because the species is not prevalent on roadsides. ODOT carefully maintains their roadside shoulders where Cook's lomatium occurs without herbicide and is able to maintain populations (USFWS, 2024).

**Stressor:** Illicit recreational cannabis (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Illicit recreational cannabis (Cannabis sativa) production has had a long history in Josephine County (Parker-Shames et al. 2021, p. 2). Until 2015, when Oregon enacted legislation to legalize growing, purchasing, using, and transporting cannabis, illicit production primarily occurred on public lands. The legalization of recreational cannabis has resulted in an increase in recreational cannabis crop production on private lands across southwest Oregon (Parker-Shames et al. 2021, p. 2). Cave Junction has been a center for illegal cannabis production for many years and this trend is likely to continue (Willamette Week 2023, website). The expansion of cannabis growing has converted at least one known population of Cook's lomatium into a cannabis crop (ODA 2021, p. 32). The crop was established within a larger Cook's lomatium population near West Side Road. Although some of these private lands are not easily accessed, agricultural crops will appear on aerial imagery, and we will infer that a population has been compromised if replaced by a crop. The majority, 67 percent, of Cook's lomatium populations occur on public

lands. Private lands include 32 percent of populations (13 of 41). For this reason, it is uncertain if cannabis crops will become an increased threat for Cook's lomatium in the future on either public or private lands (USFWS, 2024)

***Recovery***

**Reclassification Criteria:**
Reclassification from Endangered to Threatened status may be considered for Lomatium cookii when the following criteria are met: (USFWS, 2010)

a. At least 32 of 36 documented/extant Lomatium cookii occurrences (approximately 90 percent) have been protected from development. If extant occurrences become extirpated, protection of reintroduced or introduced occurrences may be substituted. Introduced or newly discovered populations outside of currently known core areas may be substituted if deemed equivalent in their contribution to recovery. (USFWS, 2010)

b. At least 90 percent of suitable habitat acreage within each Priority 1 core area (one core area in the Rogue Valley and seven core areas in the Illinois Valley) has been protected from development. At least 85 percent of suitable habitat acreage within Priority 2 core areas (three core areas in the Rogue Valley and six core areas in the Illinois Valley) has been protected from development. (See Tables IV-1, IV-2, and IV-4 of the Recovery Plan). All suitable vernal pool and wet meadow habitat must include soils and hydrology that support Lomatium cookii. This habitat includes both occupied and suitable habitat. Suitable habitat that is not currently known to be occupied must be protected to provide for corridors and dispersal habitat, restoration dynamics, provide for reintroduction/introduction sites, and to protect currently undiscovered populations. (USFWS, 2010)

c. Management plans for each protected core area are developed and implemented as soon as feasible for Lomatium cookii protection and conservation. The management plans should address vegetation control, including thatch buildup and noxious weeds; monitoring of threats and population levels in detail sufficient to quantitatively assess population trends; maintaining hydrological functions; and outreach to neighboring landowners. Management plans should take an ecosystem approach to management by ensuring the long-term maintenance of wetland and adjacent upland plant associates. (USFWS, 2010)

d. Additional Lomatium cookii occurrences identified through future site assessments, GIS and other analyses, and status surveys that are determined essential to recovery are protected. (USFWS, 2010)

e. Achievement of self-sustaining Lomatium cookii populations will be determined through species monitoring and status surveys in each protected occurrence. Population trends must be shown to be stable, increasing or showing only minor declines from high population levels for 10 years prior to consideration for reclassification. (USFWS, 2010)

f. Seed collection is accomplished at each core area as insurance against the risk of stochastic extirpations and to ensure that genetic variation can be restored if extirpations occur. Seed banking may also be necessary in order to complete the reintroductions or introductions required to meet recovery criteria (see Table IV-4 of the Recovery Plan). (USFWS, 2010)

g. Reintroductions and introductions must be carried out as described in Table IV-4 of the Recovery Plan. Introductions may replace extirpated occurrences that cannot be restored to the same site as the original occurrence. (USFWS, 2010)

Recovery Priority Number: 2C

**Delisting Criteria:**
Delisting may be considered for Lomatium cookii when all downlisting criteria plus the following criteria are met: (USFWS, 2010)

a. Status surveys, status reviews, and population monitoring show the populations are self-sustaining. Population trends must be shown to be stable, increasing or exhibiting only slight declines from high population levels during a 10-year period prior to consideration following downlisting (e.g., evidence of reproduction and recruitment) and have been determined to be stable, increasing or showing only minor declines from high population levels, and implementation of management plans is effectively managing or eliminating threats. (USFWS, 2010)

b. At least 34 of 36 Lomatium cookii occurrences (approximately 95 percent of documented/extant occurrences) have been protected from development. If extant occurrences become extirpated, protection of reintroduced or introduced occurrences may be substituted. Introduced or newly discovered populations outside of currently known core areas may be substituted if deemed equivalent in their contribution to recovery. (USFWS, 2010)

c. At least 95 percent of suitable vernal pool habitat acreage within each Priority 1 core area and 90 percent of suitable vernal pool habitat acreage within Priority 2 core areas has been protected from development. All suitable vernal pool and wet meadow habitat must include soils and hydrology that support Lomatium cookii . Reintroductions and introductions are accomplished, as necessary and applicable, to replace populations where status surveys indicate the species has been extirpated (Table IV-4). (USFWS, 2010)

d. A post-delisting monitoring plan has been developed for Lomatium cookii. (USFWS, 2010)

**Recovery Actions:**

- 1. Protect vernal pool and wet meadow habitat from loss, fragmentation, degradation, and incompatible uses. Protection of vernal pool and wet meadow habitat is the broader objective of this recovery plan, because listed species addressed in the plan are now found in mostly fragmented habitat remnants. The first step is to identify and protect remaining relatively higher quality habitat. Although we have identified core areas of suitable habitat for listed species largely based on aerial photo interpretation, Geographic Information Systems soil data layers, topographic maps, historic species occurrence data, and species population mapping, there are uncertainties that can only be resolved by conducting ground level surveys. Complementary actions (1.1 and 1.2) may be necessary steps prior to actual habitat protection actions and are presented sequentially in order as Priority 2 actions. Priority 1 actions will focus habitat protection within identified Priority 1 and 2 recovery core areas, while lower priority actions may include actions outside of core areas. In general, actions which address the most critical threats (loss, fragmentation, or degradation of habitat) are the highest priority actions. (USFWS, 2010)

- 2. Manage, monitor, and restore vernal pool and wet meadow habitat. Management plans are encouraged to be developed to conserve the listed species occurring at each site. Elements of plans may include: restriction of off-road vehicle use by fencing access roads into preserves using proper signage to restrict vehicle access and avoid inadvertent habitat destruction; habitat restoration and noxious weed prevention programs; use of mowing, burning, or managed grazing to reduce density of native and nonnative vegetation; monitoring effects of management actions for effectiveness, employing adaptive modification; continued monitoring of known Lomatium cookiipopulations on extant sites; surveys for new sites in appropriate habitat; or population introductions into unoccupied habitat. Management plans should identify responsibilities of the management agency or organization to protect species. (USFWS, 2010)
- 3. Conduct rangewide population status surveys. A status survey is a process comprising literature review, examination of herbarium or museum specimens, and a series of surveys conducted throughout a species' range. Historical localities of a species are identified, potential locations where the species may occur are predicted based on distributional and ecological data, and historical and potential locations are surveyed for presence of a species. Ground surveys may be a follow-up to determine if species still occur at site. (USFWS, 2010)
- 4. Conduct research essential to the conservation of these species. In addition to or in conjunction with current monitoring efforts, provide opportunities for further research with schools, State and local governments, or private endeavors. Study pollination vectors between and among populations. Research role of mammals, insects, birds, and wind as cyst and seed dispersal vectors. Evaluate techniques to reduce impacts from encroachment of native woody plant succession. Conduct research on prescribed burning, mowing, and native planting on introduced annual grasses. Refine research on appropriate grazing practices. Research genetic and morphologic traits among individuals and populations. Investigate restoration and recovery methods of historical vernal pool ecosystems that were degraded due to biosolid fill, and log debris fill. Determine incidence of herbivory or predation on Lomatium cookiipopulations. Develop offsite and onsite cultivation and propagation techniques for Limnanthes pumila ssp. grandiflora. Research associated soil crusts as indicators for vernal pool health and function. (USFWS, 2010)
- 5. Enhance public awareness and participation in recovery of the species. Seek to involve stakeholders in the recovery implementation process. Stakeholders are those parties that may be affected by proposed recovery actions, and may include, but are not limited to, Federal and State agencies, Tribal governments, county and city governments, nongovernmental organizations, and private landowners. Through schools, local community meetings, recovery team meetings, county, city, and State fairs, or other venues, we seek to establish contacts with private landowners to provide information about the species. (USFWS, 2010)
- 6. Develop post-delisting monitoring plans. Prior to delisting, a 5-year post-delisting monitoring plan should be developed and in effect. Monitoring and research results should be used to guide the long-term conservation of the species. These tasks are considered a lower priority until more significant and urgent conservation actions can be achieved. Complete post-delisting monitoring plan for Limnanthes pumila ssp. grandiflora. (USFWS, 2010)
- Recommendations for Future Actions: • Develop conservation easements or conservation programs for existing occurrences of Lomatium cookii on private lands. • Make visits to

historical Lomatium cookii occurrences in the Illinois and Rogue Valleys to determine whether the plants are still present or have become extirpated. • Augment Lomatium cookii on protected habitat in appropriate locations in the Illinois and Rogue Valley areas. • Conduct best management practices studies for Lomatium cookii. (USFWS, 2019)

***Conservation Measures and Best Management Practices:***

- Recommendations for Future Actions: • Cook's lomatium habitat occurs on a mix of public and private lands. Because successful conservation of Cook's lomatium will need to include voluntary contributions from private lands, an enhanced and targeted outreach effort to private landowners is needed for conservation partnerships in key areas leading to protected areas contributing to recovery. • Develop conservation easements or conservation programs for existing populations on unprotected private lands. This would directly increase protection status for Cook's lomatium. We are targeting partnerships for the protection of 10 populations on private lands in the next 5 years. • Determine locations to establish Cook's lomatium in the Illinois and Rogue Valleys. If a population is declining, we recommend careful and strategic augmentation. If plants are not present, we recommend sowing seed to reestablish plants as appropriate for the conditions. • Conduct research on the best management practices for Cook's lomatium. For example, high priority research would include best grazing, mowing, herbicide, or fire practices to address seral vegetation succession, encroachment of weedy vegetation and climate change stressors. The best management practices could promote suitable habitat conditions to increase population size and refine plant establishment techniques (USFWS, 2024).

# SPECIES ACCOUNT: *Lupinus aridorum* (Scrub lupine)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 5/7/1987; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

Woody, perennial herb, with sprawling stems up to 1 m long. The leaves are obovate-elliptic, 4 to 7 cm long and 2 to 4 cm wide. The base and end of the leaf are rounded with a sharp point at the leaf's end. The petioles are 2.0 to 4.5 cm long and the stipules are very small or absent. A silvery pubescence covers the leaves and stems. The flowers are a pale flesh-colored pink and are 4 to 5 cm long. The upper petal (standard) has a black center surrounded by a maroon area. Flowers are arranged in racemes with stalks 4 to 13 cm long. Each raceme has 5 to 14 flowers, but up to 25 on occasion. Fruits are long, woody, and elliptical with a pointed end. It is differentiated from L. villosus, the only other pink flowering lupine, in that L. aridorum is not prostrate, has hairs on the leaves and stem, and is the only upright pink-flowering lupine in Florida. (USFWS, 1999).

**Taxonomy**

Until being named L. aridorum in 1982, this taxon was identified as L. diffusus and L. westianus (52 FR 11172). Isley (1986, 1990) evaluated the systematics of L. aridorum in his floristic treatment of the pea family (Fabaceae) in the Southeast and concluded that L. aridorum belongs to the same species as L. westianus of the Gulf Coast of northwest Florida, which differs mainly in flower color (blue). Isley's taxonomic status for the central Florida plant is L. westianus var. aridorum (McFarlin ex Beckner) Isley. However, the former classification L. aridorum was used to list the species (52 FR 11172), and will be used here to maintain consistency. (USFWS, 1999; USFWS, 2016)

**Historical Range**

Historical range is two areas of central Florida: western Orange and extreme northwestern Osceola counties on the southern Mount Dora Ridge and in north-central Polk County on the Winter Haven Ridge (USFWS, 2007).

**Current Range**

Currently found on two interior ridges in central Florida: Winter Haven Ridge in Polk County and Mount Dora Ridge in Orange and Osceola Counties. (USFWS, 2016)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: Average 2-4 years, up to 6-7 years (USFWS, 2022)

**Breeding Season**

Adult: Flowers in late March-May (USFWS, 1999)

**Reproduction Narrative**

Adult: The scrub lupine has been found in bloom between March and May. The seed pods mature by June, and the seeds fall off the plant and take root nearby or remain in a long-lived seedbank. Recent information indicates the plant may bloom from one to three times throughout its life, though few seeds are produced the first year. Pollinators of this species are unknown (USFWS, 1999). Many perish after the first year, but most survive 2 to 3 years with 1 to 3 reproductive cycles. Plants have been recorded to flower at 6 to 7 years. (USFWS, 2022).

**Habitat Type**

Adult: Terrestrial (USFWS, 1999)

**Habitat Vegetation or Surface Water Classification**

Adult: Sandy openings in sand pine-rosemary-oak scrub (USFWS, 1999)

**Dependencies on Specific Environmental Elements**

Adult: Soils are very dry and have very little organic accumulation, and quite acidic with a pH from 4.0 to 4.5 (USFWS, 1999).

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Habitat is sandy openings in sand pine-rosemary-oak scrub. Soils are very dry and have very little organic accumulation, and quite acidic with a pH from 4.0 to 4.5. The scrub lupine will not grow near rosemary (Ceratiola ericoides) because of rosemary's allelopathic effects. Most of the sites where L. aridorum is now found are moderately to severely disturbed by soil scraping, road construction, land clearing, or off-road vehicles (USFWS, 1999; NatureServe, 2015).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Dispersal is not well described (USFWS, 1999).

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2007)

**Species Trends:**

3 - 4 populations extirpated since 2003 (USFWS, 2007)

**Number of Populations:**

8 (USFWS, 2022)

**Population Size:**

1 - 1000 individuals (NatureServe, 2015)

**Population Narrative:**

There has been a documented decline in the spatial distribution and historic range of scrub lupine. As of 2003, the historical records of 40 populations had declined to 11 extant lupine populations occupying about 23 acres. Three or four of these populations have been extirpated since 2003, leaving six to seven scrub lupine populations (USFWS, 2007). There are a total of 8 known sites having at least 1 plant in existence surveyed for this review in 2022. Four locations occur on each ridge within the 2 counties (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat destruction, modification, and degradation on private lands remain the primary threat range-wide to the species. Populations occurring on private lands remain subject to adverse human activity, predominately development. Additionally, lack of management — especially fire suppression — on private lands degrades the habitat over time resulting in less suitability to maintain population viability. These human activities are no longer threats to populations on public conservation lands because of protection afforded and restricted use; however, budget constraints and prioritizing available resources may preclude proper, necessary management activities on conservation lands at times. Only three natural populations occur on public lands with the majority of the populations in private ownership. Little opportunity exists for future protection or management opportunities on these lands because of the urban matrix where they occur. (USFWS, 2016)

**Stressor:** Disease or predation (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Several species of fungus have been observed on L. aridorum plant tissues: charcoal root rot (Macrophomina phaseolina), black leaf spot (Diplocarpon rosae), and recently an unknown black fungus. Little is known about the unidentified black fungus that appears to be confined to the seed coat on L. aridorum. The seed pod looks totally normal but upon opening it the fungus is apparently just on the seeds. Examinations of seed development (Stout 2016) in 2014 at the Lake McLeod NWR documented seeds from 11 of 15 plants (73%) were lost due to this fungal growth. Ten of 20 plants (50%) examined in 2015 had seed loss from fungal sources. No evidence of fungal infested seeds was detected in 2016 (30 plants in sample). Bacteria-induced wilt continues to be observed in L. aridorum populations. It is speculated that the bacteria blocks the conducting xylem tissue to the leaf. The sudden death of plants undergoing wilt may occur anytime during the year. Medium to large plants may be more subject to wilt than smaller recruits. Less than 5% of a population may die from this agent in a typical year. The moth, Uresiphita reversalis, has been a source of mortality to the lupine populations (L. aridorum, L. diffusus) studied during the last 5 years (Stout 2016). Stout (2016) documented roughly 200 L. diffuses individuals devastated by the larvae in one population with no evidence of any insects predating on the moth larvae. (USFWS, 2016)

***Recovery***

**Reclassification Criteria:**
Not defined. (USFWS, 1999).

Recovery Priority Number: 2C

**Delisting Criteria:**
1. Protect sites in Polk and Highlands counties, and establish a disturbance regime to create bare, sunny openings (USFWS, 2007).

2. Conduct demographic monitoring for the foreseeable future. Manage and rehabilitate publicly-owned habitats in Orange County (USFWS, 2007).

3. Manage and rehabilitate publicly-owned habitats in Orange County (USFWS, 2007).

**Recovery Actions:**
- Determine current distribution of L. aridorum. This species has an extremely restricted range. In South Florida, it is found only in northern Polk County off the Lake Wales Ridge. This species is found in a fast growing urbanizing area and essentially all of its habitat has been converted from the natural state. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Conduct research on life history characteristics of L. aridorum. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species more specific biological information is needed. (USFWS, 1999)
- Monitor existing populations of L. aridorum. S4.1. Develop monitoring protocol to assess population trends for L. aridorum. Develop a quantitative description of the population structure of L. aridorum. (USFWS, 1999)
- Provide public information about L. aridorum. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private land owners be appropriately informed about this species. Care is needed, though, to avoid revealing specific locality information about where L. aridorum is found. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. The public should be informed that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of L. aridorum and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)
- Habitat-level Recovery Actions: Prevent degradation of existing habitat. Restore areas to suitable habitat. Conduct habitat-level research projects. Monitor habitat/ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)
- Update and revise the recovery plan to improve and clarify the objective measurable criteria and better address the five factors. (USFWS, 2016).

- Collaboration with conservation land managers to increase habitat suitability of occupied habitat. Actively engage landowners to protect and manage occupied habitat. (USFWS, 2016)
- Continued research on biology and ecology: genetics; seed germination (soilmicrobial interactions); out planting techniques to reduce mortality; fungus and bacteria stressors. (USFWS, 2016)
- Conduct research on different habitat management techniques and their effects in regards to maintaining or improving the residual seed bank for populations. (USFWS, 2016)
- Increase existing monitoring efforts. (USFWS, 2016)

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES • Collaboration with conservation land managers to increase habitat suitability of occupied habitat by promoting beneficial management options to increase population persistence. • Actively engage landowners to protect, manage, and monitor occupied habitat. • Continued research on biology and ecology: genetics, seed germination (soil-microbial interactions), fungus and bacteria stressors. • Conduct studies of soil seed banks across the range on different habitat and seasonality for the restoration of degraded ecosystems and understanding the type of seed bank: transient, persistent, or transient: short-term and long-term persistent (USFWS, 2022).

# SPECIES ACCOUNT: *Lupinus nipomensis* (Nipomo Mesa lupine)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 03/20/2000; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

An annual herb (NatureServe, 2015). The low-spreading individuals can reach 8 inches (20 centimeters) in height (Riggins 1993). Leaves are pinnately compound into five to seven leaflets. Up to 10 pinkish-purple flowers are borne on the ends of the inflorescences (flowering stems). Leaves and stems are succulent, and provide prolonged moisture for seed development (USFWS, 2009).

**Taxonomy**

Recognized as distinct in Kartesz's 1999 Synthesis (had been questionable synonymized into Lupinus concinnus ssp. concinnus in the 1994 Checklist). Recognized as distinct by Jepson, CNDDB, and the 1999 Federal Register (NatureServe, 2015). A member of the pea family (Fabaceae) (USFWS, 2009).

**Historical Range**

Historically and currently, the species is known only from the southwestern corner of San Luis Obispo County, California, scattered over an area of approximately 2 miles wide and 2 miles long (3.2 by 3.2 kilometers (km)) (USFWS, 2009).

**Current Range**

It is currently extant at Nipomo Mesa, San Luis Obispo County, California (NatureServe, 2015). Colonies are scattered across a 2-mile (3.2-km) stretch of backdune habitat west of Highway 1 and between Black Lake Canyon to the north and Oso Flaco Lake to the south (USFWS, 2009).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: self-pollination, cross-pollination (USFWS, 2009)

**Lifespan**

Adult: One year (USFWS, 2009)

**Breeding Season**

Adult: March - May (NatureServe, 2015)

**Key Resources Needed for Breeding**

Adult: Insect pollinators, based on closely related species (USFWS, 2009)

**Reproduction Narrative**

Adult: This is an annual species. Potentially, seed production could reach on the order of 1,000 seeds; however, based on 2 years of sampling, observed seed production per plant ranged from 1 to over 200, with most plants producing less than 30 fruits (Walters and Walters 1988). Flowers are self-compatible if manipulated; however, they may require insect visitation for full complements of seeds (Center for Plant Conservation (CPC) 2009). While pollination ecology has not been specifically studied for L. nipomensis, other lupine taxa are known to be pollinated by butterflies and a variety of bee taxa, especially from the genera Bombus, Osmia, Synhalonia, and Anthidium (Moldenke 1976) (USFWS, 2009). It blooms from March to May (NatureServe, 2015).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Coastal dune scrub (USFWS, 2009)

**Dependencies on Specific Environmental Elements**

Adult: Natural disturbance (USFWS, 2009)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs < 50 m elevation (NatureServe, 2015)

**Environmental Specificity**

Adult: Very narrow (inferred from USFWS, 2009)

**Habitat Narrative**

Adult: Inhabits stabilized coastal sand dunes at < 50 m elevation. (NatureServe, 2015). It is restricted to sandy soils associated with the Callender Dune Sheet (Cooper 1967). Habitat for Lupinus nipomensis is comprised of stabilized back dunes supporting a central coastal dune scrub community. Lupinus nipomensis needs open habitat to persist. Sandy soils along the coast typically undergo a certain amount of natural disturbance from coastal winds and from the activity of wildlife (USFWS, 2009).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Nipomo Mesa lupine has an explosive seed dispersal mechanism caused by the drying out of the seed pods (Walters and Walters 1989, p. 12). Like many other lupine species, it likely has a persistent seed bank (USFWS, 2024)

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

3 (USFWS, 2024)

**Population Size:**

Variable; 81-343 (USFWS, 2024)

**Additional Population-level Information:**

There are currently three known extant Nipomo Mesa lupine EOs: Santa Maria Oil Refinery/Phillips 66 Petroleum Company (EO 1); Kathleen's Overlook Canyon ([KCO] EO 3); and BLEA (EO 10). VFWO visited areas within each EO with partners during the peak of the Nipomo Mesa lupine blooming season in April 2024. We observed the species at each location, assessed the threats, and noted overall habitat conditions. We were unable to access portions of EO 1 on the east side of the Southern Pacific Railroad at the Phillips site in April 2024. Phillips 66 gave VFWO and CDFW a tour of their property on July 11, 2023, which was not within the Nipomo Mesa lupine blooming period. We estimated that the population described at listing had fewer than 700 total individuals in the 2000 Listing Rule (Service 2000, p. 14890). Our previous 5-year reviews presented census data collected by LCSLO from 2006 to 2017 at selected locations within the Phillips 66 property (EO 1; CNDDB 2024b, website). The number of individuals within these selected monitoring plots ranged from 118 (2016) to 1,677 (2013) (Service 2019, p. 12). In 2017, LCSLO completed a comprehensive Nipomo Mesa lupine census survey throughout the Phillips 66 site and counted 911 total individuals. They also monitored Nipomo Mesa lupine at BLEA from 2015 through 2018. LCSLO and partners counted 118 Nipomo Mesa lupine individuals in 2015, 343 in 2016, 81 in 2017, and 89 in 2018 at BLEA (USFWS, 2024).

**Population Narrative:**

Lupinus nipomensis (Nipomo lupine) is a small annual plant in the pea family (Fabaceae). Historically and currently, the species is known only from the southwestern corner of San Luis Obispo County, California, scattered over an area of approximately 2 miles wide and 2 miles long (3.2 by 3.2 kilometers (km)) (Figure 1). It is restricted to sandy soils associated with the Callender Dune Sheet (Cooper 1967). For purposes of this review, we are considering the entire extent of the species to comprise one population; however, the California Natural Diversity Database (CNDDB) has divided the population into approximately 10 occurrences for tracking purposes. Over the last 4 years, the total number of individuals has fluctuated between approximately 139 and 771, depending on winter and spring climatic conditions (Land Conservancy of San Luis Obispo County (Conservancy) 2009). Over time, the species' habitat has been fragmented by State Highway 1 and oil refinery facilities, and bounded on the eastern side by development and agriculture. The small size of the populations and their proximity to a variety of human activities makes it vulnerable to stochastic extinction. (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Development (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A Notice of Preparation to expand refinery capabilities at the Conoco-Phillips plant has been received (County of San Luis Obispo 2008). The Service has also recently received a notice regarding a proposal to construct a telecommunications facility less than 0.25 mile (0.4 km) away from EO #7 (C. Mehlberg, Service, in litt. 2009). The project proponent notes that the site was previously developed with agricultural fields; whether above-ground plants or a seed bank of L. nipomensis remains is unknown. In addition, it appears that several housing developments have

been constructed within a mile of L. nipomensis habitat over the past 5 years (Google Earth 2009). The presence of a larger human population in the adjacent area is likely to introduce additional direct and indirect effects (such as trampling from recreational use, spread of invasive horticultural species used in landscaping, and loss of pollinator habitat) on the species as time goes on. Little opportunity for population expansion is available adjacent to the existing populations because habitat has already been converted to other uses, including roads, facilities, agriculture, and housing (USFWS, 2009).

**Stressor:** Pocket gophers (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** While pocket gophers are known to harvest seeds of many species in general (Martin et al. 1951), it is more likely that they consume the roots, stems, and leaves of L. nipomensis, and that seeds die prior to full maturation. However, seed that are able to complete maturation despite being excised from the plant may find suitable germination sites in the vacated gopher mounds the following winter season (Walters and Walters 1988). In addition, the listing rule stated that the presence of veldt grass increases the food source for pocket gophers and thus potentially increases their numbers and their potential harm to L. nipomensis (Walters and Walters 1988). Survey results for the 3 years from 2007 through 2009 indicate that from 28 to 31 percent of L. nipomensis individuals are consumed by pocket gophers on Conoco-Phillips property (Conservancy in litt. 2009); therefore, pocket gophers continue to be a threat to the species (USFWS, 2009).

**Stressor:** Nonnative plants (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In general, invasion of this habitat by nonnative species (particularly veldt grass (see Bossard et al. 2000)) is a threat to populations of native species because individuals cannot compete well for light, water, and resources (D'Antonio and Vitousek 1992). Veldt grass was described as "rampant" in the area at least 25 years ago (McLeod and Walters 1987); its presence can cause a shift from scrub habitat to grassland habitat (Bossard et al. 2000, California Invasive Plant Council 2009). Since 2000, the Conservancy has been actively removing veldt grass from Lupinus nipomensis habitat. While these efforts may have slowed the conversion to a monoculture of veldt grass, it is likely that the habitat will have to be managed in perpetuity to maintain the open patches that is required by L. nipomensis (USFWS, 2009).

**Stressor:** Stochastic events (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The existence of less than 10 occurrences and the small number of individuals in the occurrences place Lupinus nipomensis at risk of extinction from stochastic events. The conservation biology literature commonly notes the vulnerability of taxa known from one or very few locations and/or from small and highly variable populations (e.g., Shaffer 1981, 1987; Groom et al. 2006; Primack 2006). In particular, although the plants are apparently self-compatible and capable of self-fertilization, the small size of the population makes it difficult for this species to

persist while sustaining the impacts of habitat alteration that favors nonnative plant species and the potential loss of pollinator habitat (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Recently, the potential impacts of climate change on the flora of California were discussed by Loarie et al. (2008). Based on modeling, they predicted that species' distributions will shift in response to climate change, specifically that the species will "move" or disperse to higher elevations and northward, depending on the ability of each species to do so. Species diversity will also shift in response to these changes with a general trend of increasing diversity shifting towards the coast and northwards with these areas becoming de facto future refugia. However, predictions of climatic conditions for smaller sub-regions such as California remain uncertain. It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects (USFWS, 2009).

***Recovery***

**Reclassification Criteria:**
Nipomo lupine may be considered for downlisting when the following criteria are met: 1. At least three resilient occurrences display stable or increasing population trends averaged over 10 consecutive years; 2. Each of the three resilient occurrences is protected from habitat loss, including development activities; 3. Each of the three resilient occurrences is being managed in a way that will support continued existence of Nipomo lupine and its coastal dune scrub habitat, including management of non-native, invasive species; 4. Management is effective as shown by monitoring for 10 consecutive years; and 5. An ex situ permanent conservation seedbank is established in a Center for Plant Conservation-affiliated botanic garden that reflects the breadth of the species' genetic diversity. (USFWS, 2021)

Recovery Priority Number: 5

**Delisting Criteria:**
Once the downlisting criteria have been met, Nipomo lupine may be considered for delisting when the following criteria are met: 1. At least five resilient occurrences, are successfully established within the GuadalupeNipomo Dunes Complex, and display stable or increasing population trends averaged over 10 consecutive years; 2. Each of the five resilient occurrences is protected from habitat loss, including development activities; 3. Each of the five resilient occurrences is being managed in a way that will support continued existence of Nipomo lupine and its coastal dune scrub habitat, including management of non-native, invasive species; and 4. Management is effective as shown by monitoring for 10 consecutive years. (USFWS, 2021)

**Recovery Actions:**

- The recovery actions for Nipomo lupine are provided below. 1. Protect all currently unprotected habitat where the species occurs. The coastal dune scrub habitat associated with Nipomo lupine has a limited distribution and is considered a sensitive vegetation type. USFWS will work with potential partners to establish conservation easements, fee title agreements, or other appropriately protective measures on private lands that support the species and its habitat for conservation. 2. Conduct outplanting activities at suitable sites to establish new occurrences throughout the Guadalupe-Nipomo Dunes region. Potential outplanting locations include: • Kathleen’s Canyon Overlook – located along Black Lake Canyon, on the corner of Callender Road and State Route 1 in rural Arroyo Grande. The Land Conservancy of San Luis Obispo (LCSLO) recently purchased this 55-acre site for conservation purposes. • Coreopsis Hill – located south of Oso Flaco Lake, southwest of the town of Nipomo, and less than one mile directly inland from the Pacific Ocean. The site is jointly owned by California Department of Parks and Recreation, Oceano Dunes State Vehicular Recreation Area and private landowners that support environmental stewardship and long-term preservation of the property. However, a conservation easement for the site has not yet been established with the private entity. The site is approximately 60 acres. • USFWS Guadalupe-Nipomo Dunes National Wildlife Refuge (Refuge) – a 2,553- acre site located northwest of the town of Guadalupe and west of State Route 1. The property is part of a national system that is managed specifically for conservation purposes. • Guadalupe Oil Field – a remediation site for diluent contaminants that is owned and managed by Chevron Corporation in cooperation with several other agencies and partners. The property is located on the north side of the Santa Maria River and immediately south of the Refuge. It is 2,700 acres in size. • Dune Lakes Limited – a privately owned duck-hunting club located north of Black Lake and south of the town of Oceano. LCSLO holds a conservation easement on approximately 970 acres of this 1,255-acre property. • Oceano Dunes Natural Preserve – this property is part of the Oceano Dunes State Vehicular Recreation Area and is owned and managed by California Department of Parks and Recreation. The preserve area is approximately 500 acres and is located southwest of the town of Oceano. • Trilogy Dunes Open Space – this site is located southeast of the Phillips 66 Refinery and is designated as an open space preserve to offset impacts from two associated residential developments under the California Environmental Quality Act. The property is approximately 175 acres. 3. Manage habitat that supports the species to reduce or eliminate threats to the population (particularly non-native, invasive weeds) and to foster natural regeneration and recruitment of Nipomo lupine. 4. Collect seed and deposit accessions into the permanent conservation seedbank established for the species at the Santa Barbara Botanic Garden that includes additional backup sent to the U.S. Department of Agriculture’s National Laboratory for Genetic Resource Preservation seed vault, located in Fort Collins, Colorado. 5. Conduct annual census monitoring and experimental research projects across the occurrences to fill data gaps and document the progress of recovery implementation. 6. Determine those factors necessary for seed survival, optimal germination, and effective seedling establishment and use this information to ensure future recovery efforts. In particular, consider the role of disturbance, predation, and pollination on the species viability. 7. Conduct genetics and demographic research to better inform future recovery activities and criteria. Examples of potential projects include: • Investigate the effects of outplanting on the species genetic variability and compare variability of extant occurrences to that of propagated lines. • Determine the number of reproducing individuals required for population resiliency in any given occurrence. • Quantify seedbank longevity. 8. Develop opportunities for education and outreach within local and regional communities, and throughout San Luis Obispo County. (USFWS, 2021)

- Complete a Recovery Outline and Species Action Plan for Lupinus nipomensis as a first step in preparing a recovery plan for the species (USFWS, 2009).
- Work with Conoco-Phillips and California Department of Transportation to ensure that management of their lands and rights-of-way is consistent with the long-term persistence of

Lupinus nipomensis at those sites. In addition, work with the County of San Luis Obispo to ensure that consideration is given to L. nipomensis during projects review and implementation (USFWS, 2009).

- In partnership with Santa Barbara Botanic Garden, continue with research on seed characteristics, particularly to determine the extent of the soil seed bank present, and whether there is a difference in seed viability between those produced from self-fertilization and those produced by cross-pollination to determine if lack of pollinators is a concern (USFWS, 2009).
- In partnership with Santa Barbara Botanic Garden and the Conservancy, experiment with establishment of new populations in other coastal dune scrub habitat in coastal San Luis Obispo County (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Complete a Recovery Outline and Species Action Plan for Lupinus nipomensis as a first step in preparing a recovery plan for the species. 2. Work with Conoco-Phillips and California Department of Transportation to ensure that management of their lands and rights-of-way is consistent with the long-term persistence of Lupinus nipomensis at those sites. In addition, work with the County of San Luis Obispo to ensure that consideration is given to L. nipomensis during projects review and implementation. 3. In partnership with Santa Barbara Botanic Garden, continue with research on seed characteristics, particularly to determine the extent of the soil seed bank present, and whether there is a difference in seed viability between those produced from selffertilization and those produced by cross-pollination to determine if lack of pollinators is a concern. 4. In partnership with Santa Barbara Botanic Garden and the Conservancy, experiment with establishment of new populations in other coastal dune scrub habitat in coastal San Luis Obispo County. (USFWS, 2020)
- Trilogy Dunes Open Space – this site is located southeast of the Phillips 66 Refinery and is designated as an open space preserve to offset impacts from two associated residential developments under the California Environmental Quality Act. The property is approximately 175 acres. (USFWS, 2021)
- Clethodim Herbicide Study. Clethodim is a grass-specific herbicide widely used throughout the Guadalupe-Nipomo Dunes complex to manage veldt grass. ODSVRA maintains a California Endangered Species Act 2081(a) Management Permit (2081 permit) issued by CDFW to implement invasive species controls for Nipomo Mesa lupine recovery. Their 2081 permit authorizes them to conduct Clethodim applications at P66-west and implement other manual weed and treated thatch removal activities. In past years, CDFW required 100-ft avoidance buffers around areas occupied by Nipomo Mesa lupine where aerial Clethodim applications could not be sprayed. ODSVRA thus had to use manual techniques in buffer areas while avoiding the Nipomo Mesa lupine growing season. This was labor intensive, and the buffer areas were too large to be managed effectively. The buffers resulted in veldt grass islands that adversely affected the species and undermined treated areas by rapidly spreading seed back out into them. In 2020, ODSVRA proposed to amend their 2081 permit to reduce the size of the avoidance buffers. CDFW raised concerns that Clethodim may adversely affect Nipomo Mesa lupine growth, reproduction, and development. To address this, ODSVRA contracted CCBER to evaluate effects of Clethodim, applied either aerially or directly sprayed, on Nipomo Mesa lupine seedlings and reproductive individuals in a greenhouse setting (CCBER 2024, p. 2). CCBER also collected seeds from the treated individuals and germinated them to investigate potential effects of Clethodim on seed viability. CCBER found no significant effects from the Clethodim treatments on Nipomo Mesa lupine growth, reproduction, plant vigor, seed production, or seed viability (CCBER 2020b, p. 4–11). By November of 2022, CDFW reduced the width of the

Nipomo Mesa lupine avoidance buffers to 7.6 m (25 ft), but no less than 4.6 m (15 ft). CDFW also permitted direct Clethodim treatments in areas previously occupied by the species but where it was not observed for five years or more. These changes allow ODSVRA to conduct invasive species controls for Nipomo Mesa lupine recovery more easily and efficiently at P66- west (USFWS, 2024).

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Conduct comprehensive annual surveys of abundance, assess the overall status of the species, and evaluate current threats at each of the three EOs. Include estimates of the total number of Nipomo Mesa lupine individuals present at each location, using uniform methodologies suitable for trend analyses, and map the total occupied area. Collect other pertinent ecological and demographic data including co-occurring and co-dominant species, estimate of bare sand cover, presence and abundance of nonnative, invasive species, timing of phenology, effective population size, and continue observations of any potential insect pollinators, and seed and foliage herbivory. 2. Conduct experimental research to determine the most effective management techniques for occupied Nipomo Mesa lupine sites to ensure persistence and expansion of the species. We recommend evaluating the use of grazing and other disturbance techniques designed to manage nonnative, invasive weeds (especially veldt grass) to stimulate seed germination, to maintain sandy, open spaces required by the species, and to expand potentially suitable habitats immediately adjacent to occupied areas. 3. Conduct genetics research on Nipomo Mesa lupine to quantify the genetic diversity within the species and establish other important genetic baseline metrics for conservation. 4. Obtain conservation easements or acquire other sites within the species current range to introduce the species to new locations that have long-term management strategies to ensure success and persistence of the species. Refine existing protocols for propagation of the species from seed. 5. Continue making conservation seed bank accessions of Nipomo Mesa lupine seed. Conduct additional seed bulking activities to ensure an ample supply of seed for recovery efforts and for insurance in the event of stochastic loss or extirpation (USFWS, 2024).

# SPECIES ACCOUNT: *Lupinus sulphureus ssp. kincaidii* (Kincaid's Lupine)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 02/24/2000; Pacific Region (R1)

**Physical Description**

Lupinus sulphureus ssp. kincaidii, a dicot herbaceous perennial, was first described in 1921 by A.A. Heller as Lupinus oreganus from a collection made in Eugene, Oregon (Wilson et al. 2003). In the intervening decades, Phillips (1955) described the plant as a subspecies, L. sulphureus ssp. kincaidii. Hitchcock (1961) retained the position noted by Phillips (1955), but preferred the combination as a varietal rank, L. sulphureus var. kincaidii, although this is not accepted under the rules of botanical nomenclature (Wilson et al. 2003). Additional taxonomic work may be needed for this subspecies, and it is possible that the subspecies should be considered a distinct species, L. oreganus (Wilson et al. 2003). (USFWS, 2010) This taxonomic change for Kincaid's lupine, from the subspecies Lupinus suiphureus ssp. kincaidii to the full species Lupinus oreganus, has now been recognized by the Oregon Department of Agriculture (Oregon Department of Agriculture, 2019) and by botanical authorities such as the Oregon Flora Project's Vascular Plant Checklist (laster et al. 2019) and the Flora of Oregon (S. Meyers pers. comm. 2019). Other authorities, such as the Natural Resources Conservation Service's USDA PLANTS database (USDA PLANTS 2019), the Integrated Taxonomic Tnformation System (ITIS.GOV 2019), the Flora of the Pacific Northwest (Hitchcock and Cronquist 2018), and Washington Department of Natural Resources (Washington Natural Heritage Program 2019, p. 19) now recognize Kincaid's lupine as a variety, Lupinus oreganus var. kincaidii C.P. Sm. (the other variety being L. oreganus var. oreganus, formerly L. biddlei). Whether a full species or an infraspecies, all authorities now agree that at a minimum, Kincaid' s lupine should be recognized under the specific epithet "oreganus" instead of "suiphureus." (USFWS, 2019)

**Taxonomy**

Lupinus sulphureus ssp. kincaidii was first described in 1921 by A.A. Heller as Lupinus oreganus from a collection made in Eugene, Oregon (Wilson et al. 2003). In the intervening decades, Phillips (1955) described the plant as a subspecies, L. sulphureus ssp. kincaidii. Hitchcock (1961) retained the position noted by Phillips (1955), but preferred the combination as a varietal rank, L. sulphureus var. kincaidii, although this is not accepted under the rules of botanical nomenclature (Wilson et al. 2003). Additional taxonomic work may be needed for this subspecies, and it is possible that the subspecies should be considered a distinct species, L. oreganus (Wilson et al. 2003). (USFWS, 2010) This taxonomic change for Kincaid's lupine, from the subspecies Lupinus suiphureus ssp. kincaidii to the full species Lupinus oreganus, has now been recognized by the Oregon Department of Agriculture (Oregon Department of Agriculture, 2019) and by botanical authorities such as the Oregon Flora Project's Vascular Plant Checklist (laster et al. 2019) and the Flora of Oregon (S. Meyers pers. comm. 2019). Other authorities, such as the Natural Resources Conservation Service's USDA PLANTS database (USDA PLANTS 2019), the Integrated Taxonomic Tnformation System (ITIS.GOV 2019), the Flora of the Pacific Northwest (Hitchcock and Cronquist 2018), and Washington Department of Natural Resources (Washington Natural Heritage Program 2019, p. 19) now recognize Kincaid's lupine as a variety, Lupinus oreganus var. kincaidii C.P. Sm. (the other variety being L. oreganus var. oreganus, formerly L. biddlei). Whether a full species or an infraspecies, all authorities now agree that at a minimum, Kincaid' s lupine should be recognized under the specific epithet "oreganus" instead

of “suiphureus.” (USFWS, 2017)

**Historical Range**

"Historically, the species was documented from Vancouver Island, British Columbia, Canada (Dunn and Gillet 1966), but has not been located in that region since the 1920s (Kaye 2000). Before Euro-American settlement of the region, Kincaid’s lupine was likely well distributed throughout the prairies of western Oregon and southwestern Washington; today, habitat fragmentation has resulted in existing populations that are widely separated by expanses of unsuitable habitat" (USFWS, 2010 p. II-20).

**Current Range**

Douglas County, Oregon to Lewis County, Washington, and into southern British Columbia. Considered extirpated in British Columbia. In Oregon, in the Willamette and Umpqua Valleys. Kincaid's lupine is restricted to upland prairie habitat "Before Euro-Americans settled the Willamette Valley, prairies were one of the dominant habitat types, accounting for perhaps 30 percent of the valley floor (Altman et al. 2001). Prairies were created and maintained by natural and human-caused disturbances; the native Kalapuya peoples burned the prairies frequently to maintain high quality hunting and gathering grounds (Boyd 1986). As settlers arrived, native habitats were converted to agricultural landscapes, annual burning ceased, and native upland prairies and wet prairies now cover much less than one percent of their former area (Habeck 1961, Johannessen et al. 1971, Towle 1982), making them among the rarest of North American ecosystems (Oregon Natural Heritage Program 1983, Noss et al. 1995)." (USFWS 2010 p. I-5). "The majority of the habitat for Lupinus sulphureus ssp. kincaidii is on private lands, thus partnering with private landowners by working with nongovernmental organizations (e.g., land trusts), local governments such as soil and water conservation districts, and the Service’s Partners for Fish and Wildlife program is essential to achieve recovery." (USFWS 2019 p.7)

**Critical Habitat Designated**

Yes; 11/30/2000.

**Legal Description**

On October 31, 2006, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective November 30, 2006) for Lupinus sulphureus ssp. kincaidii (Kincaid's lupine) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes 13 critical habitat units (CHUs) in Oregon and Washington (71 FR 63862-63977).

**Critical Habitat Designation**

The critical habitat designation for Lupinus sulphureus ssp. kincaidii includes 13 CHUs in Benton, Lane, Polk, and Yamhill Counties, Oregon, and Lewis County, Washington. This species critical habitat encompasses approximately 585 acres (ac) (237 hectares (ha)). Brief descriptions are presented below; detailed coordinates and maps are included in the Final Rule (71 FR 63862-63977; USFWS, 2006).

Unit KL–1 consists of approximately 4 ac (1.6 ha) of private land in Lewis County, Washington.

Unit KL–2A and 2B encompass approximately 6.25 ac (2.5 ha) and 14.1 ac (5.7 ha) respectively, of private land in northern Yamhill County. KL–2A supports Lupinus sulphureus ssp. kincaidii patches along both the east and west sides of Oak Creek Road. KL– 2B is located approximately

0.68 miles (1.1 km) south of KL–2A along both the east and west sides of Oak Creek Road, near the junction with Fairdale Road.

Unit KL–3 consists of approximately 51 ac (20.6 ha) of private lands within Yamhill County.

Unit 4 of Lupinus sulphureus ssp. kincaidii (Unit KL–4A and 4B) Unit KL–4A and 4B consists of approximately 68.6 ac (27.8 ha) of private lands in Yamhill County and is located west of Muddy Valley Road and south of Eagle Point Road.

Unit 5 of Lupinus sulphureus ssp. kincaidii (Unit KL–5) Unit KL–5 encompasses approximately 1.7 ac (0.7 ha) of ODOT land in southern Yamhill County and is located south of State Highway 18, east of Ballston Road, and approximately 0.6 mi (1 km) south of the Yamhill River.

Unit KL–6 encompasses approximately 3.6 ac (1.5 ha) of primarily ODOT land in northern Polk County. The Lupinus sulphureus ssp. kincaidii population occurs in two patches scattered along the northeast and southwest sides of Highway 22, near the intersection with Mill Creek Road.

Unit KL–7 consists of approximately 12.3 ac (5 ha) of private lands in central Polk County. This unit is located near the junction of Highway 223 and Oakdale Avenue, and largely falls within the City of Dallas urban-growth boundary.

Unit KL–8 consists of approximately 11.5 ac (4.6 ha) of private and State lands in Benton County. This unit occurs in McDonald Forest located off Oak Creek Road and supports one of the highest quality remaining prairies.

Unit KL–9 encompasses approximately 171.6 ac (69.4 ha) of private lands within Benton County. This unit is located in Wren, Oregon, between Kings Valley Highway, Cardwell Hill Road, and Blakesly Creek Road, approximately 2 mi (3.2 km) southwest of Unit KL–8.

Unit KL–10 consists of approximately 17.9 ac (7.2 ha) of private lands within Benton County and is located north of Philomath, with the habitat occurring primarily to the south of West Hills Road and to the west of 19th Street.

Unit KL–11 encompasses approximately 64.6 ac (26.2 ha) of prairie habitat distributed across Federal and private lands in Lane County. This unit is located in West Eugene, near the Fern Ridge Reservoir, just south of Clearlake Road, and on both the east and west sides of Fir Butte Road. The area included in Units KL–11A, 11B, 11C, 11D, and 11E.

Unit KL–12 encompasses approximately 141.2 ac (57.1 ha) of prairie habitat distributed across Federal and private lands in Lane County. This unit is in west Eugene and located north of Bailey Hill Road and west of Bertelsen Road. This unit primarily occurs on lands owned by TNC and the BLM, with 4 percent occurring on private lands. The area included in KL– 12A, 12B, 12C, 12D, and 12E, collectively represents habitat with the features essential to the conservation of a functioning Lupinus sulphureus ssp. kincaidii metapopulation.

Unit KL–13 encompasses approximately 16.2 ac (6.6 ha) of private land in Lane County, and is located north of Powell Road and west of Coyote Creek.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Lupinus sulphureus ssp. kincaidii critical habitat consists of two components (71 FR 63862-63977):

(i) Early seral upland prairie, or oak savanna habitat with a mosaic of lowgrowing grasses and forbs, and spaces to establish seedlings or new vegetative growth; an absence of dense canopy vegetation; and undisturbed subsoils.

(ii) The presence of insect outcrossing pollinators, such as Bombus mixtus and B. californicus, with unrestricted movement between existing lupine patches.

**Special Management Considerations or Protections**

Lupinus sulphureus ssp. kincaidii populations respond positively to habitat restoration. Mowing, burning, and mechanical removal of weeds, when done appropriately, have all been shown to benefit Fender's blue populations. At sites managed by The Nature Conservancy (TNC), the Fender's blue butterfly and L. sulphureus ssp. kincaidii populations increased following removal of noxious non-native plants such as Rubus discolor (Himalayan blackberry) and Cytisus scoparius (Scotch broom) (Fitzpatrick 2005, pp. 6, 7, 10, 11, 20). At Baskett Slough National Wildlife Refuge in western Oregon, Wilson and Clark (1997, p. 10, 11) studied the effects of controlled fire and mowing on the Fender's blue butterfly and its native upland prairie. Although fire killed all larvae in treated patches, nearby unburned (untreated) patches provided a source of female Fender's blue butterflies that were able to recolonize the entire burned (treated) area. Wilson and Clark (1997, pp. 10, 23) also found that in the year following mowing and burning treatments, Fender's blue butterfly eggs were 10 to 14 times more abundant in treated plots than in undisturbed control plots. Woody plants were reduced by 45 percent with burning and by 66 percent with mowing. At the Corps' Fern Ridge Reservoir, the Fender's blue population has increased dramatically since fall mowing of L. sulphureus ssp. kincaidii patches has been implemented. The abundance of Fender's blue butterfly eggs and L. sulphureus ssp. kincaidii has increased as blackberry bushes have been controlled in several test plots located on BLM lands in Eugene, Oregon (Kaye and Cramer 2003, p. 10). In general, Fender's blue butterfly egg abundance increased substantially at sites treated to control non-native weeds (Schultz et al. 2003, p. 69). (USFWS, 2006)

Lupinus sulphureus ssp. kincaidii is at risk of inbreeding depression and site extirpation across their respective ranges because populations are small and isolated from one another. This species will benefit from reestablishing prairie plant patches in proximity to core populations. (USFWS, 2006)

Many remaining populations of Lupinus sulphureus ssp. kincaidii populations occur in road rights of ways and are adversely affected by maintenance activities such as mowing or spraying of herbicides at the wrong time of year. A few L. sulphureus ssp. kincaidii populations along roads persist, likely because the routine maintenance provides open, full-sun conditions characteristic of L. sulphureus ssp. kincaidii habitat.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollinated (USFWS, 2010) "Pollination is largely accomplished by small native bumblebees (Bombus mixtus and B. californicus), solitary bees (Osmia lignaria, Anthophora furcata, Habropoda sp., Andrena spp., Dialictus sp.) and occasionally, European honey bees (Apis mellifera) (Wilson et al.2003). Insect pollination appears to be critical for successful seed production (Wilson et al.2003). Kincaid's lupine reproduces by seed and vegetative spread. It is able to spread extensively through underground growth. Individual clones can be several centuries old (Wilson et al.2003), and become quite large with age, producing many flowering stems." (USFWS 2010 p. II-22)

**Dependency on Other Individuals or Species**

Adult: "Pollination is largely accomplished by small native bumblebees (Bombus mixtus and B. californicus), solitary bees (Osmia lignaria, Anthophora furcata, Habropoda sp., Andrena spp., Dialictus sp.), and occasionally European honey bees (Apis mellifera) (Wilson et al. 2003). Insect pollination appears to be critical for successful seed production (Wilson et al. 2003)." (USFWS 2010 p. II-22) Kincaid's lupine is the larval host for the Endangered Fender's blue butterfly. (USFWS 2010)

**Breeding Season**

Adult: Flowering begins in April and extends through June (USFWS 2010). As the summer dry season arrives, Kincaid's lupine becomes dormant, and is completely senescent by mid-August (Wilson et al.2003) (USFWS, 2010).

**Reproduction Narrative**

Adult: Flowering begins in April and extends through June (USFWS 2010). As the summer dry season arrives, Kincaid's lupine becomes dormant, and is completely senescent by mid-August (Wilson et al.2003). Pollination is largely accomplished by small native bumblebees (Bombus mixtus and B. californicus), solitary bees (Osmia lignaria, Anthophora furcata, Habropoda sp., Andrena spp., Dialictus sp.) and occasionally, European honey bees (Apis mellifera) (Wilson et al.2003). Insect pollination appears to be critical for successful seed production (Wilson et al.2003). Kincaid's lupine reproduces by seed and vegetative spread. It is able to spread extensively through underground growth. Individual clones can be several centuries old (Wilson et al.2003), and become quite large with age, producing many flowering stems. As part of a genetic evaluation, collections taken from small populations of Kincaid's lupine at the Baskett Slough National Wildlife Refuge were found to be genetically identical, indicating that the population consists of one or a few large clones (Liston et al.1995). Reproduction by seed is common in large populations where inbreeding depression is minimized and ample numbers of seeds are produced. In small populations, seed production is reduced and this appears to be due, at least in part, to inbreeding depression (Severns 2003). Kincaid's lupine is vulnerable to seed, fruit and flower predation by insects, which may limit the production of seeds. Seed predation by bruchid beetles and weevils and larvae of other insects has been documented, and may result in substantially reduced production of viable seed (Kaye and Kuykendall 1993, Kuykendall and Kaye 1993). Floral and fruit herbivory by larvae of the silvery blue butterfly (Glaucopsyche lygdamus columbia) has also been reported (Kuykendall and Kaye 1993). The vegetative structures of Kincaid's lupine support a variety of insect herbivores, including root borers, sap suckers and defoliators (Wilson et al.2003). Kincaid's lupine is the primary larval host plant of the endangered Fender's blue butterfly (Wilson et al.2003). Female Fender's blue butterflies lay their eggs on the underside of Kincaid's lupine leaves in May and June; the larvae hatch several weeks later and feed on the plant for a short time before entering an extended diapause, which lasts until the following spring (Schultz et al.2003). Kincaid's lupine, like other members of the genus Lupinus, is unpalatable to vertebrate grazers (USFWS, 2016).

**Habitat Type**

Adult: Upland prairie (USFWS, 2010)

**Environmental Specificity**

Adult: Moderate (Inferred from USFWS, 2016)

**Habitat Narrative**

Adult: "In the Willamette Valley and southwestern Washington, Kincaid's lupine is found on upland prairie remnants where the species occurs in small populations at widely scattered sites. A number of populations are found in road rights-of-way, between the road shoulder and adjacent fence line, where they have survived because of a lack of agricultural disturbance. Some of the populations in Washington occur in pastures and appear to benefit from light grazing by livestock, which reduces the cover of competing shrubs and grasses (Joe Arnett, Washington Department of Natural Resources, in litt 2008). Common native species typically associated with Kincaid's lupine include: Festuca idahoensis ssp. roemeri, Danthonia californica, Calochortus tolmiei, Eriophyllum lanatum, and Fragaria virginiana. The species appears to prefer heavier, generally well-drained soils and has been found on 48 soil types, typically Ultic Haploxerolls, Ultic Argixerolls, and Xeric Palehumults (Wilson et al.2003). In Douglas County, Oregon, Kincaid's lupine appears to tolerate more shaded conditions, where it occurs at sites with canopy cover of 50 to 80% (Barnes 2004). In contrast to the open prairie habitats of the more northerly populations, in Douglas County, tree and shrub species dominate the sites, including Pseudotsuga menziesii (Douglas-fir), Quercus kelloggii (California black oak), Arbutus menziesii (Pacific madrone), Pinus ponderosa (ponderosa pine), Calocedrus decurrens (incense cedar), Arctostaphylos columbiana (hairy manzanita) and Toxicodendron diversilobum. In contrast to historical ecosystem composition, invasive non-native species are a significant component of Kincaid's lupine habitat today (USFWS 2010). Common invasives include: Arrhenatherum elatius, Brachypodium sylvaticum, Dactylis glomerata, Festuca arundinacea, Rubus armeniacus and Cytisus scoparius (Wilson et al.2003). In the absence of fire, some native species, such as Toxicodendron diversilobum and Pteridium aquilinum, invade prairies and compete with Lupinus sulphureus ssp. kincaidii" (USFWS, 2010).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Increasing (USFWS, 2019)

**Resiliency:**

Moderate

**Representation:**

Moderate

**Redundancy:**

Moderate

**Number of Populations:**

21 - 80 (NatureServe, 2015) "The rangewide survey for Lupinus sulphureus ssp. kincaidii did not census every known occurrence of the species, but concentrated on those populations with the potential to contribute to the recovery goals for the species. Sites were selected for survey based on a priority system considering population size, connectivity with other populations, landownership, co-occurrence with Fender's blue butterfly, and date of most recent monitoring efforts. Small, isolated populations, especially those on private lands, were not prioritized for surveys. If sites had been monitored within the last 5 years, these sites were not resurveyed, but instead the most recent data were utilized in the report. As a result, the rangewide survey and monitoring report provides data from 84 populations of L. sulphureus ssp. kincaidii across its range (Ottombrino-Haworth et al. 2017, pp. 16, 23, 72–582). These 84 populations are distributed across six recovery zones for L. sulphureus spp. kincaidii as follows: 27 in Salem West, 26 in Corvallis West, 14 in Eugene West, 8 in Douglas County, 5 in SW Washington, and 4 in Eugene East. There are no known extant populations in the Corvallis East and Salem East recovery zones." (USFWS, 2019)

**Population Size:**

"Overall foliar cover has increased from an estimated range of 14,070 to 19,118 square meters (m2) (1.4 to 1.9 hectares (ha); 3.5 to 4.7 acres (ac)) at the time of listing to approximately 22,785 m2 (2.3 ha; 5.6 ac) today (Table 1). A few recovery zones have seen increases in foliar cover of L. sulphureus ssp. kincaidii since the 2010 5-year review, and in some cases those increases are quite large; these increases are primarily in the Corvallis West and Salem West recovery zones, where recovery efforts, including augmentation and outplanting of L. sulphureus ssp. kincaidii, have been concentrated in recent years. These zones have benefitted from the availability of seed specific to these areas (the lack of genetically appropriate seed sources is a continuing problem in many of the recovery zones), as well as the incidental advantage gained by L. sulphureus spp. kincaidii from being cultivated as the host plant for the endangered Fender's blue butterfly (Icaricia icarioides fenderi), which also occurs in those recovery zones. In contrast the foliar cover of L. sulphureus ssp. kincaidii has declined in the Douglas County and Southwest Washington recovery zones, and has remained roughly the same in Eugene West. However, as this most recent survey was the first rangewide effort using a standardized approach, at this point in time it is difficult to make any truly definitive assessments regarding population trend (Ottombrino-Haworth et al. 2017, p. 45). " (USFWS 2019 p. 4)

**Population Narrative:**

Kincaid's lupine is found in dry upland prairies from Lewis County, Washington, in the north, south to the foothills of Douglas County, Oregon; however, most of the known and historical populations are found in the Willamette Valley (USFWS 2010). Historically, the species was documented from Vancouver Island, British Columbia, Canada (Dunn and Gillet 1966), but has not been located in that region since the 1920s (Kaye 2000). Before Euro-American settlement of the region, Kincaid's lupine was likely well distributed throughout the prairies of western Oregon and southwestern Washington; today, habitat fragmentation has resulted in existing populations that are widely separated by expanses of unsuitable habitat. Range-wide, Kincaid's lupine is known at about 164 sites, comprising about 608 acres of total coverage

(USFWS 2010). In Oregon, the ONHIC (2014) reported Kincaid's lupine over 100 sites. From these locations, at least 43 populations are considered potential populations that could contribute to recovery (USFWS, OFWO, 2014, unpublished data); and 25 of those populations have protection in place for Kincaid's lupine. Until the summer of 2004, Kincaid's lupine was known from just two extant populations in Washington, in the Boistfort Valley in Lewis County, more than 160 km (100 miles) from the nearest population in the Willamette Valley (USFWS 2010). Arnett (2014) reported a total of 5 populations across 9 sites of Kincaid's lupine in 2014. At two sites, Kincaid's lupine covered more than 1,000 m2 (1,196 square yards)each (Boistfort and Cowlitz Prairie); only one plant was observed at Drew's Prairie in 2013. Only one location (Lozier Preserve within the Cowlitz Prairie population) has protection for Kincaid's lupine; all other locations are privately owned with no formal protections. Monitoring the size of Kincaid's lupine populations is challenging because its pattern of vegetative growth renders it difficult to distinguish individuals (Wilson et al.2003). Instead of counting plants, most monitoring for this species relies on counting the number of leaves per unit area, partly because there is a strong correlation between Fender's blue butterfly egg numbers and lupine leaf density (Schultz 1998, Kaye and Thorpe 2006). Leaf counts are time consuming, however, and recent evaluations have shown that lupine cover estimates are highly correlated with leaf counts, much faster to perform, and useful for detecting population trends (Kaye and Benfield 2005) (USFWS, 2016).

***Threats and Stressors***

**Stressor:** Plant succession (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** A serious long-term threat to all Willamette Valley prairie species is the change in community structure due to plant succession. The vast majority of Willamette Valley prairies would likely be forested if left undisturbed. The natural transition of prairie to forest in the absence of disturbance such as fire will lead to the eventual loss of these prairie sites unless they are actively managed (Johannessen et al.1971; Kuykendall and Kaye 1993) (USFWS, 2016).

**Stressor:** Urbanization (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Urbanization is listed as a threat to this species. Land development and alteration in the prairies of western Oregon and southwestern Washington have been so extensive that the remaining populations are essentially relegated to small, isolated patches of habitat. Habitat loss is likely to continue as private lands are developed; at least 49 of 54 sites occupied by Lupinus sulphureus ssp. kincaidii in 2000 at the time of listing were on private lands and are at risk of being lost unless conservation actions are implemented (USFWS 2000) (USFWS, 2016).

**Stressor:** Agriculture (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Agriculture is listed as a threat to this species (USFWS, 2016).

**Stressor:** Silviculture (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Silviculture practices are listed as threats to this species (USFWS, 2016).

**Stressor:** Roadside maintenance (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat/loss of individuals
**Narrative:** Roadside maintenance is listed as a threat to this species (USFWS, 2016).

**Stressor:** Habitat fragmentation (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat/loss of genetic variability
**Narrative:** Habitat fragmentation and isolation of small populations may be causing inbreeding depression in Lupinus sulphureus ssp. kincaidii. The subspecies was likely wide-spread historically, frequently outcrossing throughout much of its range, until habitat destruction and fragmentation severely isolated the remaining populations (Liston et al.1995). There is some evidence of inbreeding depression, which may result in lower seed set (Severns 2003). Hybridization between Lupinus sulphureus ssp. kincaidii and Lupinus arbustus has been detected at Baskett Slough National Wildlife Refuge (Liston et al.1995)

***Recovery***

**Reclassification Criteria:**
Not applicable.

Recovery Priority Number: 6C

**Delisting Criteria:**
Delisting will be considered when all of the following conditions have been met: (USFWS, 2010)

1. Distribution and abundance. The distribution of populations should reflect the extent of the species' historical geographic distribution to the extent practicable. See Table IV-5 in the Recovery Plan for distribution and abundance goals for this species. (USFWS, 2010)

2. Population trend and evidence of reproduction. The number of individuals in the population (or area of foliar cover for Lupinus sulphureus ssp. kincaidii or Sidalcea nelsoniana) shall have been stable or increasing over a period of at least 15 years. Stable does not mean that the population size is static over time; over a period of 15 years, the number of individuals in the population may exhibit natural year-to-year variability, but the trend must not be declining. Populations must show evidence of reproduction by seed set or presence of seedlings. (USFWS, 2010)

3. Habitat quality and management. Sites supporting populations of listed plants considered in Criterion 1 above must meet these criteria: (a) Prairie quality. Sites supporting populations of

the listed plant species must be managed for high quality prairie habitat. High quality prairie habitat consists of a diversity of native, non-woody plant species, low frequency of aggressive non-native plant species and encroaching woody species, and essential habitat elements (e.g., nest sites and food plants) for native pollinators. See Appendix D of the Recovery Plan for suggested criteria for evaluating prairie quality and diversity. (b) Security of habitat. For each listed species, a substantial portion of the habitat for the populations should either be owned or managed by a government agency or private conservation organization that identifies maintenance of the species and the prairie ecosystem upon which it depends as the primary management objective for the site, or the site must be protected by a permanent or long-term conservation easement or covenant that commits present and future landowners to the conservation of the species. (c) Management, monitoring, and control of threats. Each population must be managed appropriately to ensure the maintenance or restoration of quality prairie habitat for each species and to control threats to the species. Use of herbicides, mowing, burning or livestock grazing in management should be implemented with appropriate methods and timing to avoid impacts to listed plant species. Management should be coordinated with adjacent landowners to minimize effects of pesticide drift, changes in hydrology, timber harvest, or road/utility maintenance. Species that may hybridize with Sidalcea nelsoniana or Lupinus sulphureus ssp. kincaidii should be managed as appropriate to avoid contact with these taxa. Other potential threats relating to scientific research, overcollection, vandalism, recreational impacts, or natural herbivory/parasitism should be successfully managed so as not to significantly impair recovery of the species. (USFWS, 2010)

4. Genetic material is stored in a facility approved by the Center for Plant Conservation. The stored genetic material in the form of seeds must represent the species' geographic distribution and genetic diversity through collections across the full range of the species. Collections from large populations are particularly important as reservoirs of genetic variability within the species. (USFWS, 2010)

5. Post-delisting monitoring plans and agreements to continue post-delisting monitoring are in place and ready for implementation at the time of delisting. Monitoring of populations following delisting will verify the ongoing recovery of the species, provide a basis for determining whether the species should be again placed under the protection of the Endangered Species Act, and provide a means of assessing the continuing effectiveness of management actions. (USFWS, 2010)

**Recovery Actions:**

- Details of the Recovery Actions are available in the 2010 Recovery Plan. Presented below is the introductory paragraph only. (USFWS, 2010)
- 1. Preserve, restore, and manage populations and habitat for the listed prairie species covered by this plan. The listed prairie species of western Oregon and southwestern Washington addressed by this plan are now found only in small, highly fragmented upland and wet prairie habitat remnants. The first step in the recovery of these species is to identify and protect the remaining populations with the greatest potential for restoration. The next step is to augment and, if necessary, reintroduce populations to restore connectivity between those that are currently isolated from one another to restore gene flow and create a population structure that provides for resiliency in a dynamic natural environment. Recovery for all of these species will depend upon the successful establishment of a network of protected populations in managed, suitable prairie habitats distributed across their

historical range. As a large portion of the remnant prairie habitats within the range of these species is in private ownership, recovery will to a large extent depend upon the successful development of partnerships with private landowners and support of their efforts to protect, restore and manage native prairie habitats in the region. (USFWS, 2010)

- 2. Coordinate recovery actions to benefit other listed species and nonlisted prairie species of conservation concern. The extensive loss of both wet and upland prairie habitats throughout the geographic region addressed by this draft recovery plan has resulted in the concurrent declines of many of the native plants and animals associated with these ecosystems. In this plan we have attempted to focus not only on the recovery of the listed prairie species, but to extend these recovery efforts to the ecosystems upon which they depend. The recommended actions for restoring and reconnecting prairie habitats in western Oregon and southwestern Washington are intended to extend benefits beyond the threatened or endangered species addressed in the plan to all of the native prairie species in these regions, including nonlisted prairie species that are recognized as in decline. Proactive efforts to restore prairie systems should contribute to the arrest or reversal of these declines, thereby preventing the need to list these species in the future. Particularly on sites where listed species co-occur with nonlisted species of conservation concern, landowners or managers should be made aware so as to tailor management actions to avoid inadvertent negative impacts on any such species. Coordination with other agencies, private landowners, or other interested parties will help ensure that the recovery actions outlined in this plan benefit the habitat and populations of other native prairie species. (USFWS, 2010)
- 3. Promote protection of listed species and prairie restoration on private lands. More than 90 percent of the land in the Willamette Valley is in private ownership. The restoration of prairie systems and their native plant and animal communities can therefore only be successful with the participation of private landowners. Without active management, populations of both listed and nonlisted species endemic to prairie habitats are almost certain to experience further declines. Working with private landowners and providing incentives to participate in the recovery effort for these species are critical elements of the recovery strategy. (USFWS, 2010)
- 4. Cultivate partnerships with both public and private agencies and organizations to promote the conservation of prairie ecosystems and listed prairie species. A diverse group of agencies and organizations are involved in recovery activities for the native prairies in western Oregon and southwestern Washington, including, but not limited to, the U.S. Fish and Wildlife Service, the Willamette Valley National Wildlife Refuge Complex, the U.S. Bureau of Land Management, U.S. Army Corps of Engineers, Confederated Tribes of Grand Ronde, Oregon Department of Transportation, City of Eugene, The Nature Conservancy, Oregon State University, Institute for Applied Ecology, Greenbelt Land Trust, McKenzie River Land Trust, Oregon Oak Communities Working Group, Washington Native Plant Society, Oregon Native Plant Society, Heritage Seedlings, and Berry Botanic Garden. Information regarding the recovery efforts for the prairie species should be shared with city and county planning, parks, and natural resource departments throughout the region covered by this recovery plan. City and county governments are the primary agencies that determine future land uses, and their participation is important for the recovery and restoration of the prairies and their associated listed species. Some local agencies are already making significant contributions toward prairie restoration; the West Eugene Wetlands are an excellent example of a significant conservation accomplishment achieved through a partnership of federal and local governments and private landowners/organizations. Plans,

data, and information pertinent to the recovery of the prairie species must be synthesized and shared effectively between all agencies, groups, and individuals to leverage collective conservation efforts and achieve recovery. (USFWS, 2010)

- 5. Revise and update recovery plan as needed. Based on the results of the recommended research and monitoring efforts and the evaluation of the relative success or failure of different management techniques, the recovery plan should be revised periodically as needed to reflect this increased knowledge and improve the efficacy of future recovery actions. The scientific validity of the recovery criteria should also be reviewed and refined, if necessary, as more accurate species-specific data become available to assist with refining recovery criteria. (USFWS, 2010)
- 6. Develop post-delisting monitoring plans for each listed species prior to delisting. To ensure the continuing recovery of the listed species and adequacy of management actions to maintain the species at viable levels into the foreseeable future, a post-delisting monitoring plan must be developed and ready for implementation prior to delisting of any threatened or endangered species. Such a monitoring plan must be designed to be continued for a minimum of 5 years following the delisting action. (USFWS, 2010)
- Recommendation for Future Action from 2017 5-Year Review: Site naming conventions remain inconsistent and do not reflect “populations” as functional units. We recommend that a standard procedure for aggregating sites into populations be developed so that the Service and our partners can describe the number of populations in a more meaningful way. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: We recommend that the taxonomy of this species be reviewed as multiple names are currently being used for the same species. Naming conventions and genetics issues surrounding Kincaid’s lupine remain unresolved. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: Management is imperative for prairie species to survive. Removal of woody species, control of invasive weeds and, in some cases, reintroduction of the once common native prairie matrix species may be necessary to maintain suitable habitat for Kincaid’s lupine. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: Recovery of Kincaid’s lupine will require voluntary conservation by private landowners. The majority of this species’ habitat is privately owned and, due to the regulatory limitations, the Service is not able to prevent privately owned populations from being destroyed. Working with private landowners, conservation organizations, and local governments to conserve and protect Kincaid’s lupine is essential to achieving recovery. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: We recommend that the issue of hybridization be addressed through genetic analysis or crossing studies of Kincaid’s lupine. Current publications are limited to one known instance of hybridization between Kincaid’s lupine and spur lupine at Baskett Slough National Wildlife Refuge (Liston et al. 1 995). In order to determine the role of hybridization and the risk it poses to this species, additional genetic information is needed for Kincaid’s lupine populations throughout its range. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: The gaps in data evident in this analysis also indicate the need for accurate and up-to-date population (foliar cover) estimates for a number of sites. We recommend a complete survey effort to assess the status of all presumed extant populations of Kincaid’s lupine throughout its range. (USFWS, 2017)

- All of the General Plant Conservation Measures (Section 3.13.1) apply for Kincaid’s lupine. Additional species-specific measures include: • Broadcast application of grass-specific herbicides may be used in on up to half of an area occupied by Kincaid’s lupine between February 15 and April 15. If using a weed wiper to apply a grass-specific herbicide for a particular listed plant during the growing season, the herbicide will be applied to the upper grass stems of targeted non-native plants, thus avoiding the shorter listed plant species. • All other broadcast applications will only occur after August 15 when Kincaid’s lupine is dormant. This plant is the primary host plant for Fender’s blue butterflies (another listed species); see additional PDC, restrictions, and conservation measures that apply for Fender’s blue butterfly (USFWS, 2016).

# SPECIES ACCOUNT: *Lupinus tidestromii* (Clover lupine)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A creeping, perennial herb, 1-3 dm tall, rhizomatous. Roots bright yellow. Narrow leaves with 3-5 leaflets, arranged in a fan shape. Stems and leaves with short hairs. Inflorescence stems are 4-8 cm long, and whorls of flowers are blue to lavender. Fruits are pods containing 5-8 seeds with blackish spots (Fish and Wildlife Service 1997). (NatureServe, 2015)

**Taxonomy**

Lupinus tidestromii (Tidestrom's lupine) was described by Edward Greene in 1895 from an 1893 collection made by Ivar Tidestrom on the Monterey Peninsula. In 1938, Alice Eastwood described a similar lupine from Point Reyes (L. layneae). Philip Munz (1958) later recognized the Point Reyes plants as a variety of L. tidestrornii, and called them L. tidestrornii var. layneae to separate them from the Monterey Peninsula plants. The recent treatment by Rhonda Riggins and Teresa Sholars suggested that L. tidestromii exists as a single, variable species (Riggins and Sholars 1993) (USFWS, 1998).

**Historical Range**

Historically, Tidestrom's lupine was found extensively along the California coast (Service 2009, p. 17). At the time of listing, there were three geographically separate areas containing the species along the California coastal dunes: the southernmost populations were found at various sites on the northern tip of the Monterey Peninsula, the central populations were found in PORE, and a northern population was found at Goat Rock Beach on the Sonoma Coast State Beach (SCSB). There were also another two possible populations within the northern area in Sonoma County, one at Dillon Beach and the other at Bodega Head (Service 2009, pp. 5–6). According to the final listing rule, plants collected from Bodega Head in 1925 may have been misidentified as Tidestrom's lupine because of the limited dune habitat in the general area and the vegetative condition of the specimen (Service 1992, p. 27850). The Bodega Head population was most likely extirpated before listing and surveys have not found any evidence of the plants (D. Smith, Marin Chapter, California Native Plant Society, in litt. 2008, as cited in Service 2009). The population at Dillon Beach in Marin County has also likely since been extirpated, but follow-up surveys are needed to confirm At the time of our 2009 5-year review, populations existed at the same three sites described at the time of listing (Service 2009, p. 5). The current species distribution of Tidestrom's lupine remains limited to these three geographic locations (USFWS, 2023).

**Current Range**

This species is found in clustered colonies at 3 sites along the California coastal dunes: the southern most populations are found at various sites from Carmel Beach to Asilomar State Beach (ASB) on the northern tip of the Monterey Peninsula, the central populations are found in their highest numbers and concentration on Point Reyes National Seashore around Abbott's lagoon, and the northern most populations are found at Goat Rock Beach on the Sonoma Coast State Beach (SCSB). (USFWS, 2009)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Flowering occurs from May through June (USFWS, 1998).

**Key Resources Needed for Breeding**

Adult: Bees/Insect/Wind (USFWS, 2023)

**Reproduction Narrative**

Adult: The life history of Lupinus tidestromii is largely unknown or the information is unpublished. Flowering occurs from May through June. L. tidestrornii is probably pollinated by bees (Moldenke 1976). Within populations, plants exhibit highly congested distributions. Most lupine seeds for all 5 coastal species can be found littered at the plant base. This and large seed size is consistent with localized limited dispersal, and limited long-distance dispersal by abiotic factors. Seeds of Lupinus are generally long lived and probably forms a persistent dormant seed bank. For seeds to germinate under natural conditions, the seed coat probably must be degraded (although not necessarily scarified, as by “sandblasting” by windblown sand). Lupinus tidestromii grows in stable to slightly mobile dunes, far from “sandblasting” habitats, so very slow microbial decomposition of seed coats of long-lived seeds is the more likely route to germination. This is not a species of accreting foredunes, and it has very low burial tolerance compared with larger dune plants of the pea family (e.g., Lupinus chamissonis and Lathyrus littoralis, which grow in highly mobile dunes). As a result, Lupinus tidestromii is confined to the vast stable deflation plains next to southern Abbotts Lagoon (USFWS, 1998). The life history of Tidestrom’s lupine is that of a short-lived perennial with a long-lived seed bank. Flowering occurs from May through June, and while this species has previously been classified as bee-pollinated, recent evidence supports other methods of pollination. During regular surveys of Tidestrom’s lupine populations at Point Reyes National Seashore (PORE), no bees or flying insects were observed near a Tidestrom’s lupine plant (Park Service 2022, p. 63). Ants have been observed on individuals in the PORE populations, but their role, if any, in pollination is unclear (Park Service 2022, p. 63). It is likely that the species is at least partly wind pollinated. Tidestrom’s lupine has also been documented to be highly capable of autonomous selfing, which has led to concerns of low genetic diversity, especially for small populations (Coppoletta 2005, pp. 18–19). Within populations, plants exhibit highly clumped distribution. Seeds are large and usually found littered around the plant base. Seeds are generally long lived and form a persistent dormant seed bank. They require some type of seed coat degradation, such as scarification in blowing sand, in order to germinate. Additionally, researchers at Washington University have documented mature Tidestrom’s lupine individuals that go through nonreproductive phases where no flowers or seeds are produced (USFWS, 2023).

**Habitat Type**

Adult: Coastal dunes (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (Inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (Inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species occurs on partially stabilized coastal dunes up to about 8 m high in the mild maritime climate of the central California coast and grows in coastal dune communities in association with Menzies' wallflower, sand gilia, beach sagewort, sand verbena, and mock heather (Fish and Wildlife Service 1997) (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the specific habitat needs of this species and the limited number of known locations.

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seeds are generally long lived and probably form a persistent dormant seed bank. Very slow microbial decomposition or long term erosion of the seed coat from sand scarification is the likely route for germination. This species has a very low burial tolerance and does not survive in accreting foredune formations. In addition, Dr. Knight believes that historically, large storms moved extensive areas of sand and brought deeply buried seeds to the surface where they could germinate (USFWS, 2009).

***Population Information and Trends***

**Number of Populations:**

12 (USFWS, 2023)

**Population Size:**

1 - 1000 individuals (NatureServe, 2015)

**Population Narrative:**

The nineteen extant populations consist of 433 individuals (Fish and Wildlife Service 1997). Known from nineteen extant populations (Fish and Wildlife Service 1997). (NatureServe, 2015) While there were no abundance estimates available at the time of listing, our 1998 Recovery Plan documented 19 extant occurrences containing a total of 433 individuals of Tidestrom’s lupine within the three disjunct geographic areas mentioned above (Service 1998, p. 49). At the time of our 2009 5-year review, there were 16 known extant occurrences: nine within PORE, six in the Monterey peninsula (four on private land, one on City of Pacific Grove/U.S. Coast Guard property, and one on California State Park property), and one in Sonoma County at SCSB (Service 2009, Appendix A). Between 2001 and 2005, PORE implemented a formal sampling scheme for Tidestrom’s lupine populations within their jurisdiction (Park Service 2022, p. 33).

Surveys for most populations have continued through 2021 (Park Service 2022, p. 33). Census estimates in our 2009 5-year review varied and were not provided for all occurrences; however, general trend information was provided for most. At the time of our 2009 5-year review, the populations at PORE were considered stable or declining, the population at SCSB was increasing, and the southernmost populations that had been surveyed were considered stable (Service 2009, p. 21). Since our 2009 5-year review, two populations in the Monterey Peninsula (Diversity Database # 5 and 11) that were historically present were not found during a 2021 survey (Parr 2021, pp. 6- 7). Two populations at PORE (Diversity Database # 16 and 24) have had significant habitat degradation and were not found during surveys in 2001 and 2014 respectively (Park Service 2022, pp. 38, 45-46). Follow-up surveys are needed to confirm the presence or absence of individuals at these occurrences. Currently, there are 12 known extant occurrences of Tidestrom's lupine (Table 1). The largest population occurs over 50 acres of open dune habitat southwest of Abbott's Lagoon in PORE (Diversity Database # 13) and in 2021 was estimated to contain over 150,000 individuals (Park Service 2022, p. 46). The population at Goat Rock Beach in Sonoma County (Diversity Database # 17) has not been surveyed since 2011; however, the population numbers are believed to be stable at around 1,000 individuals (USFWS, 2023)

***Threats and Stressors***

**Stressor:** Commercial and residential development (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Commercial and residential development along coastal communities continues to be the primary threat to habitat loss while trampling from hikers and livestock, and dune stabilization from invasive species are also contributing threats. These threats are considered to be current and foreseeable and this factor is still valid (USFWS, 2009).

**Stressor:** Predation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Disease is currently not considered a threat to the species; however, predation from small mammals is considered to be a new current and foreseeable threat factor in this analysis. It is recommended that this threat be addressed in the recovery delisting criteria number 3 (Habitat and populations will be free of invasive weeds) as invasive weeds provide shelter for the mammals who prey on the seeds of L. tidestromii (USFWS, 2009).

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The Endangered Species Act is the primary Federal law that provides protection for this species since its listing as endangered in 1992. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent its status under the Act. Therefore, we continue to believe other laws and regulations have limited ability to protect the species in absence of the Endangered Species Act (USFWS, 2009).

**Stressor:** Hybridization (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Extirpation
**Narrative:** Hybridization from L. chamissonis in the Monterey Peninsula is considered to be a new, current and foreseeable threat factor in this analysis. This new threat was not considered in the original listing for Lupinus tidestromii and should be considered a new recovery criterion for the Monterey Peninsula populations (USFWS, 2009).

**Stressor:** Invasive species (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Invasive species continue to be a very significant threat with habitat loss and hybridization. The threat of invasive species is currently being addressed and managed on protected sites; however, unsecured private lands have no protection against such threats (USFWS, 2009)

**Stressor:** Trampling (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of indivduals
**Narrative:** Trampling by both humans and livestock is considered a threat to this species (USFWS, 2009)

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Impacts to the species under predicted future climate change are unclear. Current forecasts of warming are expected to raise mean temperatures and sea levels along of coast of western North America (IPCC 2007). While it appears reasonable to assume that the species may be affected, we have no knowledge of more detailed climate change information or literature specifically for this species. We lack sufficient information to predict with certainty the extent of effect that climate change along the California coast will have on the species. We do not know when or how the changes may occur, the potential changes to the ecosystem, or the level of threat posed by seasonal changes, rising mean temperatures and rising sea levels on the habitat (USFWS, 2009).

***Recovery***

**Reclassification Criteria:**
Secure habitat for the species at current known occurrences (USFWS, 2009).

Management measures at the secured habitat locations (USFWS, 2009).

Monitoring of recovery for the secured habitat locations (USFWS, 2009).

Additional restored habitat (USFWS, 2009)

Recovery Priority Number: 5

**Delisting Criteria:**
15 years of monitoring (USFWS, 2009).

Reintroduced populations within historic range through natural means (USFWS, 2009).

Habitat and populations will be free of invasive weeds (USFWS, 2009).

Average of 10,000 individuals and progress toward the eradication of beach grass and iceplant at PORE (USFWS, 2009).

Private land occurrences protected, endowments secured and managed for recovery (USFWS, 2009).

Historic populations at Dillon Beach are restored and occupied (USFWS, 2009).

**Recovery Actions:**
- Reclassification criteria: Is the criterion valid and have they been addressed: Yes, the criterion is still valid and is being addressed. Habitat at PORE, ASB and SCSB has been secured for the species; however, these current protections are not permanent. Point Reyes National Seashore has designated the majority of areas that contain Lupinus tidestromii and other federally listed plants as “wilderness” providing protection under the National Parks Service regulations regarding wilderness. This encompasses approximately 33,000 acres and contains greater than 50 percent of the individuals as of the 2008 census (PORE LUTI report 2008). This percentage varies yearly depending on stochastic population fluctuations. Asilomar State Beach has designated 25 acres of dune habitat that contain L. tidestromii and other listed species as a Natural Dune Preserve under the California State Parks regulations and is protected by such definition. From a census conducted in 2000 the preserve contains approximately 40 percent of the genetically pure (unhybridized) individuals on ASB (Madison, pers. comm. 2009). A new comprehensive census for L. tidestromii is being conducted in 2009 and will include a determination of pure and hybrid populations. Although the “wilderness” and “Dune Preserve” designations provide a higher level of protection for the listed plant and its habitat, these protections can be changed or altered through a policy change or redesignation. Sonoma Coast State Beach currently has no extra protections for the areas that contain the listed plant other than those provided by the California State Parks regulations regarding protected species on State Parks lands. Pebble Beach and Spanish Bay golf courses have protected habitat with a mitigation agreement from the private land owner. The City of Carmel has designated the North Dune an Environmental Sensitive Habitat Area (ESHA). This designation does not provide any physical protections for the plant; however, it does provide limited protection against development unless this designation is removed or changed. Several private land occurrences on the Monterey Peninsula still remain unprotected. This private land protection on the Monterey Peninsula was a criterion in the Recovery Plan; however, this criterion for private land occurrences may not be feasible at this time with the threat of hybridization in the

Monterey Peninsula populations. Listing factors addressed: (Factor A) Present or Threatened Destruction, Modification, or Curtailment of Habitat or Range, (Factor E) Other Natural or Manmade Factors Affecting Its Continued Existence (USFWS, 2009). Delisting Criteria: Is the criterion valid and have they been addressed: Yes, the criterion is still valid and is being addressed; however, they are not complete. Monitoring efforts at PORE, SCSB and ASB are currently in their 8th year and are planned through 2015. Monitoring on public and private land occurrences are being performed through public city efforts; however no plan has been enacted or planned through a future date. Monitoring has also been done sporadically by California Native Plant Society (CNPS) for the Monterey Peninsula populations on private land when access has been granted. Listing factors addressed: (Factor A) Present or Threatened Destruction, Modification, or Curtailment of Habitat or Range, (Factor D) Inadequacy of Existing Regulatory Mechanisms, (Factor E) Other Natural or Manmade Factors Affecting Its Continued Existence (USFWS, 2009).

- Reclassification criteria: Is the criterion valid and have they been addressed: Yes, the criterion is still valid and is currently being addressed. Management measures are not permanent and could be altered or withdrawn depending on the status of the protections afforded the species. Management for recovery of the species has been implemented for the secured habitat sites at PORE, SCSB and ASB. Point Reyes National Seashore is under management through National Parks Service and SCSB and ASB are under management through California State Parks. Management plans have been written for all three locations through their respective agency with regards to recovery of the species and include reduction of effects from recreation use of the parks, invasive plants removal, and dune restoration efforts. Pebble Beach and Spanish Bay golf courses in Monterey County also have management plans for the continued conservation and protection of the plant on their respective properties. The City of Carmel North Dune is not considered a secured habitat, but the city has adopted several shoreline management plans and is currently in the process of creating a long term management plan for the North Dune population. Listing factors addressed: (Factor A) Present or Threatened Destruction, Modification, or Curtailment of Habitat or Range, (Factor D) Inadequacy of Existing Regulatory Mechanisms, (Factor E) Other Natural or Manmade Factors Affecting Its Continued Existence (USFWS, 2009). Delisting Criteria: Is the criterion valid and have they been addressed: The criterion is still valid and is being addressed; however, no new occurrences beyond the extent of the populations described from the time of listing and in this review have been identified. The populations at PORE and SCSB have increased in individual numbers since the time of listing, but naturally reintroduced populations on the Monterey Peninsula are generally hybrids and currently being removed. Listing factors addressed: (Factor A) Present or Threatened Destruction, Modification, or Curtailment of Habitat or Range, (Factor E) Other Natural or Manmade Factors Affecting Its Continued Existence (USFWS, 2009).
- Reclassification criteria: Is the criterion valid and have they been addressed: Yes, this criterion has been met and has been addressed. Monitoring for recovery has been implemented at the PORE, SCSB, and ASB secured habitat sites. Research efforts by Dr. Knight and her colleagues include extensive monitoring at PORE. Monitoring for SCSB is being conducted currently by State ecologist Brendan O’Neil. Point Reyes National Seashore monitoring includes individual population counts, observing for invasive plants, small mammal predation, habitat and plant (L. tidestromii) condition. Sonoma Coast State Beach populations are being monitored for rough population counts, effects from human recreational use, habitat and plant (L. tidestromii) condition. Asilomar State Beach is being monitored for rough population counts, effects from human recreational use, and

hybridization effects. Pebble Beach and Spanish Bay golf courses have private monitoring in accordance with the mitigation agreement which includes monitoring for rough population stands. The City of Carmel North Dune is not considered a secured habitat; however, the population has been monitored and the City's ESHA designation has general monitoring incorporated in the program. This monitoring effort is superficial; it is not guaranteed and is not specific for the listed plant. Listing factors addressed: (Factor A) Present or Threatened Destruction, Modification, or Curtailment of Habitat or Range, (Factor D) Inadequacy of Existing Regulatory Mechanisms, (Factor E) Other Natural or Manmade Factors Affecting Its Continued Existence (USFWS, 2009). Delisting Criteria: Is the criterion valid and have they been addressed: Yes, the criterion is still valid and is being addressed. At the time of listing there was no substantial dune restoration or invasive weed removal efforts. Currently, extensive dune restoration efforts are ongoing at PORE. Sonoma Coast State Beach and ASB are conducting minor dune restoration efforts and continual invasive weed removal. Although these efforts have been enacted, invasive weeds have not been completely removed at any of these locations and will most likely be a continual threat Listing factors addressed: (Factor A) Present or Threatened Destruction, Modification, or Curtailment of Habitat or Range, (Factor E) Other Natural or Manmade Factors Affecting Its Continued Existence (USFWS, 2009).

- Reclassification criteria: Is the criterion valid and have they been addressed: Yes, additional restored habitat is being created at the PORE and SCSB sites to extend the range of Lupinus tidestromii at those sites. Dune restoration efforts are being conducted on several sites along the California coast; however no restoration efforts specifically for L. tidestromii are being conducted. The seed life for L. tidestromii is considerably long, so these other dune restoration efforts may provide new occurrences for L. tidestromii provided there is a viable seed bank. Listing factors addressed: (Factor A) Present or Threatened Destruction, Modification, or Curtailment of Habitat or Range, (Factor D) Inadequacy of Existing Regulatory Mechanisms, (Factor E) Other Natural or Manmade Factors Affecting Its Continued Existence (USFWS, 2009). Delisting Criteria: Is the criterion valid and have they been addressed: Yes, the criterion is still valid and is being addressed. Efforts are currently being conducted and progress towards both criterions has shown positive trends toward meeting recovery. The largest population, located near Abbott's Lagoon is estimated to have over 100,000 individuals, and this number has persisted since 2001. The dunes near Abbott's Lagoon have received a great deal of restoration attention from 2002-2006 (Ammophila arenaria removal). The second largest population, located on the dunes west of the Mendoza Ranch, was estimated at 32,528 individuals in 2003 whereas a 2007 census by Dr. Knight et al. estimated 11,668 individuals. The third largest population at PORE, located on the dunes near the Davis residence declined from 982 individuals in 2003 to 159 individuals in 2007, likely due to encroachment of iceplant. Removal of beach grass and iceplant surrounding this population was conducted in July 2008 through the mechanical removal of the beach grass (digging 3m into the ground and overturning this invasive grass) and hand removal of the iceplant. Listing factors addressed: (Factor A) Present or Threatened Destruction, Modification, or Curtailment of Habitat or Range, (Factor E) Other Natural or Manmade Factors Affecting Its Continued Existence (USFWS, 2009).
- Delisting Criteria: Is the criterion valid and have they been addressed: Yes, securing private lands for recovery is still a valid criterion; however, with the current information regarding the hybridization and until the threat of hybridization can be addressed this criterion may become obsolete for the Monterey Peninsula populations unless genetically pure individuals can be reintroduced. No private land occurrences other than Pebble Beach and Spanish Bay

golf courses are currently or under process for endowment or managed for recovery at the time of this review. Listing factors addressed: (Factor A) Present or Threatened Destruction, Modification, or Curtailment of Habitat or Range, (Factor D) Inadequacy of Existing Regulatory Mechanisms, (Factor E) Other Natural or Manmade Factors Affecting Its Continued Existence (USFWS, 2009).

- Is the criterion valid and have they been addressed: Yes, the criterion is still valid; however, currently no efforts are being made at Dillon Beach for the reintroduction of Lupinus tidestromii. This criterion would be considered vital to the expansion of the species. Dillon Beach provides highly suitable habitat, but is under threat of development and high human usage. More controlled conservation measures would need to be enacted before reintroduction could take place naturally or through manned efforts. Listing factors addressed: (Factor A) Present or Threatened Destruction, Modification, or Delisting Criteria: Curtailment of Habitat or Range, (Factor D) Inadequacy of Existing Regulatory Mechanisms, (Factor E) Other Natural or Manmade Factors Affecting Its Continued Existence (USFWS, 2009).
- Continue Dune restoration and eradication of invasive plants at PORE and SCSB (USFWS, 2009).
- Continue monitoring at PORE, SCSB and ASB. Establish structured monitoring plan for Monterey Peninsula populations on private lands (USFWS, 2009).
- Secure further conservation easements and/or acquire lands for protection of Monterey Peninsula populations (USFWS, 2009).
- Continue research of hybridization and seed predation threats (USFWS, 2009).
- Conduct accurate census of the Monterey private land occurrences (USFWS, 2009).
- Examine and implement dune restoration efforts for repopulation at Dillon Beach (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of Tidestrom’s lupine. Some of these recommendations have already been discussed in previous recovery documents (Service 1998; Service 2009) and remain valid. A list of recommended future actions for each population is included in Appendix C. 1. Habitat management and restoration. Habitat loss and degradation as a result of development and invasive plant species continue to be the primary threat to Tidestrom’s lupine. To aid in the recovery of this species, additional restored habitat should be created through the removal of invasive plant species. Two secured locations, Goat Rock Beach and PORE, have particularly high potential for the creation of additional restored habitat for Tidestrom’s lupine. PORE has conducted several large-scale dune restoration projects that involved the removal of European beachgrass, iceplant, and other invasive plant species (Appendix B; Park Service 2022 pp. 8–15). Continued removal of invasives within past restoration areas should help to keep Tidestrom’s lupine established in those areas and reduce deer mice seed predation pressure (Dangremond et al. 2010, pp. 2265– 2266; Pardini et al. 2018 p. 1193). Future restoration projects that involve the creation of newly suitable habitat and reintroductions into this habitat could increase connectivity and genetic health. The Tidestrom’s lupine population at Goat Rock Beach (Diversity Database #17) responded favorably to past restoration efforts and may be a good fit for future management actions. After a restoration project at Goat Rock Beach in 2002 that involved the removal of invasive plant species, the Tidestrom’s lupine population at this location increased from approximately 400 individuals to over 1,000 individuals as a result of a natural expansion into the newly bare sand dunes (O'Neil pers. comm. 2021). State Parks removes weeds within this population annually to prevent the invasion of non-native species and because of these efforts the Goat Rock Beach population has remained stable for almost ten years (O'Neil pers. comm. 2021). Habitat restoration in other parts of SCSB, in conjunction with reintroductions into the newly created suitable habitat, would increase the distribution and redundancy of this species as currently the single population at Goat Rock Beach is the only population north of PORE. If possible, non-natives should be mechanically removed from an area or sprayed with herbicide and then mowed or scraped to accelerate decomposition. Herbicide treatments alone can result in standing dead biomass that lasts for years before decomposing, impeding colonization of native species during that time (Parsons pers. comm. 2021). Additionally, as the Monterey Peninsula populations have been shown to be genetically distinct from those at PORE, occurrences on private lands should be protected and occurrences on public lands should be managed through the continued removal of invasives. 2. Fencing of dune habitat and/or use of boardwalks where Tidestrom's lupine occur. For populations where trampling by humans and/or off-leash dogs is of concern, fencing should be installed to demarcate sensitive dune habitat. Signs identifying environmental sensitive areas may also help keep visitors from entering the dune habitat. In highly trafficked areas in the Monterey Peninsula, cable guideline fencing has proven ineffective in preventing people and off-leash dogs from entering the dune habitat and trampling Tidestrom's lupine (Dorrell-Canepa pers. comm. 2021). Instead, the installation of wood fencing is recommended to separate and protect sensitive dune habitat in places like North Dunes in Carmel-by-the-Sea (Diversity Database # 8) where there is considerable foot traffic. Another option would be establishing boardwalks such as those at ASB (Diversity Database #4), which have appeared to be effective in keeping the public from trampling Tidestrom's lupine (Gray pers. comm. 2021). 3. Reintroductions. Reintroductions into secured habitat should be conducted to increase the redundancy of Tidestrom's lupine. Currently there is only a single population in Sonoma County at Goat Rock Beach, thus putting the northern region at risk of extirpation from a catastrophic event or impacts from climate change. Reintroductions into suitable habitat within Sonoma Coast State Beach is recommended. Additionally, reintroductions into suitable habitat within the Monterey Peninsula could help increase population numbers and expand population ranges to increase resiliency. For example, ASB had relatively low population numbers during the most recent survey in 2021 and could benefit from reintroductions in unoccupied areas with suitable habitat. Reintroductions should also be performed in conjunction with habitat restoration if natural recolonization fails to occur. 4. Caging individual Tidestrom's lupine plants. In areas with significant deer predation, caging of individual plants during flowering and fruiting season is recommended. Asilomar State Beach has had success with chicken-wire cages installed once the plants start flowering in the winter and early spring and removed in the summer once the plants go to seed (ASB 2017, pp. 1–2). Inverted gopher baskets have also been used at North Dunes in Carmel-by-the-Sea to protect newly transplanted seedlings from herbivory (Dorrell-Canepa 2020, p. 8). In populations with known herbivory by grazers, cages should be installed prior to the reproductive season on as many Tidestrom's lupine individuals as possible to increase the chances of recruitment. 5. Controlling for hybridization with Chamisso bush lupine. Hybridization of Tidestrom's lupine with Chamisso bush lupine is a primary threat to the Monterey peninsula populations. When Chamisso bush lupine is found at ASB and North Dunes in Carmelby-the-Sea the plants are removed. Hybrids, which can be identified by their size and growth patterns, are also removed (ASB 2018, pp. 2–3; Dorrell-Canepa 2020, Appendix E). Removal of true Chamisso bush lupine and known hybrids should continue to occur. 6. Research. Additional research on Tidestrom's lupine ecology and threats would help land managers understand which factors are affecting population viability. Specifically, research into genetic diversity between and among populations may help explain why some populations at PORE have continued to decline despite active management and if seed translocations would be beneficial for declining populations. An investigation into how the species is pollinated would also help identify what factors may be affecting recruitment. Research into the dominant mating strategy of this species (outcrossing vs. selfing) would be helpful in identifying the level of inbreeding occurring. Additionally, research into potential fitness effects from rust fungus and ant predation will be necessary to determine if those threats warrant future attention. 7. Monitoring. Annual monitoring of all populations is recommended to track population trends and determine how populations respond to management efforts. As this species is a short-lived perennial, population fluctuations are expected, and regular population monitoring will help managers identify overall population trends. At a minimum, monitoring should consist of annual population counts or estimates, depending on the size of the population. More detailed information concerning whether an individual is a seedling, non-reproductive plant, or reproductive plant would allow more precise population tracking and is recommended when possible. Additional observations on plant health, signs of predation, disease, and hybridization should be documented when possible (USFWS, 2023).

# SPECIES ACCOUNT: *Lysimachia asperulaefolia* (Rough-leaved loosestrife)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 7/13/1987; Southeast Region (R4)

**Physical Description**

A perennial rhizomatous herb, with erect stems 30 to 60 centimeters (cm) tall. Leaves are sessile in whorls of 3 to 4, are broadest at the base (0.8 to 2 cm wide), and have three prominent veins. The upper surface is deep yellow-green or blue-green and lustrous; the leaf margins are entire and slightly revolute (Figure 1). The yellow bisexual flowers are borne in a loose, cylindrical, terminal raceme, 3 to 10 cm long. The corolla is 1.5 cm across. There are usually five petals that have ragged margins near the apex and that have dots or streaks. The anthers are yellow-orange, and the style tapers to the simple stigma. The fruit is a capsule. Stipitate glands are usually present on most parts of the plant. Flowering is from late May to early June. Seeds are formed by August, but capsules do not dehisce until October. Although the plants are dormant in the winter, they are easy to find in the fall because of the distinctive leaf pattern and the reddish color of the leaves. (USFWS, 1995)

**Taxonomy**

Lysimachia asperulaefolia was described by Jean Louis Marie Poiret in 1814. Since listing as endangered in 1987, there have been no changes to the nomenclature of the species, however some references now spell the specific epithet as “asperulifolia” an orthographic variant of “asperulaefolia.” In addition, in the listing documents and the Recovery Plan, the common name is referred to as Rough-leaved Loosestrife; however, some references use the common name Rough-leaf Loosestrife. Ironically, the leaves are actually smooth in texture. The genus Lysimachia is now considered to be part of the Myrsinaceae family and not the Primulaceae family (Weakley 2012). (USFWS, 2014)

**Historical Range**

Southern coastal plain and sandhills of North Carolina and the sandhills of South Carolina. (USFWS, 1995)

**Current Range**

Southern coastal plain and sandhills of North Carolina and the sandhills of South Carolina. Twelve counties in North Carolina; one county in South Carolina. (USFWS, 2014)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Flowering is from late May to early June (USFWS, 1995).

**Reproduction Narrative**

Adult: The first spring shoots of L. asperulaefolia appear in late March or early April. Flowering begins in late May and extends through mid to late June. L. asperulaefolia is an obligate out-crossing species, pollinated by solitary bees: most of the pollinators are in the genus Dialictus. Pollinators were found to be scarce and inefficient, perhaps contributing to low natural fruit and seed set. Fruit and seed set were much higher when flowers were artificially pollinated (Frantz 1984). Another possible explanation for low fruit and seed set is that populations are highly clonal, with several shoots arising from one rhizome. Since self-fertilization does not occur, pollinator activity among ramets would not result in seed set. Fruits are visible within 3 weeks of fertilization, but capsules do not dehisce until October. An average of 3.2 capsules are produced by flowering stems, with an average of less than two seeds per capsule. In one germination trial, 85 percent of the seeds germinated (Frantz 1984). While fruit and seed set are low, this is not unusual for a perennial species that apparently has a life strategy based largely on rhizomatous growth and therefore does not depend upon sexual reproduction and seedlings for short-term survival (USFWS, 1995). Flowering is from late May to early June. Seeds are formed by August, but capsules do not dehisce until October (USFWS, 1995).

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Rough-leaf loosestrife occurs most often in ecotones between longleaf pine uplands and pond pine pocosins in moist, sandy or peaty soils with low vegetation that allows for abundant sunlight to the herb layer (USFWS 1993). Fire is primarily responsible for maintaining low vegetation in these ecotones which have been documented to occur between the following habitat types: longleaf pine savanna and pocosin; longleaf pine flatwood and pocosin; longleaf pine savanna and mixed herb; longleaf pine-pond pine and evergreen shrub; longleaf pine/wiregrass savanna and Carolina bay pocosin; Streamhead Pocosin and Pine/Scrub Oak Sandhill; and Sandhill Seep and Pine/Scrub Oak Sandhill (NCNHP 1993). This species often spreads from the ecotone into the open edges of the bordering habitats, for example into longleaf pine savannas and low shrub communities of Carolina bays. Other habitats and community types in which it has been found include: Low Pocosin, High Pocosin, Wet Pine Flatwoods, Pine Savanna, Streamhead Pocosin, and Sandhill Seep (Schafale and Weakley 1990), as well as creek flood basins, pond and lake margins, boggy seeps and meadows, boggy pools in shrub pocosins, and disturbed areas such as roadside depressions, powerline rights-of-way, firebreaks, and trails. In the NC Sandhills, Lysimachia asperulifolia prefers to be in lower parts of the ecotone, well within the shrub zone, even when such ecotones are well-burned. On Fort Bragg, a sizeable occurrence was found in a shrub ecotone/pocosin that had burned within four months of its discovery; most shrubs there had been 2 meters or more tall prior to burning. Low Pocosins occur in areas with deep peat overlaying wet sands and in Carolina bays. They are nutrient-poor, seasonally saturated, and dominated by a dense shrub layer, kept small by low nutrients and severe fires. L. asperulifolia occupies openings in the dense shrub layer (USFWS 1993). Rough-leaf loosestrife is also found in the ecotones between Wet Pine Flatwoods or Pine Savannas and High Pocosins where the water table is near the surface during winter and early spring. If burned, these ecotones remain open with characteristic grasses, herbs, and low shrubs (USFWS 1993) (NatureServe, 2015). Clumped spatial arrangement of the population, high ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species.

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: No information available.

***Population Information and Trends***

**Population Trends:**

See narrative.

**Number of Populations:**

53; 52 in NC and 1 in SC (USFWS, 2021)

**Population Narrative:**

When the recovery plan was prepared in 1995, Lysimachia asperulaefolia was known from the southeastern coastal plain of NC and the sandhills of NC and SC. Since the 2014 5-Year Review, 12 new sub-populations (sub-EOs) were discovered in NC. Currently, state natural heritage programs recognize 53 extant populations or principal EOs (52 in NC and one in SC). Since the 2014 5-Year Review, natural heritage program records indicate that the ranks of three populations have improved while six populations declined, indicating that those populations have fewer stems than previously observed, or possibly even disappeared. (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Development (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Residential and commercial development are listed as threats to this species (USFWS, 2014).

**Stressor:** Road construction (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Road construction is listed as a threat to this species (USFWS, 2014).

**Stressor:** Silviculture (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Silviculture (pine plantations) are listed as a threat to this species (USFWS, 2014).

**Stressor:** Wetland draining/filling (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Wetland draining and/or filling are listed as threats to this species (USFWS, 2014).

**Stressor:** Herbicide use (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Herbicide use, especially on road shoulders and powerline rights of way has potential to quickly cause negative impacts to this rhizomatous perennial (USFWS, 2014).

**Stressor:** Herbivory (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Herbivory (likely by deer) is listed as a threat to this species (USFWS, 2014).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** At the time of federal listing, this species was also listed as state endangered by the State of North Carolina under the Plant Protection and Conservation Act of 1979 (North Carolina Code Article 19B, § 106-202.12; NC Act). The NC Act provides limited protection from unauthorized collection and trade of plants listed under that statute. However, the statute does not protect the species or its habitat from destruction in conjunction with development projects or otherwise legal activities (Robinson and Finnegan 2014). The NC Act authorizes the NC Plant Conservation Program to establish nature preserves for protected species and their habitat, but that agency has not yet created any nature preserves for this species (USFWS, 2014).

**Stressor:** Fire suppression (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Fire suppression was also identified as a serious threat. The lack of fire in the habitat where this species occurs allows woody species to grow and compete for sunlight, eventually shading out this low growing species. The exclusion of fire also affects nutrient cycling and insect populations (USFWS, 2014).

**Stressor:** Small population size (USFWS, 2014)

**Exposure:**
**Response:**
**Consequence:** Loss of populations
**Narrative:** Populations that are small in size and number of individual plants are vulnerable to stochastic events (USFWS, 2014).

***Recovery***

**Reclassification Criteria:**
1. Management plans have been prepared and are being implemented for all publicly owned population centers and those owned by The Nature Conservancy (USFWS, 1995)

2. Populations at these centers have been monitored for at least 5 years and are determined to be stable. (USFWS, 1995)

Recovery Priority Number: 8

**Delisting Criteria:**
1. When the reclassification criteria are met and a binding management agreement for each population center is in place (USFWS, 1998)

**Recovery Actions:**
- 1. Protect significant sites and adjacent habitat. - Map all sites and mark sites in the field (except where there is ready public access and where signs would increase the threat of collecting): include in the marked area the adjacent habitat and buffer. - Map and search appropriate habitat for new sites within each population center. - Prepare a management plan for each population center. (USFWS, 1995)
- 2. Conduct research to more fully understand habitat conditions, fire frequency effects, seedling recruitment, genetic diversity among and within sites and population centers , population dynamics, and reestablishment techniques. (USFWS, 1995)
- 3. Enforce laws protecting the species and its habitat. Provisions of the Endangered Species Act of 1973, as amended, will be enforced. North Carolina regulations prohibit taking a protected species from private property without the landowner’s written permission and a State permit. However. at this time the collection of L. asperulaefolia plants ~ not the major threat to the species’ continued survival. In meeting their responsibilities under the Endangered Species Act, the military services involved have developed guidance directing certain actions with respect to listed species occurring on their bases. Implementation of these policies and directives should continue. (USFWS, 1995)
- 4. Reintroduce the species into historic habitat. In cooperation with the North Carolina Botanical Garden and the Center for Plant Conservation, plants should be propagated and a program of reintroduction should be initiated. Historic sites, such as the proposed Minnesott Ridge-Prescott Ridge Natural Area in Pamlico County, would be ideal sites for this program. Plants introduced into such an area should derive from the same population center, when possible, or from a nearby population source, unless genetic analyses indicate that inbreeding is a problem within populations. The genetic analysis will assist in determining appropriate reintroduction source material. (USFWS, 1995)
- 5. Negotiate binding management agreements. In order to ensure the survival of this species and proceed with delisting. permanent binding management agreements should be

negotiated between the Service and landowners. The North Carolina Plant Conservation Program or North Carolina Natural Heritage Program should assist the Service in monitoring these agreements. (USFWS, 1995)

- 6. Conduct public information and education activities. News releases concerning the status and significance of the species and recovery efforts should be prepared and distributed to newspapers on the coastal plain and in the sandhills area. Cooperation with military bases should be sought: this would be a positive public relations opportunity for them. State agencies managing lands where L. asperulaefolia occurs should prepare/distribute brochures and offer educational hikes to sites where this would be appropriate. (USFWS, 1995)
- 7. Annually review the recovery efforts. The Service, North Carolina Plant Conservation Program. North Carolina Natural Heritage Program, and South Carolina Heritage Trust should meet annually with the managers of L. asperulaefolia sites to assess progress toward the recovery goals, review new information, assign any new sites to a new or existing population center, evaluate and coordinate programs planned for the coming year, and, if necessary, redirect monitoring or management actions. (USFWS, 1995)
- Revisit known populations that have not been visited in the past three years, especially those populations that have been ranked as F (Failed to Find) or H (Historic) in the NCNHP database; monitor the condition of the habitat at each site including threats; discuss conservation options with landowners where appropriate; report the results of these site visits to the appropriate Heritage Program (USFWS, 2014).
- Search for additional populations in appropriate habitat (USFWS, 2014).
- Prioritize known sites for protection and identify recovery populations (USFWS, 2014).
- Protect additional populations (USFWS, 2014).
- Identify those populations that would contribute the most toward recovery (self-sustaining, protected, etc.) as recovery populations (USFWS, 2014).
- Determine which sites have management plans and how they are being implemented (USFWS, 2014).
- Develop and implement management plans for all remaining protected populations (USFWS, 2014).
- Determine the management techniques for sustaining populations, such as fire frequency and seasonality (USFWS, 2014).
- Update monitoring protocols and remind land managers about their commitment to monitoring this species on their property, continue to analyze monitoring data using PVA or other accepted methods (USFWS, 2014).
- Complete a population genetic analysis as suggested by Edwards (2007) (USFWS, 2014).
- Organize a meeting of land managers, researchers and other interested parties to discuss the long-term recovery of this species (USFWS, 2014).
- Work with NC Botanical Garden to conserve germplasm and further develop propagation and transplantation protocols (USFWS, 2014).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The recommended actions listed in the 2014 5-Year Review remain important to the conservation and recovery of Lysimachia asperulaefolia and efforts to accomplish those actions should continue. Since the 2014 5-Year Review, progress has been made on several of the past recommendations for future actions. • Surveys have resulted in the discovery of 12 new occurrences or sub-populations that are part of two parent populations of Lysimachia asperulaefolia. (No new isolated populations have been found.) • A management plan for Lysimachia asperulaefolia and Echinacea laevigata populations at Fort Jackson Army Base in SC was completed in 2015. • Management plans for Holly Shelter Game Land and Sandhills Game Land are available online. The plan for Holly Shelter would benefit from more information about Lysimachia asperulaefolia. The Service is planning to work with the NC Wildlife Resources Commission and NCNHP to incorporate more specific information about rare plant management in future versions of these plans. • The NCPCP received a Recovery Challenge Grant which will fund preparation of a management plan for their Boiling Springs Lakes / Hog Branch Ponds Preserves. • The Service has contacted land managers at Bladen Lakes State Forest and offered to help prepare a management plan for their populations of Lysimachia asperulaefolia. The Service has encouraged land managers to develop and implement management plans by providing a template management plan. • Jessica Roach at UNCW is currently conducting research on the genetic structure of this species. • Elsa Youngsteadt and Clyde Sorenson at NCSU are conducting research on the pollination ecology of Lysimachia asperulaefolia populations at Ft. Bragg Army Base in NC. • The NC Botanical Garden completed out-plantings at Fort Bragg Army Base from 2012 to 2014. • The Service updated and simplified monitoring protocols for land managers that participated in the 2000-2012 long-term monitoring project summarized in Robinson and Buchanan (2014). The Service recommends initiating or continuing the following efforts that will contribute to the recovery of the species: • Revisit known populations that have not been visited in the past five years, especially those populations that have been ranked as F (Failed to Find) or H (Historic) in the heritage program database; monitor the condition of the habitat at each site including threats; discuss conservation options with landowners where appropriate; and report the results of these site visits to the appropriate heritage program. • Search for additional populations in appropriate habitat. • Prioritize a list of populations that will contribute the most toward recovery (selfsustaining, protected, etc.) as recovery populations. • Work with land managers at Bladen Lakes State Forest, Boiling Springs Lakes, Holly Shelter Game Lands and Sandhills Game Lands to improve Lysimachia asperulaefolia populations. • Remind land managers about commitments to manage and monitor for this species. • Organize a meeting of land managers, researchers, and other interested parties to discuss the recovery of this species. • Work with the NC Botanical Garden to conserve germplasm and further develop propagation and best practices for transplanting and augmenting populations. • Develop a plan to augment populations to increase genetic variation and seed production. (USFWS, 2021)

# SPECIES ACCOUNT: *Macbridea alba* (White birds-in-a-nest)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 6/8/1992; Southeast Region (R4)

**Physical Description**

This perennial herb usually has one stem (often clothed with long, multicellular hairs) which may be branched. The leaves are oblanceolate or spatulate, mostly in 6-8 pairs. White flowers are borne from May through July in compressed thyrses (dense flower cluster in which the main axis is racemose and the branches are cymose). The small clusters of white buds and flowers look like eggs and little bird heads in a nest. Each flower is bisexual, has a green calyx and a white two lipped-corolla about 2.5-3 cm long; the pistil and filaments are white, and the anthers purple basally. Each flower can produce four nutlets (small fruit similar to a nut), which are about 2-2.5 mm long, narrowly obovate in outline, and light brown (Godfrey and Wooten 1981, Godt et al. 2004). (USFWS, 2009)

**Taxonomy**

The genus Macbridea, which belongs to the mint f~mily (Lamiaceae or Labiatae), consists of only two species (Kral 1983, Godfrey and Wooten 1981). Macbridea alba Chapman was first collected about 1860 by A. W. Chapman and a friend named Gausman (Roger Sanders, then a graduate student at University of Texas, currently at Bot. Res. Inst. of Texas, in litt. 1977), and it was named by Chapman (1860). (USFWS, 1994).

**Historical Range**

See current range/distribution.

**Current Range**

Endemic to the Florida panhandle and is still restricted to the same four counties: Bay, Gulf, Franklin, and Liberty. (USFWS, 2009)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

<u>Adult:</u> Sexual and vegetative (USFWS, 2009)

**Reproduction Narrative**

<u>Adult:</u> Dr. Walker surmised that Macbridea may require regular recruitment from seed and is a poor competitor with other plants, requiring bare ground to germinate and grow (USFWS, 1994). Macbridea alba is a hermaphroditic species capable of both sexual and vegetative (via rhizomes) reproduction (Godt et al. 2004). This species is capable of both 9 outcrossing and selfing. However, selfed seeds exhibit inbreeding depression (Godt et al. 2004). Pitts-Singer et al. (2002) studied the pollinator-plant relationship at two sites located on the ANF. Twenty

inflorescences were observed for 34 hours over five days. The authors observed 70 visits of nine insect and spider species. Since only bumble bees (Bombus spp.) were large enough to make contact with the reproductive structures of the flowers, the authors concluded that bumble bees are the potential pollinators of M. alba. Thus, bumble bees are probably critical to the long-term persistence of M. alba because they provide a mechanism for ensuring seed set, and facilitate gene flow between plants and plant populations (Negrón-Ortiz, pers. interpretation) (USFWS, 2009).

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits grassy vegetation on poorly drained, infertile sandy peat soils of the Florida Gulf coastal lowlands near the mouth of the Apalachicola River. Also in seepage bogs and savannas and, sparingly, on drier sites with longleaf pine and runner oaks. (Based on Ward 1979.) (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species.

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: The authors observed in the field that seeds germinated while in the infructescences (the fruiting stage of the inflorescence), suggesting that the matured ovules lack dormancy, in addition to the possibility of viviparous seedlings. About 87% of dry-stored seeds were viable (or germinable) for six months after dispersal, but viability of dry-stored and of buried seeds was insignificant after one year. They concluded that a persistent seed bank is not present, based on the lack of emergence of seedlings from soil that was field collected prior to seed dispersal. This lack of seed dormancy and seed bank means that if the established individuals are eliminated, a population cannot re-establish itself (USFWS, 2009).

***Population Information and Trends***

**Population Trends:**

Decreasing (NatureServe, 2015)

**Number of Populations:**

21 - 80 (NatureServe, 2015)

**Population Size:**

1000 - 10,000 individuals (NatureServe, 2015)

**Population Narrative:**

Plant tolerates some disturbance due to forestry operations although actual effects and population numbers unknown. Substantial areas within the small range of this plant have were converted to short rotation pine plantations during the 20th century. Decline of 30-50% Many occurrences have shown fluctuating numbers from year to year (EO data in the NatureServe central database as of April 2012). 33 occurrences verified since 1989, but some of these are sub-occurrences which are clustered into larger occurrences (EO data in the NatureServe central database as of April 2012) (NatureServe, 2015). Moderate redundancy, resiliency and representation are inferred based on the number of known populations and individuals as well as the relatively large geographic distribution of the species.

***Threats and Stressors***

**Stressor:** Logging (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The timber industry in North Florida became well established in the 1850s (FNAI 2005). It started in Franklin County in the 1870s and continued to be a prominent industry until the mid-1990s (Howell and Hartsell 1995). The St. Joe Paper Company had close to a million acres in timber in the eastern region of the panhandle. The Company also owned a paper mill in Port St. Joe until it was sold and shut down in 1999; therefore, this industry is no longer considered a primary threat (USFWS, 2009).

**Stressor:** Urban development (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Urban development continues to threaten white birds-in-a-nest. The St. Joe Company owns extensive areas of land in Northwest Florida, and focuses on commercial and residential development along roadways and near or within business districts in the region. Urbanized land in Florida, statewide, is projected to double by 2060 along with doubling of the population to 36 million (http://www.1000friendsofflorida.org/PUBS/2060/01-Northwest-Florida). According to the study, much of the new development will be focused along roadways. Many M. alba's locations are found along US 98 and other state roads. Construction activity may directly kill individual plants or convert habitat to unsuitable space; widening may convert native habitat to managed road side; and culvert modification may change drainage patterns, which may change seasonal hydrology. Therefore, road widening and new roads continue to pose a threat to the species from habitat loss (USFWS, 2009).

**Stressor:** Fire suppression (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Suppression of fire during the dormant season continues to threaten the pineland and savanna's flora, as fire is an important factor in the maintenance of flatwoods (Abrahamson and Hartnett 1990). Fire influences community structure and composition (Abrahamson and Hartnett 1990), and with insufficient frequency in longleaf pine communities, a woody midstory quickly develops (Glitzenstein et al. 1995), negatively affecting the understory diversity. Thus, fire

suppression continues to be a threat to M. alba. Lack of fire, and subsequent growth of shrubs (particularly encroachment of Cyrilla racemiflora L., commonly known as swamp titi) and saplings in the understory, inhibits this species emergence (Negrón-Ortiz, 2008, pers. observ.; FNAI 2008). Declining fire frequency reduces M. alba abundance in areas where it was previously observed in great quantities (FNAI 2008). In recently burned areas, however, plant emergence is prolific within two years of the fire event (F. Winters, 2008, pers. comm.). The ANF utilizes a 3-5 yr interval burn rotation. Several studies have shown that frequent prescribed fire regimes are important for maintenance of flatwoods diversity (Hiers et al. 2007). Therefore, frequent prescribed burnings, i.e., 4-5 yr intervals, are needed to maintain optimal M. alba populations (USFWS, 2009).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of individual plants/Loss of habitat
**Narrative:** Section 7(b)(4) and 7(b)(2) of the Act generally do not apply to listed plants species. However, limited protection of listed plants from take is provided to the extent that the Act prohibits the removal and reduction to possession of federally listed threatened and endangered plants or the malicious damage of such plants on areas under federal jurisdiction, or the destruction of endangered plants on nonfederal areas in violation of state law or regulations or in the course of any violation of a state criminal trespass law. Several populations of M. alba occur on private timberland and ROWs. While the Act requires Federal agencies to carry out programs for the conservation of endangered and threatened species, no such programs are stipulated for private landowners. Neither section of the Act provides protection for plants on private lands as long as the activity is permissible under state/local laws. The State requires permission of private landowners for collecting of state-listed plants from their property. Macbridea alba is protected under Florida State Law, chapter 85-426, which includes preventions of taking, transport, and the sale of the plants listed under the State Law. The rule Chap. 5B-40, Florida Administrative Code, contains the "Regulated Plant Index" (5B-40.0055) and lists endangered, threatened, and commercially exploited plant species for Florida; defines the categories; lists instances where permits may be issued; and describes penalties for violations (http://www.virtualherbarium.org/EPAC). Bay County code of ordinance (chapter 19-Environmental Standards), under sections 1907 and 1909, provides restrictions, constraints and requirements to protect and preserve designated habitat conservation areas for rare, threatened, or endangered species, and wetlands (http://www.municode.com/Resources/gateway.asp?pid=14281&sid=9). Gulf, Franklin, and Liberty Counties do not have such regulations. Highway ROW maintenance activities are not always reviewed for threatened and endangered species impact. However, if there is an activity (e.g., construction, reconstruction, or maintenance projects) affecting protected species, then the Service can request a consultation with the Florida Department of Transportation under the Act (M. Mittiga, 2009, pers. comm.). In the Apalachicola National Forest SR 65 ROW, it should conform to specifications and coordination between Talquin Eletric, FDOT and the Service. Currently, these protections are inadequate; see section IV, action 1 (USFWS, 2009).

**Stressor:** Herbicide (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Herbicide. While the Recovery Plan (Service 1994) mentioned that the use of herbicide or the wrong type of herbicide is a threat when it is used to control vegetation on power line rights-ofways, we no longer consider this a threat to M. alba because mowing is now the common practice to maintain transmission rights-of-ways in Florida. As discussed above, herbicide treatments along transportation rights-of-ways are still a threat to the species. Franklin County allows only “spot treatment” due to impacts concerning the Apalachicola National Forest and waters within Apalachicola Bay and River basin (USFWS, 2024).

**Stressor:** Climate Change - Catastrophic events (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate Change - Catastrophic events. As discussed above under Factor A, sea level rise may pose a significant threat to some occurrences. Hurricanes have impacted the Florida Panhandle and are expected to increase in intensity and reach major category strength as warming of the land and ocean continued. Therefore, this threat is expected to continue. According to pre/postHurricane Michael analyses by C. Anderson et al. (2020), natural communities such as sandhills were more affected, whereas scrub, scrubby flatwoods, wet flatwoods, and coastal grasslands were found more resistant to damage. Macbridea alba occurs in mesic pine flatwoods, wet savannas, seepage slopes, and ecotones between pine flatwoods, so possibly it has some resistant to this disturbance. According to the Florida Climate Center (https://climatecenter.fsu.edu/topics/climate-change), winter precipitation in the Panhandle has increased, and is expected to experience around 30-40 more extreme heat days per year. By 2050, an increase of more than 50 days with temperatures ≥ 95°F is projected to most of Florida. So even if precipitation remains constant or increase, higher temperatures will result in an increase of soil moisture loss and more intense droughts, likely affecting the persistence M. alba plants, the quality of current habitat, and habitat suitability for reintroduction (USFWS, 2024)

***Recovery***

**Reclassification Criteria:**
Not relevant. (USFWS, 1994)

Recovery Priority Number: 8C

**Delisting Criteria:**
1. When 15 populations are adequately protected and managed throughout its historic range. Existing public land (mainly the Apalachicola National Forest) does not suffice for recovery). (USFWS, 1994)

**Recovery Actions:**
- Protect population in Apalachicola National Forest and on other public lands: At present, we have about 21 protected locations with an estimated 3,967 to 7,262 plants. (USFWS, 2009)
- Manage rights-of-way: This is an ongoing action. Macbridea alba is found scattered under the Apalachicola National Forest Utility ROW of SR 65. Protective measures have been established with Talquin Electric during annual maintenance and the upcoming pole replacement. Management for other M. alba elements of occurrences found in ROW outside SR 65 has not been initiated (USFWS, 2009).

- Protect and manage these plants outside Apalachicola National Forest: 3.1. Secure protection, Develop and implement management and monitoring plans for protected sites. (USFWS, 2009)
- Systematics and other studies: Genetic structure of M. alba, and Comparison of M. alba and M. carolinensis. (USFWS, 2009)
- Garden propagation and reintroduction.  his recovery action has not been initiated. According to Schulze et al. (2002) study, an ex-situ collection of seeds is not recommended due to the lack of dormancy, and poor viability of dry-stored seeds. Although conserving this species in-situ is the best option, an ex-situ collection of established seedlings and adults is recommended (USFWS, 2009).
- 1. Manage ROW (Rights-of-Way).  Continue fostering conservation practices for utility and highway ROWs with the Forest Service, Talquin Electric, FDOT, and USFWS; a management plan should be developed and implemented (USFWS, 2009).
- 2. Establish an ex-situ collection of seedlings and adults (USFWS, 2009).
- 3. Conduct population biology studies at ANF a. Compare the demographic performance of M. alba in pinelands and road habitats i) Survey for seedling recruitment and survival of tagged individuals (plant height and reproduction) for a period of 3-5 years in roadside populations of SR 65 and pinelands. ii) Perform germination experiments (USFWS, 2009).
- 4. Revisit and conduct inventories (e.g., the total number of individuals, number of flowering vs. non-flowering plants, presence of visitors to the flowers, and whether seedling recruitment is occurring) on all the historical locations (USFWS, 2009).
- 5. Conduct surveys/inventories on potentially new sites. This action can include the use of species distribution modeling methods to initially determine potential sites, with subsequent validation or inspection of the sites for plants (USFWS, 2009).
- 6. Implement monitoring for selected populations in Bay, Gulf, Franklin, and Liberty counties. Note: Bay (Lathrop Bayou) and Gulf (SJBP) have a monitoring program. A similar monitoring protocol should be followed, thus results can be comparable across sites. Monitoring should examine density and abundance of individuals. Observations of flowering and fruiting are important and should be integrated with variables such as plant size and seedling data. Since M. alba occurs in fire prone habitats, the effect of this disturbance (including winter vs. growing season prescribed fire, fire frequency, intensity, duration, and timing) on survival and fecundity should be also monitored. Such studies should be conducted on large, protected and managed populations. Plants should be monitored several times during a 12-month cycle (e.g., flowering and fruiting seasons) the first year, then annually or biannually over an extended number of years. The results would help determining the smallest size at which a population can exist without facing extinction, i.e., the minimum viable population size (USFWS, 2009).
- 7. The recovery plan should be updated to define objective measurable criteria and better address the five factors (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Estimate the levels of clonality and distribution of genetic diversity. Knowledge of the levels and distribution of genetic variation in species of conservation concern can be important for the development of efficient and effective conservation practices, i.e., establish a representative percentage of the total genetic variation of M. alba. Sampling should occur across the range; testing clonality could involve sampling the established monitoring plots at ANF and SJSBP. a. By understanding clonality, the Service will be able to determine what is an individual and evaluate abundance. Specifically, we will be able to 1) relate flowering stems (both vegetative and flowering) to number of individuals in a given area, and 2) infer the effect of fire on flowering stems/individuals. b. The identification of populations with rare alleles or with elevated levels of genetic diversity may lead to greater efforts for their preservation relative to less genetically unique populations. 2. Establish an ex-situ collection of seeds, seedlings, and adults. There is an ongoing conversation among FDACS, ABG, FWS, and Univ. Illinois Urbana-Champaign to establish an ex-situ collection at the ABG. 3. Clarify limits of desiccation and cold tolerance for ex-situ seed storage recommendations. 4. Understand in-situ seed germination and seedling survival vs. the role of viviparous seed germination and offspring survival, and the implications of both reproductive strategy for M. alba. 5. Monitoring. Implement monitoring for selected populations outside of ANF: Bay, Gulf, and Franklin counties. It is recommended to set up more subplots and monitor abundance and survival of both flowering and nonflowering individuals over time, whether seedling recruitment is occurring, and the effect of mechanical site preparation and hurricane disturbances. 6. Censuses. Censuses are most critical for populations outside ANF and for EOs found without plants. Complete a comprehensive census (e.g., the total number of individuals, number of flowering vs. non-flowering plants, and whether seedling recruitment is occurring) throughout the present distribution including all the historical locations to determine the population numbers and range. A consistent and repeatable method should be employed. 7. Manage ROWs. Continue fostering conservation practices for utility and highway ROWs with the Forest Service, Talquin Electric, FDOT, and the Service and document commitment to these conservation practices in land management plans or agreements. (USFWS, 2020)

- RECOMMENDED FUTURE ACTIVITIES Recovery Activities 1. Censuses are critical for Element Occurrences found without plants (Fig. 1). For those EOs, a comprehensive census (e.g., the total number of individuals, number of flowering vs. non-flowering plants, and whether seedling recruitment is occurring) needs to be completed across the current distribution to determine abundance, threats, and habitat suitability. A consistent and repeatable method should be employed. 2. Reintroduction. A reintroduction approach should be designed and executed with the assistance of the Service botanist for those sites where the habitat is present and still suitable. An annual monitoring is required to examine plant survival and reintroduction success. For consideration: a. Tate’s Hell State Forest, Franklin Co. i. Florida Native Areas Inventory Element Occurrences # 57 & 58. No plants have been observed since 2008. ii. Florida Native Areas Inventory Element Occurrence #11 along east side of CR 67, Tate’s Hell State Forest, Franklin Co. was fragmented due to rights-of-way herbicide spraying and culvert reinstallation. 3. Conduct surveys/inventories on potentially new sites (targeting recently burned sites). 4. Establish (or continue) frequent growing-season fire regimes to maintain optimal conditions of populations. Re-visit sites shortly after a burn event and count individuals. Monitoring and Research Activities 1. Monitoring. a. Implement monitoring for selected populations outside of Apalachicola National Forest in Bay, Gulf, and Franklin counties. The ABG is monitoring several documented sites in Gulf and Franklin counties (Cooperative Agreement No. # F21AC02540-00). However, it is recommended to set up more subplots and monitor abundance and survival of both flowering and nonflowering individuals over time, whether seedling recruitment is occurring, and the effect of mechanical site preparation and hurricane disturbances. b. Continue the long-term monitoring in Apalachicola National Forest sites (FNAI 2024). c. As sea levels rise, seawater intrusion increases in duration, frequency, and spatial extent. To assess the effect of salinity on M. alba, sites where intrusion of salt water occurs (or will occur) should be considered for long-term monitoring. 2. Manage Rights-of-Ways. Continue fostering conservation practices for utility and transporation rights-of-ways with the Forest Service, Talquin Electric, the Department of Transportation, and the Service and document commitment to these conservation practices in land management plans or agreements. 3. Ex-situ seed studies. Since there is a possibility that seeds in long-term storage are unlikely to remain viable, examining their viability is recommended using multiple methods (USFWS, 2024).

# SPECIES ACCOUNT: *Malacothrix indecora* (Santa Cruz Island malacothrix)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

An annual herb with broadly lobed, fleshy leaves. Produces hemispheric heads, 2-6 mm wide, of yellowish-green flowers. The heads are surrounded by long bracts. Blooms April-September. (NatureServe, 2015)

**Taxonomy**

Malacothrix indecora was first described by Edward Lee Greene (1886), based on specimens collected from “islets close to the northern shore of Santa Cruz Island.” In 1957, Williams published a combination of the species as Malacothrix foliosa var. indecora (Ferris 1960) and subsequently Munz (1974) later synonymized the taxon with Malacothrix foliosa. However, Ferris (1960) and others (Smith 1976, Davis 1980) continued to recognize the taxon as Malacothrix indecora and this nomenclature has been retained in the most recent treatments of the genus (Davis 1993, Jepson 2010, Flora of North America (FNA) 2010a). There have been no changes in the taxonomic classification or nomenclature since the time of listing (USFWS, 2010).

**Historical Range**

See current range/distribution.

**Current Range**

Known from three of the northern Channel Islands (Santa Cruz Island, San Miguel Island, and Prince Island) in Santa Barbara County, California. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

Adult: Little is known about the life history ofSanta Cruz Island malacothrix. This annual species is poorly to moderately selfcompatible (Davis 1998) (USFWS, 2000).

**Habitat Type**

Adult: Coastal bluffs and flats (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

<u>Adult:</u> Low (inferred from NatureServe, 2015)

**Site Fidelity**

<u>Adult:</u> High (inferred from NatureServe, 2015)

**Habitat Narrative**

<u>Adult:</u> The species generally occurs on coastal bluffs and slopes, often on midden sites, at elevations of less than 20 meters (65 feet). The species occurs on Santa Cruz Island, Santa Rosa Island, and San Miguel Island, Santa Barbara County, California. The islands are part of Channel Islands National Park (CINP). Most of Santa Cruz Island (76%) is private property of The Nature Conservancy, CINP owns the rest of Santa Cruz Island and all of Santa Rosa Island, and San Miguel Island is owned by the Navy but is administered by CINP. Both CINP and TNC lands are managed for natural resource conservation (USFWS, 2022).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

<u>Adult:</u> No information found

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

3 extant (USFWS, 2022)

**Population Narrative:**

The status of both Malacothrix indecora and M. squalida has not changed substantially since the time of listing in 1997. Currently, there are eight known populations of M. indecora, which occur on four of the northern Channel Islands: Anacapa, San Miguel, Santa Rosa, and Santa Cruz. These populations have exhibited some decline in the number of individuals over the last 15 years and we are lacking recent or comprehensive survey data for all of the populations, which makes it difficult to draw any conclusions about the current abundance trend for this species. There are three locations of M. indecora that were recently discovered in the spring of 2010 on East Anacapa Island where large patches of iceplant were removed in 2009. These new discoveries appear to indicate that this species might be expanding its range, since it was not historically known from Anacapa Island. There are two known extant populations of M. squalida, which occur on two of the northern Channel Islands: Santa Cruz and Anacapa. These populations have exhibited some decline and overall fluctuation in numbers of individuals over the last 15 years, but the number of individuals of this species is already very low and we do not have any recent or comprehensive survey data, which makes it difficult to draw any conclusions about the current abundance trend for this species (USFWS, 2011).  Distribution: The distribution of Santa Cruz Island malacothrix has not changed since the last 5- year review (Service 2010). There are at three extant and one historical occurrences on Santa Cruz Island, one extant occurrence on Santa Rosa Island, and two presumed extant occurrences on San Miguel Island (Table 2). The San Miguel Island occurrences have not been visited in more than 20 years; whether they remain extant is unknown. Santa Cruz Island malacothrix, contrary to information in the last 5-

year review, is not known to occur on Anacapa Island (USFWS, 2022)

***Threats and Stressors***

**Stressor:** Fire and Invasive Species (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** we still believe that non-native plant species and catastrophic fires pose a risk to both the Malacothrix species. With the removal of non-native herbivores, we have also seen an increase in vegetation biomass, thus increasing the chance of larger and more frequent fires. Particularly, the vegetative biomass of non-native species has increased, due to the removal of non-native herbivores and continued exposure, thus increasing the amount of competition for resources for both Malacothrix species. There has been some speculation that climate change may further complicate these two issues; however we lack adequate information to draw any conclusions about the specific changes that may occur on the northern Channel Islands as a result of climate change (please see discussion under Climate Change below) (USFWS, 2010).

**Stressor:** Hybridization (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Extirpation
**Narrative:** Malacothrix indecora and M. squalida hybridize both with one another and with several other Malacothrix species (McEachern, in litt. 2010). In particular, there is one documented occurrence of M. indecora and M. squalida hybrids in a north-draining canyon at Potato Harbor on Santa Cruz Island (McEachern, in litt. 2010). There are two other Malacothrix species that occur on the same islands as M. indecora, but M. indecora is the only other Malacothrix species that co-occurs with M. squalida (Junak et al. 1995). Hybridization was not addressed in the listing rule or the recovery plan and we lack any specific data which would allow us to draw any conclusions about how hybridization may affect either of these species at this time (USFWS, 2010).

**Stressor:** Stochastic Extinction (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Extirpation
**Narrative:** At the time of listing, we noted that due to the limited geographic range, and limited number of individuals and populations of both Malacothrix indecora and M. squalida, these species were at risk of stochastic extinction resulting from loss of genetic diversity, through chance events affecting survival and reproduction, and through naturally occurring catastrophic events, such as fire, drought, disease, or storms (Service 1997). We believe that the existence of only two and eight relatively isolated populations of M. squalida and M. indecora, respectively, place these species at risk of extinction from stochastic events. Because both species have a relatively limited geographic range and exist as only a few populations, the genetic viability and resilience of both M. indecora and M. squalida to human-caused or natural disasters may be greatly reduced (Menges 1991, Ellstrand and Elam 1993). Studies on Santa Cruz Island have shown that unexpected, complex interactions sometimes result in substantial declines within endemic species populations that were assumed to be stable (Roemer et al. 2001). The

conservation biology literature commonly notes the vulnerability of taxa known from one or very few locations and/or from small and highly variable populations (Shaffer 1981, Groom et al. 2006, Primack 2006). In particular, although the plants are apparently self-compatible, the small size of the populations make it difficult for these species to persist while sustaining the impacts of soil damage (compaction and erosion) and habitat alteration that favors non-native species (USFWS, 2010).

**Stressor:** Climate Change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Because all of the populations for both Malacothrix species occur on coastal bluffs in close proximity to the ocean, these species are subject to a wide range of climatic conditions, such as occasional salt spray (Wilken 1996), which may directly affect the soils and plants at low elevation exposed coastal flats. Sea level rise and the continued erosion of the ocean-front cliffs on the exposed bluffs of the northern Channel Islands from high surf and storm events, in addition to climate variability, both from year to year and due to large-scale climate change, pose a threat to the relatively small and exposed Malacothrix populations (USFWS, 2010).

***Recovery***

**Reclassification Criteria:**
1. Maintain existing stable populations on San Miguel, Santa Cruz, and Santa Rosa Islands for a period of 15 years that includes the normal precipitation cycle (USFWS, 2022).

2. Seed stored in CPC cooperating facilities (USFWS, 2022).

3. Seed germination and propagation techniques understood (USFWS, 2022).

4. Successful outplanting techniques developed (USFWS, 2022)

5. Life history research conducted (USFWS, 2022)

6. Weed management plan developed and implemented (USFWS, 2022).

7. If declining, determine cause and reverse trend (USFWS, 2022)

Recovery Priority Number: 8

**Delisting Criteria:**
1. No decline after downlisting for 10 years (USFWS, 2022).

2. All potential habitat surveyed (USFWS, 2022).

**Recovery Actions:**
- Reclassification criteria: This criterion is relevant; however, it should be updated to include a more measurable and threats-based component. Additionally, it may become increasingly difficult to evaluate the population over 15 years that includes the normal precipitation

cycle due to the fact that the normal precipitation cycle is already changing and is predicted to continue to fluctuate considerably under the effects of climate change (IPCC 2007). This criterion does not include a clear definition of what constitutes a stable population for this species; therefore, it should be updated to include a more concrete definition of this term. David Keith presents a widely accepted method of evaluation of at-risk plant species that is based on The World Conservation Union (IUCN) Red List Criteria of 1994, consisting of a set a decision rules based on quantitative thresholds of population size, distributional range, rates of decline, and extinction risk (Keith 1997). We recommend that the recovery criteria for Malacothrix indecora be updated to include a more well-defined method, such as the one presented by Keith (1997), for assessing when this species can be considered stable and recovered. Despite the three new occurrences of Malacothrix indecora that were discovered this year, the most recent surveys of the M. indecora populations seem to show that overall, the number of individuals has decreased somewhat since listing (McEachern, in litt. 2010). Additionally, the precipitation cycles during the last 15 years have not been normal (Levine et al. 2009, Levine et al. 2010); therefore, this criterion has not been met (USFWS, 2010). Delisting criteria: This criterion is relevant; however it is rather vague. We recommend that this criterion be revised to take into consideration that there may be some fluctuation in the population sizes of these annual plant species; however, delisting may be considered when this species is considered recovered based on the quantitative methods of evaluation presented by Keith (1997) or some other comparable method. This criterion has not yet been met (USFWS, 2010).

- Develop and implement monitoring and adaptive management plans for all of the existing populations. Monitoring should occur at intervals of 1 to 2 years and include population abundance surveys, habitat condition assessment, and documentation of existing and potential threats. 1a. Work closely with agencies such as TNC, USGS, and NPS to continue monitoring efforts for the species and to develop a long-term adaptive management plan for special status species which occur on the northern Channel Islands (USFWS, 2010).
- Develop and implement an integrated non-native plant control program for Santa Cruz, Anacapa, San Miguel, and Santa Rosa Islands, which complements and enhances existing efforts (USFWS, 2010).
- 3. Continue to research the species' life history requirements, especially with regard to the habitat conditions favorable to both species. 3a. Specifically, we recommend a follow-up study to evaluate the response of both Malacothrix species to the removal of the non-native mammals from Santa Cruz, Santa Rosa, and San Miguel Islands and whether recovery of the soil health and stability has occurred. Because non-native large herbivores still remain on Santa Rosa Island, some baseline data could be gathered now and compared with the results that are gathered several years after the eventual removal of the remainder of these animals (USFWS, 2010).
- Update the recovery criteria for both Malacothrix indecora and M. squalida to include a more measurable and threats-based evaluation method, based on the recommendations presented in the discussion of the recovery criteria for both species on pages 16 through 18 of this review (USFWS, 2010).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Survey San Miguel Island occurrences to verify their continued persistence. 2. Establish regular monitoring for known natural populations of Santa Cruz Island malacothrix on Santa Cruz, Santa Rosa, and San Miguel Islands. 3. Enhance existing natural populations on Santa Cruz Island. 4. Establish new recovery populations on Santa Cruz Island. 5.

Improve the completeness of coverage over years for Santa Cruz Island malacothrix in conservation seed banks, for both Santa Cruz and San Miguel Islands. 6. Survey additional potential habitat on Santa Cruz and San Miguel Islands. 7. Restrict public access to the Lobo Canyon-Cow Canyon population during the Santa Cruz Island malacothrix growing season (USFWS, 2022).

# SPECIES ACCOUNT: *Manihot walkerae* (Walker's manioc)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/02/1991; Southwest Region (Region 2) (USFWS, 2016)

**Physical Description**

A perennial herb, highly branched or few-stemmed, sprawing or erect, up to 1.5 m tall. The stems are smooth, grayish-brown, 3.2 millimeters (0.13 inch) in diameter. The leaves are alternate, deeply incised, and palmately 5-lobed. Flowers are unisexual and occur in racemes with staminate flowers in the raceme opening later than pistillate ones. Staminate flowers are tubular, constricted in the middle; tepals are 1.2 centimeters (0.47 inch) long, light purplish streaked externally, and cleft one-fourth of the way down into 5 lobes; stamens are 6-10, filaments and anthers are cream-colored. Flowers from spring through autumn, probably following rains. Clusters of 2-3 fragrant, white flowers open in late afternoon and last only 1 day. There are separate male and female flowers on the same plant. (USFWS, 1993; NatureServe, 2015)

**Taxonomy**

Leon Croizat (1942) described Walker's manioc as a distinct species. Rogers and Appan (1973) place it within section Parvibracteatae of the genus Manihot. Its closest relative may be M. subspicata, another rare plant of south Texas and northeast Mexico found on caliche or rocky limestone substrates. Tom Patterson observed that the ranges of these two species overlap in the Loreto sand plain of Tamaulipas (Patterson 2008, pers. com.). (USFWS, 2009)

**Historical Range**

Walker's manioc is known only from the Lower Rio Grande Valley of Texas (Hidalgo and Starr counties) and northern Tamaulipas, Mexico. One historical location for Walker's manioc was Ringgold Barracks, an old fort located on the eastern outskirts of Rio Grande City, Starr County, Texas. (USFWS, 1993)

**Current Range**

Walker's manioc is known only from the Lower Rio Grande Valley of Texas (Hidalgo and Starr counties) and northern Tamaulipas, Mexico. (USFWS, 1993). As of 2019: Walker's manioc has been documented from as far north as Duval County in southern Texas (TXNDD 2018, p. 18) to the vicinity of Aldama (Service 2009, p. 11) in the most southern part of the state of Tamaulipas, Mexico; a distance of approximately 532 kilometers (km). (USFWS, 2019).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual and asexual (USFWS, 2009)

**Breeding Season**

Adult: Spring through fall (USFWS, 2009)

**Reproduction Narrative**

Adult: The species is self-fertile, and does not appear to require a rare or specialized pollinator (Best 2008). Flowers from spring through autumn, probably following rains. The fruit capsules contain up to three seeds, which are dispersed a distance of several meters by the spontaneous, violent dehiscence (rupturing) of the capsules upon drying, which impedes seed collection (Best 2008). Seeds may remain dormant for a year or more, but germination can be induced by exposure to heat and moisture (Simpson 1995), or gibberellic acid (a naturally occurring plant hormone) (Best 2008). Individual plants have produced up to 20 rounded tubers 2 to 3 inches (5 to 7.5 cm) in diameter, after about 3 years' growth (Best 2008). This demonstrates that the species perenniates in the wild through both seeds and tubers (Best 2008). (USFWS, 2009). Walker's manioc is capable of dormancy due to its underground tubers that remain viable even when unfavorable aboveground conditions (e.g., drought, extended period of high temperatures, freezes) result in leaves and stems dying back. The ability of the species to regenerate, or to spread to new sites, via pieces of tuber has positive implications for propagation and reintroduction recovery actions. Observations at Lower Rio Grande Valley National Wildlife Refuge (LRGV NWR) show that manioc plants can begin tuber production at less than one year of age (Best 2008 in Service 2009, p. 10) and that potted manioc plants can produce numerous, large tubers by 2.5 years. Field observations indicate that javelina (Pecari tajacu) dig up and consume tubers, but may also act as agents of dispersal by dropping tuber pieces as they move (Service 2009, p. 18). In Tamaulipas, Mexico, manioc grew from tuber pieces scattered about in a crop field (Best 2008 in Service 2009, p. 16). Tubers appear to help the species survive adverse environmental conditions as well as anthropogenic surface impacts including herbicides, mowing, and perhaps disking or plowing. Manioc has reemerged following herbicide application that killed the aboveground portions of the plants (Best 2008 and Patterson 2008 pers comm. in Service 2009, p. 10). (USFWS, 2019).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Grassland/herbaceous, shrubland/chaparral (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Widely-spaced or small clusters (USFWS, 2009)

**Environmental Specificity**

Adult: Moderate, with some key requirements (USFWS, 2009)

**Habitat Narrative**

Adult: The recorded habitat descriptions from collections of the species vary from native brush to grassland. Endemic to the Tamaulipan grassland-thornscrub community of the Lower Rio Grande Valley, where it occurs on sandy-loam soils underlain by caliche. Walker's manioc plants occupy only a small portion of the upland vegetation of the Goliad geological formation, in shallow, calcareous sandy soil overlying indurated caliche. The soil depth is often 12 in (30 cm) or less. Populations may consist of widely-spaced individual plants along bands of shallow soil, or small clusters of a few dozen individuals. Johnston (1963), Best (1995, 2005), and Poole et al. (2007) have described plant species found in close association with Walker's manioc. These include short native grasses and herbaceous plants, and low shrubs and sub-shrubs. (USFWS, 2009; NatureServe, 2015)

***Dispersal/Migration***

**Dispersal**

Adult: Low (USFWS, 2009)

**Dispersal/Migration Narrative**

Adult: The fruit capsules contain up to three seeds, which are dispersed a distance of several meters by the spontaneous, violent dehiscence (rupturing) of the capsules upon drying, which impedes seed collection (Best 2008). (USFWS, 2009)

***Population Information and Trends***

**Population Trends:**

Not available.

**Number of Populations:**

3 (USFWS, 2009). Update: 11 (USFWS, 2019).

**Population Size:**

<1,000 individuals (NatureServe, 2015)

**Population Narrative:**

A regional endemic of southern Texas and northern Mexico, this species was thought to have been extirpated from the U.S. until a single surviving plant was discovered in 1990. Three sites on LRGV NWR, consisting of up to 90 individuals each, may be large enough to be considered viable populations. Five additional sites found in Texas have as many as 30 individuals. There is probably less than 1,000 individuals. (USFWS, 2009; NatureServe, 2015). With the exception of the Duval County population, all known Texas manioc populations occur in western Hidalgo County and southeastern-to-southcentral Starr County with the majority of these populations located within 2.4 km of the Rio Grande. Although the population data show a patchy, scattered distribution, much of the potential habitat between known populations has not been surveyed. The discovery of additional sites in 2009 illustrate the likelihood of finding more populations in unsurveyed suitable habitat on which the land cover has not been mined or otherwise built over. Three of the largest Texas populations occur on protected tracts of the LRGV NWR (TXNDD 2018, pp. 6, 8, and 10; Best 1996 in Service 2009), which implements monitoring and management actions intermittently. All other populations in Texas and Mexico, except for a small site on TXDOT ROW, are on privately-owned land. The TXDOT site in Hidalgo County is considered highly vulnerable because of its location along a road (D. Price 2007, pers. comm.). (USFWS, 2019).

***Threats and Stressors***

**Stressor:** Urban and residential development (USFWS, 2009)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Urban and residential development continues at a rapid pace throughout the border region of south Texas and northern Mexico. The human populations of Starr and Hidalgo Counties are projected to grow 67% and 88%, respectively, between 2000 and 2025 (Texas State Data Center 2008). Habitat loss is likely to continue both through development of sites as well as increased surface mining of caliche for construction of roads and parking lots. (USFWS, 2009)

**Stressor:** Energy development (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Intensive energy exploration continues throughout the entire range of Walker's manioc in south Texas and northeast Mexico. Under Texas and Mexican law, mineral rights owners take precedence over surface owners. Seismic exploration, pipelines, oil and gas wells, and access roads have proliferated on private lands as well as tracts of LRGV NWR, incrementally augmenting the loss of potential habitat of this and other listed plant and animal species. Habitats and populations at LRGV NWR are potentially vulnerable to impacts from oil and gas exploration, since USFWS does not own the mineral rights pertaining to most of the refuge's tracts. (USFWS, 2009). 2019 update: At the end of 2018, there were no wind turbines, oil and gas well pads, or roads directly impacting known manioc populations. However, the two south central Starr County manioc population sites were within 4.0 km and 4.8 km from existing turbines at large wind farms to the east and north, respectively. A 56–100-turbine wind farm is proposed for construction to the northwest of these populations. In Starr and Hidalgo counties, there are five existing wind farms (USGS 2019, unpaginated) with some of the 380 turbines atop manioc-appropriate soils. Wind energy development does not have a federal nexus and is not required to carry out surveys for listed species, therefore placement of turbine pads and internal roads could impact undiscovered populations, but the level of impacts is unknown. (USFWS, 2019).

**Stressor:** Habitat loss (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The primary threats to Walker's manioc are habitat loss and competition from invasive grasses. Although the caliche outcrops where the species occurs are not conducive to production of row crops, extensive surface mining of caliche supplies much of the base material for highways, unpaved roads, well-drilling pads, and parking lots throughout the region. Surface mining of caliche is therefore a major threat to species, such as Walker's manioc, that are endemic to exposed caliche outcrops. (USFWS, 2009)

**Stressor:** Invasive plants (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Many species of Old World grasses have been introduced in the Tamaulipan region of south Texas and northeast Mexico for cattle forage and erosion control, including several that

are now highly invasive (Best, in press). The “common variety” of buffelgrass (Pennisetum ciliare) was derived from a single apomictic individual from northern Kenya (Holt 1985). Common buffelgrass was introduced in south Texas beginning in 1946 and is now abundant from Texas and Tamaulipas to Arizona and Sonora. Buffelgrass is well adapted to the welldrained calcareous soils where Walker’s manioc occurs. This forage grass is typically established by root-plowing sites with powerful tracked vehicles, then broadcasting the seed in the disturbed soil. A large amount of potentially suitable habitat for Walker’s manioc has been converted to root-plowed buffelgrass pasture. Buffelgrass often increases following soil disturbance, allowing it to spread rapidly along road, powerline, and pipeline rights-of-way. It is present at most Walker’s manioc sites, frequently dominating the herbaceous vegetation and suppressing most native species including Walker’s manioc. In the Loreto sand plain another introduced grass, pitted bluestem (Bothriochloa pertusa), may also compete with Walker’s manioc (Best 2005). (USFWS, 2009)

**Stressor:** Genetic swamping (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A closely related plant, cassava (Manihot esculenta), is an important staple crop throughout the tropics. Walker’s manioc may serve as a source of genetic material for the development of improved cassava cultivars (U.S. Fish and Wildlife Service 1990b, 1993a). The storage life of edible cassava roots is significantly diminished by post-harvest physiological deterioration (PPD). Researchers created an inter-specific hybrid between cassava and propagated specimens of a Mexican collection of M. walkerae which is the only known source of resistance to PPD (Centro Internacional de Agricultura Tropical 2005; Cuambe 2007). This research has not directly affected wild populations, since the source material came from cultivated plants. However, if the inter-specific hybrid or cultivars derived from it are able to back-cross with wild plants, this could threaten wild populations through genetic swamping. (USFWS, 2009)

**Stressor:** Predation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In September 2003, Tom Patterson reported an incidence of digging in the exact locations of Walker’s manioc plants on three tracts of LRGV NWR (Patterson 2003, pers. com.). These plants had been precisely mapped with GPS, and had been identified with numbered aluminum tags. A refuge law enforcement officer (who is a skilled tracker) and the plant ecologist investigated these sites. They determined that the digging had not been done by humans and identified numerous tracks of javelina (collared peckary) at these sites. Javelina feed heavily on plant seeds and tubers (Leopold 1972). The refuge staff observed that some partially-eaten tuber fragments had sprouted new roots and shoots (Best 2008). Feral hogs are abundant in the region, and may also constitute a serious threat to Walker’s manioc populations (Patterson 2008, pers. com.). Patterson also observed rabbits consuming the stems and leaves of Walker’s manioc (Patterson 1996, pers. com.). (USFWS, 2009)

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** According to the Intergovernmental Panel on Climate Change (IPCC) (2007) "Warming of the climate system is unequivocal, as is now evident from observations of increases in global average air and ocean temperatures, widespread melting of snow and ice, and rising global average sea level." Average Northern Hemisphere temperatures during the second half of the 20th century were very likely higher than during any other 50-year period in the last 500 years and likely the highest in at least the past 1300 years (IPCC 2007). It is very likely that over the past 50 years cold days, cold nights and frosts have become less frequent over most land areas, and hot days and hot nights have become more frequent (IPCC 2007). It is likely that heat waves have become more frequent over most land areas, and the frequency of heavy precipitation events has increased over most areas (IPCC 2007, p. 1). Some climate change models also predict increased precipitation along the Gulf Coast, largely due to increased tropical storm activity and severity (Twilley et. al. 2001). Since the species now occurs in some of the most xeric of regional habitats, increasing rainfall could reduce its competitive advantage in those marginal sites. Regardless of how changes in temperature and rainfall amounts and patterns may affect the autecology of Walker's manioc, the altered synecology may be far more significant. For example, higher winter temperatures and increased precipitation could augment competition from buffelgrass or other introduced invasive grasses. Conversely, the same changes could expand the range or increase the pathogenicity of Pyricularia grisea, a rust fungus that attacks buffelgrass, thereby reducing its invasiveness. The possible effects of climate change on the synecology of Walker's manioc habitat are infinitely complex. Therefore, the Service will continue to monitor the species and its habitat, and will adapt our recovery and management strategies when necessary to address the changing conditions. (USFWS, 2009)

**Stressor:** Quarrying/Mining (USFWS, 2019).
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Google Earth imagery dated January 2017 shows numerous pits or caliche quarries in the area between the most eastern manioc population in southern Texas and Rio Grande City, Texas. Mining is evident on this imagery to both the north and south of Highway 83 with ongoing activity at a number of the sites as evidenced by on-site vehicles. Expansion of a number of these pits can be confirmed by comparing imagery across years. All of the manioc sites in Hidalgo and Starr counties, including some on refuge tracts, are in relatively close proximity to either active quarries or what appear to be old pits that are now full of water, illustrating that the species occurs within a zone of active caliche or gravel quarrying. On private land, known populations are not currently protected by agreements and any undiscovered populations that may exist remain threatened by caliche mining. (USFWS, 2019).

**Stressor:** U.S./Mexico Border development (USFWS, 2019).
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Walker's manioc's proximity to the Rio Grande and to HWY 83 increases the vulnerability of the species to development which tends to occur along the river and HWY 83. Proximity to the Rio Grande also means more vulnerability to new roads, new border barriers, increased traffic, and other activities related to increased law enforcement and border security. (USFWS, 2019).

***Recovery***

**Reclassification Criteria:**
Maintain or establish 15 self-sustaining populations of Walker's manioc in the United States. Establish management plans (public lands) or management agreements (private lands) to insure the protection of these populations. (USFWS, 1993)

2019 Downlisting Criterion amendment: Within the Hidalgo-Starr Counties, Texas Recovery Unit, establish or maintain 15 distinct, self-sustaining populations of Walker's manioc. Each population should consist of at least 1,000 reproductive individuals. (USFWS, 2019).

Recovery Priority Number: 8C

**Delisting Criteria:**
1. Over a 30-year period, maintain at least 15 fully protected, self-sustaining populations containing at least 1,000 reproductive individuals in each, within the known U.S. range. (USFWS, 2019).

Protection and management agreements need to be perpetual to provide a permanent level of protection. (USFWS, 2019).

**Recovery Actions:**
- Protect the habitat of the existing populations on private lands in the United States and Mexico. (USFWS, 1993)
- Gather biological information necessary for management and develop a monitoring program for populations. (USFWS, 1993)
- Search for new populations in the United States and Mexico. (USFWS, 1993)
- Establish a botanical garden population. (USFWS, 1993)
- Initiate a reintroduction program into suitable habitat on the Lower Rio Grande Valley National Wildlife Refuge, Texas Parks and Wildlife Department lands and other lands made available for use. (USFWS, 1993)
- In 2019, one Recovery Unit was identified: Recovery Unit 1 – Hidalgo-Starr Counties, Texas. (USFWS, 2019).
- Criterion 1 calls for establishment or maintenance of at least 15 self-sustaining populations of 100 or more individuals. This criterion should be revised using updated methods to describe what constitutes a viable population, and the number and geographic distribution of populations necessary for recovery. (USFWS, 2009)
- Criterion 2 requires establishment of "agreements for the protection and management of all populations on private lands..." However, USFWS has no authority to require private landowners to protect endangered plants. Furthermore, because the USFWS cannot survey private lands without the owner's permission, it is not possible to quantify the number of populations requiring protection. The criterion, as currently written, tends to promulgate misinterpretation of the authority of the Endangered Species Act, and might discourage landowners from cooperating with USFWS in the conservation of this species. Finally, successful recovery may be possible without protecting all known sites. This criterion should be revised to establish quantifiable, attainable objectives. (USFWS, 2009)

- The plan should have a recovery criterion that addresses seed banking, establishment of refugium populations and reintroduction efforts, all of which serve as safeguards against the unavoidable loss of populations to development, competition from invasive species, or catastrophic events. (USFWS, 2009)
- Periodic monitoring and surveys of known sites in Texas and Tamaulipas. In particular, a quantitative survey should be conducted at the three sites on LRGV NWR to detect population trends at those sites. (USFWS, 2009)
- Additional surveys of potential habitat in Texas and Tamaulipas, focusing on sites with Goliad-formation caliche outcrops that have not previously been surveyed. (USFWS, 2009)
- Seed collection for propagation and seed banking, establishment of seed increase plots, and pilot reintroduction projects. (USFWS, 2009)
- In-situ investigation of reproductive biology and population dynamics. (USFWS, 2009)
- Investigation of the genetic structure of known populations throughout the species range. (USFWS, 2009)
- Establish cooperative efforts to promote the conservation of Goliad formation caliche outcrops. (USFWS, 2009)
- Promote cooperative efforts with Mexican agencies, scientists, and non-profit conservation organizations to conserve populations in Mexico. (USFWS, 2009)
- Conduct public outreach efforts to encourage conservation of the species and its habitat on private lands. (USFWS, 2009)
- Determine whether inter-specific hybrids of M. esculenta and M. walkerae, or cultivars derived from those hybrids, are able to create fertile progeny with wild M. walkerae. (USFWS, 2009)

# SPECIES ACCOUNT: *Marshallia mohrii* (Mohr's Barbara's buttons)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 10/7/1988; Southeast Region (R4)

**Physical Description**

Erect perennial herb, 3 to 7 decimeters (1 to 2.3 feet) tall. The leaves are alternate, 8 to 20 centimeters (cm) (3.2 to 7.8 inches) long, firm-textured, three-nerved, and lanceolate-ovate in shape. Leaves are often clustered near the base and gradually reduce in size upwards. The flowers are typically produced in several heads in a branched arrangement. The heads are approximately 2.5 cm (1 inch) broad and consist of disk flowers (tubular in shape) which are pale pink or white in color. The fruit is an achene (USFWS, 1991).

**Taxonomy**

In the sunflower family (Asteraceae) (USFWS, 1991). The taxon is currently recognized as valid by the Integrated Taxonomic Information System (ITIS) (ITIS 2015), as well as national and regional floras (e.g., Flora of North America [Watson 2006] and Flora of the Southern and Mid-Atlantic States [Weakley 2015]). While the taxonomic status of this species is not affected, some authors use the alternate common name Coosa Barbara’s-buttons (e.g., Noss 2012, Spaulding 2013, Weakley 2015) rather than Mohr’s Barbara’s buttons used by the Service and others (e.g., Chafin 2007, ITIS 2015, NatureServe 2015). (USFWS, 2016)

**Historical Range**

Historical records exist for Walker County, Georgia, and Walker and Cullman Counties, Alabama, in addition to the current range (USFWS, 1991).

**Current Range**

Currently known from Bibb, Cherokee, and Etowah Counties, Alabama, and Floyd County, Georgia (USFWS, 1991)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Abiotic, Insect (EPA, 2016)

**Breeding Season**

Adult: Flowering in mid-June; fruiting in July to August (EPA, 2016)

**Key Resources Needed for Breeding**

Adult: Insects for pollination (EPA, 2016)

**Reproduction Narrative**

Adult: Mohr’s Barbara’s button flowers mid-May to June (Patrick et al. 1995). Flowers are pollinated by beetles, butterflies, and other small insects and must be cross-pollinated to set viable fruit (USFWS, 2019).

**Habitat Type**

Adult: Wetland, Terrestrial (NatureServe, 2015b)

**Habitat Vegetation or Surface Water Classification**

Adult: Barrens, forest edges, meadows, grasslands (NatureServe, 2015b)

**Dependencies on Specific Environmental Elements**

Adult: sandy clays, which are alkaline, high in organic matter, and seasonally wet (USFWS, 1991)

**Environmental Specificity**

Adult: Narrow (NatureServe, 2015b)

**Habitat Narrative**

Adult: The habitat is moist prairie-like openings in woodlands, along shale-bedded streams, and meadows. The soils are sandy clays, which are alkaline, high in organic matter, and seasonally wet. Most currently known populations occur on soils of the Conasauga-Firestone Association. Plants occur in full sun or partial shade in a grass-sedge community (USFWS, 1991; NatureServe, 2015).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seeds are probably dispersed by birds and other small mammals (USFWS, 2019).

***Population Information and Trends***

**Population Trends:**

Not available.

**Number of Populations:**

19 extant (USFWS, 2022)

**Population Size:**

Up to 6,740 individuals estimated (USFWS, 2016)

**Population Narrative:**

Schotz (2014) estimated the total range-wide population to be up to 6,740 individuals. Additional recent survey data from some of these sites and other sites not visited by Schotz in Alabama (e.g., AANG 2015, TVA 2015) suggests that this estimate is low; however, 2015 surveys by Malcolm Hodges (pers. comm. 2015) did not relocate plants at three small sites in Georgia where Schotz had previously found them. Together, this recent survey data suggests that the range-wide Mohr’s Barbara’s buttons population size may approach 10,000 plants (Schotz 2014, AANG 2015, M. Hodges pers. comm. 2015, TVA 2015). Individual sites may range from fewer than 20 plants to well over 1,000 (Schotz 2014, AANG 2015, TVA 2015); although, most (27

[79%]) of the 34 extant sites surveyed by Schotz support 200 or fewer plants. Furthermore, two-thirds of the plants encountered during Schotz's surveys were found at only seven sites. Additionally, Schotz noted that at a given site, plants may be clustered in areas of approximately 50 square feet or can be scattered across several acres, which is similar to observations made by others (i.e., AANG 2015, TVA 2015). (USFWS, 2016).   19 known extant populations (USFWS, 2022)

***Threats and Stressors***

**Stressor:** Destruction and Degradation of Habitat (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Clearing, conversion, and agricultural activities remain persistent threats to various Mohr's Barbara's buttons' occurrences (Schotz 2014). Nearly one-third (11 of 34) of extant sites Schotz (2014) surveyed have been converted to pine plantations and/or had been impacted by recent timber harvests. In addition, logging is thought to have extirpated Etowah County, Alabama's only known population (Schotz 2014, D. Spaulding pers. comm. 2015), while conversion to row crop agricultural field has likely extirpated one population in Cherokee County, Alabama (Schotz 2014). Suitable habitat for Mohr's Barbara's buttons remains vulnerable to loss. As described above, most Coosa Valley prairies are thought to have been lost since the early 1800s with the only known remnants of this habitat currently located in Floyd County, Georgia (Duncan 2013). Similarly, Bibb County, Alabama's Ketona dolomite glades are unique and exceedingly rare habitats and are vulnerable to damage by recreational uses and adjacent logging activities. Schotz (2014) noted damage to two glades by recreational traffic (e.g., ATV use) and logging damage or vulnerability of two others. Construction of a borrow pit is thought to have reduced available habitat for one site in Floyd County, Georgia (Schotz 2014). Furthermore, development and associated habitat destruction are projected to continue for decades to come throughout the southeastern United States (Stein et al. 2010), which could further encroach upon and limit habitat suitable for Mohr's Barbara's buttons.  (USFWS, 2016)

**Stressor:** Inadequate/Incompatible Habitat Management (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** An important threat to Mohr's Barbara's buttons' continued survival is incompatible and inadequate land management. While the species is apparently able to survive certain types of forestry practices (e.g., limited timber harvesting that opens up the canopy), its apparent inability to tolerate heavy shading likely increases it susceptibility to practices that promote vegetation succession and encroachment of invasive species (e.g., fire suppression). Fire may be an important mechanism for maintaining the open character of some of Mohr's Barbara's buttons habitats. Inadequate fire regimes threaten some occurrences by allowing competing vegetation—particularly hardwoods—to grow unchecked, thereby encroaching upon available habitat for Mohr's Barbara's buttons and reducing availability of resources (e.g., light) that the species requires to survive and thrive (Patrick et al. 1995, Schotz 2014). Fire exclusion was noted as a primary threat to 24% of sites surveyed by Schotz (2014), whereas succession was considered a threat to 29%. Highway and utility rights-of-way are currently home to various Mohr's Barbara's buttons sites. The known extent of three extant populations are restricted to a

TVA utility right-of-way (in Jefferson County, Alabama), whereas portions of at least six other populations occur in either utility or road rights-of-way (Allison 1993, Schotz 2014, M. Hodges pers. comm. 2015). As such, these sites are heavily dependent upon compatible management regimes to maintain healthy populations (e.g., Schotz 2014, AANG 2015, TVA 2015). Mohr's Barbara's buttons is particularly vulnerable to herbicides and incompatible mowing regimes within its habitats; however, appropriate mowing regimes may also serve as valuable conservation tools in these areas (Schotz 2014). Schotz (2014) noted that nearly one-third of all sites surveyed were vulnerable to incompatible management regimes within rights-of-way throughout the species' range. Furthermore, at least one site along a road right-of-way in Cherokee County, Alabama is thought to have been extirpated by incompatible management (Schotz 2014). Additional emphasis on reintroducing fire or fire surrogates (e.g., mowing) is needed to promote healthy populations and maintain open conditions that this species requires. (USFWS, 2016)

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Mohr's Barbara's buttons is a State threatened plant in Georgia (Patrick et al. 1995) and, therefore, receives State protection from non-permitted collection and sale; however, State law does not provide protection against habitat destruction in Georgia. Collection of this species on public lands without a permit is prohibited in Georgia under the Georgia Wildflower Preservation Act of 1973, O.C.G.A. 12-6-170. No such provisions are afforded to plants found on privately owned lands in the State. The species does not receive any specific legal protections from State laws or regulations in Alabama. (USFWS, 2016)

**Stressor:** Invasive Species (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** During the most recent range-wide survey, Schotz (2014) noted that invasive species are a potential threat to some Mohr's Barbara's buttons populations. Indeed, Schotz (2014) observed encroachment of exotic invasive plants species at 14 Mohr's Barbara's buttons sites. These species—predominantly Chinese privet (Ligustrum sinense)—left unchecked have the potential to degrade habitat quality and out-compete Mohr's Barbara's buttons for resources (e.g., moisture, nutrients, light, and recruitment sites). Currently, threats posed from invasive plants at most sites appears to be minimal (Schotz 2014); however, habitat management (e.g., fire, mechanical or hand thinning, etc.) may be required to control invasive species where they threaten Mohr's Barbara's buttons. (USFWS, 2016). Wild Hogs Rooting by wild hogs (Sus scrofa), which are non-native invasive species, was noted in the vicinity of some Mohr's Barbara's buttons occurrences in Bibb County, Alabama, but was not observed directly impacting Mohr's Barbara's buttons (M.S. Wiggers, pers. obs., August 2017). Although no direct impacts to Mohr's Barbara's buttons by wild hogs have yet been observed, wild hogs may represent an emerging threat to some populations. As has been summarized elsewhere, wild hogs can cause myriad deleterious effects—ranging from direct destruction of plants to degradation of habitat—on the communities in which they are found (cf. Massei and Genov 2004, Barrios-Garcia and Ballari 2012). Continued monitoring is needed to further assess the potential impacts and threats posed by wild hogs (USFWS, 2022).

**Stressor:** Small Population Size (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Most extant populations of Mohr’s Barbara’s buttons are comprised of a number of small, fragmented occurrences. While population sizes (i.e., number of plants obtained from counts or estimates) are not available for all sites/populations of Mohr’s Barbara’s buttons, the most recent range-wide status assessment by Schotz (2014) found that most sites had small local population sizes and that most of the range-wide population was contained in only a few sites with comparatively large local populations. Indeed, Schotz found that 53% (18 of 34) of extant sites had local populations of ≤100 individuals and 79% (27 of 34) of these sites had ≤200 individuals. Together, sites with ≤200 individuals accounted for about one-third of the total population evaluated by Schotz. By contrast, only three sites evaluated were found to have 500 or more plants, which accounted for nearly half of the entire population evaluated range-wide. Small population sizes increase the vulnerability of individual sites to environmental and anthropogenic perturbations and chance events. In addition, small population sizes increase the risks posed by inbreeding and genetic drift, which may limit the species’ adaptive capacity and ability to cope with future stressors (Ellstrand and Elam 1993). (USFWS, 2016)

**Stressor:** Climate Change (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The precise magnitude and impacts of climate change on the southeastern United States are uncertain, but models have projected that climate change in the region may include increased temperatures of 2 to 4°C (3.6 to 7.2°F) accompanied by reduced average annual precipitation by the end of the century (Joyce et al. 2011). Specific impacts of climate change on populations of Mohr’s Barbara’s buttons are poorly understood; however, a variety of impacts are possible. Climate change has the potential to affect distribution and abundance of plants by influencing seasonal weather patterns, frequency and timing of severe weather events, and myriad plant physiological responses (Hawkins et al. 2008). Davenport (2007) suggested that Mohr’s Barbara’s buttons may be negatively impacted by climate change within Alabama as available habitat becomes constricted. In addition, climate change may disrupt plant-pollinator interactions via phenological shifts in flowering and/or pollinator activity (Memmott et al. 2007, Hawkins et al. 2008), which may thereby reduce sexual reproduction of Mohr’s Barbara’s buttons. While disease is not currently known to threaten Mohr’s Barbara’s buttons, climate change has the potential to promote the spread of infectious diseases among plants, particularly if arthropod vectors become more widespread and abundant (Anderson et al. 2004, Garrett et al. 2006, Hawkins et al. 2008). Given the variety and complexity of climate change’s potential effects (cf. Hawkins et al. 2008, Walther 2010), more research is needed to assess its potential long-term impacts on Mohr’s Barbara’s buttons populations and habitats. (USFWS, 2016)

***Recovery***

**Reclassification Criteria:**
Not applicable.

Recovery Priority Number: 14

**Delisting Criteria:**
1. There are 15 viable populations and all are protected from present and foreseeable human-related and natural threats (USFWS, 1991)

2. At least three populations each should be located within the two physiographic regions represented by its historic range (Cumberland Plateau, Ridge and Valley) (USFWS, 1991).

3. At least three of the 15 populations should be located within Alabama and three in Georgia. Viability of populations will be assessed through monitoring for a period not less than 15 years (USFWS, 1991).

**Recovery Actions:**
- Protect existing populations from any present or foreseeable threats, and search for additional populations (USFWS, 1991)
- Determine population size. Conduct demographic studies and gather life history information (USFWS, 1991).
- Determine habitat characteristics. An understanding of this species ecology is an important component to determining what factors limit its distribution (USFWS, 1991).
- Determine parameters of a viable population. The long-term survival of the species will be ensured only if a sufficient number of viable populations are protected. (USFWS, 1991).
- Determine and implement appropriate management. Management of habitat, as well as protection, appears to be essential for ensuring that vigorous populations are maintained (USFWS, 1991).
- Conduct monitoring studies. A general monitoring program should be devised and implemented on sites in order to track population trends and evaluate the effectiveness of recovery efforts (USFWS, 1991).
- Preserve genetic material. Protection of the gene pool should be accomplished through seed bank storage and by maintaining material in cultivation (USFWS, 1991).
- Recommendations for Future Actions from 2016 5-Year Review: •Work with federal and state entities, non-governmental organizations, and private individuals to permanently protect and manage existing habitats and populations, including the development and implementation of management plans, as needed. •Conduct studies to determine the number and distribution of populations required to maintain the species’ genetic diversity. •Investigate metapopulation structure and dynamics of the species. •Conduct studies into the species’ life history, biology, and ecology. •Investigate efficacy of habitat management techniques (e.g., fire). Update and improve monitoring and habitat management methods. •Update the species’ recovery plan to reflect current knowledge (e.g., distribution, habitats) and needs (e.g., data/knowledge deficiencies, management). (USFWS, 2016)
- Personnel of the Alabama Highway Department (Department) are aware of the plants on or near the ROWs they maintain and of the importance of protecting them. An informal agreement exists between the U.S. Fish and Wildlife Service (Service) and the Department for protection of the plants on their ROWs (USFWS, 1991).
- One population on private land in Cherokee County is protected through a long-term Cooperative Agreement (USFWS, 1991).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIVITIES The following actions are recommended to support and promote recovery of Mohr's Barbara's buttons. Use of a numbered list for these recommendations is for convenient reference and does not necessarily imply prioritization of any action over others. 1. Work with federal and state entities, non-governmental organizations, and private individuals to permanently protect and manage existing habitats and populations, including the development and implementation of management plans, as needed. 2. Investigate efficacy of habitat management techniques (e.g., fire). Update and improve monitoring and habitat management methods. 3. Conduct studies to determine the number and distribution of populations required to maintain the species' genetic diversity. 4. Investigate metapopulation structure and dynamics of the species. 5. Conduct studies into the species' life history, biology, and ecology. 6. Update the species' recovery plan to reflect current knowledge (e.g., distribution, habitats) and needs (e.g., data/knowledge deficiencies, management) (USFWS, 2022).

# SPECIES ACCOUNT: *Mentzelia leucophylla* (Ash Meadows blazingstar)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A biennial herb, up to 5 dm high. The leaves are densely covered with soft white hairs. Bright yellow flowers bloom from late May into September. Flowers open only for brief periods in late afternoon. (NatureServe, 2015)

**Taxonomy**

Possibly a variant of M. oreophila per Jim Morefield, NVHP. (NatureServe, 2015)

**Current Range**

Western slope and bajadas of mountain range in Ash Meadows, south Nye County, Nevada. (NatureServe, 2015)

**Critical Habitat Designated**

Yes; 5/20/1985.

**Legal Description**

On May 20, 1985, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Mentzelia leucophylla (Ash Meadows blazingstar) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in Nevada (50 FR 20777-20794).

**Critical Habitat Designation**

The critical habitat designation for Mentzelia leucophylla includes one CHU in Nye County, Nevada (50 FR 20777-20794).

Nevada, Nye County, Ash Meadows.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation.  The PCEs of Mentzelia leucophylla critical habitat consists of one component (50 FR 20777-20794):

Known primary constituent elements include sandy or saline clay soils along canyon washes and near springs and seeps.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

<u>Adult:</u> Sexual (inferred from USFWS, 1990)

**Breeding Season**

Adult: Flowering continues from June to September (USFWS, 1990)

**Other Reproductive Information**

Adult: Flowering is exhibited by bright yellow flowers arranged in open, broad infloresences (USFWS, 1990)

**Reproduction Narrative**

Adult: The Ash Meadows Blazingstar is inferred to reproduce sexually. Its flowering season occurs from June to September. Flowers are bright yellow, arranged in open and broad infloresences (USFWS, 1990).

**Habitat Type**

Adult: Desert wetland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Springs and seeps that are fed by an extensive groundwater system; light-colored, fine-grained soils with a high salt content (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Local distribution of small populations (USFWS 1990)

**Environmental Specificity**

Adult: Very Narrow (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from USFWS 1990)

**Habitat Narrative**

Adult: This species inhabits desert wetland, near springs and along canyon washes maintained by springs and seeps that are fed by an extensive groundwater system. Found in light-colored, fine-grained soils with a high salt content, often growing with 2 other narrowly endemic plants: the Ash Meadows milk-vetch (Astragalus phoenix) and the Ash Meadows sunray (Enceliopsis nudicaulis var. corrugata) (NatureServe, 2015). The species is distributed locally in small populations. Tolerance ranges are inferred to be low (USFWS, 1990).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Little or no information exists on seed dispersal, seed germination, or seedling establishment in the wild. Additional dispersal/migration information is also lacking (inferred from USFWS, 1990).

***Population Information and Trends***

**Number of Populations:**

2 Max scale, 12 minimum scale (USFWS, 2020)

**Population Size:**

1,513 (USFWS, 2020)

**Population Narrative:**

There is little information about population level and species level trends. In 1997 there were 8 known populations, but the current population number estimate has been reduced to 1-5 populations (NatureServe, 2015).

***Threats and Stressors***

**Stressor:** Habitat disruption (USFWS 1990)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Approximately 65 miles of gravel and unimproved roads now exist within the essential habitat, directly affecting this species (USFWS, 1990)

**Stressor:** Agricultural use (NatureServe, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Agricultural use presents a general threat to this species (NatureServe, 2015)

**Stressor:** Trampling by horses, cattle, and sheep (NatureServe, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Destruction by horses presents a general threat to this species (NatureServe, 2015)

**Stressor:** Proposed MX missile system (NatureServe, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The proposed MX missile system is considered to be a possible threat to this species (NatureServe, 2015)

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 8

**Delisting Criteria:**
1. All non-native animals and plant species must be eradicated from essential habitat. These non-native species currently include sailfin mollies, mosquitofish, largemouth bass, black bullheads, bullfrogs, crayfish, turban snails, wild horses, salt cedar and Russian olive (USFWS, 1990).

2. Secure and protect the Ash Meadows aquifer so that all spring flows return to historic discharge rates, and the water level in Devils Hole is maintained at a minimum level of 1.4 feet below the copper washer (USFWS, 1990).

3. Reestablish water to historic springbrook channels, which are free of barriers that eliminate genetic exchange between populations by preventing movement of native fishes throughout their historic range (USFWS, 1990).

4. The essential habitat must be secure from detrimental human disturbance including mining, OHVs, and the introduction of non-native species (USFWS, 1990).

5. Secure, protect, and maintain in natural vegetation, corridors, and adjacent buffer areas for gene flow and dispersal of listed plant species within the essential habitat (USFWS, 1990).

6. Native plant communities and aquatic communities have been reestablished to historic structure and composition within all essential habitats (USFWS, 1990).

7. All of the listed plant species and the candidate plant species are present in all the sites that they have historically occupied as identified in Appendix A Table XV of the Recovery Plan. Within each critical habitat unit, the listed plant has a frequency value equal to or greater that the frequency value determined by Task 644 needed as an indicator of a self-sustaining plant population (USFWS, 1990).

**Recovery Actions:**

- Secure habitat and water sources for the Ash Meadows ecosystem (USFWS, 1990)
- Conduct research on the biology of the species (USFWS, 1990)
- Conduct management activities within essential habitat (USFWS, 1990
- Reestablish populations/monitor new & existing populations (USFWS, 1990)
- Determine/verify recovery objectives (USFWS, 1990)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Over the next five years, the Service should focus on: • Monitor compliance with Nevada Revised Statute Order 1197A (January 12, 2018), Curtailment of New Appropriations of Groundwater within the Amargosa Valley Hydrographic Basin 230, that prohibits new applications for water or water diversions within 25 miles of Devils Hole (and by proximity Ash Meadows NWR). Order 1197A supersedes 1197, which imposed similar regulations at 10 miles from Devils Hole. Water levels in Devils Hole are affected by pumping centers in the Amargosa Desert and the Ash Meadows groundwater basins (Halford and Jackson 2020). • Collaborate with the Ash Meadows NWR to implement the Desert National Wildlife Refuge Complex – Ash Meadows, Desert, Moapa Valley, and Pahranagat National Wildlife Refuges Final Comprehensive Conservation Plan and Environmental Impact Statement, Volume I – August 2009 (Service 2009) and also the Draft Ash Meadows Natural Resource Management Plan in review (Service 2020); • Support Ash Meadows blazingstar research at the Ash Meadows NWR to monitor the population as identified in the Recovery Plan for the Endangered and Threatened Species of Ash Meadows (Service 1990); and • Monitor the future activity of mineral rights in the Ash Meadows area. The BLM ACEC surrounding the refuge is withdrawn from mining and entry until 2029 (PLO# 7737, signed November 2, 2009), but requires renewal every 20 years. Mining can still occur on private inholdings within the refuge, but no active mining permits exist at this time.(USFWS, 2020)

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Monitor compliance with the January 12, 2018, Nevada Revised Statute Order 1197A, Curtailment of New Appropriations of Groundwater within the Amargosa Valley Hydrographic Basin 230, to ensure groundwater levels in Devils Hole can support the population (Nevada State Engineer 2018). Order 1197 is no longer in effect. Water levels in Devils Hole are affected by pumping centers in Amargosa Desert and the Ash Meadows groundwater basins (Halford and Jackson 2020); 2. Collaborate with the Ash Meadows NWR to implement the Desert National Wildlife Refuge Complex – Ash Meadows, Desert, Moapa Valley, and Pahranagat National Wildlife Refuges Final Comprehensive Conservation Plan and Environmental Impact Statement, Volume I – August 2009 (Service 2009) and the Ash Meadows Natural Resource Management Plan (Service 2020b); 3. Support Ash Meadows blazingstar research at the Refuge to monitor the population as identified in the Recovery Plan for the Endangered and Threatened Species of Ash Meadows (Service 1990); and 4. Monitor the future activity of mineral rights in the Ash Meadows area. The BLM Area of Critical Environmental Concern surrounding the Refuge is withdrawn from mining and entry until 2029 (PLO# 7737, signed November 2nd, 2009), but requires renewal every 20 years. Mining can still occur on private inholdings within the Refuge, but no active mining permits exist at this time. (USFWS, 2025)

# SPECIES ACCOUNT: *Mimulus michiganensis* (Michigan monkey-flower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Great Lakes-Big Rivers Region (R3) (USFWS, 2015)

**Physical Description**

The Michigan monkey-flower is a member of the Scrophulariaceae (snapdragon) family and is an aquatic to semi-aquatic glabrous perennial herb with lax stems averaging 36 cm (14 in) in length. It roots at its lower stem nodes to produce clones of up to several hundred stems. The broadly ovate to roundish, opposite leaves are inconspicuously to coarsely sharp-toothed and evenly distributed along the stem. Bright yellow, snapdragon-like, tubular flowers, ranging from 16 to 27 mm (0.6 to 1.1 in) in length, are produced from the upper leaf axil and are borne on slender pedicels that may be longer than the leaves. The flowers have two upper lips and three-lobed lower lips, with the lower lip and tube irregularly spotted.

**Taxonomy**

Direct final rule (revised the scientific name from Mimulus glabratus var. michiganensis to Mimulus michiganensis) effective December 13, 2010. (USFWS, 2018).

**Current Range**

There are 19 element occurrences, including two historical occurrences (MNFI 2012) of MMF, ranging from Benzie and Leelanau counties to Mackinac County (Figure 3 and Appendix A). However, the majority of occurrences are clustered within the Mackinac Straits region. The newest colony was discovered in 2008 (MNFI 2012). Overall, the entire population is stable, although MMF colonies at a few sites are in decline (MNFI 2012). However, this information was obtained from records in which most have not been updated in more than 10 years (MNFI 2012). A systematic survey would provide a more accurate description of MMF abundance and population trends.

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: bloom from approximately mid-June to mid-August, extending occasionally into October.

**Reproduction Narrative**

Adult: Michigan monkey-flowers bloom from approximately mid-June to mid-August, extending occasionally into October. The fruit, which is seldom produced, consists of an oblong, pointed capsule around 8–10 mm (0.3–0.4 in) long, containing numerous oval seeds with longitudinal striations. Michigan monkey-flower essentially has no pollen viability and is nearly totally dependent on vegetative propagation via rhizomes (Bliss 1983, Bliss 1986). The Maple River population is the only population that has viable pollen and is capable of self-pollination (Posto and Prather 2000, Posto 2001). The taxon as a whole is also highly unlikely to produce seed asexually (Posto and Prather 2000). Because MMF depends primarily on vegetative propagation for reproduction, dispersal is greatly limited and likely occurs only locally through the fragmentation of clonal colonies.

**Habitat Type**

Adult: Alkaline spring seepages and streams

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Michigan monkey-flower is a very rare Michigan endemic that is restricted to cold, alkaline spring seepages and streams, usually in association with northern white cedar (Thuja occidentalis) swamps found along current or post-glacial Great Lakes shorelines. It frequently occurs in cedar swamps formed in drainages found at the base of relatively steep, moraine slopes and bluffs. Colonies of MMF have been found in muck-covered sand in cold, flowing water that ranged in temperature from 8.7° to 16.6°C (47.6° - 61.9°F), and with a pH of 7.66 to 8.21. However, research (Posto 2001) has shown that MMF seeds germinate best in light at approximately 23°C, suggesting that seed germination is probably highest along the water margins in the sun, rather than under water. Optimal habitat conditions for this plant are comprised of a combination of moderate to high light availability, cool substrate, and high nutrient availability within a narrow pH range, demonstrating its relatively specialized habitat requirements.

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Increasing (USFWS, 2018).

**Number of Populations:**

18 (USFWS, 2023)

**Population Size:**

1 - 1000 individuals (NatureServe, 2015)

**Population Narrative:**

There are 19 element occurrences, including two historical occurrences (MNFI 2012) of MMF, ranging from Benzie and Leelanau counties to Mackinac County (Figure 3 and Appendix A). However, the majority of occurrences are clustered within the Mackinac Straits region. The newest colony was discovered in 2008 (MNFI 2012). Overall, the entire population is stable, although MMF colonies at a few sites are in decline (MNFI 2012). However, this information was obtained from records in which most have not been updated in more than 10 years (MNFI 2012). A systematic survey would provide a more accurate description of MMF abundance and population trends. Occurrences of Michigan monkey-flower are often localized, sometimes consisting of small but dense patches restricted to small seeps, springs, and depressions, whereas others are comprised of numerous patches of plants widely dispersed along small streams and spring-fed seeps within northern white cedar swamps (Penskar and Higman 2001). Large to moderately-sized populations include occurrences on Glen Lake, Burt Lake, and portions of the Mackinac County shoreline within the Manitou Payment Highbanks formation in the Brevort to Epoufette region (Penskar and Higman 2001). Relatively little population monitoring has been conducted for MMF, and thus the demography of its populations cannot be characterized. However, observations of colonies of the taxon through summer and winter seasons indicate that in fall colonies die back and become more or less dormant in streams and springs where water flow and temperature stay relatively constant, with colonies re-initiating growth in spring. Occurrences of Michigan monkey-flower are often localized, sometimes consisting of small but dense patches restricted to small seeps, springs, and depressions, whereas others are comprised of numerous patches of plants widely dispersed along small streams and spring-fed seeps within northern white cedar swamps (Penskar and Higman 2001). Large to moderately-sized populations include occurrences on Glen Lake, Burt Lake, and portions of the Mackinac County shoreline within the Manitou Payment Highbanks formation in the Brevort to Epoufette region (Penskar and Higman 2001). Range and distribution: Currently Michigan monkey-flower has 18 extant element occurrences. Recent surveys have indicated that at two areas, populations had extended beyond the area previously thought to be occupied and therefore, some adjacent element occurrences have been combined. The previous status review (2018) for Michigan monkey-flower listed 23 element occurrences. The species still occurs in the same six Michigan counties – Benzie, Leelanau, Charlevoix, Emmet, Cheboygan, and Mackinac (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Invasive Plants
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The greatest threat to MMF is direct destruction and modification of its habitat. Michigan monkey-flower’s habitat has been developed for recreational and residential purposes, which has led to severe impacts to and, in some cases, extirpation of historical populations. Hydrological disruptions also constitute a serious threat, as water diversion, warming of water sources, and other groundwater alterations lead to less than optimal habitat conditions. Consequently, this species may be inadvertently impacted by offsite activities. Populations of MMF are particularly vulnerable to extirpation due to low numbers and limited capability for sexual reproduction. Additionally, periodic high water levels of the Great Lakes and strong winter storms impact MMF habitat that occurs near the Great Lakes shoreline by redirecting seepage streams and opening the overstory by felling cedars. However, opening of the overstory may also benefit MMF by allowing for colonization. Invasive species, such as coltsfoot (Tussilago farfara) and reed canary grass (Phalaris arundinacea), represent an additional threat. Coltsfoot (Figure 2) is a very aggressive invasive plant growing within several MMF patches in the Glen Lake area (Jody Marquis, Mama Bear Restorations, Inc., pers. comm. 2010). It spreads rapidly via vegetative reproduction by rhizomes and windborne distribution of dandelion-like seed heads. The Glen Lake area provides habitat to several high-ranking MMF colonies and without intervention and control of coltsfoot, localized extirpations are likely. Reed canary grass, although not a current threat to MMF colonies, is present in the vicinity. Control of reed canary grass when it is not yet considered a threat, is most successful at this stage, and minimizes its chances of negatively impacting MMF in the Glen Lake area. (USFWS, 2016). Additional invasive plant threats posed by

marsh thistle (Cirsium palustre) and Canada thistle (Cirsium arvense). (USFWS, 2018).

**Stressor:** Climate change
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Our analyses under the Endangered Species Act include consideration of ongoing and projected changes in climate. The terms “climate” and “climate change” are defined by the Intergovernmental Panel on Climate Change (IPCC). “Climate” refers to the mean and variability of different types of weather conditions over time, with 30 years being a typical period for such measurements, although shorter or longer periods also may be used (IPCC 2007). The term “climate change” thus refers to a change in the mean or variability of one or more measures of climate (e.g., temperature or precipitation) that persists for an extended period, typically decades or longer, whether the change is due to natural variability, human activity, or both (IPCC 2007). Various types of changes in climate can have direct or indirect effects on species. These effects may be positive, neutral, or negative and they may change over time, depending on the species and other relevant considerations, such as the effects of interactions of climate with other variables (e.g., habitat fragmentation) (IPCC 2007). In our analyses, we use our expert judgment to weigh relevant information, including uncertainty, in our consideration of various aspects of climate change. Climate change models predict the climate of the Great Lakes region will grow warmer and drier over the next century, with precipitation increasing in winter and decreasing in summer (AMEC 2006; Anton Reznicek, University of Michigan, pers. comm. 2004; Kling et al. 2003). Average temperatures in the Great Lakes region could increase by 3 to 7°C in winter and 3 to 11°C in summer by the year 2100. While average annual precipitation could increase by 10–20 percent, significant changes in the seasonal precipitation cycle are likely, with winter and spring rain increasing and summer rain decreasing by up to 50 percent (Kling et al. 2003). A warmer, drier summer will affect surface and groundwater levels, as well as soil moisture, which is projected to decrease by 30 percent in summer (Kling et al. 2003). Earlier models had indicated that increased precipitation, higher air temperatures, and reduced ice cover would increase evaporation in the Great Lakes, resulting in lake level drops of 1.5 feet to as much as 8 feet (Sousounis and Glick 2000, AMEC 2006, Kling et al. 2003). However, more recent models show a more variable response in lake levels. A majority of the model simulations run by Angel and Kunkel (2010) resulted in reductions in lake levels, yet also showed a high degree of uncertainty in possible future lake levels, depending on future emissions. Furthermore, Hayhoe et al. (2010) suggested that the competing effects of shifting precipitation and warmer temperatures will result in little change in Great Lakes levels until the end of the century, when net decreases in lake levels are expected under higher emission scenarios. A warmer climate will also likely cause an increase in water temperatures that may facilitate the invasion of warm water-adapted species or exotic species (MacIsaac et al. 2002; AMEC 2006). Increased water temperatures will also result in decreased ice cover and, when combined with an expected intensity of winter storms, will leave coastal areas more vulnerable to the effects of winter storms and flooding (Fang and Stefan 2000, AMEC 2006). Additionally, AMEC (2006) predicts that increased precipitation will increase the flow rates of some rivers and streams, resulting in increased scouring, deposition of sediment, nutrients and pesticides, bank erosion, channel widening, and siltation of gravel beds and estuaries. Thus, climate change could significantly alter the natural stream morphology and likely make the habitat unsuitable for this Michigan endemic.

**Stressor:** Predation (USFWS, 2018).

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The NPS at Sleeping Bear Dunes National Lakeshore (Jennifer Chaffin, NPS pers. commun. 2011) observed evidence of deer browse in the past and, more recently, evidence of insect browse on Michigan monkey-flower plants in the vicinity of their Orr Restoration Site. The average insect browse in 2011 was three percent for the whole Michigan monkey-flower population within the restoration site while deer browse prior to 2011 was observed to be as much as 25 percent (Chaffin, pers. commun. 2011). (USFWS, 2018).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 8C

**Recovery Actions:**

- The Michigan Monkey-flower Recovery Plan was approved on September 17, 1997 (USFWS 1997). The objective of the recovery plan is to secure long-term protection for all occurrences of MMF, thereby allowing reclassification, and ultimately, removal from the Federal List of Endangered and Threatened Wildlife and Plants. Michigan monkey-flower may be considered for reclassification from endangered to threatened status when protection is secured for all eight occurrences ranked “A - excellent” or “B - good” and delisted when all occurrences are sufficiently protected. The recovery goals listed in the recovery plan are: (1) long-term protection for all known existing occurrences, with primary emphasis on the preservation of essential habitat; (2) field surveys for new occurrences and to determine the specific status of recently discovered and historical sites; (3) biosystematics research to determine the most appropriate taxonomic classification, and; (4) demographic, physiological, breeding system, and genetic studies to understand population biology, specific habitat requirements, floral biology, and genetic variability, and long-term post-delisting viability monitoring.
- New in 2018 - 1: Develop a plan for conducting regular surveys, assessments, and monitoring at all known extant and historical Michigan monkey-flower locations. Continue exploration for new occurrences in the Lower Peninsula and eastern Upper Peninsula, and provide detail mapping of all occurrences. Document habitat and status conditions and population trends during these assessments. Recovery plan action numbers: 2-21, 2-22, 2-23, 2-45  Penskar (2012) was not able to access the Manitou Payment Highbanks occurrence due to a lack of permission from the landowner, and the historical Mullet Lake-West Shore occurrence was not accessed due to insufficient time and resources. Both of these sites should be considered priorities for future surveys. (USFWS, 2018).
- 2018 - 2: Research is needed to understand the genetic diversity within and between patches or populations. Recovery plan action number: 2-44 (USFWS, 2018).
- 2018 - 3: Research is needed to understand the genetic diversity within and between patches or populations. Recovery plan action number: 2-44 (USFWS, 2018).
- 2018 - 4: Work with public and private landowners, site managers, and other stakeholders to protect the species and its stream/seep habitat upstream, if possible. Acquire land containing occupied or suitable Michigan monkey-flower habitat. Recovery plan action numbers: 2-13, 2-15. (USFWS, 2018).

- 2018 - 5: Provide education and outreach to stakeholders and the public. Recovery plan action number: 1-121 (USFWS, 2018).
- 2018 - 6: Monitor approach of non-native species and control as appropriate. Recovery plan action number: N/A (USFWS, 2018).
- 2018 - 7: Evaluate if the fundamental recovery objective in terms of the number of previously known and newly discovered occurrences requiring long-term protection warrants revision. (USFWS, 2018).

***Conservation Measures and Best Management Practices:***

- Recommendations for future actions • Develop a plan for conducting regular surveys, assessments, and monitoring at all known extant and historical Michigan monkey-flower locations. It is especially important to prioritize populations that have not been surveyed in the last decade. An updated population status is crucial for these areas. Continue exploration for new occurrences in the Lower Peninsula and eastern Upper Peninsula and provide detail mapping of all occurrences. Document habitat and status conditions and population trends during these assessments. Recovery plan action numbers: 2-21, 2-22, 2-23, 4-45 • Monitor non-native and aggressive native species and control as appropriate. • Genetic research to understand the diversity among and between populations. Recovery plan action number: 2-44 • Acquire land containing occupied or suitable Michigan monkey-flower habitat. Create outreach materials for public and private landowners, site managers, and general stakeholders to inform and protect the species and its habitat. Recovery plan action numbers: 1-121, 1-122, 1-123, 1-15 (USFWS, 2023).

# SPECIES ACCOUNT: *Mirabilis macfarlanei* (MacFarlane's four-o'clock)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 11/29/1979; Pacific Region (R1)

**Physical Description**

A herbaceous perennial with a deep-seated, thickened root. This species typically blooms from May through June. The bright pink flowers are conspicuous, up to 25 millimeters (1 inch) long by 25 millimeters (1 inch) wide. The flowers occur in inflorescences, which consist of a group of three to seven flowers subtended by a five-lobed involucre (saucer-shaped bract). The flowers are funnel-shaped with awidely expanding limb. Leaves are opposite, somewhat succulent, and broadly lanceolate to ovate. (USFWS, 2000)

**Taxonomy**

Mirabilis macfarlanei is a member of the four-o’clock family (Nyctaginaceae). It was first described in 1936 (Constance and Rollins 1936) from specimens collected along the Snake River Canyon. Mirabilis macfarlanei is morphologically similar to Mirabilis greenei, found in the Klamath region of California and Oregon. In contrast to M greenei, M macfarlanei has broader leaves and shorter, nearly round bracts (Constance and Rollins 1936). At least two other species of Mirabilis occur in the Pacific Northwest (M linearis and M bigelovii var. retrorsa), but these species do not overlap in distribution with M macfarlanei (Hitchcock and Cronquist 1973). (USFWS, 2000)

**Historical Range**

M. macfarlanei was known from only three populations along the Snake River Canyon in Oregon (Hell’s Canyon National Recreation Area) and the Salmon River Canyon in Idaho. (USFWS, 2000)

**Current Range**

Portions of the Snake, Salmon, and Imnaha river canyons in Wallowa County in northeastern Oregon, and adjacent Idaho County in Idaho. (USFWS, 2000)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Asexual (USFWS, 2016); Sexual (USFWS, 2000)

**Lifespan**

Adult: > 20 years (based on observations of individual plants) (USFWS, 2000)

**Breeding Season**

Adult: Seeds are typically dispersed in June and July, and seed germination probably occurs in early spring.(USFWS, 2000)

**Other Reproductive Information**

Adult: Specific conditions required for germination and seedling survival are unknown (USFWS, 2000)

**Reproduction Narrative**

Adult: Mirabilis macfarlanei reproduces by seed, as demonstrated by the presence of seedlings with cotyledons and the documented survival of some of these seedlings in population monitoring studies (Kaye 1992). Vegetative reproduction by off-shoots beneath the soil surface also occurs. M. macfarlanei is primarily an outcrosser, but is able to produce a small proportion of one-seeded fruits through autogamy (self-pollination). Inflorescences bagged to exclude pollinators produced fewer fruits than open-pollinated inflorescences. Seed dispersal has not been studied, but apparently seeds fall to the ground and are transported by gravity and rain (Kaye 1992). Seed viability is low.; Mirabilis macfarlanei is a taprooted perennial that reproduces by seed, but also colonizes via long spreading rhizomes. Individual plants tend to produce a few to several hundred stems in clusters ranging up to about nine square meters in size (Callihan 1988). The species has been able to persist in areas historically grazed by livestock since the 1870's, and presently in poor ecological condition. Preliminary data suggests grazing may have a negative effect on plant height, but additional research is needed (Kaye 1995). The most serious consequences of livestock grazing are likely indirect, most notably habitat degradation. At one site in Idaho, the number of M. macfarlanei plants appears to be stable several years after a range fire. An increase in Bromus tectorum, however, suggests that habitat degradation is an ongoing problem. The underground stems of M. macfarlanei would survive most natural fires, especially since they would likely occur later in the summer, when the plant is dormant. Genetic studies (Barnes 1994; 1995; Wolf et al. 1994) have shown that measures of genetic diversity in M. macfarlanei were lower than for plants with a similar life history. The greatest level of gene flow occurred between populations that were 0.5 km apart. Levels of gene flow decreased as distances between populations increased.; ASEXUAL; Perfect; Predominantly outcrossing (NatureServe, 2015).

**Habitat Type**

Adult: River canyon slopes (USFWS, 2016)

**Environmental Specificity**

Adult: Narrow (USFWS, 2016)

**Habitat Narrative**

Adult: Gentle to very steep, open river canyon slopes. Aspects vary, but are usually southeast to west. Soils are often sandy and underlain by talus. Mirabilis macfarlanei occurs in river canyon habitats characterized by regionally warm and dry conditions. Precipitation occurs mostly as rain during the winter and spring. Sites are dry and open, or with scattered shrubs. Plants can be found on all aspects, but most often on southeast to western exposures. Slopes are often steep, but range to nearly flat. Plants can occur along any slope position. Soils vary from sandy to rocky. Talus rock often underlies the soil substrate and several sites are relatively unstable and prone to erosion. The associated vegetation is usually in early to mid-seral condition, and the grasslands are typically grazing modified versions of Agropyron spicatum communities. In a habitat analysis study conducted at a site in Oregon, the vegetation associated with a population of M. macfarlanei appeared to be influenced by aspect, soil development and topographic position, at least on a local scale (Kaye 1992). Nearby sites without M. macfarlanei had a higher number of weedy annual species, and more gentle slopes with deeper, more stable soils (USFWS, 2016).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seeds apparently fall near the parent plant and are transported by gravity and rain water. It is possible that M macfarlanei seeds may be dispersed by birds or mammals, but seed dispersal has not been studied for this species. No information exists on whether M macfarlanei maintains a soil seed bank (USFWS, 2000)

***Population Information and Trends***

**Population Trends:**

Stable (USFWS, 2016)

**Number of Populations:**

13 (USFWS, 2022)

**Population Narrative:**

Mirabilis macfarlanei occurs within the geographic area identified in the 2000 Recovery Plan: the Salmon, Snake, and Imnaha river canyons in Idaho and Oregon. The species occurs in 13 Element Occurrences (EOs), 9 in Idaho and 4 in Oregon. Land ownership is comprised of BLM, Forest Service, and private lands. Of the 13 EOs, 5 are located on BLM land, 1 is located on both BLM and private land, 4 are located on Forest Service land, 1 is located on both Forest Service and private land, and 2 are located solely on private land. Both the BLM and the Forest Service continue to conduct surveys for Mirabilis macfarlanei. The Forest Service conducted surveys in the Hells Canyon National Recreation Area, Wallowa-Whitman National Forest annually from 2007 through 2014. Approximately 4,700 acres of suitable habitat were surveyed over the 8 year period, with an average of nearly 600 acres per year. The BLM surveyed an average of approximately 1,000 acres of suitable habitat on BLM lands annually from 2010 through 2015. Despite these survey efforts, no new M. macfarlanei populations have been discovered since the last 5-year review in 2009. The BLM has established a new population of Mirabilis macfarlanei at the Lower Otto Creek Conservation area located on BLM land. The BLM worked cooperatively with a local private landowner to transplant approximately 25 rhizomes from private property to the Lower Otto Creek Conservation area in April 2015 (in accord with the FWS Section 7 Biological Opinion (dated July 22, 2011) prepared for the Shroyer Trail and Lower Otto Creek Conservation Area project). This population has not yet been counted as a new EO. Future monitoring will document the success of this transplanting. Monitoring data show an overall stable population trend for Mirabilis macfarlanei. In 2000, one of the action items identified in the M. macfarlanei Recovery Plan was to monitor population trends (U.S. Fish and Wildlife Service 2000). In 2007, the Service funded a project to synthesize and analyze monitoring data collected by the BLM between 1981 and 2004, and the Wallowa-Whitman NF from 2001 to 2006, and to provide a general review of the respective monitoring programs (Mancuso and Shepherd 2008). Among its results, analysis found no significant change in M. macfarlanei ramet abundance over the years at most monitored occurrences. Mirabilis macfarlanei forms colonies from an extensive lateral root system that can extend up to 10 meters (33 feet; Yates 2007).

Clonal shoots emanating from the same root system are referred to as ramets. Collectively, these genetically identical ramets comprise a genet (or the individual plant). While this review acknowledged the impressive monitoring datasets, which included over 20 years of data collection, it also included a set of recommendations to improve the efficiency and value of the BLM and Forest Service monitoring efforts. One of these recommendations was the development and implementation of a rangewide monitoring strategy (U.S. Fish and Wildlife Service 2007; U.S. Fish and Wildlife Service 2009). In response, a collaborative effort to develop and implement a new, standardized, rangewide monitoring program for M. macfarlanei was initiated in 2010. Development of the new monitoring program was guided by management objectives identified by the Service, the BLM, and the Forest Service. The overall purpose of the new monitoring plan is to provide more comprehensive documentation and a better understanding of the rangewide conservation status of M. macfarlanei. The monitoring program is designed to collect quantitative information on M. macfarlanei and its habitat. A full description of the monitoring protocol is provided in Mancuso 2011. Ten Mirabilis macfarlanei transects were sampled in 2010 to test the proposed new monitoring protocols. Transect locations represented eight suboccurrences within six M. macfarlanei EOs. Monitoring results comparing 2010 results to pre-2010 datasets indicated that overall, M. macfarlanei percent frequency values for 2010 were similar to pre-2010 mean values and analysis found no significant difference ($p<0.05$) in 2010 frequency compared to pre-2010 mean values for any of the monitoring plots sampled in 2010 (Mancuso 2011, p. 13). These data support the 2008 findings by Mancuso and Shepard (2008) that suggest the Mirabilis macfarlanei "population size" is stable rangewide (Mancuso 2011, p. 13). Monitoring data has not been reanalyzed since 2005 because the new monitoring protocol has not yet been established at all Mirabilis macfarlanei EOs. In addition, monitoring sites that have been established are monitored on a rotation. Annual monitoring is not conducted due to concerns regarding excessive researcher disturbance that can result from trampling of the fragile soils on steep slopes where these plants occur (USFWS, 2016). The species occurs in 13 officially recognized Element Occurrences (EOs), 9 in Idaho and 4 in Oregon, with just a few thousand individual plants occurring among them [Idaho Fish and Wildlife Information System (IFWIS) database; the Oregon Biodiversity Information Center (ORBIC) database; and additional reports from Idaho (Hill et al. 2020)]. An EO is the distinct geographic location where a species occurs. Plants are typically tracked as EO records by State or province Natural Heritage Programs or Conservation Data Centers and are determined by grouping together occurrences into a single population (or "Element Occurrence") if they occur within 1.6 kilometers (1 mile) of one another. While Idaho uses the 1.6 km separation distance it should be noted that Oregon uses a 500-meter separation distance. The 13 officially recognized EOs includes one established population, Lucile Caves (EO ID 7), which was established by the BLM in 1988. In addition to the 13 officially recognized EOs, an additional EO, Lower Otto, was established in 2015 by the BLM, bringing the total number of MacFarlane's four-o'clock populations to 14. Because this population was recently established, it has not been included in the IFWIS database and therefore does not have an EO number yet. These established populations will be discussed in more detail below under Population Augmentation and Establishment. See Table 1 for a list of all EOs and associated land ownership (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Grazing by livestock and wildlife
**Exposure:**

**Response:**
**Consequence:** Loss of habitat
**Narrative:** Although it is uncertain whether most or all M macfarlanei populations have been grazed by domestic livestock in the past, livestock grazing still occurs at some sites. Livestock impact this species directly by trampling or consuming plants, and can result in reduced reproduction (i.e., seed set) for M macfarlanei plants. Native and introduced ungulate species, including Rocky Mountain bighorn sheep (Ovis canadensis), Rocky Mountain elk (Cervus elaphus), and mountain goats (Oreamnos americanus), are found in the vicinity of M macfarlanei habitat in Hell's Canyon National Recreation Area and the Salmon River Canyon. Although evidence of herbivory by rabbits and deer has been observed, native wildlife species do not appear to significantly threaten this species. However, the potential introduction of additional Rocky Mountain bighorn sheep or mountain goats by State or Federal agencies could threaten M macfarlanei habitat. Mountain goats and other ungulate species can impact rare plant habitat by trampling or consuming plants and by exposing mineral soil. (USFWS, 2000)

**Stressor:** Invasive nonnative plant species
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Exotic (non-native) plant species pose a serious threat to M macfarlanei and other native plants since they compete with native species for space, light, water, and nutrients. Two of the most serious exotic species are Brornus tectorum (cheatgrass) and Centaurea soistitiatis (yellow star-thistle). Centaurea sotstitialis infestations have increased significantly in the Snake River Canyon over the past decade. Efforts to control Centaurea sotstitialis have been initiated at a few sites containing M macfarlanei(USFWS, 2000). This threat was listed as a primary threat in the 2015 5-year review (USFWS, 2015).

**Stressor:** Wildfire or Fire History
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Specific effects of historic and current fire regimes on M macfarlanei are unknown. Fire suppression activities and rehabilitation efforts, including seeding with normative species, are a potential threat to this species. It is possible that M macfarlanei habitat has bumed less frequently in the past 100 years due to fire suppression. Sites where fire has been excluded are vulnerable to accelerated succession, e.g., the invasion of shrubs or trees into grassland or meadow communities. However, the invasion of cheatgrass alters natural community dynamics by producing greater fine fuel levels, which may result in frequent, large-scale range fires. In areas where cheatgrass has invaded sagebrush-grass communities, altered fire dynamics have converted formerly productive, perennial communities to annual-dominated communities with increased fire management problems. Wildfires that occur during summer and fall months when M macfarlanei plants are dormant may have minimal direct effects on this species since the underground rhizomes will be largely insulated from fire. However, fires may result in adverse changes in the ecological condition of sites and lead to the subsequent invasion of exotic species. Burning may also result in concentrations of ungulates grazing within the burned areas, which might cause increased trampling of M macfarlanei plants. The primary concern from wildfires appears to be during the active growing period (typically April through June) when the aboveground plants would be susceptible to fire kill or injury (USFWS, 2000). This threat was

stated to be a primary threat in the 2015 5-year review (USFWS, 2015).

**Stressor:** Herbicide and pesticide spraying
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Spraying vegetation in areas where M macfarlanei occurs could potentially have an adverse effect on this species if weed control activities are not carefully implemented and monitored. (USFWS, 2000)

**Stressor:** Landslides and flood damage
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Activities associated with flood damage repair, including maintaining roads, trails, and facilities damaged by landslides or flooding, should be considered as a potential threat to M macfarlanei habitat. (USFWS, 2000)

**Stressor:** Insect damage and disease
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Some M. macfarlanei plants have been damaged by insects, including lepidopterans and spittle bugs. A type of fungal disease was also previously noted from M macfarlanei plants. Because of connections between ramets, diseases may spread rapidly through clonal plant populations. Although damage from insects and disease do not currently appear to be significant in M macfarlanei populations, these threats should be monitored. (USFWS, 2000)

**Stressor:** Trampl‌ling, off-road vehicle use, road maintenance/construction
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Off-road vehicles:  Several M macfarlanei colonies are found within 0.5 kilometer (1/4 mile) of existing roads or highways in Idaho and Oregon. In addition, many M macfarlanei colonies are on steep slopes that are particularly vulnerable to erosion. Uncontrolled off-road vehicle use is a potential threat to this species on both public and private lands. -- Road and trail construction and maintenance:  Some M macfarlanei populations in Idaho and Oregon are located near existing roads and trails, and could be adversely impacted by road or trail maintenance activities. The construction of new roads or trails is also a threat to this species. (USFWS, 2000)

**Stressor:** Collection
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Mirabitis macfarlanei is an attractive plant that could be sought by amateur or professional botanists for scientific or horticultural purposes. Because some colonies are readily accessible, collection of M macfarlanei should be considered a potential threat to this species.

(USFWS, 2000)

**Stressor:** Mining
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Although no populations are currently known to be impacted by mining, one M macfarlanei population is located near an existing gravel mining operation along the Salmon River in Idaho County, Idaho. In addition, road construction is often associated with mining activity. The Hell's Canyon National Recreation Area is closed to any new mining claims. However, expansion of existing mining operations and development of future mining operations(e.g., borrow pits) should be considered a potential threat to M macfarlanei. (USFWS, 2000)

**Stressor:** Competition for pollinators
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Preliminary observations have shown that successful pollination of M macfarlanei may be hindered by competition from adjacent plant species. For example, researchers have noted the presence of mixed pollen loads on solitary bees, which are considered to be potential pollinators of M macfarlanei. No data currently exists on the natural history (e.g., biotic and abiotic requirements) of the primary pollinators of M macfarlanei. It is unknown whether pollinator populations are adequate for the successful reproduction of M macfarlanei at all sites, although one study found that seed set in M macfarlanei does not appear to be pollen limited. (USFWS, 2000)

**Stressor:** Inbreeding depression.
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Some observers have noted that seedling recruitment isapparently rare in populations of M macfarlanei. This could be influenced by extrinsic factors such as competition, inadequate pollination, nutrient levels, or annual precipitation. Inbreeding depression could result in poorseed viability, reduced germination success, orpoor seedling survivorship. If new individuals are not successfully added to the population, the population viability of M macfarlanei may decrease over time. (USFWS, 2000)

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 11

**Delisting Criteria:**
A minimum of 11 populations are secure from threats and naturally reproducing with stable or increasing population trends for at least 15 consecutive years. (USFWS, 2015)

Population sizes are above the minimum necessary to maintain the viability of the species. (USFWS, 2015)

Populations of this species occur throughout its current range in each of three geographic areas (i.e., Imnaha, Snake, and Salmon River areas). (USFWS, 2015)

Management practices reduce and control threats. On Federal land, habitat management plans are in place and monitoring is used to ensure implementation and effectiveness of conservation management practices. On non-Federal lands, M. macfarlanei populations are managed and conserved. (USFWS, 2015)

A post-delisting monitoring program for the species is developed and implemented. This program will be developed through coordination with the BLM, Forest Service, FWS, and other interested parties. (USFWS, 2015)

**Recovery Actions:**

- Task 1: Protect essential habitat and control threats: Protect essential (occupied and potentially suitable) habitat and implement actions that may be necessary to eliminate or control threats. Manage habitat to maintain or enhance viable populations of M macfarlanei. Habitat should be managed to allow for the maintenance of natural ecosystem functions and processes and contribute to the long-term preservation of this species. Because M macfarlanei populations are genetically distinct), all populations should be protected in order to maintain the genetic variability of this species. (USFWS, 2000)
- Task 2: Monitor population trends and habitat conditions: Achieving recovery will require monitoring of both M. macfarlanei individuals and habitat throughout its range in Idaho and Oregon. Monitoring will provide information on threats to M macfarlanei habitat, and will also provide feedback on the effectiveness of management and conservation activities. (USFWS, 2000)
- Task 3: Conduct research essential to the conservation of the species: Additional research on the reproductive biology and life history of M. macfarlanei needs to be conducted to ascertain whether these recovery objectives are valid. Information on life history, population characteristics, and habitat requirements should be obtained to allow specification of management and population goals. Partnerships with other State, Federal, or private agencies and individuals should be developed where possible in order to meet these objectives. The Fish and Wildlife Service will work with appropriate agencies to ensure that adequate funding can be obtained to conduct essential research on M. macfarlanei . (USFWS, 2000)
- Task 4: Conduct surveys in potential habitat areas. Manage and protect any newly discovered M. macfarlanei populations.: Intensive field work should be conducted to locate additional populations of this species in each of the three geographic areas in which it is currently known (i.e., along the Imnaha, Salmon, and Snake River corridors in Idaho and Oregon). The habitat of any newly discovered populations should be protected and managed as necessary and appropriate following the protocol given in Task 1.
- Task 5: Establish propagule banks, including a long-term seed storage facility for M. macfarlanei. Seeds of M. macfarlanei should be collected according to currently accepted protocol, and stored at a long-term seed storage facility such as the Berry Botanic Garden (Portland, Oregon). Seeds from many M. rnacfarlanei sites are currently being stored at the Berry Botanic Garden. Additional seeds will be collected to capture as much of the species'

genetic variability as possible. Berry Botanic Garden staff will also be conducting germination and propagation studies for M. macfarlanei. The Fish and Wildlife Service will assist with securing permits for activities as appropriate. (USFWS, 2000)

- Task 6. If warranted. establish and maintain new populations. If M. macfarlanei is extirpated from formerly occupied areas, or if population viability analyses suggest that additional populations are needed for full recovery, new populations of M. macfarlanei may be established as necessary and appropriate. (USFWS, 2000)
- Task 7. Validate and revise recovery objectives, as needed. The recovery plan should be modified to incorporate any new information as it becomes available. In particular, the results of any population viability analyses conducted for M macfarlanei will be considered in future recovery plan revisions. The recovery plan should be reviewed every 5 years. and updated if necessary. (USFWS, 2000)
- Continue working as an interagency technical team to collaborate on recovery actions for this species. (USFWS, 2015)
- Continue control efforts of invasive nonnative plant species and noxious weeds. The Service suggests developing site-specific management plans and monitoring schedules for individual EOs. (USFWS, 2015)
- Develop and implement studies to assess general life history and ecological needs, including studies addressing soil chemistry and moisture regimes. (USFWS, 2015)
- Continue to pursue opportunities to work with landowners towards conservation of this species on private lands. (USFWS, 2015)
- Continue the rangewide monitoring program and conduct and a 10-year analysis of the data set. (USFWS, 2015)
- Continue survey efforts to locate potential new populations. (USFWS, 2015)

***Conservation Measures and Best Management Practices:***

- Recommendations for Future Actions: • Conduct an SSA for Macfarlane's four-o-clock, with an emphasis on incorporating more current climate change modeling. • Using the information gathered in the SSA determine if a revised Recovery Plan is warranted. • Continue working as an interagency technical team to collaborate on recovery actions for this species. • Complete site-specific HMPs. • Continue the plant propagation program (through both nursery and micropropagation), identification of appropriate areas for population establishment, and associated outplanting efforts at new and existing populations. • Continue control of invasive nonnative plant species and noxious weeds, and conduct research to inform effectiveness of these treatments. • Continue to work with partners to mitigate impacts from livestock grazing. • Develop and implement studies to determine if sexual reproduction is occurring. • Utilize the recommendations in the 2020 rangewide monitoring report to revise the monitoring protocol and continue the rangewide monitoring program. • Continue survey efforts to locate new populations using the newly developed Habitat Suitability Model (USFWS, 2022).

# SPECIES ACCOUNT: *Monardella viminea* (Willowy monardella)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A perennial herb or subshrub in the Lamiaceae (mint family) with a woody base and aromatic foliage. (USFWS, 2012)

**Taxonomy**

Monardella viminea was previously recognized and listed as Monardella linoides ssp. viminea. In 2003, Elvin and Sanders proposed a taxonomic split of this entity into two distinct species. Upon recognition of this taxonomic change and species split, the range of the listed entity was reduced, and the southernmost occurrences were reclassified as Monardella stoneana. For more details regarding the taxonomic classification of Monardella linoides ssp. viminea as a distinct species (M. viminea) and reclassifying a portion of Monardella linoides ssp. viminea as a separate species (M. stoneana), and the consequences of recognizing this split, please refer to the revised final listing and revised critical habitat rule published in the Federal Register on March 6, 2012 (USFWS 2012b, pp. 13394–13447) (USFWS, 2022).

**Current Range**

Occurs in coastal sage scrub and riparian scrub in sandy bottoms and on banks of ephemeral washes in canyons where surface water flows for usually less than 48 hours after a rain event (Scheid 1985, p. 3; Elvin and Sanders 2003, p. 430; Kelly and Burrascano 2006, p. 51). Monardella viminea is a geographically narrow endemic species restricted to three watersheds north of Kearny Mesa in San Diego County, California 2012 5-year Review for Monardella viminea 3 (Elvin and Sanders 2003, p. 431). Within these watersheds, M. viminea occurs on land owned by the Department of Defense at Marine Corps Air Station (MCAS) Miramar, the City of San Diego, the County of San Diego, and private parties. (USFWS, 2012)

**Critical Habitat Designated**

Yes; 3/6/2012.

**Legal Description**

On March 6, 2012, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Monardella viminea (Willowy monardella) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes two critical habitat units (CHUs), in California (77 FR 13394-13447).

**Critical Habitat Designation**

The critical habitat designation for Monardella viminea includes two CHUs in San Diego County, California. This species critical habitat encompasses approximately 122 acres (ac) (50 hectares (ha)) (77 FR 13394-13447).

Unit 1: Sycamore Canyon: Unit 1 consists of 118 ac (48 ha), and is located in Sycamore Canyon at the northeastern boundary of MCAS Miramar, north of Santee Lakes in San Diego County, California. These acres fall within the boundaries of the City of Santee, which has no approved

MSCP. This canyon is the only place where Monardella viminea is found in oak woodland habitat, and is one of the few areas in the range of M. viminea with mature riparian habitat (Rebman and Dossey 2006, p. 23). Sycamore Canyon is essential to the recovery of the species because it supports over 350 individual plants, or approximately 18 percent of the species' total population (City of San Diego 2010a, p. 257; Tierra Data 2011, p. 12), meaning this is an important unit that supports genotypes and diversity not found among the more impoverished occurrences. Additionally, this canyon is one of few that contains seedlings and juveniles (Tierra Data 2011, pp. 16–17), demonstrating that reproduction is occurring and the habitat in this unit is currently suitable to support all lifehistory phases of this declining species. The habitat in this unit provides redundancy and resiliency for M. viminea and, since there are areas of suitable habitat within the canyon where plants are not currently growing, the unit provides space for the growth and expansion of the species. This unit contains the physical or biological features essential to the conservation of M. viminea, including riparian channels with a natural hydrological regime, ephemeral drainages made up of rocky or sandy alluvium, sandy soil with sediment and cobble deposits, and surrounding vegetation that provides semi-open foliar cover. The PCE may require special management considerations or protection to address threats from nonnative plant species and erosion of the canyon (City of San Diego 2005, p. 68; 2006, p. 10; 2009, p. 2). Please see the Special Management Considerations or Protection section of this final rule for a discussion of the threats to M. viminea habitat and potential management considerations.

Unit 2: West Sycamore Canyon: Unit 2 consists of 4 ac (2 ha) of land owned by water districts, and is located in West Sycamore Canyon adjacent to the eastern section of MCAS Miramar, in San Diego County, California. The northernmost point of the unit is just outside the boundary of MCAS Miramar. West Sycamore Canyon, in which Unit 2 is found, is essential to the recovery of Monardella viminea because it contains the largest number of M. viminea individuals of any canyon in the species' range and over 25 percent of the species' total population (Tierra Data 2011, p. 12), meaning this is an important unit that supports genotypes and diversity not found among the more impoverished occurrences. Additionally, this canyon is one of few that contains seedlings and juveniles (Tierra Data 2011, pp. 16–17), demonstrating that reproduction is occurring and the habitat in this unit is currently suitable to support all lifehistory phases of this declining species. The plants in this canyon were recently observed to be in good health with little to no pressure from herbivores, in contrast to many other areas such as San Clemente or Carroll Canyon, where individuals are declining or are in poor health (Tierra Data 2011, p. 25; Ince 2010, Table 3). The habitat in this unit provides redundancy and resiliency for M. viminea, and because there are areas of suitable habitat within the canyon where plants are not currently growing, the unit provides space for the growth and expansion of the species. Unit 2, which contains critical habitat for M. viminea in that portion of West Sycamore Canyon located outside of MCAS Miramar, includes the physical or biological features essential to the conservation of M. viminea, including riparian channels with a natural hydrological regime, ephemeral drainages made up of rocky or sandy alluvium, sandy soil with sediment and cobble deposits, and surrounding vegetation that provides semi-open foliar cover. The PCE in this unit may require special management considerations or protection to address threats associated with erosion from heavy rainfall events. Please see the Special Management Considerations or Protection section of this final rule for a discussion of the threats to M. viminea habitat and potential management considerations.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Monardella viminea critical habitat consists of four components (77 FR 13394-13447):

(i) With a natural hydrological regime, in which: (A) Water flows only after peak seasonal rainstorms; (B) High runoff events periodically scour riparian vegetation and redistribute alluvial material to create new stream channels, benches, and sandbars; and (C) Water flows for usually less than 48 hours after a rain event, without long-term standing water;

(ii) With surrounding vegetation that provides semi-open, foliar cover with: (A) Little or no herbaceous understory; (B) Little to no canopy cover; (C) Open ground cover, less than half of which is herbaceous vegetation cover; (D) Some shrub cover; and (E) An association of other plants, including Eriogonum fasciculatum (California buckwheat) and Baccharis sarothroides (broom baccharis);

(iii) That contain ephemeral drainages that: (B) Are made up of coarse, rocky, or sandy alluvium; and (C) Contain terraced floodplains, terraced secondary benches, stabilized sandbars, channel banks, or sandy washes; and

(iv) That have soil with high sand content, typically characterized by sediment and cobble deposits, and further characterized by a high content of coarse, sandy grains and low content of silt and clay.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the physical or biological features within the geographical area occupied by the species at the time of listing that are essential to the conservation of the species may require special management considerations or protection. The areas designated as critical habitat will require some level of management or protection to address the current and future threats to the physical or biological features. In all units, special management considerations or protection may be required to provide for the sustained function of the ephemeral washes on which Monardella viminea depends. The features essential to the conservation of Monardella viminea may require special management considerations or protection to reduce the following threats, among others: Cover by nonnative plant species that crowds, shades, or competes for resources; habitat alteration due to altered hydrology from urbanization and associated infrastructure; and any actions that alter the natural channel structure or course, particularly increased water flow that could erode soils inhabited by M. viminea or cover them with sediment deposits. Special management considerations or protection are required within critical habitat areas to address these threats. Management activities that could ameliorate these threats include, but are not limited to: Removal of nonnative vegetation by weeding, planting of native species along stream courses in canyons to help control erosion, use of silt fences to control erosion, restriction of development that alters natural hydrological characteristics of stream courses in canyons, and implementation of prescribed burns. Additionally, specialized dams and smaller barriers could be installed in canyons to help address floodwater runoff that results from upstream development (which can cause erosion and loss of clumps of Monardella viminea), although these dams must be of adequate size and strength to withstand increased storm flow caused by urbanization.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Vegetative (USFWS, 2008); Sexual (USFWS, 2012)

**Dependency on Other Individuals or Species**

Adult: Bees and butterflies (USFWS, 2012)

**Reproduction Narrative**

Adult: The willowy monardella is a perennial species that reproduces at least in part vegetatively (USFWS, 2008). It also reproduces sexually. Monardella viminea is visited by numerous bees and butterflies, and is likely pollinated by a diverse array of insects. Specific species which pollinate M. viminea have not been identified (USFWS, 2012).

**Habitat Type**

Adult: Sandy washes and floodplains (USFWS, 2008)

**Dependencies on Specific Environmental Elements**

Adult: Perennial streams; ecosystem culture, function, and integrity; coarse, rocky, and sandy alluvium on terraced floodplains; semi-open canopies of coastal sage and riparian scrub with limited herbaceous understory (USFWS, 2008)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2008)

**Habitat Narrative**

Adult: The willowy monardella inhabits sandy washes and floodplains. The species is dependent on several environmental elements: perennial streams; ecosystem culture, function, and integrity; coarse, rocky, and sandy alluvium on terraced floodplains; semi-open canopies of coastal sage and riparian scrub with limited herbaceous understory (USFWS, 2008)

***Dispersal/Migration***

**Dispersal**

Adult: Low (inferred from USFWS, 2008)

**Dispersal/Migration Narrative**

Adult: The species is inferred to have low dispersal ability based on a limited historic range and its proximity and vulnerability to urban development (inferred from USFWS, 2008)

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2008)

**Number of Populations:**

16 Extant EO's (USFWS, 2022)

**Population Size:**

Up to 6,000 total individuals, as many as six populations of fewer than 15 individuals (USFWS, 2008)

**Population Narrative:**

The willowy monardella is in decline at the population level. There are 8 extant occurrences (USFWS 2012) and at least 10 documented extirpated occurrences. The overall population is 6,000 individuals, but as many as six populations have fewer than 15 individuals. Species resiliency, representation, and redundancy are inferred to be low based on its vulnerability to stochastic events (USFWS, 2008). In summary, monitoring for Monardella viminea has occurred at 20 occurrences since 2012 (Table 1), providing new information about the species presence and abundance. We reassessed our previous occurrence status determinations and updated the status of four occurrences. Additionally, information was added for 3 EOs omitted from the previous 5-year review, 1 was merged with another EO, and 10 are new occurrences reported since 2012. Based on those updates, there are now 30 occurrences of M. viminea (Figure 1; Table 1) of which 16 are extant, 2 are presumed extant, 2 are possibly extirpated, and 10 are extirpated (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Grazing/trampling; urban and residential development; recreational activities; altered hyrological regimes; road construction; soil removal; sand and gravel mining; trash dumping; erosion; wildfires; invasive plants (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The species is threatened by several anthropogenic activities including grazing/trampling,urban and residential development, recreational activities, altered hydrological regimes, road construction, soil removal, sand and gravel mining, trash dumping, and erosion. Wildfires have also had an adverse effect on the species. Invasive plants such as bulrush and willow can take over otherwise suitable habitat for willowy monardella, a process likely exacerbated by fires (USFWS, 2008). Trampling of M. viminea occurs via human travel through the species' habitat. Nonnative plants threaten the species as they frequently out-compete native species for limited resources and grow more quickly, can smother seedling and mature M. viminea and prevent natural growth (Rebman and Dossey 2006, p. 12). Nonnative plants also have the potential to lower water tables and alter rates of sedimentation and erosion by altering soil chemistry, nutrient levels, and the physical structure of soil (USFWS, 2012).

**Stressor:** Urbanization and development (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Urbanization and development were recognized as threats to Monardella viminea in the listing rule and the 2012 revised final listing and critical habitat rule (USFWS 1998, p. 54946; 2012b, pp. 13398–13399). While most occurrences of M. viminea are found on land conserved or owned by MCAS Miramar, and the City or County of San Diego, development continues to be a threat at four occurrence (EOs 8, 12, 14, and 24) and was a contributing factor to extirpation at

seven occurrences historically (EOs 3, 4, 5, 6, 11, 25, and 39). Since the last 5-year review, EOs 5, 6, and 39, which were not discussed in the previous 5-year, are considered extirpated due to development (Table 1). Additionally, M. viminea occurrences remain indirectly threatened from surrounding urbanization due to higher levels of impervious surface areas that increase dry season runoff (AECOM 2022, p. 3). This increased runoff converts ephemeral drainages to a permanently wet state, promoting conversion to riparian habitat (USFWS, 2022)

**Stressor:** Altered Hydrology (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Altered hydrology was discussed as a significant threat to habitats that support Monardella viminea at listing and in the 2012 revised final listing and critical habitat rule (USFWS 1998, p. 54950; 2012b, p. 13399). Natural hydrological systems are required by M. Viminea to maintain and deposit material for secondary benches and streambeds on which the species grows (Sheid 1985, pp. 30–31, 34–35). Furthermore, a natural hydrological regime helps reduce competition from woody riparian species and nonnative grasses through scouring and erosion events; however, excessive scouring and erosion can reduce growth or damage M. viminea (Vernadero 2021, p. 53). Hydrological changes may occur within watersheds due to upstream urban development and precipitation changes that affect daily median and minimum discharges, dry season runoff, and flood magnitudes (White and Greer 2006, pp. 133–136). In the 2012 analysis, EOs 3, 4, and 11 were listed as extirpated due to altered hydrological patterns. Altered hydrology has continued to threaten Monardella viminea habitat throughout its range. Since the last review, altered hydrology has been identified as a threat during monitoring conducted by SDMMP on MSPA lands at EOs 1 (MOLIV_6LOCA004), 8 (MOLIV_4SYCA006), 21 (MOLIV_4WSCA003), and 29 (MOLIV_4SYCA001; MOLIV_4SYCA002) (CBI and AECOM 2021a, pp. 345–346). Loss or damage of M. viminea clumps was documented on MCAS Miramar following large scouring events during the 2015–2016 and 2016–2017 growing seasons (Vernadero 2021, pp. 53, 57). Additionally, some plants located in San Clemente Canyon (EO 35) were washed away after heavy rains in the past several years (Gordon 2022, pers. comm.). In summary, 10 occurrences are potentially impacted by the threat of altered hydrology (CDFW 2021) (USFWS, 2022).

**Stressor:** Nonnative Plant Species (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Nonnative plants were identified as a threat to Monardella viminea in the listing rule and in subsequent 5-year reviews (USFWS 1998, p. 54950; 2008, pp. 11–12; 2012b, p. 13404). This threat is ongoing, and nonnatives are listed as a threat at 11 out of 30 occurrences (CDFW 2021, pp. 1, 4–5, 9, 11–12, 15, 18, 22, 25, 37). Nonnative plants are present throughout all canyons on MCAS Miramar where M. viminea occurs. During the 2020 surveys, Vernadero (2021, pp. 32–34) observed nonnative plant cover in all but two monitoring plots. In some plots, nonnatives were the dominant plant species cover (Vernadero 2021, p. 32). In review comparing plot photographs captured in 2012 to photos captured in 2017 and 2020, surveyors noted the most distinguishable pattern was the increase in nonnative species (Vernadero 2021, p. 52). In monitoring completed off the MCAS Miramar base, SDMMP noted nonnatives as a medium (threat occurs in 10 to 50 percent of area within maximum extent) or high (threat occurs in 50 to

100 percent of area within maximum extent) level threat in 5 out 7 occurrences monitored in 2019 (CBI and AECOM 2021a, pp. 343–346) (USFWS, 2022).

**Stressor:** Climate Change (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The term “climate change” refers to a change in the mean or variability of one or more measures of climate (e.g., temperature or precipitation) that persists for an extended period, typically decades or longer, whether the change is due to natural variability, human activity, or both (IPCC 2013, p. 1450). Downscaled projections under several future climate scenarios are available for the range of Monardella viminea (USFWS, 2022).

***Recovery***

**Reclassification Criteria:**
None listed

Recovery Priority Number: 8

**Recovery Actions:**

- The Cities of San Diego and Santee have purchased private property as reserve land for Monardella viminea (USFWS, 2012)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The recommended actions listed below are to be initiated over the next 5–10 years. Successful implementation of these actions will reduce threats to Monardella viminea and provide information to better understand the biological and physical factors limiting population growth and distribution. We recognize that conservation of this taxon will require cooperation and coordination with partners to minimize impacts from current threats and aid future restoration efforts. 1. Continue to monitor known M. viminea occurrences to update occurrence status, size, and threats. That information can be used to identify high-priority occurrences for management or areas for restoration. Work with landowners to implement management strategies as identified in the MSP Framework Rare Plant Management Plan (see CBI and AECOM 2021a, pp. 354–369). 2. Determine habitat characteristics that support M. viminea growth, survival, and reproduction. Identify areas of potential supportive habitat for reintroduction. 3. Enhance habitat where M. viminea occur, through nonnative plant control, flood control, and anti-erosion measures where necessary. Test available herbicides to learn their effect on M. viminea and determine whether it could be used to control nonnative grasses and forbs without negatively affecting M. viminea. 4. Identify suitable introduction/reintroduction sites to expand current distribution of M. viminea in areas where suitable habitat is present. Conduct habitat restoration to support pollinators, if necessary. 5. Research effects of drought and high temperatures on M. viminea recruitment and survivorship (USFWS, 2022).

# SPECIES ACCOUNT: *Monolopia (=Lembertia) congdonii* (San Joaquin wooly-threads)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 07/19/2000; California/Nevada (Region 8) (USFWS, 2015)

**Physical Description**

The common name "woolly-threads" is derived from the many long (up to 45 cm; 18 in), trailing stems covered with tangled hairs. However, San Joaquin woolly-threads plants also can be tiny (< 7 cm (3 in)) and erect with a single stem (Cypher 1994a). The tiny, yellow flower heads are clustered at the tips of the stems and branches. Each flower head is approximately 6 mm (0.25 in) long and contains two types of florets (the tiny flowers characteristic of the aster family); the four to seven outer florets differ in shape from the numerous inner florets. The two types of florets produce achenes (tiny, one-seeded fruits) that also differ in shape (Johnson 1993, Taylor 1989). (USFWS, 1998)

**Taxonomy**

n 1883. Gray named San Joaquin woolly-threads as Eatonella congdonii. The type specimen had been collected by Congdon near Deer Creek (Tulare County) in that same year. The current name, Leinbertia congdonii, was published by Greene in 1897, who determined that San Joaquin woolly-threads should be separated from snowy eatonella (Eatonella nivea). Subsequent taxonomists have upheld Greene's taxonomy (Johnson 1993, Taylor 1989). San Joaquin woolly-threads is the sole species in the genus Lembertia, which is in the aster family (Asteraceae). (USFWS, 1998)

**Historical Range**

The historical range of San Joaquin woolly-threads is based on 47 herbarium specimens and literature reports dating from 1883 to 1983; 30 of the occurrences were from the floor of the San Joaquin Valley, four were from the CuyamaValley. and the remainder were in the hills west of the San Joaquin Valley. These occurrences were concentrated in eight areas (in descending order of abundance): (1) the plains between Avenal and Mendota in Kings and Fresno Counties, (2) from Bakersfield to Shafter in Kern County, (3) the inner Coast Ranges of western Fresno and eastern San Benito Counties, (4) from north of Lokern to Lost Hills in Kern County, (5) the Carrizo and Elkhorn Plains in San Luis Obispo County, (6) the Cuyama Valley in Santa Barbara County, (7) east of Edison in Kern County, and (8) the type locality. However, 33 of the historical occurrences had been eliminated by 1989 (Taylor 1989). (USFWS, 1998)

**Current Range**

The Service states that Monolopia congdonii occur in Fresno, Kings, Kern, San Benito, San Luis Obispo, and Santa Barbara Counties. Nineteen populations of Monolopia congdonii were extant (55 FR 29361). Twelve populations remained in the San Joaquin Valley and adjoining foothills from the vicinity of Panoche Pass (San Benito County) southeasterly to Caliente Creek east of Bakersfield (Kern County). Another seven populations occurred to the southwest in the Cuyama Valley (San Luis Obispo and Santa Barbara Counties) and Carrizo Plain (San Luis Obispo County). Thirty-three of 52 historical populations had been lost (55 FR 29361), including a population from Tulare County (Taylor 1989). (USFWS, 2010)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: February to April (USFWS, 2010)

**Reproduction Narrative**

Adult: San Joaquin woolly-threads is an annual herb, and its phenology varies with weather and site conditions. Monolopia congdonii typically flowers between late February and early April (B. Delgado pers. comm. from Service 1998). Each plant may have from 1 to more than 400 flower heads. Seed production depends on plant size and the number of flower heads but can range from 10 to 2,500 seeds per individual (Mazer and Hendrickson 1993; Cypher 1994; E. Cypher unpublished data from Service 1998). (USFWS, 2010)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Chenopod scrub, valley and foothill grassland; sand dunes (Skinner, 1997). (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Prefers less than 10% shrub cover; found at elevations between 200 to 850 feet on the San Joaquin Valley and from 2,000 to 2,600 feet in San Luis Obispo and Santa Barbara counties (USFWS, 2010)

**Spatial Arrangements of the Population**

Adult: Scattered (USFWS, 2010)

**Environmental Specificity**

Adult: Narrow/specialist

**Habitat Narrative**

Adult: Monolopia congdonii occurs scattered in Nonnative Grassland, Valley Saltbush Scrub, Interior Coast Range Saltbush Scrub, and Upper Sonoran Subshrub Scrub communities (Service 1998). Plants that often occur with Monolopia congdonii include Bromus rubens (red brome), Erodium cicutarium (red-stemmed filaree), Schismus spp. (Arabian grass), Lasthenia spp. (goldfields), and Vulpia myuros (mouse tail fescue). Monolopia congdonii typically occupies microhabitats with less than 10 percent shrub cover, although herbaceous cover may be either sparse or dense, and cryptogamic crust (a layer of moss, lichen, and algae on the soil surface) may or may not be present. Monolopia congdonii occurs on neutral to sub-alkaline soils that were deposited in geologic times by flowing water. On the San Joaquin Valley floor, this species typically is found on sandy or sandy loam soils, particularly those of the Kimberlina series, whereas on the Carrizo Plain, it occurs on silt rich soils. Monolopia congdonii frequently occurs on sand dunes and sandy ridges as well as along the high-water line of washes and on adjacent terraces. Occurrences have been reported at elevations ranging from approximately 200 to 850 feet on the San Joaquin Valley floor and surrounding hills, and from 2,000 to 2,600 feet in San Luis Obispo and Santa Barbara Counties (Service 1998). (USFWS, 2010)

***Dispersal/Migration***

**Dependency on Other Individuals or Species for Dispersal**

Adult: Possibly wind, water and animals (USFWS, 2010)

**Dispersal/Migration Narrative**

Adult: Seed dispersal agents are unknown, but possible candidates include wind, water, and animals. Insect pollinators are not known to be required for seed-set in M. congdonii (Mazer and Hendrickson 1993); however, animals may be important to this plant species in other ways. (USFWS, 2010)

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2020)

**Number of Populations:**

87 (USFWS, 2020)

**Population Narrative:**

Currently, there are 87 extant and presumed extant Diversity Database occurrences, and 24 extirpated and possibly extirpated occurrences. (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Agricultural conversion and urbanization (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The loss and modification of habitat due to agricultural conversion and urban development remain the largest threats to Monolopia congdonii. As discussed in the final listing rule (55 FR 29361), 96 percent of the native habitats of the valley floor had been lost primarily to urbanization and agricultural land conversion by 1987. The Central Valley Project (CVP) is the largest surface water storage and delivery system in California, with a geographic scope covering 35 of the State's 58 counties. Agricultural conversions and related operations either directly or indirectly facilitated by the Central Valley Project include: conversion of native habitats to agricultural fields; conversion of land use to more water intensive purposes; disposal of agricultural drainwater; application of pesticides; and other mowing and harvesting operations. Agricultural conversion and related operations have contributed to the loss and degradation of several habitat types, including grasslands and alkali scrub associated with declines of multiple listed species (Service 1998). Currently, fewer than 150,000 acres on the San Joaquin Valley floor remain uncultivated; most of the remaining undeveloped land is located near, or in, the

foothills at the valley perimeter.  Significant portions of these lands not cultivated for agriculture or urbanized have been developed for petroleum extraction, strip-mined for gypsum and clay, or occupied by roads, canals, airstrips, oil-storage facilities, pipelines, and evaporation and percolation basins.  In addition, natural communities have been permanently altered by the introduction and proliferation of nonnative plants, which now dominate many remaining natural habitats (USFWS 1998).  Residual natural communities are typically comprised of marginal and highly fragmented habitats.  Habitat conditions are so marginal in many of these residual communities that the elimination of listed species is likely, if catastrophic events such as drought or floods were to occur (Service 1998).    The California Department of Conservation (CDC) estimates that the conversion of farming or grazing land to residential or industrial uses between 2002 and 2004 in the San Joaquin Valley occurred at a rate of 26 acres per day (CDC 2007).  The projected rate of development is anticipated to increase (American Farmland Trust 2007).  As urbanization encroaches into valley floor agricultural areas, Monolopia congdonii habitats of the foothills are increasingly converted to perennial cropland. Other effects due to agriculture include soil salinization resulting from irrigation; a pattern that has been observed throughout history (Jacobsen and Adams 1958) where agriculture land use dominates arid regions.  Soil salinization due to agriculture is common in California's San Joaquin Valley (Schoups et al. 2005; T. Maurer, Service, pers. comm. 2010) and may result in impairment to soil that would make restoration of habitat unlikely. In Fresno County, where Monolopia congdonii occurs, human population growth and urbanization have steadily increased.  For the period between 1990 and 2000, population growth in Fresno County increased 16.5 percent (California Department of Finance 2007). (USFWS, 2010)

**Stressor:** Oil and gas extraction and conveyance (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Oil and gas extraction and conveyance continue to threaten Monolopia congdonii. Adverse effects of oil and gas development on M. congdonii include the loss of habitat, change in habitat quality, destruction of individuals or populations and their seedbank, habitat fragmentation, and increased competition from nonnative plant species due to habitat degradation. On the BLM lands where Monolopia congdonii occurs, oil and gas exploration is also a threat to the species' survival and recovery. (USFWS, 2010)

**Stressor:** Habitat threats from solar power developments (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Solar power development projects pose potential threats to and may impact large amounts of habitat.  These projects can destroy, fragment, or impact Monolopia congdonii habitat by:  altering landscape topography, vegetation, and drainage patterns; and reducing habitat quality through interception of solar energy normally reaching the ground surface, affecting ambient air temperatures through habitat shading, and altering soil moisture regimes (Smith 1984; Smith et al. 1987 as cited in J.R. Single, CDFG. in litt. 2010).  Moreover, recently proposed solar projects tend to be large contiguous blocks of disturbance in undeveloped habitat lands, ranging from hundreds to several thousand acres. (USFWS, 2010)

**Stressor:** Off road vehicle use

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Off road vehicle use for recreational purposes is among the threats to Monolopia congdonii recorded in the CNNDB since 1990. The Kettleman Hills BLM population is reportedly under increasing threat from off road vehicle trespass (O'Dell in litt. 2007). Off road vehicle recreational use on Federal lands is often difficult to control due to limited staffing and area remoteness such as in the Kettleman Hills (O'Dell in litt. 2007). As of 2010, off road vehicle use continues to be a threat at Kettleman North Dome where BLM land is "checker-boarded" with Chevron oil fields. Chevron is making efforts to exclude off road vehicles by improving their fences and patrolling the area. There is also some existing threat of off road vehicle activity impact to the species and its habitat on Monocline Ridge, although this threat is lower than at the much more accessible Kettleman North Dome (O'Dell in litt. 2010). Off road vehicle use has been reported as a minor threat on the Carrizo Plain National Monument (BLM 2009). The threat of off road vehicle recreation use on private lands where Monolopia congdonii persists is unknown. (USFWS, 2010)

**Stressor:** Conservation measures (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The California Wildlife Conservation Board purchased 3,000 acres from TNC in December 1988 and 2,500 acres in 1989 to be managed by CDFG. Currently, the Carrizo Plain National Monument (formerly the Carrizo Plain Natural Area) contains over 200,000 acres of natural habitat. The Monument is jointly managed by the BLM, CDFG and The Nature Conservancy (TNC) (California Resources Agency 2008). Although, as discussed above, 130,000 acres within the Monument are open to potential oil and gas development. (USFWS, 2010)

**Stressor:** Grazing (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In the final rule (55 FR 29361) we listed overgrazing (by domestic livestock) as a threat. Currently, we think that either the complete removal of grazing, uncontrolled grazing, or grazing that continues during the flowering time of Monolopia congdonii are threats to M. congdonii. Cattle grazing exclusion in one of BLM's populations in Jacalitos Canyon appears to have resulted in extirpation of that population, coincident with heavy accumulation of annual grass biomass (O'Dell in litt. 2010). The Bakersfield BLM office has noted the same effect of livestock exclusion resulting in plant number declines on part of population at Kettleman Middle Dome (O'Dell in litt. 2010). In contrast, cattle grazing on one of BLM's populations at Kettleman North Dome has maintained grass biomass low to the ground, which has greatly benefitted Monolopia, resulting in a population numbering in the thousands that is continuing to increase in size (O'Dell in litt. 2010). Grazing may be detrimental if it continues into the flowering period of M. congdonii (Cypher 1996). (USFWS, 2010)

**Stressor:** Herbivory (USFWS, 2010)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** Herbivory by giant kangaroo rats has been shown to reduce the reproductive capacity of individual Monolopia congdonii plants by up to 30 percent. The intensity of the damage to individual plants is correlated with distance from a burrow (Mazer and Hendrickson 1993). Monolopia congdonii growing on kangaroo rat precincts has been noted and attributed to the suggestion that the species is a poor competitor with introduced annual grasses (Taylor 1989). On the Carrizo Plain, greater M. congdonii plant size and flower head production has been associated with giant kangaroo rat activity (Mazer and Hendrickson 1993) as have been earlier seed germination and maturation (Cypher 1994). (USFWS, 2010)

**Stressor:** Competition from non-native grasses (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The southern San Joaquin Valley of California, as with much of western North America, has been invaded by nonnative plant species during the past 100 to 200 years. These include the following species: Bromus rubens (red brome), Vulpia myuros (mouse tail fescue), Schismus arabicus (Arabian grass), Hordeum murinum ssp. glaucum (known locally as foxtail and elsewhere as smooth barley), Bromus diandrus (ripgut brome), and Bromus hordeaceus (soft chess) (Biswell 1956; Heady 1977; Germano et al. 2001). These introduced grasses often germinate with the first October rains (J. Jones, Live Oak Associates, pers. comm. 2007) and become established before Monolopia congdonii seeds germinate. This allows nonnative plants to out-compete native plant species for water, nutrients, and sun light and places M. congdonii at a reproductive disadvantage. An overabundance of residual thatch from the previous year's nonnative grass production can have similar adverse effects by shading out or obstructing M. congdonii seedlings. Competition from nonnative grasses affects Monolopia congdonii on both private and public lands including the Carrizo Plain National Monument. (USFWS, 2010)

**Stressor:** Nitrogen deposition/landscape nitrification (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Elevated atmospheric nitrogen (N) deposition is particularly harmful to N-limited ecosystems such as Monolopia congdonii habitat in the arid southern San Joaquin Valley where it leads to increases in nonnative annual grasses which outcompete the native flora (Fenn et al. 2003). Dry nitrogen deposition estimates for Bakersfield, Kern County near a CNDDB Monolopia congdonii occurrence, are 10 to 20 kilograms of N per hectare per year (22 to 44 pounds of N per 2.5 acres per year) (Blanchard et al. 1996). Nitrogen limited ecosystems of the western United States, such as the arid/semi-arid San Joaquin Valley, are adversely affected by N deposition as low as 3 to 8 kilograms of N per hectare per year (7 to 18 pounds of N per 2.5 acres per year) (Fenn et al. 2003). (USFWS, 2010)

**Stressor:** Trampling by livestock and soil compaction (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Trampling by livestock reduces survival of Monolopia congdonii in areas where livestock congregate, such as around water troughs. Trampling from livestock is a threat when it

reduces or eliminates the reproductive ability of the plant by, for example, damaging blossoms or seeds. Soil compaction resulting from domestic livestock may be less of an effect in habitat areas where soils have a low clay fraction than in soils with a high clay fraction. In some areas, such as the valley floor, M. congdonii is typically found on sandy or sandy loam soils (Service 1998). The Kimberlina soil series, which the plant is known to occupy, consists of very deep, well drained soils on flood plains and recent alluvial fans (Natural Resources Conservation Service 2003). In other types of soil, compaction is likely a threat to individual Monolopia congdonii. (USFWS, 2010)

**Stressor:** Climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The change in global climate presents a threat to Monolopia congdonii. Climate models predict for California an overall warming of 1.7 degrees to 5.8 degrees Celsius (3.0 degrees Fahrenheit to 10.4 degrees Fahrenheit) by 2100 (Cayan et al. 2006) but vary in their predictions for precipitation. VanRheenen et al. (2004), however, predicts a decrease in precipitation in the southern San Joaquin Valley. Any significant changes in temperature or precipitation could have drastic effects on M. congdonii populations. Climate change will likely result in changes in the vegetative communities of M. congdonii habitat and potentially increase nonnative species. However, there is insufficient data available at this time to predict the specific effects of climate change on M. congdonii. (USFWS, 2010)

***Recovery***

**Reclassification Criteria:**
1. 95 percent of occupied habitat on public land is secured and protected from incompatible uses. (USFWS, 2010)

2. A management plan is approved and implemented for recovery areas that include survival of the species as an objective. (USFWS, 2010)

3. Population monitoring in specified recovery areas shows stable or increasing numbers in all protected areas through one precipitation cycle. (USFWS, 2010)

**Delisting Criteria:**
1. 640 acres (260 hectares) or more of occupied habitat in the Lost Hills (Kern County) and one or more other sites on the San Joaquin Valley floor of 640 acres or more has been secured and protected from incompatible uses. (USFWS, 2010)

2) Population monitoring in specified recovery areas shows no decline after downlisting, if declining, determine cause and reverse trend. (USFWS, 2010)

3) Though not explicitly stated, the delisting criteria include meeting all of the downlisting criteria (Service 1998). (USFWS, 2010)

**Recovery Actions:**

- Develop and implement a regional cooperative program and participation plan. (USFWS, 1998)
- Protect and secure existing populations. (USFWS, 1998)
- Determine distributions and population statuses of featured species. (USFWS, 1998)
- Conduct important research and monitoring. (USFWS, 1998)
- Maintain and establish linkages in existing natural lands and between islands of habitat on the Valley floor and natural lands around the fringe of the Valley. (USFWS, 1998)
- Apply adaptive management to protected areas (Priority 3). (USFWS, 1998)
- If necessary, reintroduce selected featured species to appropriate habitat within their historic range. (USFWS, 1998)
- Periodically review the status of candidates and species of concern to determine if listing as endangered or threatened is necessary. (USFWS, 1998)
- Protect existing habitat in the San Joaquin Valley for Monolopia congdonii. (USFWS, 2010)
- Conduct surveys to determine trends in the range-wide status of the species and population abundance. (USFWS, 2010)
- Collect seeds from multiple populations adhering to the Center for Plant Conservation Guidelines (1991). Store seeds in facilities certified by the Center for Plant Conservation. (USFWS, 2010)
- When BLM revises the ACEC management plan, address invasive species, wildlife habitat improvements, and the protection/enhancement of special status species throughout the Panoche-Coalinga ACEC. Ensure that habitat can be protected in blocks of at least 160 acres and buffer zones of 500 feet or more are protected beyond the occurrence margins of Monolopia congdonii to reduce external influences and to allow for plant population expansion. (USFWS, 2010)
- Conduct research to determine the degree or intensity of threat from livestock grazing to the plant and its habitat. Include the variables of cattle stocking rate, relative weight or size of animals, numbers, and cattle sheltering or shade selection behavior. (USFWS, 2010)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: The following recommendations for future actions are from the 2010 5-year review (Service 2010), scientific literature, and as a result of discussions with species experts. 1. Protect existing habitat in the San Joaquin Valley for San Joaquin woolly-threads. 2. A comprehensive evaluation should be completed for all known occurrences (both extant and extirpated). The site-specific evaluation should include, at minimum, whether the species is present, the estimated population/occurrence size, and an in-depth analysis of threats at that location. 3. Implement and/or continue yearly surveys utilizing a standardized methodology to determine trends in the range-wide status of the species as well as population/occurrence abundance. 4. Continue studies that advance the understanding of the species' propagation requirements, knowledge of the physical and chemical elements of the soil required for successful re-establishment, the presence and role of mutualistic soil fungi, the species and role of pollinators, genetics, and seed dispersal mechanisms. 5. Conduct research to determine the degree or intensity of threat from livestock grazing to the plant and its habitat. Include the variables of cattle stocking rate, relative weight or size of animals, numbers, and cattle sheltering or shade selection behavior. 6. Analyze the potential for habitat degradation due to climate change and implement appropriate measures to ameliorate these threats. (USFWS, 2020)
- Habitat Conservation Plans are planning documents required as part of an application for an incidental take permit. They describe the anticipated effects of the proposed taking; how those

impacts will be minimized, or mitigated; and how the Habitat Conservation Plan is to be funded. Habitat Conservation Plans can apply to both listed and non-listed species, including those that are candidates or have been proposed for listing. Regional Habitat Conservation Plans develop large-scale conservation strategies within a specific region that are designed to conserve functional ecological systems and the covered species that depend on them. Such Habitat Conservation Plans aim to avoid a fragmented conservation landscape by working with local land use authorities and a designated implementing entity to conserve, enhance, and manage a preserve system. Project-level Habitat Conservation Plans are designed to fully offset the impacts associated with the permitted activity by contributing to a larger conservation design. Being included as a covered species under a Habitat Conservation Plan can result in habitat being set aside and managed for the species as mitigation for impacts associated with covered activities, such as planned urban development, within the Habitat Conservation Plan permit area. In addition to mitigation, avoidance, minimization, and other conservation measures (e.g. monitoring, seasonal work windows, habitat management, etc.) are implemented. Habitat Conservation Plans can also utilize banks, in-lieu fee programs, or other mechanisms to preserve habitat in perpetuity and contribute to a regional conservation strategy. The following are Habitat Conservation Plans that include this species and the year the permit for the Habitat Conservation Plan was issued: PG&E San Joaquin Valley Operations & Maintenance Habitat Conservation Plan 2007, Nuevo-Torch 1999, Kern Water Bank 1997, and Chevron Pipeline 1996. More information about Habitat Conservation Plans that include San Joaquin woolly-threads as a covered species can be found at: https://ecos.fws.gov/ecp0/profile/speciesProfile?sId=3746 (USFWS, 2020)

# SPECIES ACCOUNT: *Navarretia fossalis* (Spreading navarretia)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 10/13/1998; California/Nevada (Region 8) (USFWS, 2015)

**Physical Description**

Navarretia fossalis (spreading navarretia), a member of the Polemoniaceae (phlox family), is a low, mostly spreading or ascending annual plant, 4 to 6 in (10 to 15 cm) tall. The leaves are 0.4 to 2 in (1 to 5 cm) long and finely divided into slender spine-tipped lobes. The lower portions of stems are mostly hairless (glabrous). The flowers are arranged in flat-topped, compact, leafy heads. The white to lavender-white petals (corolla) are joined at their bases to form a tube, although the tips (lobes) are free. The fruit is an ovoid, two-chambered capsule. Each seed is covered by a layer that becomes sticky and viscous when the capsule is moistened. (USFWS, 2010)

**Taxonomy**

The range of N. fossalis overlaps with two other species in the genus Navarretia: N. intertexta (needle-leaved navarretia) and N. prostrata (prostrate navarretia). Navarretia fossalis is distinguished from the other two species by its linear corolla lobes, spreading or ascending habit, flat topped inflorescences, calyx size and shape (sepals collectively), and the position of the corolla relative to the calyx (Day 1993, p. 846). (USFWS, 2010)

**Historical Range**

See current range/distribution.

**Current Range**

The range of Navarretia fossalis extends from northwestern Los Angeles County to western Riverside County, and coastal San Diego County in California, to northwestern Baja California, Mexico (Figure 1). At the time of listing, 34 populations were considered extant in the United States, including populations contained in the listing rule and in the Recovery Plan. Nearly 60 percent of these populations were concentrated at three locations: Otay Mesa in southern San Diego County, alongside the San Jacinto River in western Riverside County, and near Hemet in western Riverside County (Bramlet 1993, pp. 10, 14; Bauder 1986a, pp. 4-11, 4-14). At listing, N. fossalis occupied less than 300 acres (120 hectares) of habitat in the United States (Service 1998b, p. 54978) (USFWS, 2023).

**Critical Habitat Designated**

Yes; 10/7/2010.

**Legal Description**

On October 7, 2010, the U.S. Fish and Wildlife Service (Service), designated final revised critical habitat for Navarretia fossalis (spreading navarretia) under the Endangered Species Act of 1973, as amended (75 FR 62192 - 62255). In total, approximately 6,720 acres (ac) (2,720 hectares (ha)) of habitat in Los Angeles, Riverside, and San Diego Counties, California, fall within the boundaries of the critical habitat designation. This final rule constitutes an overall increase of approximately 6,068 ac (2,456 ha) from the 2005 critical habitat designation for N. fossalis.

**Critical Habitat Designation**

The revised critical habitat designation for Navarretia fossalis includes six units totaling 6,720 acres in in Los Angeles, Riverside, and San Diego Counties, California. The units are Unit 1: Los Angeles Basin-Orange Management Area, Unit 2: San Diego: Northern Coastal Mesa Management Area, Unit 3: San Diego: Central Coastal Mesa Management Area, Unit 4: San Diego: Inland Management Area, Unit 5: San Diego: Southern Coastal Mesa Management Area, and Unit 6: Riverside Management Area.

Unit 1: Los Angeles Basin—Orange Management Area. Unit 1 is located in northwestern Los Angeles County and consists of two subunits totaling 176 ac (71 ha) of private land. Subunit 1A: Cruzan Mesa. Subunit 1A is located near the City of Santa Clarita in Los Angeles County. This subunit is on Cruzan Mesa, northwest of Forest Park and the Sierra Highway and southwest of Vasquez Canyon Road. Subunit 1A consists of 156 ac (63 ha) of private land and meets the selection criteria as satellite habitat. Cruzan Mesa is one of the only areas in Los Angeles County that supports mesatop vernal pools. As satellite habitat, this subunit supports a stable occurrence of Navarretia fossalis, provides potential connectivity with Subunit 1B, and likely supports a genetically distinct occurrence because of the separation of these two northern occurrences from other occurrences of N. fossalis. This subunit and Subunit 1B (described below) represent the most northern occurrences of this species. Subunit 1A contains the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species and activities (such as mowing or grading) that occur in the vernal pool basins. Subunit 1B: Plum Canyon. Subunit 1B is located near the City of Santa Clarita in Los Angeles County. This subunit is in Plum Canyon, west of Forest Park and the Sierra Highway and north of Plum Canyon Road. Subunit 1B consists of 20 ac (8 ha) of private land and meets the selection criteria as satellite habitat. As satellite habitat, this subunit supports a stable occurrence of Navarretia fossalis, provides potential connectivity with Subunit 1A, and likely supports a genetically distinct occurrence because of the separation of these two northern occurrences from other occurrences of N. fossalis. The Plum Canyon vernal pool habitat occurs on a flat area down-slope from the vernal pools on Cruzan Mesa. The vernal pools on Cruzan Mesa (Subunit 1A) and Plum Canyon represent the only habitat for N. fossalis in Los Angeles County and the most northern occurrences of this species. Subunit 1B contains the physical or biological features essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species within this subunit.

Unit 2: San Diego—Northern Coastal Mesa Management Area. Poinsettia Lane Commuter Station. Unit 2 is located in the City of Carlsbad in San Diego County and contains 6 ac (3 ha) of land owned by the North County Transit District and 3 ac (1 ha) of private land. This unit is loosely bounded by Avenida Encinas on the north, a housing development on the east, Poinsettia Lane on the south, and train tracks on the west. Unit 2 meets the selection criteria as satellite habitat because it supports a stable occurrence of Navarretia fossalis and provides potential connectivity between occurrences on MCB Camp Pendleton and Subunits 4C1, 4C2, and 4D. The Poinsettia Lane vernal pool complex consists of a series of vernal pools that run parallel to a berm created by the train tracks. Unit 2 contains the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this unit may require special management considerations or protection to address threats from nonnative plant species and activities (such as unauthorized recreational use) that occur in the vernal pool basins.

Unit 3: San Diego—Central Coastal Mesa Management Area. Unit 3 is located in central coastal San Diego County and consists of three subunits totaling 103 ac (42 ha). This unit contains 102 ac (42 ha) owned by State and local governments, and approximately 1 ac (less than 1 ha) of private land. Subunit 3B: Carroll Canyon. Subunit 3B is located in the City of San Diego in San Diego County. This subunit is located to the southwest of the intersection of Parkdale Avenue and Osgood Way, and is loosely bounded by residential development on the north, open space to the east, and a quarry to the south and west. Subunit 3B consists of approximately 18 ac (7 ha) that includes 17 ac (7 ha) of land owned by State or local governments and 1 ac (less than 1 ha) of private land. Subunit 3B meets the selection criteria as satellite habitat because it supports a stable occurrence of Navarretia fossalis and provides potential connectivity between occurrences in Subunits 3A and 3C. The Carroll Canyon vernal pool complex consists of a group of vernal pools on the edge of a mesa north of Carroll Canyon. Historically, there may have been more habitat for this species; however, the majority of vernal pool habitat in the vicinity of this subunit has been developed. Subunit 3B contains the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species and activities (such as trespass or illegal trash dumping) that occur in the vernal pool basins. Subunit 3C: Nobel Drive. Subunit 3C is located in the City of San Diego in San Diego County. This subunit is loosely bounded by the 805 interstate on the northeast, train tracks on the south, and Nobel Drive on the northwest. Subunit 3C consists of 37 ac (15 ha) of land owned by local government and meets the selection criteria as satellite habitat because it supports a stable occurrence of Navarretia fossalis and provides potential connectivity between occurrences in Subunits 3B and 3D. The Nobel Drive vernal pool complex consists of a group of vernal pools on a mesa-top north of Rose Canyon. Subunit 3C contains the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species and activities (such as unauthorized recreational use) that occur in the vernal pool basins. Subunit 3D: Montgomery Field. Subunit 3D is located in the City of San Diego in San Diego County. This subunit is located at Montgomery Field (airport) to the northeast of the runway area. Subunit 3D consists of 48 ac (20 ha) of land owned by the City of San Diego and meets the selection criteria as satellite habitat. As satellite habitat, this subunit supports a stable occurrence of Navarretia fossalis and provides potential connectivity with the occurrence in Subunit 3C. The Montgomery Field vernal pool complex consists of a large group of vernal pools east of the runway area at Montgomery Field, although only the northeastern portion of this vernal pool complex is being designated as critical habitat because the southeastern portion of this vernal pool complex has been hydrologically disconnected from other vernal pools by past development, is now isolated, and does not meet the definition of essential habitat. Navarretia fossalis has not been documented in the southeastern portion of this vernal pool complex. Subunit 3D contains the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species that occur in the vernal pool basins.

Unit 4: San Diego—Inland Management Area. Unit 4 is located within inland San Diego County and consists of four subunits totaling 206 ac (83 ha). This unit contains 18 ac (7 ha) owned by State and local governments, and 188 ac (76 ha) of private land. Subunits 4C1, 4C2, and 4D: San Marcos. Subunits 4C1, 4C2, and 4D are located in the City of San Marcos in San Diego County. These three subunits consist of three separate vernal pool complexes. The first (Subunit 4C1) is loosely bounded by La Mirada Drive on the northeast, Las Posas Road on the southeast, Linda Vista Drive on the southwest, and South Pacific Street on the northwest. The second (Subunit 4C2) is loosely bounded by Linda Vista Drive on the northeast, Las Posas Road on the east, West San Marcos Boulevard on the south, and South Pacific Street on the west. The third (Subunit 4D) is loosely bounded by South Bent Avenue on the northeast, commercial development on the southeast and southwest, and Linda Vista Drive on the northwest. Subunit 4C1 consists of 34 ac (14 ha) of private land, Subunit 4C2 consists of 15 ac (6 ha) of land owned by local government and 17 ac (7 ha) of private land, and Subunit 4D consists of 5 ac (2 ha) of private land. These three subunits meet the selection criteria as satellite habitat areas because they support stable occurrences of Navarretia fossalis and provide potential connectivity between occurrences in Unit 2 and Subunit 4E. The Service grouped these vernal pool complexes because of the clustered nature of these occurrences. These subunits have separate subunit numbers to be consistent with the numbering identified in the 2005 critical habitat designation. Subunits 4C1, 4C2, and 4D contain the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in these subunits may require special management considerations or protection to address threats from nonnative plant species and activities (such as commercial development, trespass, or OHV use) that occur in the vernal pool basins. Subunit 4E: Ramona. Subunit 4E is located in the unincorporated community of Ramona. This subunit is loosely bounded by the Ramona Airport and Ramona Airport Road on the north, Sawday Road on the east, Santa Maria Creek on the south, and a series of rock outcrops on the west. Subunit 4E consists of approximately 135 ac (55 ha) that includes 3 ac (1 ha) of land owned by State or local governments and 132 ac (53 ha) of private land. Subunit 4E meets the selection criteria as satellite habitat because it supports a stable occurrence of Navarretia fossalis and provides potential connectivity with occurrences in Subunits 4C1, 4C2, and 4D. The vernal pools in this subunit occur in gently sloping grassland habitat and are at the highest elevation where N. fossalis is known to occur. Subunit 4E contains the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species and activities (such as agricultural activities or recreational use) that occur in the vernal pool basins.

Unit 5: San Diego—Southern Coastal Mesa Management Area. Unit 5 is located in southern San Diego County and consists of six subunits totaling 748 ac (303 ha). This unit contains 28 ac (11 ha) of federally owned land, 330 ac (134 ha) of land owned by State and local governments, and 390 ac (158 ha) of private land. Subunit 5A: Sweetwater Vernal Pools. Subunit 5A is located southwest of the Sweetwater Reservoir. This subunit is loosely bounded by the Sweetwater Reservoir on the north, steeply sloping topography on the east, State Route 125 on the south, and an unnamed drainage on the west. Subunit 5A consists of approximately 95 ac (38 ha) and includes 23 ac (9 ha) of Federal land that is part of the San Diego National Wildlife Refuge Complex, 1 ac (less than 1ha) of land owned by the State, and 71 ac (29 ha) of land owned by local government. This subunit meets our selection criteria as satellite habitat. This satellite habitat subunit supports a stable occurrence of Navarretia fossalis and provides potential connectivity between occurrences in Subunits 5B and 5F. Some of the area occupied by N. fossalis was lost during the construction of State Route 125. The soil from that area was salvaged and is being used to restore other vernal pools in this subunit. Subunit 5A contains the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species and activities (such as unauthorized recreational use) that occur in the vernal pool basins. Subunit 5B: Otay River Valley. Subunit 5B is located in the City of Chula Vista and unincorporated San Diego County. This subunit is loosely bounded by Olympic Parkway on the north, a housing development on the east, and a landfill to the southwest. Subunit 5B consists of 24 ac (10 ha) of private land and meets the selection criteria as satellite habitat because it supports a stable occurrence of Navarretia fossalis and provides potential connectivity between occurrences of N. fossalis in Subunits 5A and 5H. Subunit 5B contains the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species and activities (such as unauthorized recreational use) that occur in the vernal pool basins. Subunit 5C: Otay Mesa. Subunit 5C is located on the eastern portion of Otay Mesa, directly northwest of and adjacent to the George F. Bailey Detention Facility at the terminus of Alta Road. Subunit 5C consists of 26 ac (11 ha) of State and local governmentowned land, and 16 ac (7 ha) of private land, and it meets the selection criteria as satellite habitat because it supports a stable occurrence of Navarretia fossalis and provides potential connectivity between occurrences of N. fossalis in Subunits 5G and 5I. Subunit 5C contains the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species and activities (such as unauthorized recreational use) that occur in the vernal pool basins. Subunit 5F: Proctor Valley. Subunit 5F is located between the unincorporated communities of Eastlake and Jamul in San Diego County. This subunit is located along Proctor Valley Road in Proctor Valley. Subunit 5F consists of approximately 88 ac (36 ha) and includes 51 ac (21 ha) of land owned by the City of San Diego and 37 ac (15 ha) of private land. Subunit 5F meets the selection criteria as satellite habitat because it supports a stable occurrence of Navarretia fossalis and provides potential connectivity between occurrences of N. fossalis in Subunits 5A and 5G. The vernal pools in this subunit occur in Proctor Valley on a flat area that is slightly elevated from the stream channel that runs through this valley. The vernal pools in this subunit to the west of Proctor Valley Road are severely impacted by OHV use, but the vernal pools to the east of Proctor Valley road remain relatively intact. Subunit 5F contains the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species and activities (such as unauthorized recreational use or OHV use) that occur in the vernal pool basins.  Subunit 5G: Otay Lakes. Subunit 5G is located east of the City of Chula Vista in San Diego County. This subunit is loosely bounded by Lower Otay Reservoir to the north and west and by the slopes of Otay Mountain to the southeast. Subunit 5G consists of 140 ac (57 ha) of land owned by State or local governments and meets the selection criteria as satellite habitat because this location supports a stable occurrence of Navarretia fossalis and provides potential connectivity between occurrences of N. fossalis in Subunits 5F and 5I. The vernal pool complexes in this subunit are located on the flat areas to the south of Lower Otay Reservoir. Subunit 5G contains the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species and activities (such as unauthorized recreational use) that occur in the vernal pool basins. Subunit 5H: Western Otay Mesa vernal pool complexes. Subunit 5H is located within the Otay Mesa Community planning area of the City of San Diego. Subunit 5H consists of approximately 139 ac (56 ha) that includes 41 ac (17 ha) of land owned by local governments and 98 ac (40 ha) of private land. Subunit 5H and Subunit 5I encompass the core habitat on Otay Mesa. As core habitat, this subunit contains a large area of habitat that supports sizable occurrences of Navarretia fossalis and provides potential connectivity between occurrences in Subunits 5G and 5I. This subunit contains several mesa-top vernal pool complexes on western Otay Mesa (Bauder vernal pool complexes J 2N, J 2S, J 2W, J 4, J 13N, J 13S, J 14, J 33, J 34 as in Appendix D of City of San Diego, 2004). Subunit 5H contains the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species and activities (such as unauthorized recreational use or residential and commercial development) that occur in the vernal pool basins.  Subunit 5I: Eastern Otay Mesa vernal pool complexes. Subunit 5I is located in the City of San Diego. This subunit contains several mesa top vernal pool complexes on eastern Otay Mesa. Subunit 5I consists of 221 ac (89 ha) of private land. Subunit 5I and Subunit 5H encompass the core habitat on Otay Mesa. As core habitat, Subunit 5I contains a large area of habitat that supports sizable occurrences of Navarretia fossalis and provides potential connectivity between occurrences in Subunits 5B and 5H. This subunit contains several mesa-top vernal pool complexes on eastern Otay Mesa (Bauder vernal pool complexes J 22, J 29, J 30, J 31N, J 31S as in Appendix D of City of San Diego, 2004 and Service GIS). Subunit 5I contains the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species and activities (such as unauthorized recreational use or residential and commercial development) that occur in the vernal pool basins.

Unit 6: Riverside Management Area. Unit 6 is located in western Riverside County and consists of three subunits totaling 5,477 ac (2,217 ha). This unit contains 1,504 ac (609 ha) of land owned by the State of California’s Department of Fish and Game and 3,973 ac (1,608 ha) of private land. Subunit 6A: San Jacinto River. Subunit 6A is generally located along the San Jacinto River near the cities of Hemet and Perris in Riverside County. This subunit is loosely bounded by Mystic Lake on the northeast and by the Perris Airport on the southwest. Subunit 6A consists of approximately 4,312 ac (1,745 ha), including 1,504 ac (609 ha) of land owned by State or local governments and 2,808 ac (1,136 ha) of private land. Subunit 6A encompasses core habitat along the San Jacinto River. As core habitat, this subunit contains a large area of habitat that supports sizable occurrences of Navarretia fossalis and provides potential connectivity between occurrences in Subunits 6B and 6C. This subunit consists of seasonally flooded alkali vernal plains that occur along the San Jacinto River. Subunit 6A contains the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species and activities (such as manure dumping or flood control) that occur in the vernal pool basins and associated watershed area. Subunit 6B: Salt Creek Seasonally Flooded Alkali Plain. Subunit 6B is located near the City of Hemet and west of the Hemet-Ryan Airport in Riverside County. This subunit is loosely bounded by Devonshire Avenue on the north, the boundary for the City of Hemet on the east, train tracks on the south, and lowlying hills on the west. Subunit 6B consists of 930 ac (376 ha) of private land that encompasses the core habitat along the Upper Salt Creek drainage west of the City of Hemet. As core habitat, this subunit contains a large area of habitat that supports sizable occurrences of Navarretia fossalis and provides potential connectivity between occurrences in Subunits 6A and 6C. This subunit consists of seasonally flooded alkali vernal plains not subject to U.S. Army Corps of Engineer jurisdiction. Subunit 6B contains the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species and activities (such as manure dumping, grazing, flood control, or discing for vegetation control) that occur in the vernal pool basins and associated watershed area. Subunit 6C: Wickerd and Scott Road Pools. Subunit 6C is located in the City of Menifee in Riverside County, California. This subunit is loosely bounded by low lying hills north of Garbani Road on the north, Briggs Road on the east, Scott Road on the south, and Menifee Road on the west. Subunit 6C consists of 235 ac (95 ha) of private land. This subunit meets the selection criteria as satellite habitat because this location supports a stable occurrence of Navarretia fossalis and provides potential connectivity among occurrences of N. fossalis in Subunits 6A, 6B, and with Subunit 6D that the Service is excluding under section 4(b)(2) of the Act (see Application Section 4(b)(2) of the Action section). This subunit consists of two large vernal pools. Subunit 6C contains the physical and biological features that are essential to the conservation of N. fossalis, including ephemeral wetland habitat (PCE 1), intermixed wetland and upland habitats that act as the local watershed (PCE 2), and the topography and soils that support ponding during winter and spring months (PCE 3). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species and activities (such as manure dumping, residential or agricultural development, discing for vegetation control, or maintenance of existing pipelines) that occur in the vernal pool basins and associated watershed area.

**Primary Constituent Elements/Physical or Biological Features**

Within these areas, the primary constituent elements (PCEs) for Navarretia fossalis consist of three components:

(i) PCE 1—Ephemeral wetland habitat. Vernal pools (up to 10 ac (4 ha)) and seasonally flooded alkali vernal plains that become inundated by winter rains and hold water or have saturated soils for 2 weeks to 6 months during a year with average rainfall (i.e., years where average rainfall amounts for a particular area are reached during the rainy season (between October and May)). This period of inundation is long enough to promote germination, flowering, and seed production for Navarretia fossalis and other native species typical of vernal pool and seasonally flooded alkali vernal plain habitat, but not so long that true wetland species inhabit the areas.

(ii) PCE 2—Intermixed wetland and upland habitats that act as the local watershed. Areas characterized by mounds, swales, and depressions within a matrix of upland habitat that result in intermittently flowing surface and subsurface water in swales, drainages, and pools described in PCE 1.

(iii) PCE 3—Soils that support ponding during winter and spring. Soils found in areas characterized in PCEs 1 and 2 that have a clay component or other property that creates an impermeable surface or subsurface layer. These soil types include, but are not limited to: Cieneba-Pismo-Caperton soils in Los Angeles County; Domino, Traver, Waukena, Chino, and Willows soils in Riverside County; and Huerhuero, Placentia, Olivenhain, Stockpen, and Redding soils in San Diego County.

**Special Management Considerations or Protections**

Critical habitat does not include manmade structures existing on the effective date of this rule and not containing one of more of the primary constituent elements, such as buildings, aqueducts, airports, and roads, and the land on which such structures are located.

Special management considerations or protection are required within critical habitat areas to address threats. Management activities that could ameliorate these threats include (but are not limited to) fencing Navarretia fossalis occurrences to prevent soil compaction and providing signage to discourage encroachment by hikers, cattle, sheep, and OHV activity; control of nonnative plants using methods shown to be effective; guiding the design of development projects to avoid impacts to N. fossalis habitat; enacting local ordinances to prohibit manure dumping; and restoring and maintaining natural hydrology and floodplain dynamics of watersheds associated with N. fossalis occurrences where feasible. These management activities will protect the PCEs for the species by reducing soil compaction to help maintain an impermeable surface (PCE 3) that supports ephemeral wetland habitat (PCE 1), which is needed to promote germination, flowering, and seed production for N. fossalis. Additionally, management of critical habitat lands will help maintain both the wetland and upland habitat that acts as the local watershed and provides intermittent flowing water on the surface and subsurface (PCEs 2 and 3).

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (NatureServe, 2010)

**Lifespan**

Adult: 1 year (USFWS, 2010)

**Breeding Season**

Adult: May to June (USFWS, 2010)

**Reproduction Narrative**

Adult: Navarretia fossalis (spreading navarretia), a member of the Polemoniaceae (phlox family), is a low, mostly spreading or ascending annual plant. Plants usually flower in May and June because vernal pools must be devoid of standing water before plants begin to flower. Navarretia fossalis has a low pollen to ovule ratio, suggesting there is frequent self-pollination (Spenser et al. 1998, p. 81; D. Boose, Gonzaga University, pers. comm. 2008). Outcrossing, rather than self-pollination, could be advantageous for many vernal pool specialists because it provides a way to better adapt and evolve to the changing conditions of vernal pool habitat through the recombination of beneficial genes (Spenser et al. 1998, p. 81). (USFWS, 2010)

**Habitat Type**

Adult: Palustrine and terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Grassland/herbaceous, playa/salt flat, vernal pools (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Dependent on the ephemeral inundation cycle found in vernal pool habitat and playa; temperature and moisture likely affect timing of germination; fruit absorbs water and expand to break open the fruit after rain (USFWS, 2010)

**Geographic or Habitat Restraints or Barriers**

Adult: Requires areas that are ephemerally wet in winter and spring but dry in summer and fall; vernal pools range in size from 10 to 164 feet wide (USFWS, 2010)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2010)

**Habitat Narrative**

Adult: Navarretia fossalis is typically found in vernal pool (seasonal depression wetlands) habitat, particularly in Los Angeles and San Diego Counties. In western Riverside County, however, N. fossalis is associated with seasonally flooded alkali vernal plain habitat that includes alkali playa (highly alkaline, poorly drained), alkali scrub, alkali vernal pool, and alkali annual grassland components. Vernal pools form in swales, shallow drainages, and depressions that are part of an undulating landscape where soil mounds are interspersed with basins, all above water-impervious soil layers. The hydrologic regime in western Riverside County, however, is unique. Navarretia fossalis here is associated with alkali soils series (Bramlet 1993, p. 1; USFWS 1994, p. 64812), which facilitate a hydrologic regime for this habitat involving sporadic flooding in combination with slow drainage on the alkaline soils. The listing rule states that Navarretia fossalis can also occur in ditches and other artificial depressions often associated with degraded vernal pool habitat (USFWS 1998b, p. 54978; Moran 1977, p. 155). Pools range in size from 10 to 164 feet (3 to 50 meters) across (Zedler 1987, p. 1). Navarretia fossalis abundance also varies from year to year depending on precipitation and the inundation/drying time of the vernal pool. Navarretia fossalis is dependent on the ephemeral inundation cycle found in vernal pool habitat and playas, but may also occur in man-made depressions and ditches that have the same hydrological dynamics. For many vernal pool plant species, temperature and moisture affect the timing of plant germination (Myers 1975, p. 67). Although not proven, it is likely that N. fossalis uses these same cues for germination. Most Navarretia species have indehiscent fruit, or fruit with fibers that absorb water and expand to break open the fruit after a substantial rain (Spenser et al. 1998, p. 82). The timing of germination is important so that the plant germinates under favorable conditions in the spring rather than the summer, autumn, or winter. Navarretia fossalis abundance also varies from year to year depending on precipitation and the inundation/drying time of the vernal pool. (USFWS, 2010)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: We have minimal information on the dispersal of Navarretia fossalis seeds. However, we know the seed has a layer that becomes viscous and sticky when wet. The seed could stick to an animal or bird passing through the vernal pool, providing a method of dispersal. On the other hand, theories also suggest the layer helps secure the seed during seed establishment (Sorenson 1986, p. 444). (USFWS, 2010)

***Population Information and Trends***

**Population Trends:**

Long-term trends suggest a decline of >90%, while short-term trends indicate a decline of 50-70% (NatureServe, 2015)

**Number of Populations:**

55 extant occurrences; 17 presumed extant (USFWS, 2023)

**Population Narrative:**

Currently, there are 48 extant occurrences of N. fossalis. It is estimated that greater than 90 percent of the vernal pool habitat in southern California has been lost due to human activities (Bauder and McMillan 1998, Keeler-Wolf et al. 1998 cited in USFWS 2005). Long-term population trends suggest a decline of >90%, while short-term trends indicate a decline of 50-70%. Individual plants numbering 375,000 were estimated at one California occurrence in 1991-1992 and 100,000 individuals at another in 1998; these occurrences, both in Riverside County, are the largest known for the species (USFWS 2005). Other occurrence counts have indicated a range of sizes from 20 to 50,000+ individuals, but overall most occurrences outside the two largest are believed to be relatively small (< 1,000) (USFWS 2005). The total California population might be around 500,000-600,000 individuals in a wet year, but given that this species is an annual and that single sites are known to vary greatly in population size due to year-to-year variations in precipitation and temperature (USFWS 2005), estimates of plant numbers based on short-term data should be used very cautiously. (USFWS, 2010; NatureServe, 2015). In 2009, of 51 occurrences that were examined, 48 occurrences were considered extant. This included 17 occurrences that had not been known at listing, 12 occurrences where suitable habitat remained but the species had not been located during surveys, and 7 occurrences that had not been surveyed since listing. The 2009 review did not include 9 occurrences in Baja California, or 12 occurrences that had not been seen since prior to listing. In addition, the 2009 review considered the occurrences at Cruzan Mesa, the San Jacinto River, Upper Salt Creek, and Otay Lakes each to be single populations, while this review includes multiple occurrences at those locations. Currently, of 100 Navarretia fossalis populations we examined, 55 are extant, 17 are presumed extant, 6 are possibly extirpated, and 22 have been extirpated. Of the 22 extirpated occurrences, 12 had not been seen since prior to listing, though two of these (EO 2, 58) were included as extant in the 2009 review. In addition, 3 were in Baja California, and 2 were extirpated in the early 2000s (EO 77, EO 1) but the adjacent mitigation areas (EO 20, 53) were addressed as extant in the 2009 review. Finally, 3 were documented as extirpated in the 2009 review; However, one of these (EO 69) was observed in 2020 but has since been extirpated. Two additional populations (EO 46, EO 76) have been extirpated in the time since the last review (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Urbanization (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The threat of development has lessened since listing due to a limited amount of permanent protection and some conservation measures now in place, although urbanization is still a predominant threat to N. fossalis. Components of urbanization include the direct loss of habitat from development, alteration of hydrology, transportation and flood control projects, grading, pipeline construction, and OHV use. The population of Riverside County is predicted to

grow 46.3 percent from 2000 to 2020 while Los Angeles and San Diego Counties are predicted to grow 20.2 and 14.6 percent, respectively (California Department of Finance 2007, Table 2). These predictions suggest urbanization pressures will continue to rise within the range of Navarretia fossalis, posing an increasing threat to remaining populations near growing cities in southern California. (USFWS, 2010)

**Stressor:** Direct habitat loss to development (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since listing, three (possibly four) Navarretia fossalis occurrences were extirpated by development (S. Brown, U. S. Fish and Wildlife Service, pers. obs. 2008). Wickerd Pool in Riverside County was affected by the installation of a water pipeline across the occurrence (USFWS 2001a, p.1). Also, 9 of the 48 occurrences are proposed for development (San Jacinto River, Stetson-Warren/Hemet, Menifee, Scott Pool, Date Street, Los Caballos, Pacific Street, Montgomery Field, J 29-30). Development plays a role in the fragmentation and habitat isolation of Navarretia fossalis. Habitat fragmentation within Navarretia fossalis occurrences or groups of nearby occurrences may also disrupt hydrological systems and create barriers to dispersal. The Service encourages project proponents to develop projects that avoid isolating vernal pools or dividing occurrences into ecologically separate fragments, and to configure preserved or restored sites adjacent to and continuous with existing preserve areas. Whenever vernal pools in a complex are impacted by development, some degree of fragmentation occurs within and among complexes. Fragmentation and associated impacts to hydrology and dispersal continue to threaten N. fossalis throughout its range. Since listing, many Navarretia fossalis occurrences impacted by development have been restored or partially restored. These restorations help offset impacts from development of vernal pool habitat. The threat to N. fossalis habitat from urbanization has decreased since listing, although habitat loss from development is an ongoing predominant threat. (USFWS, 2010)

**Stressor:** Agricultural Conversion (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Conversion of land for the purposes of grazing or farming was cited in the listing rule as a threat to Navarretia fossalis, especially in Riverside County (USFWS 1998b, p. 54985). These factors continue to threaten the San Jacinto River and flood plain in Riverside County, but are not threats in San Diego or Los Angeles Counties (Table 2). Five occurrences in Riverside County are documented as affected by agricultural practices (San Jacinto River, Stowe Pool, Menifee Pool, Wickerd Pool, and Johnson Ranch). (USFWS, 2010)

**Stressor:** Discing (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Discing for weed abatement, fire suppression, and dry-land farming were listed as threats to Navarretia fossalis in the final listing rule (USFWS 1998, 63 FR 54984). Discing turns up the soil and inhibits N. fossalis from germinating. It can destroy vernal pools and affect the long-term viability of N. fossalis. Vernal pools are frequently selected as sites to implement fire

prevention measures, such as discing, because they are in open areas near development and often support a considerable cover of highly flammable, nonnative grass. Since listing, discing along roads and around development for weed abatement or fuel modification has continued. Discing for agricultural conversion is most abundant in Riverside County, where often such land is considered historically agricultural and therefore is exempt from many of the conservation measures in the Western Riverside County Multiple Species HCP (Western Riverside County MSHCP). Navarretia fossalis habitat was observed to be disced at Stowe Pool, historically one of the most abundant occurrences of the species (Brown, pers. obs. 2006a). Discing continues to be a threat to N. fossalis. (USFWS, 2010)

**Stressor:** Manure dumping (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Although not identified at the time of listing, manure dumping has become a threat to the longterm viability of Navarretia fossalis in some areas of western Riverside County. This threat is especially evident along the San Jacinto River, which harbors the most extensive occurrences of N. fossalis (Roberts 2005, p. 4 and Attachment A; Brown, pers. obs. 2006b; F. Roberts, USFWS, pers. comm. 2008; A. Braswell, pers. obs. 2008; E. Kashac, Santa Ana Regional Water Quality Control Board, pers. comm. 2008). The Wickerd Pool occurrence has also been affected by manure dumping. When manure or water that leaches through it washes into the flood plain and river, it changes the pH and the soil composition. This inhibits germination of N. fossalis and increases nutrients, which promotes the growth of invasive nonnative plant species such as Chenopodium spp. (goosefoot), Brassica nigra (black mustard), and Salsola tragus (Russian thistle) (Roberts 2004, p. 7). (USFWS, 2010)

**Stressor:** Alteration of hydrology (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Increased urban runoff and channelized drainage of lands can change the inundation of a pool (USFWS 1998b, pp. 54984-54985). At listing, alteration of hydrology was considered a predominant threat to Navarretia fossalis. Instances of wetlands drainage for purposes of agriculture or development in Riverside County resulted in the loss of N. fossalis populations (USFWS 1998b, p. 54985). The Service considered the remaining wetlands available to N. fossalis as smaller and more vulnerable to the effects of surrounding development than they were earlier in the century. Since listing, there have been five accounts (San Jacinto River, Scott Pool, Mesa de Burro, Pacific Street, and Sweetwater High School) of direct alteration of hydrology to vernal pools or complexes that support Navarretia fossalis. Development can alter the timing, frequency, and duration of vernal pool inundation as well as water temperature. Modifications to the uplands surrounding a vernal pool can negatively affect the pool’s hydrology, even if such modifications occur outside the pool’s surface watershed. For example, grading cuts near pools can accelerate the flow of water out of the subsoil (Bauder 1986b, p. 210). As such, graded slope-cuts adjacent to the watersheds of depressional features may result in “leakage” of water out of the watersheds. Such grading of the watershed was observed at the Mesa de Burro occurrence when a road adjacent to the vernal pool was graded in 2003 without authorization (D. Stadlander, U. S. Fish and Wildlife Service, pers. obs. 2003). Disturbance may also allow invasive plants or non-vernal pool species to occupy the pools and compete with vernal pool

plant species (Bauder 1986a, pp. 21-22), or may also alter the composition of native species of a vernal pool. As an obligate wetland species, Navarretia fossalis depends on compatible, seasonal inundation. Navarretia fossalis is vulnerable to changes in water levels and periods of inundation. Although some watersheds have been conserved and instances of runoff avoided through section 7 consultations, alteration of hydrology remains a predominant threat to many N. fossalis occurrences. (USFWS, 2010)

**Stressor:** Transportation and flood control projects (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The listing rule identified SR 125 construction on Otay Mesa as a project that could impact Navarretia fossalis habitat. This transportation project is completed and directly impacted the occurrences at Sweetwater Reservoir and J 29-30 vernal pool complexes. State Route 11 is planned southeast of SR 125 on Otay Mesa. Though habitat is present, N. fossalis was not detected and Caltrans anticipates future potential indirect impacts in the form of edge effects to occurrences if they are discovered in the area (USDOT and Caltrans 2008, pp. 3.20-11-3.20-15). Scott Road in Riverside County was also widened, threatening but not destroying the Scott Pool occurrence (Terra Nova 2007, Exhibit 6). The San Jacinto River Improvement Project is an ongoing proposal identified at the time of listing that is not yet complete. The proposed project will affect some sections of N. fossalis habitat along the San Jacinto River, and preserve other sections (Dudek and Associates 2003, pp. 7-59). State Route 79 was proposed to run through the Upper Salt Creek occurrence in Hemet prior to the listing of N. fossalis, but now an alternate route is being proposed. Through mitigation and avoidance measures, the Service believes that transportation and flood control projects are not a predominant threat to N. fossalis at this time. (USFWS, 2010)

**Stressor:** Grading (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The grading of vernal pool habitat was identified as a threat to Navarretia fossalis in the listing rule (USFWS 1998b, p. 57984). Grading can change vernal pool hydrology, turn up the soil, and destroy the habitat and vegetation. Since listing, Service files indicate that three occurrences have been graded: 1) the Cruzan Mesa occurrence; 2) the Arjons area, which is along the east edge of the Carroll Canyon Preserve occurrence; and 3) the aforementioned grading at the Mesa de Burro occurrence (Table 2). Since grading continues to occur, we still consider it a threat to N. fossalis. (USFWS, 2010)

**Stressor:** Pipeline construction (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A pipeline project was identified as a threat to Navarretia fossalis in the listing rule (USFWS 1998b, p. 54984). Since that time, there have been two cases of pipeline construction through a vernal pool (Table 2). First, a pipeline was run directly through Wickerd Pool in Riverside County with no mitigation for the effects of the project (USFWS 2001b, p.1). Second, a proposed storage pond and pipeline for a recycled water storage system would destroy 200 acres

(81 hectares) of land on the San Jacinto River Wildlife Area (USFWS 2008, p.1). Since listing, pipeline construction has affected the habitat of N. fossalis without mitigation or avoidance of vernal pools and we still consider pipeline construction a threat. (USFWS, 2010)

**Stressor:** Off-highway vehicles (OHV) (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, OHV use was described as an ongoing threat to Navarretia fossalis in Riverside and San Diego Counties (USFWS 1998b, p. 54984). This type of activity may alter the hydrology, degrade habitat, and compromise the existence of N. fossalis within vernal pools (e.g., crush plants). Currently, OHV impacts fall into three categories: recreational (often illegal) on private or public property, Border Patrol activities, and emergency response actions. Since listing, OHV activity has impacted the majority of pools in the Otay Mesa region, and is documented in 12 pools in San Diego County and 1 pool in Los Angeles County (Table 2). Most of these accounts are from recreational vehicles trespassing on protected property, despite efforts of landowners to deter illegal trespass. However, vernal pools at Otay Mesa are threatened by OHV use associated with Border Patrol activities (City of San Diego 2006, pp. 136-140). These roads are often used and expanded by recreational OHV users. Despite attempts to deter this activity using fencing and signage, off-highway vehicle activity remains a threat to N. fossalis. To a lesser degree, OHV use for emergency response (e.g., fire suppression and aviation emergencies) and law enforcement actions may impact Navarretia fossalis habitat. Many vernal pools occur within areas that are prone to fire, such as the vernal pools at Otay Lakes that burned in the 2003 Otay Fire. Fire suppression activities may impact vernal pools and N. fossalis due to vehicle and people/equipment movement through pools or creation of firebreaks. Additionally, aviation emergency response may occur at vernal pools near the Ramona, Montgomery Field, and Marine Corps Air Station (MCAS) Miramar airports. Today, OHV use remains a threat to Navarretia fossalis, especially from Border Patrol and recreational activities near vernal pools on Otay Mesa. Installation and maintenance of fencing and signage are needed to help protect N. fossalis habitat from the impact of OHV users. (USFWS, 2010)

**Stressor:** Grazing (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Sheep herbivory and cattle grazing were reported at listing as threats to Navarretia fossalis under Factor A, but are treated under Factor C in this 5-year review. There has been only one reported incident of grazing affecting N. fossalis since listing. Sheep grazed on Stowe Pool and reportedly ate the flowering heads of N. fossalis and trampled the pool (Roberts, pers. comm. 2005). Disease and predation are not considered wide spread or rangewide threats for N. fossalis. (USFWS, 2010)

**Stressor:** Competition with invasive non-native plants (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The listing rule stated that nonnative species of grasses and forbs invade many plant communities often as an indirect result of habitat disturbance (USFWS 1998b, p. 54988). At

listing, many vernal pools on Otay Mesa or in the City of San Macros were dominated by the nonnative Lolium perenne (perennial ryegrass). The ryegrass displaced Navarretia fossalis in many vernal pools because ryegrass is more tolerant of inundation. The listing rule cited another nonnative grass, Crypsis schoenoides (swamp pricklegrass), as replacing N. fossalis in the San Jacinto River Wildlife Area in Riverside County (USFWS 1998b, pp. 54988-54989). Approximately 60 percent (29 of 48) of the existing N. fossalis occurrences are threatened by invasive nonnative plants. Invasive nonnative plants that may impact Navarretia fossalis are divided into three groups: (1) upland species with less tolerance for inundation, (2) plants with inundation tolerance comparable to native vernal pool species, and (3) marsh or wetland species that require a long inundation period (Bauder 1996, p. 2). Altered hydrology can change the inundation period of an area and indirectly affects species that are less or more water tolerant than native vernal pool species, resulting in elimination from or invasion into vernal pool habitat (Bauder 1986b, p. 210). Alternatively, if natural hydrology persists, the number of nonnatives able to invade may be limited by the inundation period (Bauder 1996, p. 2). Development and OHV use (both discussed under Factor A), human access, and disturbance effects (see below) typically alter the hydrology of vernal pools. Additionally, manure dumping can change soil chemistry and facilitate invasives in normally unfavorable areas. These alterations lead to a higher disturbance level and therefore a greater likelihood of invasion by nonnative species (Bauder 2005, p. 2134). Depending upon conditions, certain invasive nonnative plants, such as the grasses discussed above, may replace Navarretia fossalis. Therefore, we consider invasive nonnative plants to be a continuing threat to N. fossalis. (USFWS, 2010)

**Stressor:** Human access and disturbance effects (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Separation of Navarretia fossalis occurrences through habitat loss and fragmentation is often accompanied by the introduction or exacerbation of indirect effects associated with human access, or disturbance associated with adjacent development. Examples include trash dumping, trampling, and nonnative plant invasions. In the listing rule for N. fossalis, trash dumping, trampling, and invasive nonnative plant species were cited as threats to the species (USFWS 1998b, p. 54988). All known occurrences of Navarretia fossalis may potentially be affected by human access and disturbance impacts from surrounding development (Table 2). Since listing, impacts associated with adjacent development have been documented to occur at 35 (71 percent) of the N. fossalis occurrences (Table 2). For example, asphalt was dumped at the Upham occurrence in San Macros during road repairs in 2001 (J. Upham, owner, pers. comm. 2001). This small property is completely surrounded by development and is highly impacted by human-related disturbance. Pedestrians can introduce invasive nonnative plants that result in altered hydrology and competition with native plants. Protective fencing is used in many conserved occurrences to protect vernal pool complexes. Though implementing this protective measure has lessened the impacts of human access and disturbance, such effects still pose a predominant threat to N. fossalis. (USFWS, 2010)

**Stressor:** Climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** The listing rule stated that drier conditions and drought are threats to Navarretia fossalis, which relies on seasonal rainfall and the pooling of water. Drier conditions physiologically stress the species and reduce its germination and survival rates (USFWS 1998b, p. 54989). Additionally, other threats may have an increased impact when combined with impacts from climate change. Data from 1986 to 1992 indicate drought was related to a decrease in the abundance of N. fossalis (USFWS 1998b, p. 54989; Table 1). However, there is no evidence to suggest that this was caused by climate change rather than normal climatic cycles. Currently, drier conditions and drought remain a threat to all occurrences of Navarretia fossalis. Predictions for California indicate prolonged drought and other climate-related changes will continue in the future (e.g., Field et al. 1999, pp. 8–10; Lenihen et al. 2003, p. 1667; Hayhoe et al. 2004, p.12422; Breshears et al. 2005, p. 15144; Seager et al. 2007, p. 1181; IPCC 2007, p. 9). In habitat such as vernal pools that is isolated and dependent on certain hydrological regimes, these climatic changes are expected to become even more dramatic and intense (Graham 1997). It is expected that climate change will alter the hydrology of the region, and therefore threaten the existence of vernal pool habitat and associated species such as Navarretia fossalis (Bauder 2005, pp. 2133-2134). While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to particular species (including N. fossalis) or sites at this time. However, it is possible that drying could be expected to adversely affect the long-term viability of N. fossalis in its habitat. (USFWS, 2010)

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 8

**Delisting Criteria:**
1. All the existing vernal pools and their watersheds should be secured from further loss and degradation in a configuration that maintains habitat function and viability (as determined by prescribed research tasks). (USFWS, 1998)

2. Secured vernal pools must be enhanced or restored such that population levels of existing species are stabilized or increased. (USFWS, 1998)

3. Population trends must be shown to be stable or increasing for a minimum of 10 consecutive years prior to consideration for reclassification. (USFWS, 1998)

**Recovery Actions:**
- Design and establish a vernal pool habitat preserve system within each Management Area that will maximize the ecological distribution for each listed and proposed species, minimize risk of habitat loss, retain genetic differentiation, and provide the opportunity for expansion of populations. (USFWS, 1998)
- Within each Management Area, reestablish vernal pool habitat to historic structure and composition to increase genetic diversity and population stability. (USFWS, 1998)
- Within each Management Area, rehabilitate and enhance secured vernal pool habitats and their constituent species. (USFWS, 1998)
- Manage protected habitat. (USFWS, 1998)
- Monitor protected habitat and listed species. (USFWS, 1998)

- Coordinate with Riverside County and city governments to enact ordinances banning manure dumping in areas containing sensitive species, such as the San Jacinto River flood plain. Such a measure could reduce threats and meets Criteria 1 and 2 for the Recovery Plan. (USFWS, 2010)
- Determine the breeding system, distribution of genetic diversity of Navarretia fossalis, and best management practices to maintain genetic diversity within the species. This would allow a better understanding of the methodology needed to meet Criterion 4. (USFWS, 2010)
- Consider revising the Recovery Plan by incorporating new information and addressing issues discussed in Recovery Criteria section of this review. Consider revising recovery criteria to be threats-based and to include quantifiable thresholds to down list and delist. Additionally, areas of high value to the species should be identified and preserved. (USFWS, 2010)
- In order to analyze trends in abundance, standardize methods for sampling abundance of Navarretia fossalis. Use quantitative indices in data collection protocol. Any empirical approach in methodology will prove a more reliable method to analyze population data required in Criteria 3 and 4. (USFWS, 2010)
- Work with partners to help conserve Navarretia fossalis, by conducting surveys of all occurrences within the next 5 years to have more information (abundance, spatial distribution, and threats) about the status of the species. Recovery Plan Criteria 3 and 4 require that populations are monitored and stabilized. (USFWS, 2010)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS These actions are intended to help reduce impacts from threats to Navarretia fossalis over the next 5 years. We recognize that cooperation and coordination with our partners will aid future restoration efforts for this species. The recommended actions listed below includes actions from the past 5-year review and new actions that are relevant to the conservation of N. fossalis: 1. Work with partners to identify opportunities for conservation of Navarretia fossalis occurrences on private lands. Support land acquisition to meet Habitat Conservation Plan goals. Work with local, State, and Federal partners to identify and leverage funding (i.e., section 6) to acquire Navarretia fossalis habitat. 2. Survey or monitor occurrences to provide more information about the status of the species (abundance, spatial distribution, and threats) and assess management effectiveness. Recovery Plan Criteria 3 and 4 require that populations are monitored and stabilized. a. Standardize methods for sampling abundance of Navarretia fossalis to analyze abundance trends. Use quantitative indices in data collection protocols (Supports Recovery Plan Criteria 3 and 4). 3. Adaptively manage vernal pool habitat to maintain, enhance, or restore habitat and maintain population viability over time. a. Manage nonnative plants in vernal pool habitat. Coordinate with partners to develop best practices for nonnative species prevention and eradication to benefit Navarretia fossalis habitat. 4. Maintain or enhance Navarretia fossalis genetic diversity. Conduct a population genetics study to characterize genetic variation and structure in N. fossalis and determine the species’ breeding system. Based on study results, develop best management practices to maintain genetic diversity within the species (Supports Recovery Plan Criterion 4). 5. Work with partners in Baja California, Mexico to survey additional areas for Navarretia fossalis and identify conservation opportunities (USFWS, 2023).

# SPECIES ACCOUNT: *Navarretia leucocephala ssp. pauciflora (=N. pauciflora)* (Few-flowered navarretia)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A much-branched, spreading annual herb, about 1-4 dm tall, with linear, or linear-lobed, leaves. The inflorescence is a cluster of 2-15 blue or white flowers, subtended by long, spiny, leaf-like bracts. Blooms May-June. (NatureServe, 2015)

**Current Range**

Volcanic ash vernal pools in Lake County, California. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Flowering occurs from May to June (USFWS, 2023)

**Reproduction Narrative**

Adult: Flowering occurs from May to June and the fruit is a papery capsule that breaks open only when wet. Few-flowered navarretia has fewer flowers per head and fewer lobes on the outer bracts than the closely related many-flowered navarretia (Navarretia. leucocephala ssp. plieantha) which is also federally-listed as endangered. However, some plants exhibit characteristics intermediate between the few-flowered navarretia and the many-flowered navarretia and cannot be assigned definitively to either subspecies (USFWS, 2023).

**Habitat Type**

Adult: Vernal Pools (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Vernal Pools (NatureServe, 2015)

**Environmental Specificity**

Adult: Very narrow (Inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Vernal pools with a volcanic ash substrate in chaparral, grassland, or mixed coniferous forest communities. (NatureServe, 2015)

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

10 (USFWS, 2023)

**Population Size:**

1000 - 2500 individuals (NatureServe, 2015)

**Adaptability:**

Volcanic ash substrate very vulnerable to erosion. (NatureServe, 2015)

**Population Narrative:**

Volcanic ash substrate very vulnerable to erosion. (NatureServe, 2015). Currently, the Diversity Database reports ten presumed extant occurrences of the species; eight in Lake County and two in Napa County (see Table 1; Diversity Database 2022). Two occurrences (occurrence #11 and #12) in Lake County have been added to the Diversity Database since the 2008 status review; these occurrences are within the known range of the species and do not change our understating of the species distribution. Occurrence 11 is located along Highway 29 between two previously identified occurrences (occurrence #4 and #5). This occurrence is known from an observation in 2003 and a Caltrans survey in 2011 (Diversity Database 2022). Occurrence 12 was added to the Diversity Database for the Breems Lake historical record. This occurrence is mapped to a general area at the west base of Mount Konocti as the exact location of the historical observation remains unknown (Diversity Database 2022). As mentioned in the 2008 5-year review, the historical records have extremely vague locality descriptions and may represent other already known sites by different names (Service 2008, p. 12). It is also possible that few-flowered navarretia have been extirpated from the historical occurrences (occurrence #3, #10, and #12). There is no new information regarding the Cobb area locality, which is discussed in the 2008 status review but is not reported in the Diversity Database, or the Loch Lomond Vernal Pool Ecological Reserve (occurrence #1) and Boggs Lake (not reported in the Diversity Database) occurrences, which may contain many-flowered navarretia or an intermediate (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Climate change (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** It is unknown at this time if climate change in California will result in a localized, relatively small cooling and drying trend, or a warmer trend with higher precipitation events. However, it is possible that either scenario would result in negative effects to vernal pool species. Cooling and drying trends could adversely affect fewflowered navarretia through decreased inundation periods that do not allow the species sufficient time to complete its life cycle. In contrast, warmer conditions with higher precipitation could increase the area of vernal pools, which would not necessarily be a negative effect because increased vernal pool area could increase available habitat for few-flowered navarretia. There could also be increased competition from nonnative plants. Monitoring of vernal pool ecosystems to determine effects from climate change is necessary to determine what adaptive land management practices would be the most

appropriate to ensure the sustainability of vernal pool species, including few-flowered navarretia (USFWS, 2008).

**Stressor:** Habitat destruction and modification (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Threats to the habitat of few-flowered navarretia include alteration of hydrology, effects from road maintenance activities, agriculture land conversion, construction of a stock pond, off-road vehicle use, inappropriate grazing regimes, and competition from invasive weedy plant species (USFWS, 2008).

**Stressor:** Nonnative plants (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Competition from invasive plant species continues to pose a threat to this species. The localities at Hesse Flat and Manning Flat have been reported to be threatened by invasive plant species such as yellow star thistle (Centaurea solstitialis). Although specific information regarding adverse effects from invasive plant species is not available for all sites, it is likely that many of the localities of few-flowered navarretia are currently threatened by invasive plants to some degree. Further research and monitoring are necessary to determine the degree that this species is threatened by non-native invasive plant species (USFWS, 2008).

**Stressor:** Stochastic events (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Small numbers of localities makes it difficult for this species to persist while sustaining the impacts from competition from nonnative plant species, intensive grazing, changes in hydrology, adjacent development, drought, or other unknown factors. Such populations may be highly susceptible to extirpation due to chance environmental disturbances. If a locality of fewflowered navarretia has several consecutive years of poor rainfall, intensive grazing, changes in hydrology from adjacent development, or intense competition from other plant species, it is possible that the locality will become extirpated. Populations that decline to zero may not always be capable of rebounding from the soil seed bank and the population is likely to become extirpated (USFWS, 2008).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 3

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of the few-flowered navarretia. Some of these recommendations have already been discussed in the Recovery Plan for Vernal Ecosystems of California and Southern Oregon and the 2008 status review (Service

2005, pp. III-5–III-93; Service 2008, pp. 18–19) and remain valid. 1. Erosion control measures should be implemented at Manning Flat to prevent further erosion of this site and to prevent the destruction of the few-flowered navarretia locality found there. 2. The majority of known localities of this species are on private land and not protected. Preservation of suitable habitat in core areas should be pursued to preserve known localities that are currently not protected. 3. Once additional sites are protected, management plans should be prepared for the protected sites. Results from standardized monitoring discussed in item 4, below, should be included in the management plans for these protected sites. Grazing management and invasive weed control should be primary components of these management plans. 4. Conduct research at as many of the extant localities as possible to incorporate research recommendations outlined in the Recovery Plan. The following research should be prioritized over the next five years: a. Develop a standardized monitoring method to monitor species status and population trends at all known locations. This will better our understanding of potential threats to the species, and will aid in the development of methods to ameliorate these threats. b. Conduct research on the genetic structure of the species to determine the taxonomic status of the Navarretia leucocephala group. 5. Regional vernal pool working groups should be created for the Lake-Napa Vernal Pool Region where few-flowered navarretia is known to occur to aid with monitoring and management efforts. 6. Comprehensive mapping of Lake County and Napa County vernal pool habitat should be completed to better understand the amount of suitable habitat available for the species within the recovery core areas. 7. The Recovery Plan describes both down- and de-listing criteria as preliminary that will need periodic reassessment because data was lacking at the time the Recovery Plan was developed. Therefore, reassess both down- and de-listing criteria for the few-flowered navarretia and develop stepdown success parameters, if appropriate, that reflects the species' life history and narrow range to help us better understand the status of the species (USFWS, 2023).

# SPECIES ACCOUNT: *Navarretia leucocephala ssp. plieantha* (Many-flowered navarretia)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 06/18/1997; California/Nevada (Region 8) (USFWS, 2015)

**Physical Description**

Navarretia leucocephala ssp. plieantha forms mats 5 to 20 cm (2.0 to 7.9 in) across and 1 to 3 cm (0.4 to 1.2 in) high. The stems have a peeling, white surface and are highly branched. Stem thickness is 0.8 to 1.4 mm (0.03 to 0.06 in) and is more or less uniform throughout its length. The leaves are 3 to 4 cm (1.2 to 1.6 in) long and are either entire or have a few thread-like lobes. Flower heads are 1.5 to 2 cm (0.6 to 0.8 in) across and contain between 10 and 60 pale blue flowers. Each flower in the head is 5 to 6 mm (0.20 to 0.24 in) long. The capsule and seeds are similar to those of N. leucocephala ssp. pauciflora; each fruit may contain as many as three seeds (Mason 1946, Day 1993b). (USFWS, 2005)

**Taxonomy**

The name first assigned to many-flowered navarretia was Navarretia plieantha. The type locality for the species is Boggs Lake, in Lake County (Mason 1946). Day (1993a) later reduced many-flowered navarretia to the rank of subspecies, under the name Navarretia leucocephala ssp. plieantha. As explained in the species account for Navarretia leucocephala ssp. pauciflora, some populations of Navarretia consist of individuals intermediate in characteristics between two subspecies. Dr. Day (in litt. 1997) has distinguished two types of intermediate specimens, which others have identified as N. leucocephala ssp. plieantha. One group is intermediate between N. leucocephala ssp. pauciflora and N. leucocephala ssp. plieantha, and the other is intermediate between N. leucocephala ssp. plieantha and N. leucocephala ssp. bakeri (Baker’s navarretia). (USFWS, 2005)

**Historical Range**

Typical Navarretia leucocephala ssp. plieantha was known historically only from Boggs Lake (A. Day in litt. 1993, 1997). The other reported occurrences include six sites with plants that are intermediate between N. leucocephala ssp. plieantha and other subspecies, and two sites where Dr. Alva Day does not have access to specimens to confirm the identity of the plants (A. Day in litt. 1993, 1997). Three historical occurrences in Lake County (Loch Lomond, Mount Hannah Lodge, and Siegler Springs Road) have plants intermediate between N. leucocephala ssp. pauciflora and N. leucocephala ssp. plieantha. At least three occurrences in the Santa Rosa area, in Sonoma County, consist of plants intermediate between N. leucocephala ssp. plieantha and N. leucocephala ssp. bakeri (A. Day in litt. 1993, 1997). (USFWS, 2005)

**Current Range**

The five occurrences reported as extant in the final rule (U.S. Fish and Wildlife Service 1997b) were Boggs Lake, Loch Lomond, Mount Hannah Lodge, Siegler Springs Road, and Stienhart Lake, which are in the Lake-Napa Vernal Pool Region (Keeler-Wolf et al. 1998). These occurrences are still believed to be extant, although only three populations have been revisited since 1989 (California Natural Diversity Data Base 2005). (USFWS, 2005)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: 1 year (USFWS, 2009)

**Breeding Season**

Adult: May to June (NatureServe, 2015)

**Reproduction Narrative**

Adult: Navarretias are an annual herb of the phlox family that bloom from May to June. Each fruit may contain as many as three seeds (Mason 1946; Day 1993b). (USFWS, 2009; NatureServe, 2015)

**Habitat Type**

Adult: Palustrine and terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Forest/Woodland, temporary pools (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Requires temporary pools or wet ground in forest openings (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist

**Habitat Narrative**

Adult: The many-flowered navarretia is extremely rare. This species is found only on substrates of volcanic origin and is dependent on vernal pools, vernal lakes, and swales for survival. Its life history is closely linked to the hydrology of these wetlands. Extant localities of this species are located in Lake and Sonoma counties (USFWS, 2023)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

8 (USFWS, 2023)

**Population Narrative:**

The five occurrences reported as extant in the final rule (U.S. Fish and Wildlife Service 1997b) were Boggs Lake, Loch Lomond, Mount Hannah Lodge, Siegler Springs Road, and Stienhart Lake, which are in the Lake-Napa Vernal Pool Region (Keeler-Wolf et al. 1998). These occurrences are still believed to be extant, although only three populations have been revisited since 1989 (California Natural Diversity Data Base 2005). The typical population of Navarretia leucocephala ssp. plieantha at Boggs Lake has not declined (Baldwin and Baldwin 1991, California Natural Diversity Data Base 2005). (USFWS, 2005). Currently, the Diversity Database reports eight known occurrences of this species: six in Lake County and two in Sonoma County (Diversity Database 2022). All eight occurrences are presumed extant. One occurrence (Occurrence #14) has been identified since the 2009 status review (Diversity Database 2022). This occurrence is located in proximity to other previously known occurrences and is found within the Boggs Mountain Demonstration Garden managed by the California Department of Forestry and Fire Protection. Two of the many-flowered navarretia occurrences are protected within reserves. One of the protected populations occurs at Boggs Lake Ecological Reserve that is co-owned and managed by California Department of Fish and Wildlife and The Nature Conservancy (Diversity Database 2022, occurrence # 1). The second protected population documented in the Diversity Database is at Loch Lomond Vernal Pool Ecological Reserve which is managed by the California Department of Fish and Wildlife (Diversity Database 2022, occurrence #4). The other five documented populations are on private lands (Diversity Database 2022, occurrence #5, 9, 10, 11, 12). Since the 2009 status review, the presence of the species has been verified at five occurrences and recent abundance estimates are available for three of those occurrences. See Table 1 for the most recent occurrence and survey data. Status surveys and updates continue to be infrequent. More monitoring is needed to identify abundance and population trends for many-flowered navarretia throughout its current distribution (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Invasive species (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The primary threat to Navarretia leucocephala ssp. plieantha at Boggs Lake is infestation by invasive species including Cirsium spp. (thistle), Centaurea spp. (knapweed), and Typha spp. (cattail) (CNDDB 2007). Competition from invasive plant species continues to pose a threat to this species. The localities at Mt. Hannah Lodge and Boggs Lake have been reported to be threatened by invasive plant species (CNDDB 2007) including infestation by invasive Centaurea solstitialis (star thistle) and Taeniatherum caput-medusae (medusahead). Although site specific information regarding adverse effects from invasive plant species is not available, we believe it is likely that many of the localities of Navarretia leucocephala ssp. plieantha are currently threatened by invasive plants to some degree. (USFWS, 2009)

**Stressor:** Off-highway vehicles (OHVs) (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** The primary threat to Navarretia leucocephala ssp. plieantha at this site is offhighway vehicles (OHV's) and California Department of Transportation activities next to the preserve (CNDDB 2007). The occurrence is adjacent to State Route 175, where road maintenance activities could still result in the loss of plants. Occasional fence vandalism and vehicle trespass still occur at Loch Lomond (S. Zalusky, Northwest Biosurvey, pers. comm. 2008). (USFWS, 2009)

**Stressor:** Urban lane use (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Plants at Seiglers Springs are threatened by urban land use (CNDDB 2007). (USFWS, 2009)

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Pyke 2005). However, climatic conditions for smaller sub-regions such as California remain uncertain (Pyke 2005). It is unknown at this time if climate change in California will result in a localized, relatively small cooling and drying trend, or a warmer trend with higher precipitation events (Pyke 2005). However, it is possible that either scenario would result in negative effects to vernal pool species (Pyke 2004; Pyke and Marty 2005). Cooling and drying trends could adversely affect Navarretia leucocephala ssp. plieantha through decreased inundation periods that do not allow the species sufficient time to complete its life cycle. In contrast, warmer conditions with higher precipitation could increase the area of vernal pools, which would not necessarily be a negative effect because increased vernal pool area could increase available habitat for N. leucocephala ssp. plieantha. There could also be increased competition from nonnative plants. Monitoring of vernal pool ecosystems to determine effects from climate change is necessary to determine what adaptive land management practices would be the most appropriate to ensure the sustainability of vernal pool species (Pyke and Marty 2005), including N. leucocephala ssp. plieantha. (USFWS, 2009)

**Stressor:** Small numbers of localities/stochastic extinction (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The conservation biology literature commonly notes the vulnerability of taxa known from one or very few locations (e.g., Shaffer 1981, 1987; Primack 1998; Groom et al. 2006). In particular, small numbers of localities makes it difficult for this species to persist while sustaining the impacts from competition from nonnative plant species, intensive grazing, changes in hydrology, adjacent development, drought, or other unknown factors. Such populations may be highly susceptible to extirpation due to chance events or additional environmental disturbance (Goodman 1987; Gilpin and Soule 1988). If a locality of Navarretia leucocephala ssp. plieantha has several consecutive years of poor rainfall, intensive grazing, changes in hydrology from adjacent development, or intense competition from other plant species, it is possible that the locality will become extirpated. (USFWS, 2009)

**Stressor:** Cattle grazing (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Threats to the Saunders Road locality include cattle grazing, wastewater irrigation, and potential urban development. Additionally, grazing has eliminated many native species (CNDDB 2007). Threats to Shiloh Ranch include grazing, trampling, and urban development (CNDDB 2007). (USFWS, 2009)

**Stressor:** Neonicotinoid pesticides (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In June 2022, the Environmental Protection Agency (EPA) released the final biological evaluation on clothianidin, imidacloprid, and thiamethoxam, a group of insecticides known as neonicotinoids (EPA 2022a, entire; EPA 2022b, entire; EPA 2022c, entire). All three neonicotinoids are registered for use on a variety of agricultural crops, as well as some nonagricultural applications. These three neonicotinoids are highly toxic to terrestrial and aquatic invertebrates but are much less toxic to other vertebrate and plant taxa. The EPA evaluated the effects of labelled use of these neonicotinoids to determine whether they may affect one or more species listed under the Endangered Species Act or their designated critical habitats. The reliance of listed species on invertebrate species as prey or pollinators was considered in the biological evaluations. The EPA determined through moderate evidence that these neonicotinoids are likely to adversely affect (LAA) many-flowered navarretia (EPA 2022a, entire; EPA 2022b, entire; EPA 2022c, entire). The LAA determination means that the EPA reasonably expects that at least one individual animal or plant, among a variety of listed species, may be exposed to the pesticide at a sufficient level to have an effect, which will be adverse. However, the overall importance of pollinating insects for many-flowered navarretia is poorly understood and additional research is needed. The EPA anticipates releasing amended proposed interim decisions in 2023, which will include updates to some of the previously proposed mitigation measures to reduce neonicotinoid exposures for listed species. Mitigation measures will be finalized in the interim decisions, which the EPA expects to release in 2024 and the Service will consider these final mitigations during consultation (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
1. Habitat protection: Accomplish habitat protection that promotes vernal pool ecosystem function sufficient to contribute to population viability of the covered species. Suitable vernal pool habitat within each prioritized core area for the species is protected. Species localities distributed across the species geographic range and genetic range are protected. Protection of extreme edges of populations protects the genetic differences that occur there. Reintroduction and introductions must be carried out and meet success criteria. Additional localities that are detected (and determined essential to recovery goals) are permanently protected. Habitat protection results in protection of hydrology essential to vernal pool ecosystem function, and monitoring indicates that hydrology that contributes to population viability has been maintained through at least one multi-year period that includes above average, average, and below average

local rainfall as defined above, a multi-year drought, and a minimum of 5 years of post-drought monitoring. (USFWS, 2009)

2. Habitat management and monitoring plans that facilitate maintenance of vernal pool ecosystem function and population viability have been developed and implemented for all habitat protected. Mechanisms are in place to provide for management in perpetuity and long-term monitoring. Monitoring indicates that ecosystem function has been maintained in the areas protected under 1A-D for at least one multi-year period that includes above average, average, and below average local rainfall, a multi-year drought, and a minimum of 5 years of post-drought monitoring. Seed banking actions have been completed for species that would require it as insurance against risk of stochastic extirpations or that will require reintroductions or introductions to contribute to meeting recovery criteria. (USFWS, 2009)

3. Status surveys, 5-year status reviews, and population monitoring show populations within each vernal pool region where the species occur are viable (e.g., evidence of reproduction and recruitment) and have been maintained (stable or increasing) for at least one multi-year period that includes above average, average, and below average local rainfall, a multi-year drought, and a minimum of 5 years of post-drought monitoring. Status surveys, status reviews, and habitat monitoring show that threats identified during and since the listing process have been ameliorated or eliminated. Site-specific threats identified through standardized site assessments and habitat management planning also must be ameliorated or eliminated. (USFWS, 2009)

4. Research actions necessary for recovery and conservation of the covered species have been identified (these are research actions that have not been specifically identified in the recovery actions but for which a process to develop them has been identified). Research actions (both specifically identified in the recovery actions and determined through the process) on species biology and ecology, habitat management and restoration, and methods to eliminate or ameliorate threats have been completed and incorporated into habitat protection, habitat management and monitoring, and species monitoring plans, and refinement of recovery criteria and actions. Research on genetic structure has been completed (for species where necessary – for reintroduction and introduction, seed banking) and results incorporated into habitat protection plans to ensure that within and among population genetic variation is fully representative by populations protected. Research necessary to determine appropriate parameters to measure population viability for each species have been completed. (USFWS, 2009)

5. Recovery Implementation Team is established and functioning to oversee rangewide recovery efforts. Vernal pool regional working groups are established and functioning to oversee regional recovery efforts. Participation plans for each vernal pool region have been completed and implemented. Vernal pool region working groups have developed and implemented outreach and incentive programs that develop partnerships contributing to achieving recovery criteria 14. (USFWS, 2009)

Recovery Priority Number: 3

**Delisting Criteria:**
Same as reclassification criteria.

**Recovery Actions:**

- Recovery actions are not available.
- The majority of known localities of this species are on private land and not protected. Preservation of Zone 1 core areas should be pursued to preserve known localities that are currently not protected. (USFWS, 2009)
- Conduct research at as many of the extant localities as possible to incorporate research recommendations outlined in the 2005 Recovery Plan. The following research should be prioritized over the next five years: a. Develop a standardized monitoring method to monitor species status and population trends at all known locations. This will better our understanding of potential threats to the species, and will aid in the development of methods to ameliorate these threats. b. Conduct research on the genetic structure of the species to determine the taxonomic status of the Navarretia leucocephala group. (USFWS, 2009)
- Once additional sites are protected, management plans should be prepared. Results from standardized monitoring discussed in item 3, below, should be included in the management plans for these protected sites. Grazing management and invasive weed control should be primary components of these management plans. (USFWS, 2009)
- Regional vernal pool working groups should be created in regions where Navarretia leucocephala ssp. plieantha is known to occur to aid with monitoring and management efforts. (USFWS, 2009)
- Potential habitat should be surveyed for new populations and if located, those populations should be protected. (USFWS, 2009)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of the many-flowered navarretia. Some of these recommendations have already been discussed in the Recovery Plan and the 2009 status review (Service 2005, pp. III-5–III-93; Service 2009, p. 19) and remain valid. 1. The majority of known localities of this species are on private land and not protected. Preservation of suitable habitat in the core areas should be pursued to preserve known localities that are currently not protected. 2. Conduct research at as many of the extant localities as possible to incorporate research recommendations outlined in the Recovery Plan. The following research should be prioritized over the next five years: a. Develop a standardized monitoring method to monitor species status and population trends at all known locations. This will better our understanding of potential threats to the species and will aid in the development of methods to ameliorate these threats. b. Conduct research on the genetic structure of the species to determine the taxonomic status of the N. leucocephala group. 3. Once additional sites are protected, management plans should be prepared. Results from standardized monitoring discussed in recovery criterion 2A, above, should be included in the management plans for these protected sites. Grazing management and invasive weed control should be primary components of these management plans. 4. A regional vernal pool working group should be created for the Lake-Napa Vernal Pool Region where many-flowered navarretia is known to occur to aid with monitoring and management efforts. 5. Comprehensive mapping of Lake County and Sonoma County vernal pool habitat should be completed to better understand the amount of suitable habitat available for the species within the recovery core areas. 6. Potential habitat should be surveyed for new populations and if located, those populations should be protected. 7. The Recovery Plan describes both down- and de-listing criteria as preliminary that will need periodic reassessment because data was lacking at the time the Recovery Plan was developed. Therefore, reassess both down- and de-listing criteria for the many-flowered navarretia and develop stepdown success parameters, if appropriate, that reflects the species' life history and narrow range to help us better understand the status of the species (USFWS, 2023).

# SPECIES ACCOUNT: *Nitrophila mohavensis* (Amargosa niterwort)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A perennial herb. Leaves ovate, small, bright green. Flowers small, inconspicuous, pink, becoming white. (NatureServe, 2015)

**Historical Range**

See current range/distribution.

**Current Range**

Known only from the Amargosa River drainage in extreme southeastern Inyo County, California (Reveal, 1989) and from Nye county in bordering Nevada. (NatureServe, 2015)

**Critical Habitat Designated**

Yes; 5/20/1985.

**Legal Description**

On May 20, 1985, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Nitrophila mohavensis (Amargosa niterwort) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in California (50 FR 20777-20794).

**Critical Habitat Designation**

The critical habitat designation for Nitrophila mohavensis includes one CHU in Inyo County, California (50 FR 20777-20794).

California, Inyo County, Ash Meadows: W ½ sec. 5. E ½ sec. 6, NE ¼ and E ½NW ¼ sec. 7, NW ¼ sec. 8, T25N, R6E.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Nitrophila mohavensis critical habitat consists of one component (50 FR 20777-20794):

Known primary constituent elements include salt-encrusted alkaline flats.

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Flowering occurs in the late spring (USFWS, 1990).

**Reproduction Narrative**

Adult: Flowering occurs in the late spring; flowers are small, apetalous, and axial (Munz and Roos 1955, Reveal 1978c) (USFWS, 1990).

**Habitat Type**

Adult: Alkaline flats (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits playas (clay, mesic) (Skinner, 1997). Alkaline flats associated with Distichlis spicata var. stricta, Cordylanthus tecopensis, and Cleomella brevipes (Reveal, 1989). (NatureServe, 2015). High ecological integrity of the population and site fidelity and low tolerance ranges are inferred based on the restricted geography this specie inhabits along with the specific habitat requirements of this species.

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Decreasing (USFWS, 2007)

**Number of Populations:**

4 Population Services (USFWS, 2020)

**Population Size:**

~235,628 (USFWS, 2020)

**Population Narrative:**

Wetland habitat (Bittman 1998). Populations described as containing thousands of plants (Bittman 1998). Known from two occurrences in California (Bittman 1998), and three in Nevada. (NatureServe, 2015). Low resiliency, representation and redundancy are inferred based on the low number of known populations and restricted geographic range.

***Threats and Stressors***

**Stressor:** Threats from Groundwater Development (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Given our current understanding of Amargosa niterwort demographic and hydrologic trends at the Lower Carson Slough population, coupled with the rate of groundwater extraction in the Amargosa Valley, the relative magnitude and imminence of groundwater development are considered high (USFWS, 2007).

**Stressor:** Threats of Habitat Loss or Degradation from Surface Mining (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Given the importance of the Lower Carson Slough and Crystal Reservoir populations and the threat posed by mineral claims on roughly 25 percent of the critical habitat , we conclude the magnitude of this threat is high. Currently, the economic viability of mineral extraction is unknown; therefore, we consider the imminence of this threat to be unknown (USFWS, 2007).

**Stressor:** Threat of Habitat Degradation from Ash Meadows Road (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** At the time of listing, Ash Meadow Road did not pose a threat to the Amargosa niterwort. In late 1999 and early 2000, the California Department of Transportation (Caltrans) improved Ash Meadows Road where it crosses the Lower Carson Slough and Amargosa niterwort habitat. Caltrans imported fill and raised the roadbed where it crosses the Lower Carson Slough and in doing so, impacted individual Amargosa niterwort plants. The raised roadbed now poses an indirect threat to the Amargosa niterwort population by altering sedimentation patterns in the Carson Slough during thunderstorms or rare high flow events. Several low-water crossings with drainage pipes are present under the highway; however, during unusually high-volume flows the pipes may be filled with sediment, causing the roadbed itself to act as a dam that retains sediment that could bury a portion of the Lower Carson Slough population (Service 1999). Given the importance of the Lower Carson Slough population, the magnitude of this threat is high. However, given the relative infrequency of flash floods, the overall magnitude and imminence of this threat is low (USFWS, 2007).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The 1985 final rule recognized establishment of the Refuge did not provide any protection for the Amargosa niterwort (50 FR 20777-20794) because the only known population for the Amargosa niterwort was located in California. Presently, with the discovery of the Crystal Reservoir population, a small portion, roughly 5 percent, is now protected on the Refuge and within the adjacent BLM Area of Critical Environmental Concern. Protection under the Act continues to be the most important regulatory mechanism for protecting the Amargosa niterwort because it is the only regulatory mechanism that spans both California and Nevada

state jurisdictions and it is the only mechanism that is able to protect Amargosa niterwort habitat from mining and groundwater pumping in certain situations. For this reason we conclude the magnitude of the threat posed by inadequate regulatory mechanisms is high. We consider this threat to be imminent because groundwater pumping is now at 200 percent above sustainable levels (USFWS, 2007).

**Stressor:** Trampling by wild horses and OHV activity (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Amargosa niterwort populations on the Refuge are relatively well protected; however, the Crystal Reservoir population was impacted by illegal OHV activity in the early 2000s. The effects of OHV activity on this population were scattered over a 0.5 acre area, but were less than 0.01 acre in total. The Tecopa population appears to be at the highest risk to damage from OHV activity. The area is unfenced and tire tracks have been observed going through the small Amargosa niterwort population (Edwards 2006). Given the fencing that has been installed to protect the lower Carson Slough population and the Refuge, which together compose roughly 98 percent of the known distribution, we consider the magnitude and threat posed by trampling by wild horses and OHV activity to be low and non-imminent (USFWS, 2007).

**Stressor:** Invasive Species and Fire (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat/loss of indivduals
**Narrative:** Invasive species were described as a threat in the rule to list the species in 1985. Amargosa niterwort habitat consists of barren, salt-encrusted mudflats with little to no vegetation. With the exception of salt cedar (Tamarix sp.), most invasive species present at Ash Meadows lack the special adaptations needed to survive in Amargosa niterwort habitat. Salt cedar is known to be a significant threat to wetlands in the vicinity (Service 2006a). However, salt cedar does not currently appear to be establishing in Amargosa niterwort habitat in either the Lower Carson Slough or below Crystal Reservoir (Servic2006a). Neither the Refuge nor BLM has an active program to remove salt cedar in or near occupied habitat. Fire has recently been identified as a threat to other Ash Meadows endemic plant species due to the increase in non-native species that would carry a fire (e.g., Ash meadows gumplant 5-year review, Service 2007); however, given the sparse cover and open structure of Amargosa niterwort habitat, fire is not expected to pose a significant threat. Given the available information, we conclude the threats posed by non-native species and fire are low and non-imminent (USFWS, 2007).

**Stressor:** Failure of Crystal Spring Dam (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals/Loss of habitat
**Narrative:** A breach of the reservoir would affect the area immediately below the dam, Lower Crystal Marsh, as well as the Lower Carson Slough at Ash Meadows Road (Service 2005). Given the severity of a potential impact, the magnitude of this threat is considered high. However, given the infrequent nature of catastrophic flash flooding and earthquakes in the vicinity that could cause the failure of Crystal Spring Dam, and the absence of human habitation or structures, we consider the imminence of this threat to be low. Nonetheless, Amargosa niterwort habitat

occurs in low-lying areas susceptible to flooding. The Amargosa niterwort population in the Lower Carson Slough has likely survived previous flash floods. However, because the Lower Carson Slough population is now smaller than it was in the 1950s and 1960s, when it was described as extensive, it is less protected against stochastic events such as flash flooding. Further compounding potential impacts from a flash flood event are the hydrologic modifications at Ash Meadows Road (see discussion under Factor A). Given the severity of a potential impact, the magnitude of this threat is considered high. However, given the infrequent nature of catastrophic flash flooding in the vicinity, the imminence of this threat is low (USFWS, 2007).

***Recovery***

**Reclassification Criteria:**
All non-native animals and plant species must be eradicated from essential habitat (USFWS, 2007).

Secure and protect the Ash Meadows aquifer so that all spring flows return to historic discharge rates and the water level in Devils Hole is maintained at a minimum level of 1.4 feet below the copper washer (USFWS, 2007).

Essential habitat must be secure from detrimental human disturbance including mining, off-road vehicles, and introduction of non-native species (USFWS, 2007).

Amargosa niterwort is present in all localities that it has occupied historically as identified in Appendix A, Table XV, of the Recovery Plan (USFWS, 2007).

Recovery Priority Number: 8

**Delisting Criteria:**
Criteria shown above for downlisting from endangered to threatened (USFWS, 2007).

Secure, protect, and maintain in natural vegetation, corridors, and adjacent buffer areas for gene flow and dispersal of listed plant species within the essential habitat (USFWS, 2007).

Native plant communities and aquatic communities have been reestablished to historic structure and composition within all essential habitat (USFWS, 2007).

All of the listed plant species are present in all the sites that they have historically occupied as identified in Appendix A, Table XV, of the Recovery Plan, and within each critical habitat unit, the listed plant has a frequency value equal to or greater than the frequency value determined by Recovery Plan Task number 644 needed as an indicator of a selfsustaining plant species. Task number 644 requires that for each listed plant species, frequency data must be gathered from examples of vegetation that is unaltered, to quantify recovery objectives. Sampling method must be determined, including the size/shape of sampling units and the number of units needed to accurately estimate frequency values (USFWS, 2007).

**Recovery Actions:**

- Downlisting criterion #1, the removal of all non-native animals and plant species from essential habitat, has been partially achieved (Factor E). While non native species are not currently a direct threat to the Amargosa niterwort, salt cedar (Tamarix ramosissima) is generally a problem in the Carson Slough and wetlands on the Refuge. The Refuge has recently prepared an Integrated Pest Management Plan (Service 2006a). This plan provides a framework for managing invasive species, including salt cedar. In addition, the Refuge recently secured funding for salt cedar removal activities. These activities have only recently been implemented and have not yet produced on-the-ground results. The Bureau of Land Management (BLM) Las Vegas District has recently completed an Interagency Agreement with the Lake Mead National Recreation Area Exotic Plant Management Team for spot removal of non-native species within the Upper Carson Slough watershed. This work is ongoing (USFWS, 2007). Delisting is contingent on completion of the downlisting criteria described above. Delisting criterion #1, successful completion of the downlisting criteria, has not been completed. Criteria #2, 3 and 6 which address establishing corridors and re-establishing historical plant community structure are beginning to be addressed but have not been completed. The Refuge recently completed a Geomorphic and Biological Assessment for the Refuge (Service 2006b) which describes targets states for hydrologic and biologic functioning. The Refuge also recently completed an Integrated Pest Management Plan which outlines a strategy for managing weeds on the Refuge (Service 2006a). These efforts are just beginning and no tangible on-the-ground results have been achieved (USFWS, 2007).

- Downlisting criterion #2, secure and protect the Ash Meadows aquifer so that all spring flows return to historic discharge rates and the water level in Devils Hole is maintained at a minimum level of 1.4 feet below the copper washer, has only partially been achieved (Factor A). See discussion in section II.C.2.a. Protecting a minimum water level in Devils Hole will protect Amargosa niterwort occurrences on the Refuge; however, it may not protect critical habitat and the Lower Carson Slough occurrence which depend in part on subsurface flows from the Amargosa Valley (USFWS, 2007).
- Downlisting criterion #4, securing essential habitat from detrimental human disturbance including mining, off-road vehicles, and introduction of non-native species, has been partially achieved (Factor A). See discussion under section II.C.2.a. Occurrences on the Refuge receive protection from off-road vehicles and surface mining on lands where the Service owns mineral rights. The Lower Carson Slough population receives limited protection from fencing installed on both sides of Ash Meadows Road. Active mining claims are present adjacent to the Lower Carson Slough population; this population could be indirectly affected by dewatering or other mining activities. Public minerals are available and minerals claims can be made on the Crystal Reservoir population; the economic incentive for these claims is unknown (USFWS, 2007).
- Downlisting criterion #6 has not been completed. Amargosa niterwort is not present in all localities that it has occupied historically as identified in Appendix A, Table XV (USFWS, 2007).
- For the Amargosa niterwort, implementing population monitoring and investigating the factors that affect recovery are crucial (as described in tasks 4 and 6 in the Recovery Plan). Determining population trends for this species as described in the Recovery Plan is imperative and should be the first priority and should be performed over the next five years. Groundwater pumping will likely continue to increase in the Amargosa Valley. Documenting population trends will be paramount to identify any changes associated with such pumping. Before monitoring surveys are implemented, a long-term population monitoring plan for the Amargosa niterwort should be prepared to ensure that the necessary statistical rigor is included. Permanent plot markers were placed as part of the mapping and sampling plots

set up during a demographic study by San Diego State University (SERG 2004). These plots offer a unique opportunity to gather quantitative population trend data for the species. This study should be incorporated into the longterm population monitoring plan (USFWS, 2007).

- Additional research into the hydrology of the Central and Lower Carson Slough as it relates to the Ash Meadows and Alkali Flat/Furnace Creek hydrologic subbasins is needed. This should be the second priority for this species. Additional groundwater monitoring wells should be installed in the Central and Lower Carson Slough as part of the research (USFWS, 2007).
- Limiting potential flash flood or failure of Crystal Spring Dam impacts to the Lower Carson Slough population is critical. To accomplish this, modifications to Ash Meadows Road should be pursued to restore the natural hydrology that supports the Amargosa niterwort. Additionally, the repair, modification or removal of Crystal Spring Dam should be studied and implemented. These actions should be the third priority for this species (USFWS, 2007).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: I. Monitor compliance with Nevada Revised Statute Order 1197A (January 12, 2018), Curtailment of New Appropriations of Groundwater within the Amargosa Valley Hydrographic Basin 230, that prohibits new applications for water or water diversions within 25 miles of Devils Hole (and by proximity Ash Meadows NWR). Order 1197A supersedes 1197, which imposed similar regulations at 10 miles from Devils Hole. Water levels in Devils Hole are affected by pumping centers in the Amargosa Desert and the Ash Meadows groundwater basins (Halford and Jackson 2020). II. Collaborate with the Ash Meadows NWR to implement the Desert National Wildlife Refuge Complex – Ash Meadows, Desert, Moapa Valley, and Pahranagat National Wildlife Refuges Final Comprehensive Conservation Plan and Environmental Impact Statement, Volume I – August 2009 (Service 2009) and also the Draft Ash Meadows Natural Resource Management Plan in review (Service 2020); and III. Support Amargosa niterwort research across its range to monitor populations as identified in the Recovery Plan for the Endangered and Threatened Species of Ash Meadows (Service 1990); and IV. Monitor the future activity of mineral rights in the Ash Meadows area. The BLM ACEC surrounding the refuge is withdrawn from mining and entry until 2029 (PLO# 7737, signed November 2nd, 2009), but requires renewal every 20 years. Mining can still occur on private inholdings within the refuge, but no active mining permits exist at this time. (USFWS, 2020)

# SPECIES ACCOUNT: *Oenothera deltoides ssp. howellii* (Antioch Dunes evening-primrose)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A biennial herb that forms tufts of coarse, heavily-branched, drooping stems. Lower leaves grayish, pubescent, form basal rosette. Flowers bell-shaped, acquiring a blush of pink with age (Smithsonian Institution 1980). (NatureServe, 2015)

**Taxonomy**

Oenothera deltoides subsp. howellii is a short-lived perennial in the primrose family (Onagraceae) (USFWS, 2019).

**Historical Range**

See current range/distribution.

**Current Range**

Endemic to the Antioch Dunes, known from Contra Costa County and introduced in Sacramento County, California (Skinner 1997). (NatureServe, 2015)

**Critical Habitat Designated**

Yes; 8/31/1978.

**Legal Description**

On August 31, 1978, the U.S. Fish and Wildlife Service, designated critical habitat for Oenothera deltoides ssp. howellii (Antioch Dunes evening-primrose) under the authority of the Endangered Species Act of 1973 (43 FR 39042 - 39044). Critical habitat was designated for one unit in California.

**Critical Habitat Designation**

One critical habitat unit is designated in California, described as: An area of land, water, and airspace in Contra Costa County with the following components: T. 2 N. R. 2 E. SW 1/4 section 17, E 2/3 of S 1/3 of section 18 (43 FR 39042 - 39044).

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements are not described (43 FR 39042 - 39044).

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Self-incompatible, requiring cross-pollination for viable seed, insect pollinated (USFWS, 1984; 2019)

**Reproduction Narrative**

Adult: The Antioch Dunes evening-primrose is vespertine; the flowers open in early evening and close by mid-morning. In the garden, the plant flowers from “March to May and briefly in September’ (Roof 1969). This Oenothera is self-incompatible (Klein 1970) and thus requires cross-pollination for sound seed. Arnold (pers. Comm. 1982) believes that bees are the primary pollinating agent at Antioch. Although hawkmoths were not known on the dunes until 1983, they have been reported as pollinators of other Oenothera species (Gregory 1963). Their role as pollinators of Antioch Dunes evening-primrose has not been documented. Studies are needed to determine the phenology, pollinators and seed dispersal mechanisms of this subspecies (USFWS, 1984).

**Habitat Type**

Adult: Interior dunes on the "Antioch Dunes" along the shore of the San Joaquin River in Contra Costa County, California , occurring in nearly pure and shifting sand (USFWS, 2019).

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits inland dunes; this species will not mature where adult plants have previously grown unless fresh sand is deposited (Smithsonian Institution 1980 and Skinner 1997 in NatureServe, 2015). O.d. subsp. howellii is considered almost entirely restricted to the reamaining Anitoch Dunes habitat at the Anitoch Dunes Natural Wildlife Refuge, which encompasses 67 acres (the 41-acre Stamm Unit, owned by the Service and the 26-acre Sardis Unit, of which 14 acres are owned by the Service and 12 acres are owned by Pacific Gas and Electric)(USFWS, 2019).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2019)

**Number of Populations:**

4 (Stamm Unit, Sardis Unit, transplanted location on Browns Island, and Brannan Island)(USFWS, 2019).

**Population Size:**

2,368 (as of 2017)(USFWS, 2019)

**Population Narrative:**

According to the CNDDB (2018a), Oenothera deltoides subsp. howellii is known from 10 EOs, nine of which are presumed extant and one of which is considered likely extirpated (Table 2). Of the nine presumed extant EOs, six are considered natural occurrences and three are considered transplanted outside of native habitat and/or range. The total population in 2017 was estimated at 2,368 individuals, with 2,334 plants counted at the ADNWR (2,008 at the Stamm Unit and 326 at the Sardis Unit) and 34 plants at one of the transplanted locations at Browns Island (Table 2). Population numbers have shown some improvement since the 2008 Five-Year Review, as illustrated by plant count numbers from ADNWR (Figure 5; Service 2018a, Service No Date). However, despite the improvement, the overall population is still not considered stable or self-sustaining due to the overall low population numbers, low redundancy of populations, and continuing and increasing threats (USFWS, 2019).

***Threats and Stressors***

**Stressor:** Habitat destruction from sand mining, industrial and urban/suburban development, and/or conversion to agriculture
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat for the Lange's metalmark, O.d. subsp. howellii, E.c. var. angustatum, and pollinators, and area available for habitat restoration is threatened by destruction and conversion to other uses. This threat is largely ameliorated on the ADNWR and other properties with protection/management agreements in place, but not on properties without such agreements (USFWS, 2019).

**Stressor:** Habitat degradation due to loss of natural disturbance regime
**Exposure:**
**Response:**
**Consequence:** Loss of habitat/loss of individuals
**Narrative:** The reduction in sand deposition in Antioch Dunes habitat as a result of water management/use (dams, levees, etc.) in the Sacramento/San Joaquin River Delta system and reduced effectiveness of wind-driven dispersal of sand and disturbance of dunes has and continues to reduce overall size and connectedness of the dune natural community (USFWS, 2019).

**Stressor:** Habitat degradation due to non-native and native invasive vegetation
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Invasive vegetation colonizes open sand habitat, reducing available suitable Lange's metalmark, O.d. subsp. howellii, E.c. var. angustatum, and pollinator, habitat. Invasive plants out-compete native species, including Lange's metalmark host and food plants, and O.d. subsp. howellii and E.c. var. angustatum, for sunlight, space, nutrients, and moisture. They also stabilize the sand/soil, eliminating the natural disturbance regime and may cause soils to become more eutrophic (Thomson 2005a, Thomson 2005b, Chin 2012, McNally 2014). The 2008 Five-Year Review notes that the proliferation of non-native invasive plants has been increasing rapidly since 1998 (Service 2008) and these conditions continue (Chin 2012, McNally 2014, Service 2018a, Service 2018b, Service 2018c, Service 2018d). The use of herbicides to control non-native and native invasive vegetation may also present potential threat to Lange's metalmark host and food plants, O.d. subsp. howellii, and E.c. var. angustatum occurring in the same vicinity. Applying

herbicides selected for the target species and using appropriate rates and technique should minimize effects to non-target Lange's metalmark host and food plants, O.d. subsp. howellii, and E.c. var. angustatum. These practices have been instituted at the ADNWR, so this threat is considered largely ameliorated there (Service 2008), but it may pose a risk to current and future occurrences of these listed species elsewhere. Additionally, some herbicides may pose threat directly to Lange's metalmark. In a study of Behr's metalmark, a close relative of Lange's metalmark butterfly, the herbicides triclopyr, sethoxydim, and imazapyr were found to reduce the number of adults that emerged from pupation by 24-36% after exposure to typical field application rates (Stark et al 2012 in Richmond et al 2015) (USFWS, 2019).

**Stressor:** Habitat degradation due to gypsum dust deposition from neighboring plant (facility)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The 2008 Five-Year Review reported that gypsum dust building up on plants may reduce exposure to sunlight and decrease photosynthesis. It may also alter soil chemistry due to introduction of calcium and sulphates, which may affect the growth of Lange's metalmark host and food plants, O.d. subsp. howellii and E.c. var. angustatum and promote colonization by invasive species. Deposition is noted as affecting mostly the Sardis Unit. The ADNWR staff have met with Georgia-Pacific (G-P) about concerns over the dust and G-P increased efforts to reduce airborne gypsum (beyond the standards for air pollution control) by keeping it wetted down when possible during production activities. At the time of the 2008 Five-Year Review, staff noted a reduction in dust from G-P efforts. The review noted that there was no evidence that gypsum dust was adversely affecting any of the three species (Service 2008). However, it also cited a study that demonstrated that dusts may adversely increase transpiration through the cuticle of insect larvae and cause desiccation and abrasion of the cuticle (Wigglesworth 1945 in Service 2008), which may affect Lange's metalmark and pollinators of O.d. subsp. howellii or E.c. var. angustatum. The ADNWR staff reported an increase in gypsum dust deposition at ADNWR in 2017-2018 (Susan Euing pers. comm. December 12, 2018). In 2018, staff noted that gypsum was being deposited on the refuge at concentrations that coats plants, leading to cancellation of surveys for the Lange's metalmark in some parts of the refuge (Susan Euing pers. comm. August 17, 2018). In 2019, after several weeks into the Lange's metalmark survey season, ADNWR staff confirmed that no surveys had been canceled due to concerns about gypsum dust deposition (Louis Terrazas pers. comm. September 10, 2019). The magnitude of this potential stressor requires further investigation and Service partnership with G-P is ongoing (USFWS, 2019).

**Stressor:** Habitat degradation due to rogue hiking/trails
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This activity may cause direct injury or mortality to the Lange's metalmark, to its host and food plants, and to O.d. subsp. howellii and E.c. var. angustatum from trampling while also increasing potential for accidental introduction of wildfire from hikers. These threats and stressors were significantly reduced when ADNWR was fenced in 1986 and the 2008 Five-Year Review (Service 2008) no longer considered recreational and pedestrian traffic to be a significant threat. However, ADNWR staff note that incidence of trespassing and human encampments at ADNWR has increased in the past several years (Susan Euing pers. comm. December 12, 2018) (USFWS, 2019).

**Stressor:** Overutilization for commercial, recreational, scientific, or educational purposes
**Exposure:**
**Response:**
**Consequence:** Extirpation
**Narrative:** These activities represent a threat to the Antioch Dunes species from direct mortality of any individual(s) collected and a reduction in annual recruitment by killing or injuring reproductive individuals (USFWS, 2019).

**Stressor:** Disease or predation
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Evidence exists of O.d. subsp. howellii infestation by beetles (possibly family Chrysomelidae), which feed on petals, pollen, and seed pods. Also, in the early 1980s up to 50% of O.d. subsp. howellii was infested with small mirid bugs (family Miridae of the insect order Hemiptera) that prey upon O.d. subsp. howellii, and these insect predators remained an identified threat in 2008 (Service 2008). The magnitude of this stressor requires further investigation (USFWS, 2019).

**Stressor:** Wildfire
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Wildfire may cause direct mortality of O.d. subsp. howellii and E.c. var. angustatum plants during vulnerable life stages. These stages include the period from germination during the beginning of the wet season in December through the deposition of seeds in mid-summer. However, historical evidence indicates that the native plants may recover rather quickly from a wildfire (Service 2008). Any mortality would also result in reduced annual recruitment by killing or injuring reproductive individuals. The threat extends to pollinators and other pollinator plant species (USFWS, 2019).

**Stressor:** Fuelbreak discing
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fuelbreak discing may cause direct injury or mortality to Lange's metalmark, its host and food plants, and to O.d. subsp. howellii, and E.c. var. angustatum. However, it also creates open, disturbed, sand/soil that may be suitable for colonization by O.d. subsp. howellii and E.c. var. angustatum, as well as invasive vegetation. The net impact of this activity to listed plant resilience is unquantified (USFWS, 2019).

**Stressor:** Loss of pollinators
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Lange's metalmark is addressed as a pollinator for this discussion of the potential threat posed by possible insecticide drift from mosquito abatement spraying on neighboring

properties (Richmond et al 2015). The Mosquito Abatement District allows for spraying of insecticides to reduce the incidence of West Nile Virus at a wetland adjacent to the Stamm Unit of the ADNWR. The spray could drift on to the refuge and affect pollinators, such as Lange's metalmark and those that pollinate O.d. subsp. howellii or E.c. var. angustatum. While ADNWR staff have worked with county mosquito control staff to minimize effects from this potential threat, the magnitude of this stressor requires further investigation. As of the 2008 Five-Year Review, there was no evidence that lack or loss of pollinators has negatively impacted O.d. subsp. howellii or E.c. var. angustatum (Service 2008), but both species require cross-pollination, so an adequate pollinator population is necessary. Bees are suspected pollinators for both species and hawkmoths may also be pollinators for the primrose; however, actual pollinator taxa are unknown. This potential threat requires investigation (USFWS, 2019).

**Stressor:** Low population numbers
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Oenothera deltoides subsp. howellii and E.c. var. angustatum are threatened by few and small populations that are limited to a small and localized distribution, which increases the risk of extirpation and extinction due to: (1) Reduced resiliency (the ability of a species to withstand stochastic disturbance; resiliency is positively related to population size and growth rate and may be influenced by connectivity among populations); (2) Low redundancy (spreading risk among multiple populations or a large area to minimize the potential loss of the species from catastrophic events); and (3) Low representation (the breadth of genetic and environmental diversity within and among populations that influences the ability of a species to adapt to changing environmental conditions over time) (USFWS, 2019).

**Stressor:** Climate change
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Oenothera deltoides subsp. howellii and E.c. var. angustatum are threatened by multiple environmental effects anticipated with climate change, which may result in loss of habitat, altered temperature and moisture regimes causing direct mortality and/or impaired reproduction, and altered temperature and moisture regimes causing indirect mortality and/or impaired reproduction via phenological mismatches with pollinators and between pollinators and their host and/or other nectar plants (Richmond et al 2015) (USFWS, 2019).

***Recovery***

**Reclassification Criteria:**
There are at least five separate self-sustaining (all plants are naturally recruiting*) populations, including: at least three populations, each with a 15-year moving median of at least 4,800 flowering plants; and at least two populations, each with a 15-year moving median of at least 1,500 flowering plants (USFWS, 2019).

A distance of at least 1,500 feet and a natural and/or man-made firebreak separates individual populations (USFWS, 2019).

Populations should be protected and have in place a long-term management plan for the conservation of O.d. subsp. howellii and commitment for implementation of the plan (USFWS, 2019).

**Delisting Criteria:**
There are at least seven separate self-sustaining (all plants are naturally recruiting (*Any flowering individuals counted as naturally recruiting would have to be ≥ two flowering seasons post-outplanting. This would indicate the individual has completed the life cycle in situ.)) populations including: at least five populations, each with a 15-year moving median of at least 4,800 flowering plants; and at least two populations, each with a 15-year moving median of at least 1,500 flowering plants. OR, population viability analysis determines that O.d. subsp. howellii has a range-wide 95% probability of persistence over a 100-year period. a. A distance of at least 1,500 feet and a natural and/or man-made firebreak separates individual populations. b. Populations should be protected and have in place a long-term management plan for the conservation of the O.d. subsp. howellii and commitment for implementation of the plan. (USFWS, 2019)

A post-delisting monitoring plan for the species has been developed (USFWS, 2019).

**Recovery Actions:**

- The final supporting actions for Primary Action 1 include identification of other essential habitat and developing an MOU with the landowner to develop protective alternatives and actions. Since listing, the only new habitat identified for conservation is the property owned by the Pioneer Companies, Inc., and currently occupied by the McCullogh-Kemwater North American Company. All three of the Antioch Dunes species have been surveyed on this property (USFWS 2005). Currently, this property is for sale and the Service is considering alternatives that include purchasing this valuable habitat (USFWS, 2008).
- The initial supporting actions for Primary Action 2 are essentially the same for all three endangered Antioch Dunes species, and include conducting annual census of population and habitat; captive breeding (Lange's metalmark butterfly) or propagation and outplanting (Antioch Dunes evening-primrose, Contra Costa wallflower); developing and implementing a habitat restoration plan; and conducting studies of the biology of the species which include life history (Lange's metalmark butterfly), autecological studies (Antioch Dunes evening-primrose, Contra Costa wallflower), habitat requirements (Lange's metalmark butterfly), population biology (Lange's metalmark butterfly), and reproductive studies (Antioch Dunes evening-primrose, Contra Costa wallflower). Out-planting buckwheat host plants is also needed for Lange's metalmark butterfly. All of these actions have been ongoing and are discussed below in section IIC. Another group of supporting actions includes rebuilding the natural dune substrate and topography to the degree feasible by negotiating with the Army Corps of Engineers (Corps) and the Port of Stockton for sandy dredged material, preparing the sites for deposition of dredged material, and surveying the sites for candidate and listed species in order to ameliorate any negative effects. Several sources of sand were used in restoration efforts since listing the three species. Dredged material was found to contain a substantial amount of fine non-silica sediment which proved to stabilize too quickly for use as a substitute for the original dune sand (C. Smith in litt. 2007). Antioch Dunes NWR staff recently located several sources of local high-silica content sand that should prove useful in the restoration; however, although funding sources are being sought for purchasing and delivering the sand, current plans tentatively include testing the composition of the

imported sand prior to using it to supplement the refuge. (C. Smith in litt 2007; L. Terrazas, USFWS, pers. comm. 2008). Other actions include removal of a vineyard and removal of other non-native invasive vegetation throughout the Antioch Dunes NWR. The vineyard was removed in 1983 and removal of non-native invasive vegetation has been an ongoing effort (see section IIC for updated status on the restoration) (USFWS, 2008).

- Supporting actions for this include erecting interpretive signs, printing and distribution of leaflets describing the Antioch Dunes NWR's unique dune ecosystem and the need for restoration, and the development of an environmental education program. These actions were completed in the early 1980s; however, the public awareness effort is a dynamic and ongoing process (USFWS, 2008).
- Continue restoration of riverine dune habitat at Antioch Dunes NWR (USFWS, 2008)
- Conduct controlled propagation of the Lange's metalmark butterfly until natural populations at Antioch Dunes NWR are at a self-sustainable level (USFWS, 2008)
- Continue research into life history, habitat requirements, and population studies, including annual population monitoring surveys (USFWS, 2008)
- Acquire the McCulloch/Kemwater property abutting the eastern boundary of the Sardis Unit of the Antioch Dunes NWR (USFWS, 2008)
- Consider revising the Recovery Plan for the three endangered species endemic to Antioch Dunes, California (USFWS, 2008)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Several areas of future action are suggested over the next five years, which build on the actions articulated in the revised recovery plan (Service 1984) and the riverine dune ecosystem conservation strategies articulated in Service (2019b). These areas include: continuing to restore riverine dune habitat at ADNWR and considering nearby locations for restoration activities; continuing research on the habitat requirements, life history, and seed bank dynamics of Antioch Dunes evening-primrose; improving statistical analysis and numerical modeling related to Antioch Dunes evening-primrose; considering development of a publicly-accessible website for documents, literature, and data related to Antioch Dunes evening-primrose; and establishing an Antioch Dunes Recovery Implementation Team or recovery working group. Continued research on the habitat requirements and seed bank dynamics of Antioch Dunes evening-primrose could include identifying areas for possible development of new populations of Antioch Dunes evening-primrose. For example, the Service's experience with dune restoration at the Refuge in combination with the work of Jones et al. (2019) provides a strong foundation for expanding dune restoration work over the coming years. This future work could include an analysis of how environmental variables, such as precipitation and temperature patterns influence population dynamics in currently occupied areas and colonization of newly restored dunes. It is also not currently clear which invertebrate species are the most important pollinators of Antioch Dunes evening-primrose. A study of the current pollinators of primrose at Antioch Dunes would help add to our understanding of the natural history of this subspecies and identify which potential pollinators to monitor to ensure that healthy pollinator populations continue to occur at and near the Antioch Dunes ecosystem. Statistical and numerical modeling, such as with habitat suitability analysis and population dynamics modeling, can provide insights into possible future locations for development of Antioch Dunes evening-primrose populations, and future dynamics of these populations. Jones et al. (2019) began developing habitat suitability models for primrose using remote sensed vegetation metrics (NDVI; Normalized Difference Vegetation Index). It is possible that a continuation of this line of investigation will lead to improved insights into where and how to develop additional restored sand dunes that will support the recovery of this subspecies. It may also be useful to consider developing population viability analyses (PVA) that are specifically developed for Antioch Dunes evening-primrose. For example, it is possible that the stagestructured matrix population model developed by Thomson (2005a) could be used to form a foundation for PVA analysis. It is also possible that building and parameterizing such a model, and then projecting this model into various possible futures, including under the influence of changing climate conditions, could help provide insights beyond the PVA's suggested by recovery criteria in Service (2019a). As part of efforts to improve statistical analysis and modeling, creating a well-vetted and archived dataset of all Antioch Dunes evening-primrose surveys, and resolving any discrepancies in counts identified during this review will be critical to progressing on this objective. In late 2019, staff of the Bay-Delta Fish and Wildlife Office met with the staff of the ADNWR and considered formally convening a recovery implementation team (RIT) for the listed species that occur at the Refuge, including Antioch Dunes evening-primrose. The primary purpose for convening this group would be to encourage Service biologist and managers and external experts to consider recovery priorities for these species and the Antioch Dunes ecosystem, and continue to stay abreast of emerging research related to primrose, riverine dune ecology, and other relevant topics. This group would also help develop a recovery implementation strategy for Antioch Dunes. (USFWS, 2020)

# SPECIES ACCOUNT: *Opuntia treleasei* (Bakersfield cactus)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A flat-padded (beavertail) opuntia cactus, with the eye-spots (which are not sunken) having spines as well as bristles. Typically flowers in May. (NatureServe, 2015)

**Taxonomy**

USFWS treats as Opuntia treleasei (8/93). (NatureServe, 2015)

**Historical Range**

Historically, Bakersfield cactus was distributed in the low foothills northeast of Oildale and along the southeastern portion of the San Joaquin Valley floor to the low foothills of the Tehachapi Mountains south of Arvin in Kern County (Service 1990, p. 29363). In the late 1980s, its range was extended to the south when Bakersfield cactus was identified in several locations northwest of the community of Wheeler Ridge (Service 1998, p. 50). At the time of listing in 1990, Bakersfield cactus was documented in five general populations in Kern County: oilfields northeast of Oildale, Kern River Bluffs northeast of Bakersfield, bluffs and rolling hills west and north of Caliente Creek east of Bakersfield, Comanche Point on the Tejon Ranch southeast of Arvin, and northwest of Wheeler Ridge (Service 1990, p. 29364). (USFWS, 2025)

**Current Range**

California: San Joaquin Valley (central Kern County). Other reports are no longer considered to be this taxon (cf. Munz 1974; Benson 1982; Brown and Cypher 1997).

**Critical Habitat Designated**

Yes;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollinated/Vegetative reproduction (USFWS, 1998)

**Lifespan**

Adult: at least 48 years (USFWS, 1998)

**Breeding Season**

Adult: Bakersfield cactus typically flowers in May (Munz and Keck 1959) (USFWS, 1998).

**Reproduction Narrative**

Adult: Bakersfield cactus is a perennial. The life span of wild plants has not been determined, but clumps in cultivation at the Rancho Santa Ana Botanic Garden in Claremont, California, survived for 48 years, until extremely wet winter weather caused the pads to rot (R. van de

Hoek pers. comm.). Bakersfield cactus typically flowers in May (Munz and Keck 1959). Reproductive biology of this taxon has not been studied, but certain other Opuntia species require cross-pollination for seed-set and many are pollinated by bees (Benson 1982, Spears 1987, Osborn et al. 1988). One potential pollinator of Bakersfield cactus is the native solitary bee Diadasia australis ssp. caIifornia, which is known to occur in Kern County and which specializes in collecting pollen from Opuntia species (Thorp in litt. 1998). Vegetative reproduction, which is the production of new plants from sources other than seed, is typical in Bakersfield cactus and several related species (Benson 1982). Fallen pads root easily if sufficient water is available (Twisselmann 1967, Benson 1982, Mitchell 1988), but Bakersfield cactus does not survive prolonged inundation (ESA Planning and Environmental Services 1986a). Bakersfield cactus produces seeds infrequently. Van de Hoek (pers. comm.) noted that the frequency of seed set in extant populations is similar to the proportion of seeds he observed in herbarium specimens. Cactus seeds require warm, wet conditions to germinate, a combination which is extremely rare in the Bakersfield area (Benson 1982). Pads may be dispersed by flood waters (ESA Planning and Environmental Services 1986a), but seed dispersal agents are unknown (USFWS, 1998).

**Habitat Type**

Adult: Grasslands (USFWS, 1998)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits sandy soils or sand flats and low hills mostly in grassland at 120-550 m (Benson 1982; Brown and Cypher 1997). Characteristic in Sierra-Tehachapi Saltbush Scrub community, but also in Blue Oak Woodland and a riparian woodland.  (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on its specific habitat needs and low number of known populations.

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Pads may be dispersed by flood waters (ESA Planning and Environmental Services 1986), but seed dispersal agents are unknown (USFWS, 2011).

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

51 extant (USFWS, 2025)

**Population Narrative:**

Overall, the current distribution of Bakersfield cactus is similar to as described in the 2020 status review, and no status changes have occurred in the Diversity Database. There are 62 total occurrences composed of nine extirpated, two possibly extirpated, and 51 presumed extant occurrences (Diversity Database 2025b, entire). Of the presumed extant occurrences, six are transplants outside of the species' native habitat or range (Diversity Database 2025b, pp. 63–68; see Conservation). (USFWS, 2025)

***Threats and Stressors***

**Stressor:** Agricultural Conversion and Urbanization (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The primary threats to Bakersfield cactus over its entire habitat range continue to be residential development and conversion to agriculture. Continuing threats to localized populations that were identified in the listing rule include urbanization events such as; road expansion and maintenance (Oildale Area (within the MBNKR Recovery Site), Wheeler Ridge, and Sand Ridge), expansion of the Kern River Power Plant (Kern Canyon), the county airport (MBNKR), and the Bena landfill (Caliente-Bena Hills); as well as oil and gas development (Oildale Area (within the MBNKR) and Wheeler Ridge), Off road vehicle use (MBNKR and Cottonwood Creek), sand and gravel mining (Sand Ridge) and California Aqueduct right-of-way maintenance (Wheeler Ridge) (Cypher pers comm. 2010). All of these activities continue to threaten Bakersfield cactus by the modification of its habitat, the removal of Bakersfield cactus clumps, and the further fragmentation of existing populations. Table 2 summarizes land ownership and protected status (USFWS, 2011).

**Stressor:** Oil and Gas Extraction and Conveyance (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Oil and gas extraction and conveyance continue to threaten Bakersfield cactus. Adverse effects of oil and gas development on Bakersfield cactus include the loss of habitat, change in habitat quality, destruction of individuals or populations and their seedbank, habitat fragmentation, and increased competition from nonnative plant species due to habitat degradation. According to our HCP database (Service 2010), there is one HCP that covers oil and gas production that includes Bakersfield cactus as a covered species. The Nuevo Energy Company and Torch Operating Company (Nuevo/Torch) HCP was permitted in 1999 for a 30-year permit term. The project size is 21,800 acres with 1,700 acres impacted. The mitigation includes 800 acres to be created, enhanced, or restored, and 840 acres to be protected. Approximately 1,328 acres of the total 21,900 acres in the Nuevo/Torch Plan Area may be suitable for Bakersfield cactus (Nuevo/Torch 1999). Only those Nuevo/Torch lands east of Highway 99 overlap with reported occurrences of Bakersfield cactus. Bakersfield cactus has a limited range and is only found in western Kern County. Therefore Nuevo/Torch proposed avoidance and minimization measures are particularly important for this species. Oil and gas development is often limited and linear in nature in terms of well pads and pipeline construction but where oil and gas fields are developed into production sites, the cumulative impact can be large. Three of the five largest U.S.

oil fields are in Kern County and span more than one million acres (USFWS, 2011).

**Stressor:** Conservation Efforts (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Approximately 1068.40 acres (74.6 percent) of occupied presumed extant Bakersfield cactus habitat is on private land that is not protected from agricultural conversion, urbanization, oil and gas development, and off road vehicle use. About 144.35 acres (10.1 percent) of occupied presumed extant Bakersfield habitat is on private land that is protected. About 115.03 acres (8 percent) of presumed extant Bakersfield cactus habitat is on public land that is not protected from oil and gas development, off road vehicle use, and utility operation and maintenance; 104.37 acres (7.3 percent) is on protected public lands (USFWS, 2011).

**Stressor:** Overutilization for Commercial, Recreational, Scientific, or Educational Purposes (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** At the time of listing we stated that many cacti are collected and cultivated by plant collectors, or offered for sale or trade by cactus growers. Although there have been no reports of such trade in Bakersfield cactus, the species may still be collected and cultivated (Service 1990). Currently, we have no evidence whether this has occurred. Currently, the lack of monitoring means that we probably would not detect collection or vandalism, especially on private land (USFWS, 2011).

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** In summary, the Endangered Species Act is the primary Federal law that provides protection for this species since its listing as endangered in 1990. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent its status under the Act. Therefore, we continue to believe other laws and regulations have limited ability to protect the species in absence of the Endangered Species Act (USFWS, 2011).

**Stressor:** Nonnative annual grasses and increased fire frequency (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Nonnative annual grasses directly threaten the survival of mature cactus plants and hinder the establishment of new plants (ESA Planning and Environmental Services 1986; Mitchell 1988). In 2002-2004, mortality of Bakersfield cactus clumps and low rates of vegetative and sexual reproduction at Sand Ridge Preserve were attributed to competition with nonnative annual grasses for water during years with below-average precipitation (Cypher and Fiehler 2006; Cypher pers. comm. 2006). Nonnative annual grasses also indirectly affect Bakersfield cactus in three ways. First, indirect effects from nonnative annual grasses include increased fire frequency

(Service 1998; Brooks 1999; Brooks and Pyke 2001; Brooks 2003), damage from insects (Burger and Louda 1994), and rot of cactus pads during wet years (Service 1998). Fire suppression has allowed the extensive growth of nonnative grasses in some areas to the detriment of Bakersfield cactus (Moe 1989). Also, nonnative annual grasses, which are adapted to fire, increase the fuel load in fire-intolerant saltbush (Atriplex sp.) habitat, where Bakersfield cactus is found, resulting in an increase in fire frequency (Brooks 1999; Brooks and Pyke 2001; Brooks 2003). Although the effect of repeated fires on Bakersfield cactus has not been determined, the survival of Bakersfield cactus plants was monitored following single fire events at Sand Ridge (R. Hewett, Sand Ridge Preserve Manager, in litt. 1987) and near the Rio Bravo Hydroelectric Power Plant in Kern Canyon (Lawrence 1987; George Lawrence and Associates 1988). All of the Bakersfield cactus clumps survived the fires at both sites, despite wilting and browning of the pads. During the following spring, Bakersfield cactus plants that were subjected to low-intensity flames flowered; however, those subjected to moderate-intensity flames produced only vegetative growth. Second, dense grass also may harbor insects that damage cactus, as was observed with related species of Opuntia in Nebraska grasslands (Burger and Louda 1994), but not yet studied in Bakersfield cactus. Third, the dense grass cover creates a moist microclimate which may promote the growth of decay organisms and cause cactus pads to rot more in years of above-average precipitation (Service 1998) (USFWS, 2011).

**Stressor:** Loss of genetic diversity (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Extirpation
**Narrative:** The destruction of Bakersfield cactus habitat by agriculture and urban sprawl has left the remaining populations highly fragmented and small. The small size of many of the populations (Moe 1989; CNDDB 2010), presumed lack of gene flow between populations, and infrequent sexual reproduction (Menges 1986) may result in a lack of genetic diversity (Service 1998) although this has not been tested in Bakersfield cactus. Populations that are low in genetic variation are more vulnerable to diseases and parasites (Burdon and Marshall 1981) and to chance events, including environmental fluctuations, catastrophes, and genetic drift (Menges 1991). Several of the occurrences have few individuals (CNDDB 2010) and could be subject to loss of genetic diversity (USFWS, 2011).

**Stressor:** Flooding (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Bakersfield cactus populations located in floodplains are threatened by flooding. Bakersfield cactus plants cannot survive long periods of inundation (ESA Planning and Environmental Services 1986; Service 1998). Populations within the Caliente Creek floodplain have been extirpated due to flooding, and flooding continues to be a threat for the Caliente - Bena Hills populations (Service 1998; CNDDB 2010). Populations of Bakersfield cactus within the California Aqueduct right-of-way are also potentially threatened by flooding. Kern County identified earthquakes as highly significant hazard to all regions of Kern County. Large earthquakes can cause secondary hazards including landslides, fire, and flooding. The California Aqueduct crosses the White Wolf Fault at Wheeler Ridge and parallels the San Andreas Fault within 25 miles for most of its length in Kern County (Kern County Fire Department Office of Emergency Services 2005). The largest concentration of clumps in the Wheeler Ridge population

is located adjacent to an overflow drain for the Aqueduct, which could lead to flooding if an earthquake occurred anywhere along its length (Service 1998) (USFWS, 2011).

**Stressor:** Air pollution (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Reduced reproduction
**Narrative:** The Recovery Plan cites Messick (1987) as stating that air pollution is suspected to have contributed to the decline of Bakersfield cactus. Messick noted that populations of Bakersfield cactus appeared to be reproducing less and losing vigor and that soft tissues may be adversely affected by acid deposition or ozone. He suggested that study of possible air pollution effects was needed (USFWS, 2011).

**Stressor:** Reproductive threats (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Reduced reproductive success
**Narrative:** Reproduction of Bakersfield cactus may be threatened by the loss of pollinators. The reproductive biology of Bakersfield cactus has not been studied, but other Opuntia species are known to require cross-pollination for seed-set and many are pollinated by bees (Benson 1982; Spears 1987; Osborn et al. 1988; Thorp in litt. 1998). Pollinators are threatened by the use of both regulated (e.g., malathion) and unregulated pesticides (e.g., pyrethroids) (Service 2000; DPR 2006; Keith 2006). Malathion, a broad spectrum insecticide, has been used to control the beet leaf-hopper (Circulifer tenellus) in rangeland habitat, fallow fields, oil fields, and cultivated areas on both public (BLM) and private lands in the San Joaquin Valley, and in adjacent valleys and foothills. Increasingly, malathion is used to kill agricultural pests and mosquitoes, which are documented as vectors of the West Nile Virus. Its application therefore, is not limited to agricultural areas but includes residential and commercial zones thereby increasing the regional areas in which it is used. Hymenopterans (ants, wasps, bees, etc.) are particularly susceptible to malathion exposure (Dobroski and Lambert 1984) (USFWS, 2011).

**Stressor:** Climate change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Climate models predict for California an overall warming of 1.7 degrees to 5.8 degrees Celsius (3.0 degrees Fahrenheit to 10.4 degrees Fahrenheit) by 2100 (Cayan et al. 2006), but they vary in their predictions for precipitation. VanRheenen et al. (2004) predict a decrease in precipitation in the southern San Joaquin Valley. Bakersfield cactus seeds require warm, wet conditions to germinate (Benson 1982). Therefore, a sufficient decrease in precipitation could hinder Bakersfield cactus growth by sexual reproduction. Additionally, studies at Sand Ridge Preserve revealed increases in Bakersfield cactus mortality and lowered rates of vegetative and sexual reproduction in years of below-average precipitation due to competition for water with nonnative annual grasses (Cypher and Fiehler 2006; Cypher pers. comm. 2006). Conversely, increases in annual precipitation would possibly promote the growth of decay organisms resulting in the rot of cactus pads (Service 1998). Bakersfield cactus cannot tolerate prolonged periods of inundation as observed in the Caliente Creek floodplain (ESA Planning and Environmental Services 1986; Service 1998; CNDDB 2010). The effect of such changes in climate

on nonnative species and parasites is unknown, but could accelerate their establishment in Bakersfield cactus habitat. If such changes in climate occur, and the resulting changes in precipitation occur, Bakersfield cactus could be extirpated with no available refugia (USFWS, 2011).

**Stressor:** Pesticides (USFWS, 2025)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** As discussed in our previous review, Bakersfield cactus may require pollinators to produce seeds (Service 2011, p. 14). The taxon's reproductive biology has not been thoroughly studied, and the primary reproductive mechanism appears to be vegetative, but several other Opuntia species require cross-pollination, including by bees, to set seeds (Cypher et al. 2015, p. 5; Grant and Grant 1979, pp. 322–324; Osborn, Kevan, and Lane 1986, pp. 90–92). Potential pollinators of Bakersfield cactus are Diadasia rinconis, a native miner bee that has been observed visiting Bakersfield cactus flowers, and potentially Diadasia australis ssp. californica (a miner bee) and Anthophora fulvicauda (a digger bee), which occur in California and have been observed visiting O. basilaris var. basilaris (Grant and Grant 1979, p. 323). Pesticides affecting these pollinators can thus constitute a threat to Bakersfield cactus. The Environmental Protection Agency (Agency) released final biological evaluations assessing the effects of labeled uses of three neonicotinoid pesticides on listed species (Agency 2022a, entire; Agency 2022b, entire; Agency 2022c, entire). The Agency anticipates releasing amended proposed interim decisions, and a national consultation with the Agency is pending. We cannot speculate as to the outcome of the consultation and final rulemaking, but it could have bearing on Bakersfield cactus's conservation status if the cactus requires cross-pollination by bees (USFWS, 2025).

**Stressor:** Invasive plants and herbivory (USFWS, 2025)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** As discussed in the 2011 status review, invasive annual grasses are widespread in Kern County and are a threat to Bakersfield cactus (Service 2011, p. 25). Grasses compete with Bakersfield cactus for space and resources, especially soil moisture (Cypher and Fiehler 2006, p. 9). Invasive grasses also hinder the establishment of new cacti, contribute to increased fire frequency and intensity, harbor insects that may damage cacti through herbivory, and create a moist microclimate that may result in rotting of cactus pads (Service 2011, p. 25). Invasive grasses that impact Bakersfield cactus populations include wild oats (Avena spp.), bromes (Bromus spp.) and Saharan mustard (Brassica tournefortii) (Cypher et al. 2011, p. 15; Rogers, Warrick, and Labbé in litt. 2025, p. 4). During the summer months of 2020 and 2021, The Wildlands Conservancy staff noticed herbivory of Bakersfield cactus colonies at Wind Wolves Preserve (Wind Wolves) during outbreaks of grasshoppers (Melanoplus devastator and Dissosteira spurcata) and katydids (Tettigoniidae family) (Wind Wolves 2025, p. 16). These colonies correspond to Diversity Database occurrences #44 and 75–80 (Diversity Database 2025a; Diversity Database 2025b, pp. 41, 63–80). Insect damage varied in intensity, with some cactus clumps dying soon after the outbreaks, while others declined in health over two to three years and eventually died (Wind Wolves 2025, p. 16). Staff observed that insect invasions were more intense in areas with more residual dried annual grasses, which supports the idea that invasive grasses can harbor insects that may damage cacti (Wind Wolves 2025, p. 17). Additionally, there

appeared to be fewer insects and less severe damage to Bakersfield cactus in areas where livestock grazing had reduced grass density (Wind Wolves 2025, p. 17). Livestock grazing also reduces the biomass of grasses that compete with cactus colonies and reduces wildfire fuels (Cypher et al. 2011, p. 15). Therefore, appropriate levels of grazing seem to benefit Bakersfield cactus. However, intense grazing may result in trampling and other mechanical damage to Bakersfield cactus, so grazing should be properly implemented and monitored, and newly established cactus clumps can be protected with rocks, chicken wire, or rebar (Cypher et al. 2011, p. 16; Wind Wolves 2025, p. 11). (USFWS, 2025)

***Recovery***

**Reclassification Criteria:**
1) Secure and protect specified areas from incompatible uses A) 95 percent of occupied habitat on public lands; 75 percent of Bakersfield cactus clumps and 75 percent of occupied habitat in the Caliente-Bena Hills, Comanche Point, Kern Bluff, Sand Ridge, and Wheeler Ridge areas (addresses Listing Factor A) (USFWS, 2011);

2) A management plan has been approved and implemented for the recovery areas that includes survival of the species as an objective (addresses Listing Factors C and E) (USFWS, 2011);

3) Population monitoring in specified recovery areas shows: stable or increasing populations at all protected sites for a 5-year period (addresses Listing Factor E) (USFWS, 2011).

**Delisting Criteria:**
1) 90 percent of existing clumps and occupied habitat in the areas specified in the downlisting criteria (i.e. Caliente-Bena Hills, Comanche Point, Kern Bluffs, Sand Ridge, and Wheeler Ridge areas) and in the Fuller Acres, Cottonwood Creek, Granite Station, and Kern Canyon populations are protected (as defined in the downlisting criteria) (USFWS, 2011);

2) 100 or more clumps each in other populations north and south of the Kern River are protected (USFWS, 2011);

3) A management plan exists for all protected areas identified as important to the continued survival of the species; and (USFWS, 2011)

4) All protected populations show evidence of reproduction (USFWS, 2011)

**Recovery Actions:**
- 1. Protect populations within Bakersfield City limits in the Kern Bluff area and south of highway 178 (USFWS, 2011).
- 2. Work with willing land owners to establish a conservation easement or fee title to the property at the mouth of Kern Canyon (USFWS, 2011).
- 3. Complete the draft Department of Water Resources Habitat Conservation Plan (USFWS, 2011).
- 4. Conduct census of known populations and monitor the reproductive status of known populations (USFWS, 2011).

- 5. Determine suitable management methods for reducing nonnative annual grasses and increasing native perennials, including Bakersfield cactus, and communicate the benefits of such management to rangeland landowners (USFWS, 2011).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Protect existing habitat in the San Joaquin Valley for Bakersfield cactus. 2. Survey both extant and extirpated occurrences that have not been visited in the past few years to determine the status of these occurrences. Conduct yearly surveys at extant locations utilizing a standardized methodology to determine trends in the range-wide status as well as population/occurrence abundance. 3. Determine suitable management methods for reducing nonnative annual grasses and increasing native perennials, including Bakersfield cactus, and communicate the benefits of such management to rangeland owners. (USFWS, 2020)
- RECOMMENDATIONS FOR FUTURE ACTIONS Here we propose several management, conservation, and research recommendations which will aid in the recovery and conservation of Bakersfield cactus. Some of these recommendations have already been discussed in previous recovery documents (Service 1998, pp. 53–54; Service 2011, pp. 31–32; Service 2020, p. 4) and remain valid. 1. Habitat acquisition, management, and site-specific restoration. All native occurrences of Bakersfield cactus should be protected and secured through land acquisition, conservation easement, or other means. Additional suitable but unoccupied habitat should be protected and restored as future translocation sites. Adaptive and site-specific management of occurrences should be implemented under long-term management plans with a focus on maintaining suitable habitat conditions. Specifically, plans should address threats including competition from nonnative species, insect herbivory, trash dumping, and trampling by livestock, foot traffic, and off-highway vehicles. 2. Determine distribution and population dynamics through regular monitoring. Conduct range-wide status surveys at five-year intervals to quantify changes in Bakersfield cactus distribution and population trends. “Clumps”, which are groups of pads that are rooted at the same point, should be more precisely defined, such as by quantifying the area of the rooted point. Surveys should use Cypher et al. (2011, entire) methodology. Occurrences that have not been surveyed in the previous 10 years should be prioritized. Develop a plan to monitor abundance and population trends through regular surveying. Supplementary data may include habitat conditions, presence of invasive species and other threats, precipitation levels, temperature, and pollinator visitations. 3. Conduct genetic and morphological studies to clarify taxonomy and range. The genetic study conducted by Smith (2013, entire) should be repeated to clarify taxonomy, genetic partitioning within the metapopulation, and range. The study should include all known populations of Bakersfield cactus, Opuntia populations of intermediate morphology adjacent to the historical Bakersfield cactus range, and additional outgroups. In conjunction, a morphological study analogous to Zika and Wilson (2012, entire) should be conducted to determine whether physical characteristics can reliably distinguish Bakersfield cactus from other Opuntia. In addition to clarifying taxonomy and range, the genetic study results should be used to develop genetic management plans for each population, with a focus on populations that are actively augmented. 4. Continue translocation and population augmentation efforts under a genetic management plan. As translocation and augmentation efforts are all conducted through vegetative propagation of pads, a genetic management plan can help determine whether translocation should occur between genetically similar populations to avoid outbreeding depression or between dissimilar populations to increase diversity and representation. Extirpated occurrences should also be reintroduced. Additionally, an alternate translocation method through sexual propagation should be tested by collecting fruits, germinating mature seeds, caring for seedlings in a nursery, then planting at the translocation site when cacti are at a suitable size (Rogers, Warrick, and Labbé in litt. 2025, p. 4). This study can help determine whether seeds are

viable and, if successful, would increase genetic diversity. 5. Explore effectiveness of controlled burns and grazing on reducing invasive grasses. Appropriately managed grazing seems effective at reducing invasive grasses in Bakersfield cactus habitat. Further study the intensity, frequency, and timing of grazing that would confer the most benefit to Bakersfield cactus while minimizing trampling by livestock. Controlled low- to moderate-intensity burns may be another solution to the threat of invasive grasses. Conduct a feasibility test to determine the appropriate intensity and magnitude of fire for grass control and monitor health of Bakersfield cactus for adverse impacts. Compare grazing and controlled burns in terms of effectiveness at reducing invasive grasses, minimal impacts to Bakersfield cactus, cost to implement, and impacts on overall habitat and co-occurring species. 6. Clarify extent and population composition of recovery sites. Increased survey and translocation efforts have resulted in a greater number of known populations since the Bakersfield cactus recovery sites were defined in the Recovery Plan for Upland Species of the San Joaquin Valley (Service 1998, pp. 185–186). The boundaries of each recovery site should be clearly defined based on habitat surveys and aerial imagery to ensure that occurrences included in each recovery site appropriately represent a population. The recovery criteria should be reassessed based on this information (USFWS, 2025).

# SPECIES ACCOUNT: *Oxypolis canbyi* (Canby's dropwort)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015) 2/25/1986

**Physical Description**

A perennial herb with strong, fleshy rhizomes. Plants have slender stems, often more than 1 m tall. Leaves are thin and quill-like. Herbage smells slightly of dill. From mid-August to October the plants bear compound clusters of small white flowers (sometimes tinged with red) (NatureServe, 2015).

**Taxonomy**

Molecular and morphological studies have shown evidence that the genus Oxypolis as currently circumscribed, including compound-leaved and rachis-leaved species, is not monophyletic: the rachis-leaved species of Oxypolis (which include O. canbyi) are transferred to their own genus, Tiedemannia (Feist and Downie 2008 and Feist et al. 2012) (NatureServe, 2015).

**Historical Range**

See Current

**Current Range**

Native to the coastal plain, from southwestern Georgia through South Carolina to southeastern North Carolina (mostly in the middle and inner Coastal Plain), and from eastern MD to (historically) Delaware (Weakley 2008). (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

Adult: Existing populations of Oxypolis canbyi are maintained mainly through asexual reproduction. This species is strongly clonal, reproducing vegetatively by means of stoloniferous rhizomes. Stems also become decumbent and root at the nodes, especially in drier sites where there is little or no water to support the stems. The flowers can be either unisexual or bisexual. Bisexual flowers may facilitate some self-pollination; however, the flowers are protandrous, which is indicative of some degree of outcrossing.; Existing populations of O. canbyi are maintained mainly through asexual reproduction. This species is strongly "clonalizing," reproducing vegetatively by means of stoloniferous rhizomes. Stems also become decumbent and root at the nodes, especially in drier sites where there is little or no water to support the stems. Perfect (bisexual) flowers are produced which may result in some self-pollination; however, the flowers are protandrous which may ensure some degree of outcrossing. The potential for outcrossing may be higher in those umbels which produce inner male flowers and outer female flowers. Outcrossing results in increased recombination and heterozygosity, thereby ensuring increased evolutionary potential. Sexual reproduction theoretically should act as a sort of evolutionary buffer enabling the species to survive environmental changes. This may not be the case in O. canbyi due to a possible high selfing rate and/or the isolation of small populations. Predation by the caterpillar of the black swallowtail butterfly (Papilio polyxenes asterius) may be a factor in reducing the sexual reproductive potential of O. canbyi. This caterpillar chews through the stems just below the inflorescence (NatureServe, 2015).

**Habitat Type**

Adult: Coastal Plains (NatureServe, 2015)

**Environmental Specificity**

Adult: Moderate (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Moderate (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: Moderate (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: O. canbyi has been found in a variety of Coastal Plain habitats prone to long periods of inundation, including pond cypress ponds, grass-sedge dominated Carolina bays, wet pine savannahs, shallow pineland ponds and cypress-pine swamps or sloughs. The largest and most vigorous populations reported occur in open bays or ponds which are flooded throughout most of the year and which have little or no canopy cover. Many sites are on a sandy loam or loam soil which is underlain by a clay layer. Based on county soil surveys, known soil types which support populations of O. canbyi include Rembert loam, Portsmouth loam, McColl loam, Grady loam, Coxville fine sandy loam, and Rains sandy loam. These soil types are similar in that they have a medium to high organic content, high water table, and are deep, poorly drained, and acidic. Historically, fire was a key element maintaining the open nature of the habitat at many O. canbyi sites. The following species are frequently found associated with O. canbyi: Ilex myrtifolia, Nyssa biflora, Taxodium ascendens, Pinus serotina, Stillingia aquatica, Rhynchospora tracyi, R. inundata, Manisuris rugosa, Rhexia aristosa, Polygala cymosa, Pluchea rosea, Lobelia boykinii and Hypericum denticulataum (NatureServe, 2015). Moderate ecological integrity of the community, tolerance ranges and site fidelity are inferred based on the variety of habitat in which the species can be found.

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: The vectors of seed dispersal are not well understood, but at least some seed dispersal is by wind (USFWS, 1990).

***Population Information and Trends***

**Population Trends:**

Decreasing (NatureServe, 2015)

**Number of Populations:**

18 (17 natural and 1 introduced) (USFWS, 2022)

**Population Size:**
10,000 - 100,000 total individuals (NatureServe, 2015)

**Population Narrative:**
Historically, Canby's dropwort occurred in Delaware, Maryland, North and South Carolina, and Georgia. Today, Canby's dropwort only occurs in three states: Maryland, South Carolina, and Georgia. Further, Canby's range within these states has been reduced greatly overtime with Canby's dropwort being extirpated from 11 counties since the time it was listed. Habitat loss and wetland degradation combined with lack of habitat management through natural or prescribed fire has resulted in a continued decline of this species since its listing. To date, seventeen populations remain extant, and one population has been introduced, bringing the total number of extant populations to 18. Eleven Canby's dropwort populations are partially protected. Because many populations are owned by several landowners, protection and management of populations is difficult to achieve. Species experts defined a self-sustaining population as having a minimum of 1000 stems for five years. Currently, only five Canby's dropwort populations have 1000 stems or more. These populations occur in a small part of the species' former range in Maryland, South Carolina, and Georgia with populations being extirpated from Delaware and North Carolina. Because of existing and future threats and the limited number of populations that appear to be selfsustaining, this species still meets the definition of an endangered species. (USFWS, 2022)

***Threats and Stressors***

**Stressor:** Wetland draining (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The most significant threat to Canby' dropwort is the direct loss or alteration of its rare wetland habitat. Ditching and draining of wetland areas, primarily for agriculture and silviculture, have reduced the frequency, depth and duration of surface water, lowered the groundwater table, and changed the vegetative composition in many areas of the mid-Atlantic coastal plain where the species historically occurred. Reducing surface water, changing soil moisture levels and lowering of the water table enables other plants to become established, modifies vegetative succession, and makes sites less conducive overall to the plant's growth and reproduction (Murdock and Rayner 1990). As a result, many sites have been invaded by shrubs and some sites have been planted in pine. Other sites have been dredged thus breaking the clay hardpan and draining the wetland (Murdock and Rayner 1990, Gaddy 2006) (USFWS, 2015).

**Stressor:** Fire suppression (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** On sites that are not actively disturbed by logging, ditching or dredging, habitat management is often needed to prevent encroachment of shrubs or trees that increase evapotranspiration, lower the water table and shade out Canby's dropwort. Periodic fires probably limited this encroachment under natural conditions but many sites are no longer

surrounded by pine forest subject to regular fires and few sites are managed with prescribed burning. An example is the Big Cypress Meadow which is owned by The Nature Conservancy and is the only site in North Carolina. Young trees, shrubs and maidencane have invaded much of the meadow and the number of Canby's dropwort has declined from as many as 10,000 plants in 1986 to only a few plants in recent years and none in 2006 (Gaddy 2006) (USFWS, 2015).

**Stressor:** Predation (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:** Loss of plants
**Narrative:** Black swallowtail butterfly, grasshoppers, rabbits and rodents have all been known to damage/eat these plants (USFFWS, 2015).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** There is currently little regulatory protection of Canby's dropwort habitat. The U.S. Army Corps of Engineers (Corps) generally does not regulate dredge and fill activities in isolated wetlands because of a 2001 U.S. Supreme Court opinion. The 2001 opinion was issued in the Solid Waste Agency of Northern Cook County (SWANCC) v. the U.S. Army Corps of Engineers et al. and ruled in favor of SWANCC. The Corps' requirement for a Clean Water Act Section 404 permit to fill isolated wetlands to construct a landfill was overturned. The Corps had asserted jurisdiction on the isolated intrastate waters based solely on use by migratory birds (Findlaw 2007). Since that ruling isolated wetlands are generally not considered jurisdictional by the Corps. Therefore, there is no Federal nexus and consultation under section 7 of the Endangered Species Act is not required. Because Canby's dropwort grows only in isolated wetlands, there is currently no Federal regulatory control of actions that would affect its habitat. In South Carolina and Georgia, where almost all Canby's dropwort populations occur, there are no State laws that protect the isolated wetlands that provide Canby's dropwort habitat. Maryland and North Carolina, with one Canby's dropwort population each, do regulate isolated wetlands and therefore offer some protection to the habitat (Maryland Department of the Environment 2010, North Carolina Department of Environment and Natural Resources 2010). The Endangered Species Act prohibits the taking of endangered plants from Federal lands without a permit and regulates trade of listed plants. In addition, the Endangered Species Act prohibits the malicious damage or destruction of plants on Federal lands; and, their removal, cutting, digging, damaging, or destroying in knowing violation of any state law or regulation, including criminal trespass law. The State of Maryland prohibits taking of the species from private property without the landowner's permission and from State property without a permit and regulates trade in the species (Code of Maryland regulations 08.03.08). The State of North Carolina prohibits taking of the plant without a permit and the landowner's permission and regulates trade (North Carolina General Statute 19-B, 202.12-202.19). The State of Georgia prohibits digging, removal, or sale of State listed plants from public lands without the approval of the State management authority, and regulates sale or transport of State listed plants from private property (Georgia Wildflower Preservation Act of 1973). The State of South Carolina does not have any regulations that protect endangered plants on private land. However, regulations prohibit the unauthorized taking of plants from South Carolina Heritage Preserves and State Parks (South Carolina Code of Laws: Sections 50-11-2200, 50-11-2210, and 51-3-140) (USFWS, 2015).

***Recovery***

**Delisting Criteria:**
Canby's dropwort (Oxypolis canbyi) will be considered for delisting when there are at least 19 self-sustaining populations in existence that are protected to such a degree that the species no longer qualifies for protection under the Endangered Species Act (see criteria below). A self-sustaining population is a reproducing population that is large enough to maintain sufficient genetic variation to enable it to survive and respond to natural habitat changes. The number of individuals necessary and the quantity and quality of habitat needed to meet this criterion will be determined as one of the recovery tasks. The populations should be distributed throughout the species' historic range. This recovery objective is considered an interim goal because of the lack of data on biology and management requirements of the species. As new information is acquired, the estimate of self-sustaining populations required for the species' survival may be readjusted. The recovery objective for 0. canbyi will be reassessed at least annually in light of any new information that becomes available (USFWS, 1990).

**Recovery Actions:**
- Conduct surveys and habitat assessments at all surveyed sites by Gaddy (2006) that are not routinely monitored to determine the species presence and to assess habitat quality (USFWS, 2015).
- Protect known Canby's dropwort populations on private lands with conservation easements or Wetland Reserve Program easements (USFWS, 2015).
- Assess moribund and extirpated sites as well as other isolated wetlands for suitable habitat and resource availability (USFWS, 2015).
- Improve our understanding of the relationship between precipitation (and other parameters) and Canby's dropwort population viability (USFWS, 2015).
- Determine objective, quantitative criteria for self-sustaining populations (USFWS, 2015).
- For populations confined within roadside or powerline right-of-ways, promote management actions that shift Canby's dropwort populations away from right-of-ways and towards the interior of adjacent wetlands (USFWS, 2015).
- Conduct demographic studies that further examine genetic variability, population structures, preproduction, and indeterminate growth factors (USFWS, 2015).

***Conservation Measures and Best Management Practices:***
- RECOMMENDATIONS FOR FUTURE ACTIVITIES 1. Protect known Canby's dropwort populations on private lands with conservation easements or Wetland Reserve Program Easements such as Monkey Bay in Clarendon County, SC, Perrion Pond (Burke County), Layfield Pond (Dooly County), Forrester Flats (Lee County), Roadside Park (Lee County), West Daniels Pond (Burke County), Greater Unadilla Pond (Dooly County), and Harmony Church Pond (Dooly County), GA. 2. Improve extant populations with fewer than 1,000 individuals by removing shrub/tree encroachment with prescribed fire, canopy thinning, or other techniques: a. Crosby Heritage Preserve, Colleton County, SC. b. Monkey Bay, Clarendon County, SC. c. Black Pond, Jenkins County, GA. d. Harmony Church Road, Dooly County, GA. e. Greater Unadilla Pond, Dooly County, GA. 3. Search for new populations on property that has suitable habitat within the species range. 4. Propagate and reintroduce Canby's dropwort by rhizome cuttings in a way that retains genetic diversity (e.g., taking rhizome cuttings from multiple individuals). 5. Collect seeds from all populations across the range to safeguard at a Center

for Plant Conservation Site, such as North Carolina Botanical Garden (NCBG). (USFWS, 2022)

# SPECIES ACCOUNT: *Oxytropis campestris var. chartacea* (Fassett's locoweed)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened 09/28/1988; Great Lakes-Big Rivers Region (R3) (USFWS, 2015)

**Physical Description**

A perennial herb with compound leaves and with herbage that is covered with dense, white-silky hairs, giving the plant a silvery-gray appearance. Spikes of rose-purple flowers, each about 2 cm long, bloom from late spring-early summer. (NatureServe, 2015)

**Taxonomy**

A distinct taxon. (NatureServe, 2015)

**Historical Range**

Historic populations in Bayfield and Waushara counties. (NatureServe, 2015)

**Current Range**

Restricted to small inland lakes at eight sites in central and northwestern Wisconsin: Waushara, Portage, and Bayfield counties. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 2013)

**Lifespan**

Adult: Mean 1-4 years; up to 14 years (USFWS, 2013)

**Dependency on Other Individuals or Species**

Adult: Pollinated by bees and butterflies (USFWS, 2013)

**Breeding Season**

Adult: Flowers primarily late May to mid-June (USFWS, 2013)

**Other Reproductive Information**

Adult: Tippery (2015) found that seed germination in Fassett’s locoweed is highly dependent on physical damage to the seed coat, similar to many other plants in the Fabaceae (legume) family. In germination experiments, seeds with an intact seed coat had a very low rate of germination (about 7.8%) when compared to germination rates of seeds cut with a razorblade (61.1%) or seeds rubbed between sandpaper (71.1%). Seeds with thicker seed coats will persist longer in the seed bank, and since Fassett's locoweed relies on an extensive seed bank to recover from population crashes, this adaptation likely heavily contributes to the persistence of the species (Tippery 2015). Seed germination is also predicted by the ability of seeds to absorb water. During a trial, locoweed seeds that did not increase in size after being soaked in water overnight, were determined to have insufficient damage to the seed coat. Seeds that did absorb water had a germination rate of almost 100% (Tippery 2016). Ultimately, findings from these studies found that for germination to be successful, there must be absorption of water, which is not possible without scarification (nicking, breaking, softening, or weaking of the outer shell to speed up seed germination)(Tippery 2015, Tippery 2016). Tippery (2016) found that during the early stages of germination, Fassett's locoweed seedlings grow a root of 4 centimeters (cm)(1.6 inches (in)) or more in length. In germination experiments, seeds that were planted at the soil surface grew a hypocotyl (the part of the stem of an embryo plant beneath the stalks of the seed leaves and directly above the root) of 1 cm in length. In wild populations, there is no visible hypocotyl, and cotyledons (the embryonic leaf, first leaves to appear from a germinating seed) are usually visible just at the soil surface. This indicates that naturally seeds germinate at a depth of 1 cm (0.4 in) or more. In germination experiments, the effect of water depth on seedling establishment was tested using different length pipes to plant seeds. There were no observed differences in germination of seeds in 5 cm (2.0 in), 10 cm (3.9 in), or 15 cm (5.9 in) under water depth setups (USFWS, 2022).

**Reproduction Narrative**

Adult: Fassett's locoweed blooms primarily at the end of May through mid-June, although occasional plants bloom as late as November (Tracy Feldman, pers. obs., 2009-2012). The mean lifespan of Fassett's locoweed appears to vary from 1-4 years depending upon the life stage, the lake from which data were used, and the year data were collected, but the maximum can range to potentially over 14 years (Tracy Feldman, pers. comm., 2013). Seed production is variable, having the potential to vary from zero (even in a "reproductive" plant) to well over 10,000 seeds per plant, but actual numbers range from fairly low in small plants to several hundred (or even in the 1000s) of seeds for larger plants, on average (Tracy Feldman, pers. comm., 2012) (Feldman 2012). Data suggest that the seed banks on Plainfield and Pickerel Lakes are patchy but could be very large (Feldman 2010). While seed banks may be large, seed germination rates vary, and in the field germination rates may be low, from 50-95%; however, only 0-1% of intact seeds germinated in greenhouse and field germination experiments. Seeds appear to germinate in bands along the shoreline at some range of distances above the water line. (Feldman 2012) (USFWS, 2013)

**Habitat Type**

Adult: Palustrine (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Open gravelly lake (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Fluctuating lake levels (USFWS, 1991)

**Spatial Arrangements of the Population**

Adult: Pure stands to scattered individuals (USFWS, 1991)

**Environmental Specificity**

Adult: Narrow. Specialist with key requirements common. (NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from USFWS, 1991)

**Habitat Narrative**

Adult: Fassett's locoweed occurs on sandy or gravelly shorelines of small landlocked seepage lakes. It is apparently intolerant of competition and shading and dependent on lake level fluctuations to eliminate competition and maintain an open habitat. (NatureServe, 2015) In all cases, Fassett's locoweed occurs in areas which are completely exposed to sunlight or receive only partial shade from other species. Particularly along the open shorelines but also throughout the sandy lakeside habitat, the soil surface is subjected to extreme temperature fluctuations, high solar radiation, strong winds, and soil moisture stress. However, it is in these areas, where competition from other plant species appears to be very low, that Fassett's locoweed occurs in the densest colonies. (USFWS, 1991)

***Dispersal/Migration***

**Dispersal**

Adult: Low (USFWS, 1991)

**Dispersal/Migration Narrative**

Adult: The mature fruits release numerous, small black seeds which have no evident adaptation for dispersal. As in many other plant species (Harper 1977, Johnson and Anderson 1986), the seeds of Fassett's locoweed probably tend to disperse in a clumped pattern around the parent plant. However, they may be moved short distances by wind, rain, or lake water during periods of inundation. (USFWS, 1991)

***Population Information and Trends***

**Population Trends:**

Fluctuating, but apparently increasing (USFWS, 2013)

**Species Trends:**

Fluctuating, but apparently increasing (USFWS, 2013)

**Population Growth Rate:**

Fluctuating (USFWS, 2013)

**Number of Populations:**

9 (USFWS, 2022)

**Population Size:**

Approximately 190,000 in 2012 (USFWS, 2013)

**Adaptability:**

Low (USFWS, 2013)

**Population Narrative:**

Of the 10 lakes that support Fassett's locoweed, the plant currently occurs in highest numbers (thousands) at four lakes; Pigeon, Mountain, Plainfield, and Pickerel lakes. Populations of Fassett's locoweed have fluctuated considerably over time. From 2009 to 2012, populations at Plainfield and Pickerel lakes have been stable or increasing due to increases in the number of seedlings (in the thousands) and small plants, most of which do not survive long enough to reproduce (Feldman 2009, 2010, 2011, 2012). Numbers of reproductive plants have decreased over the last four years at these two lakes. Predictions using projection matrix population models indicate that these populations have the potential to decrease in the near future (Feldman 2012). Up to 2000 plants were observed at Second Lake from 2006-2008, however the current population level is unknown. Populations number in the hundreds at Weymouth and Sherman (Marks) lakes. Very small populations (30 plants or less) have been consistently recorded at Lake Huron, Deer Print Lake, and Wolf Lake. (USFWS, 2013)Fluctuations in water levels maintain habitat but also determine population size from year to year. In one year, unusually high water levels may reduce populations to only a few plants and in the next year, lower water levels may result in thousands of plants (USFWS 2009). (NatureServe, 2015). Fassett's locoweed is a rare endemic species with a very limited distribution. Found in only a maximum of 9 sites (7 in central Wisconsin and 2 in northwest Wisconsin), any factor that impacts its habitat adversely could have major consequences (USFWS, 2022)

***Threats and Stressors***

**Stressor:** Development (USFWS, 1991; 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Development, primarily construction of homes and cottages, was considered a significant threat in the Recovery Plan (USFWS, 1991). This threat has been reduced through acquisition of locoweed sites, conservation education and agreements, protective signage, designation of State Natural Areas which are managed to protect and maintain native landscapes. Residential development is still an issue for the Lake Huron site, although many homeowners at this site are caging plants, distributing information and occasionally pulling invasive weeds. (USFWS, 2013)

**Stressor:** Human impacts (USFWS, 1991; 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A county boat ramp on Pickerel Lake is a threat, along with fishing and swimming. A summer camp is also on this lake. In the past, Fassett's locoweed areas on camp property had been roped off (Darcy Kind, pers. comm., 2012), however no ropes were in place as of at least 2009. ATV use and hiking may trample plants. (USFWS, 1991; 2013)

**Stressor:** Other vegetation (USFWS, 1991; 2013)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Invasive plants, such as the non-native sweet clover can spread readily in open areas. It is considered a threat to recovering prairies, because it may compete with native species for resources or otherwise alter the edaphic conditions of the plant community (Eckardt 1987). The invasive orange hawkweed is quite abundant a few meters above the high waterline and grows in association with Fassett's locoweed in that zone. This species is of concern because of its possible allelopathic properties and the potential impact on Fassett's locoweed (Waller 1989). Trees and other vegetation may grow sufficiently to block out sunlight required by the locoweed. (USFWS, 1991; 2013)

**Stressor:** Nutrient enrichment (USFWS, 1991; 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Fassett's locoweed recovery plan (USFWS 1991) identified nutrient enrichment of shorelines supporting Fassett's locoweed resulting from run-off as a threat, as this may result in loss of habitat due to competition from other plant species that would not typically be able to compete with Fassett's locoweed in its nutrient poor habitat. (USFWS, 2013)

**Stressor:** Reduced groundwater levels (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fassett's locoweed is found on sandy-gravel lakeshores of seepage lakes, fed by groundwater, with fluctuating lake levels. Fluctuating lake levels are critical in maintaining suitable open shoreline habitat for the species. Aggressive plant competitors may be eliminated during periods of high water. Fluctuating water levels also help maintain low substrate fertility (preferred by the species) and distribute seeds within the site. The amount of available habitat at each site depends on current and recent lake levels. Generally, lower lake levels expose more shoreline area which provides more suitable habitat for the species, resulting in higher population numbers, especially of seedlings. However, continued low water conditions may decrease habitat due to succession. High lake levels which eliminate shoreline habitat, generally reduce overall population numbers. In addition, water level fluctuations within seasons may cause mortality of plants through submersion or desiccation (Tracy Feldman, UW-SP, pers. comm., 2012.) Lake levels may be affected by the use of high capacity wells used for crop irrigation. (USFWS, 2013)

**Stressor:** Herbivory (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Flowers have been eaten from a number of plants at one site, possibly by deer (WDNR, unpublished data). At Plainfield and Pickerel lakes in 2009-2012, Feldman observed racemes removed from Fassett's locoweed plants, potentially by deer. Insect herbivores may also affect Fassett's locoweed plants and seeds. At Plainfield and Pickerel lakes between 2009 and 2012, Tracy Feldman (UW-SP) observed caterpillars on racemes, spittlebugs on leaves, and occasional chewed leaves or racemes. At Pickerel Lake in 2012 he also observed holes in mature Fassett's locoweed fruits, reminiscent of weevil damage. (USFWS, 2013)

**Stressor:** Herbicides (USFWS, 1991; 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbicide and pesticide use is heavy in the agricultural areas. In addition, many of the lakes with Fassett's locoweed are lined with residential properties and lawns. Problems are possible from spray drift or run-off onto Fassett's locoweed habitat. Any decrease in the protective wooded buffer around each lake could result in increased overland flow of sediment-laden run-off into the water. (USFWS, 1991) The threat from herbicides is ongoing. (USFWS, 1991; 2013)

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 9

**Delisting Criteria:**
Removal of Fassett's locoweed from the list of US. Endangered and Threatened Species will be considered when six populations are permanently protected and managed, and monitoring indicates the populations to be self-sustaining. (USFWS, 1991)

**Recovery Actions:**
- Protect and manage Fassett's locoweed at all sites with naturally-occurring populations. This includes the six extant [now 10 (USFWS, 2013)] populations as well as any new occurrences which might be found. Adequate protection will be accomplished not only through legal agreements with landowners but by increasing public awareness on the high-use lake shorelines. Education must be seen as integral to protection. (USFWS, 1991)
- Management to maintain appropriate habitat, including such activities as fencing populations in certain areas or removing invading, nonnative species, will be necessary at some sites. (USFWS, 1991)
- It is essential to conduct research which will contribute to recovery. Included here are seed bank research and genetic studies. (USFWS, 1991)
- Introduction of the species may become a future priority if protection of extant populations cannot be achieved. (USFWS, 1991)
- Land protection and site monitoring (USFWS, 2013)
- Site protection (USFWS, 2013)
- Population monitoring at Plainfield and Pickerel lakes (USFWS, 2013)
- Population augmentation (USFWS, 2013)
- Searches for new sites and potential reintroductions (USFWS, 2013)
- Actions to address threats due to continued low lake levels (USFWS, 2013)
- Pollinator studies (USFWS, 2013)
- Seed storage (USFWS, 2013)
- Seed bank studies (USFWS, 2013)

# SPECIES ACCOUNT: *Paronychia chartacea* (Papery whitlow-wort)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 2/20/1987; Southeast Region (R4)

**Physical Description**

The papery whitlow-wort is mat-forming with many bright yellowish-green branches radiating flatly from a strong taproot (Kral 1983, Small 1933). The stems are 5 to 20 cm long and are wiry. The leaf blades are sessile, 1.5 to 3.0 mm long, ovate to triangular-ovate in shape, and strongly revolute. It has numerous small cream-colored to greenish flowers (Small 1933, FWS 1996) that produce a very thin-walled utricle (Kral 1983). There are two geographically isolated subspecies of this small herb: P. chartacea ssp. chartacea in central Florida and P. chartacea ssp. minima L. Anderson in the Florida panhandle. Much of the distinction between the two subspecies is a matter of degree (Anderson 1991). The P. chartacea ssp. minima is somewhat less pubescent than ssp. chartacea. There are also differences in their base stems, leaf width, and flower cluster (Anderson 1991). (USFWS, 1999)

**Taxonomy**

The papery whitlow-wort was first named by Small (1925) as Nychia pulvinata. In 1936 Fernald transferred the species to the genus Paronychia as P. chartacea because the name P. pulvinata was pre-empted (Anderson 1991). In 1991 Anderson formally described two geographically distinct subspecies, P. chartacea ssp. chartacea and P. chartacea ssp. minima. The subspecies P. chartacea ssp. minima was formally described by Anderson (1991), several years after P. chartacea had been listed as a threatened species. Because the entire species was listed as threatened, the newly described subspecies is also protected. (USFWS, 1999)

**Historical Range**

See current range/distribution.

**Current Range**

P. chartacea ssp. chartacea occurs in the Lake Wales Ridge in Highlands, Polk, Osceola, Orange, and Lake counties, Florida. P. chartacea ssp. minima occurs in the karst region of the Florida panhandle, Washington and Bay counties. (USFWS, 1999)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

Adult: Flowering and fruiting occur in late summer or fall (Anderson 1991) and the seeds mature in September or October (T. Race, Bok Tower Gardens, personal communication 1996). This species is a short-lived perennial (Anderson 1991 and observations by staff at the Historic Bok Sanctuary).

**Habitat Type**

Adult: Sand scrub/rosemary balds

**Environmental Specificity**

Adult: Narrow (Inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Papery whitlow-wort is most frequently seen in open, sunny gaps in rosemary balds within scrub vegetation (Abrahamson et al. 1984, Christman 1988, Menges and Kohfeldt 1995). At Archbold Biological Station, rosemary scrubs are found only on the higher ridges and knolls surrounded by scrubby flatwoods with dense oaks. The main soil types are St. Lucie and Archbold (Abrahamson et al. 1984), which are both well-drained white sands (U.S. Dept. of Agriculture, Soil Conservation Service 1989). The fire cycle in rosemary scrub can range from 10 to as long as 100 years (Johnson 1982, Myers 1990). Rosemary scrub has abundant Florida rosemary (Ceratiola ericoides) and scrub oaks including Chapman oak (Quercus chapmannii), sand live oak (Q. geminata), Archbold oak (Q. inopina) and occasional sand pine (Pinus clausa). The open sandy areas of rosemary scrub contain small herbs and lichens (Abrahamson et al. 1984, Hawkes and Menges 1996). These gaps in the dense vegetation are more persistent in rosemary scrubs than in scrubby flatwoods (Hawkes and Menges 1996). Papery whitlow-wort also occurs in high pineland (upland longleaf pine vegetation, also called "sandhill") in the Walk in the Water tract of LWR State Forest (A. Cox, Florida Division of Forestry, personal communication 2002), at TNC's Crooked Lake Sandhill Preserve (B. Pace-Aldana, TNC, in litt. 2002), and at the Tiger Creek Preserve. In studies of the responses of plants to fire in rosemary balds, Johnson and Abrahamson (1990) and Ostertag and Menges (1994) identified two groups of scrub plants—those that resprout after a fire and those that return from seed. They found that papery whitlow-wort appeared in rosemary balds after fires, even though it had been rare or absent prior to the burn. This strongly indicates that papery whitlow-wort maintains seed banks in the soil, waiting for suitable germination conditions. Within about 9 to 12 years after a fire, papery whitlow-wort was displaced by Florida rosemary and reindeer lichens (Cladonia and Cladina) (Johnson and Abrahamson 1990). Some gap plants such as snakeroot and Highlands scrub hypericum disappear relatively quickly after fires and require large populations consisting of tens of thousands of plants to persist (Quintana-Ascencio and Menges 2000), but papery whitlow-wort persists longer after fire and it has many large populations over a relatively large geographic range, compared to other LWR endemic plants. The density of papery whitlow-wort increases in relation to available open space (Hawkes and Menges 1996; Menges and Kohfeldt 1995), so the species is most abundant in disturbed, sandy areas such as road rights-of-way and recently cleared high pine (Abrahamson et al. 1984; Christman 1988; Service 1996). Papery whitlow-wort can become very abundant after a fire or on disturbed sites such as along fire lanes or trails (Service 1996; Johnson and Abrahamson 1990) and is least likely of the federally-listed scrub plants to suffer local extirpations as open areas become covered by shrubs. Loose sand affects papery whitlow-wort. According to research by Petru and Menges (2004), "the demographic responses of the species to sand movements indicate that mobile sands create constantly shifting arrays of microsites that can influence post-dispersal seed germination, survival, and growth of Florida scrub herbs. Roadside habitats have more dynamic patterns of sand movement than natural gaps and may alter selection regimes important for demographic variation of endemic Florida scrub plants." Papery whitlow-wort persists on road edges in the absence of fire in the vegetation. These roadside sandy areas constitute habitats that are significantly different from the bare areas within the vegetation, and may be less suitable for persistence of the species. This research bolsters the already-substantial evidence that prescribed fire is essential to maintain Florida scrub vegetation and its biota, including other federally listed plants and animals. Management for papery whitlow-wort requires burning regimes that mimic the natural fire cycles of rosemary scrub. Relationships among fire, open space, and plant distributions within a xeric scrub are complex and need to be studied further (Hawkes and Menges 1996). Management practices for rosemary scrub should include fire at intervals suitable for a variety of plants and animals, rather than at intervals optimized for just a single species (Hawkes and Menges 1996; Quintana-Ascencio et al. 2003).

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

< 24 EORs ( Element Occurrence Records) (USFWS, 2021)

**Population Size:**

2500 - 10,000 individuals (NatureServe, 2015)

**Adaptability:**

Found in disturbed sites; can tolerate and probably promoted by fire. (NatureServe, 2015)

**Population Narrative:**

Papery whitlow-wort occurs on the Lake Wales and at least one smaller nearby ridge (Kral 1983), in Highlands, Polk, Osceola, Orange, and Lake Counties (Anderson 1991). It is present on the small ridge at the Lake McLeod tract of LWR National Wildlife Refuge, but not on the Bombing Range Ridge on Avon Park Air Force Range. On the LWR, it is present in essentially all of the scrub conservation lands. Since the last comprehensive survey (Schultz et al. 1999), it has been found in high pineland at the Walk in Water tract of LWR State Forest (Anne Cox, LWR State Forest, personal communication 2002). It is also present in high pineland on the Tiger Creek Preserve, owned by The Nature Conservancy. The northern range limit of papery whitlow-wort is in Lake County, where it occurs on the north side of Lake Louisa at Crooked River Preserve, owned by the Lake County Water Authority. It was possibly present at a nearby site, Schofield Sandhill, which had been proposed for acquisition under the Florida Forever program, but the acquisition proposal did not come to fruition. The only site on conservation lands in Orange County (also at the northern range limit) is the small Shadow Bay Park (formerly Lake Cane-Marsha Park) near where the Florida Turnpike crosses Interstate 4. The species was reported from localities in western Orange County, but the area has since become urbanized, and there are few if any opportunities for setting aside conservation lands in this area. The only papery whitlow-wort site in Osceola County for that has been proposed for State acquisition is at Lake Davenport, in the northwestern corner of the County. It has not been purchased (Florida Natural Areas Inventory 2005). Papery whitlow-wort is present on essentially all conservation lands with scrub on the LWR in Polk and Highlands Counties. The southernmost sites on conservation lands are Gould Road (part of the LWR Wildlife and Environmental Area operated by the FWC) and Archbold, both in Highlands County south of Lake Placid (Schultz et al. 1999). During 2003, the Florida Fish and Wildlife Conservation Commission and Archbold Biological Station purchased adjoining portions of a ranch that bordered the Biological Station's preserve to the west. The recently-acquired land provides an important buffer for Archbold, and it protects additional habitat for this species, both occupied and restorable. Although FNAI data provide the best available overall view of the distribution of this species, intensive local inventories add important detail. The LWR State Forest is represented in the FNAI database by nine element occurrences, yet the Arbuckle tract of the Forest has 188 records of this plant in its GIS database, based upon an inventory by K. DeLaney in 1988 (data provided by A. Cox, LWR State Forest). Of the 188 records, 23 represented more than 100 individuals. Archbold Biological Station has not monitored this plant because it thrives in fire lanes that usually do not have exotic plant problems (E. Menges and M. Deyrup, Archbold, personal communication 1995, in Service 1996). The propensity of this species to occupy fire lanes, roadsides, and other artificially disturbed areas is a primary conservation concern for the papery whitlow-wort, because it tends to be far more abundant in such disturbed areas than within the vegetation itself. This situation was researched by Petru and Menges (2004), and they confirmed that prescribed fire is essential to create and restore open, sandy habitat for this and other plants. The papery whitlow-wort occurs in association with several other federally listed species: in scrub, Florida bonamia, Highlands scrub hypericum, wireweed, Florida perforate cladonia, snakeroot, and scrub blazing star. In high pineland at the Tiger Creek Preserve, pygmy fringe tree, pigeon wings, scrub buckwheat, Britton's beargrass, scrub plum, and Carter's mustard. Papery whitlow-wort is the most abundant and widespread of the listed LWR scrub and high pineland plants, and it has benefited greatly from acquisition of conservation lands in its range. Like several other scrub species, including Highlands scrub hypericum, is particularly abundant in human-disturbed areas such as road edges and fire lanes. Researchers based at Archbold Biological Station are interested in finding ways to lessen these plants' dependence on such artificial habitats through restoration of fire regimes.

***Threats and Stressors***

**Stressor:** Habitat destruction or modification
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** For subspecies chartacea, about 30% of FNAI EORs are not protected from threats that are range-wide in scope. Fire suppression is pervasive at unprotected sites and gradually alters habitat over a period of years. Habitat loss through agricultural and residential development is immediate, ongoing, and cumulative. Seventy percent of FNAI EORs occur within one of the 26 managed areas listed in C(1)(d) above. Loss of populations off the LWR in Orange, Polk, and Glades Counties would constitute a significant curtailment of the historic range of chartacea (Turner et al. 2006). Some of these sites may already have been lost. For subspecies minima, it is unknown how many populations have already been lost and its historical range has apparently not been documented. Eight of 12 extant sites appear to be in imminent danger of being lost; all are on privately owned land and could be destroyed if development or habitat modification occurs on those lands. For both subspecies a range-wide survey is needed to determine the current status of populations and the threats to each. (USFWS, 2008)

**Stressor:** Inadequacy of existing regulatory mechanisms
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Papery whitlow-wort is listed as endangered by the State of Florida on the Regulated Plant Index (Florida Department of Agriculture and Consumer Services Rule 5B-40). This law regulates the taking, transport, and sale of listed plants. Property owners are not prohibited under this law from destroying populations of listed plants nor are they required to manage habitats to maintain populations. Existing federal and state regulations prohibit the removal or destruction of listed plant species on public lands. However, they afford no protection to listed plants on private lands. In addition, state regulations are less stringent than federal regulations on land management practices that may adversely affect populations of listed plants. Existing regulatory mechanisms are inadequate to protect this species. (USFWS, 2008)

**Stressor:** Inadequate management (fire or mechanical disturbance)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Maintenance of viable populations of imperiled plant species depends largely on the determination of the appropriate management regime of populations on managed areas. For subspecies chartacea, inadequate use of fire or the use of mechanical treatments as a surrogate for fire may reduce population sizes or adversely affect demographic performance. For subspecies chartacea, appropriate management means burning Florida rosemary scrub often enough to maintain large gaps within the rosemary shrub matrix. In the absence of data on the biology and autecology of subspecies minima, its management eeds cannot be determined. The preferred habitat of subspecies minima on the margins of karst ponds suggests that disturbances other than fire may be required for the maintenance of its populations. (USFWS, 2008)

***Recovery***

**Reclassification Criteria:**
Not relevant. (USFWS, 1999)

Recovery Priority Number: 8

**Delisting Criteria:**
I. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations and sites needed to ensure 95% probability of persistence for 100 years. (USFWS, 1999)

2. When these sites, within the historic range of P. chartacea, are adequately protected from habitat loss, degradation, and fragmentation. (USFWS, 1999)

3. When these sites are managed to maintain the rosemary phase of xeric oak scrub communities to support P. chartacea. (USFWS, 1999)

4. When monitoring programs demonstrate that these sites support the appropriate numbers of self-sustaining populations, and those populations are stable throughout the historic range of the species. (USFWS, 1999)

**Recovery Actions:**

- Determine current distribution of P. chartacea. Some portions of P. chartacea's range have been well surveyed yet a total distribution has not been ascertained for this species. A thorough survey is needed to determine the distribution for this species. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, has been isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Conduct research on life history characteristics of P. chartacea. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species, more specific biological information is needed. (USFWS, 1999)
- Monitor populations of P. chartacea. Develop monitoring protocol to assess population trends for P. chartacea. Develop a quantitative description of the population structure of P. chartacea. (USFWS, 1999)
- Provide public information about P. chartacea. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. Care is needed, though, to avoid revealing specific locality information about P. chartacea. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of P. chartacea and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)
- Habitat-level Recovery Actions: Prevent degradation of existing habitat. Manage and enhance habitat. Restore areas to suitable habitat. Conduct habitat-level research projects. Monitor habitat/ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)
- A taxonomic study evaluating the distinctiveness of the two subspecies should be conducted. (USFWS, 2008)
- A study of the reproductive biology of the two subspecies should be conducted to determine the degree of floral dimorphism/sexual gender and sex ratios of populations. (USFWS, 2008)
- For P. c. chartacea, surveys should be conducted to assess the status of the FNAI EORs that occur on unprotected sites and to evaluate the feasibility of protecting additional populations. Following Turner et al. (2006), extant parcels in the Green Swamp and at Fisheating Creek, Avon Park Lakes, Lake Davenport and other sites should be targeted for acquisition. Acquisition of these sites would also extend protection to other federally listed plants. (USFWS, 2008)
- For P. c. minima,It is unclear how well existing FNAI EORs reflect the historic range of the taxon. It is possible that additional surveys of areas with appropriate habitat are needed. The possibility of acquiring additional populations also needs to be assessed. (USFWS, 2008)
- Habitat maintenance requirements of P. c. minima need to be investigated. (USFWS, 2008)
- For both subspecies, the minimal monitoring should be establishment of level 2 monitoring (sensu Menges and Gordon 1996) to track changes in population sizes over time. Level 2 monitoring requires that surveys be repeated at defined intervals (e.g., annually, biannually, every five years, or both before and after imposition of management treatments) and that

surveys take place within well-defined areas (e.g., within plots small enough to be searched thoroughly within a minimum of effort). ABS' s Population Dynamics of Endemic Plants (PDEP) project was designed as a model of level 2 monitoring that can be deployed by other agencies. Presence/absence data (level 1 monitoring sensu Menges and Gordon 1996) or the periodic accumulation of GPS points cannot provide meaningful data for determining population trends or for quantifying responses to prescribed fire or other management activities.(USFWS, 2008)

- To conduct population viability analyses, detailed demographic data (level 3 monitoring sensu Menges and. Gordon 1996) should be collected from multiple populations of both subspecies. These data need to be collected across the full geographic range of both subspecies, from populations in contrasting habitats (e.g., rosemary scrub vs. roadsides for subspecies chartacea, pond margins vs. sandhill for subspecies minima), and in sites with differing management histories. (USFWS, 2008)
- Studies should be conducted to understand the genetic diversity of both subspecies; this may aid in the identification of new acquisition needs. (USFWS, 2008)
- Where monitoring is being conducted, data should be collected on fire management activities to aid in the interpretation of trends and identifying the most favorable treatments. (USFWS, 2008)
- A revised recovery plan should be developed to address the existence of two subspecies with separate geographic ranges and their potential need for differing management practices to ensure recovery. (USFWS, 2008)
- Habitat for P. c. chartacea needs to be maintained through burning Florida rosemary scrub within the modal fire return interval defined by other gap specialists and by Florida rosemary (Menges 2007). (USFWS, 2008)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • Conduct surveys for P. c. var. minima in areas with appropriate habitat and unknown occupancy to assess the possibility of additional populations and help identify the historic range of the variety. This could include a habitat suitability analysis to help guide surveys. • Purchase for conservation or work with private landowners to develop conservation agreements for unprotected lands with P. c. var. minima. • Manage Florida rosemary scrub habitat for P. c. chartacea through prescribed fire within a fire return interval of 10 to 30 years (Menges et al. 2019). • Investigate the habitat maintenance requirements of P. c. minima, particularly with respect to hydrology. • Institute or continue Level 1 monitoring for P. c. var. chartacea between August and November when plants are most abundant. • Conduct more intensive monitoring of P. c. var. minima. However, its short lifespan and the very dynamic nature of pond hydrology at most sites will make this monitoring challenging. Understanding seed dormancy in P. c. var. minima will be key to understanding its limits with respect to hydrological variation. • Conduct population viability analyses, including detailed demographic data (level 3 monitoring sensu Menges and Gordon 1996) collected from multiple populations of both subspecies. Collect data across the full geographic range of both varieties, from populations in contrasting habitats (e.g., rosemary scrub vs. roadsides for subspecies P. c. var. chartacea, pond margins vs. sandhill for subspecies P. c. var. minima), and in sites with differing management histories. Relate demographic research on P. c. var. chartacea to fire management parameters, including fire frequency, time-since-fire, fire intensity, and fire patchiness. Couple such data for P. c. var. minima with current and historical data on pond hydrology. • Conduct studies to understand the genetic diversity of both varieties; this may aid in the identification of new acquisition needs. • Conduct a study of the reproductive biology of the two varieties to determine the degree of floral dimorphism/sexual gender and sex ratios of populations. (USFWS, 2021)

# SPECIES ACCOUNT: *Paronychia congesta* (Bushy whitlow-wort)

***Species Taxonomic and Listing Information***

**Listing Status:** Proposed Endangered

**Physical Description**

Bushy whitlow-wort is a perennial herbaceous plant of the Carnation Family (Caryophyllaceae). Correll (1966) described Paronychia congesta as a new species, based on specimens collected about 1.6 kilometers (km) (1.0 miles (mi)) south of Thompsonville in northwest Jim Hogg County, Texas. (Thompsonville is now a dispersed rural community (Garza 2020); the former town site is uninhabited). Individuals have multiple stems, from 6 to 24 centimeters (cm) (2.4 to 9.4 inches (in)) tall, radiating from a perennial caudex (woody rootstock) (see cover photograph and Figure 1.b). The narrow, stemless, sharply-pointed leaves are arranged in opposing pairs, often appressed to the stems; leaves and bracts are crowded and overlapping at the bases of stems and primary branches. Each leaf is 4 to 7 millimeters (mm) (0.2 to 0.3 in) long and 0.5 mm (0.02 in) wide; stipules are long, thin, silvery, membranaceous, hairless, and about as long as the leaves. The stems, leaves, and sepals are covered with dense, short, spreading hairs. Dense clusters of 7 to 28 tiny flowers are arranged in blueish-green cymes at the tips of stems (Figure 1.a). Bisexual flowers are subtended by bracts, lack petals, and have 5 petal-like calyx lobes that are lemon-yellow on the inner side and fade from green to reddish-brown on the outer side. Calyx lobes are 2.5 to 3.1 mm (0.10 to 0.12 in) long and are longer than bracts; each lobe has a hooded tip from which emerges a stiff, short awn 0.5 to 0.7 mm (0.02 to 0.3 in) long. Each flower has 2 to 5 stamens and a single pistil with two styles united nearly to the stigmas. Fertilized flowers can produce a bladder-like fruit, called a utricle, with a single ovoid seed 0.8 to 0.9 mm (0.03 to 0.04 in) long (USFWS, 2023).

**Taxonomy**

There are about 110 species of Paronychia, of which 26 occur in North America (Hartman et al. 2005a, p. 30). Turner (1983a) reviewed the taxonomic status of the Texas species of Paronychia. He observed that P. congesta was most similar to P. jamesii, a more common species that is widely distributed from west Texas and Arizona to Nebraska and Wyoming; he concluded that they are distinct taxa, based on the geographic separation of their ranges (p. 10) and the more congested inflorescences, gradually tapered calyx lobes, and non-divergent awns of the former species (p. 18). Another very rare endemic Paronychia, P. maccartii, occurs in Webb County just 16 km (10 miles) west of the P. congesta type location. However, these species are not closely related and are easily distinguished in the field (see Table 1); furthermore, P. maccartii inhabits loose, sandy soils, while P. congesta is found on calcareous rock outcrops (Turner 1983b, p. 3). A phylogenetic study based on a relatively small sample of 21 taxa within the tribe Paronychieae indicated that the genus Paronychia, as currently circumscribed, may be polyphyletic (Oxelman et al. 2002, p. 231). Nevertheless, P. congesta continues to be recognized as a unique, valid species (USFWS, 2023).

**Current Range**

The two documented populations of bushy whitlow-wort occupy nearly barren, exposed, sloping outcrops of calcareous rock and/or indurated caliche along the boundary of the Goliad and Catahoula geological formations, known locally as the Bordas Escarpment. The species is likely to be a geo-endemic that is uniquely adapted to the soil or geological features that occur there.

Some observers describe the unique substrates of occupied sites as calcareous tuff, which occurs in discrete sites along the Goliad/Catahoula boundary. We developed a potential habitat model based on the distribution of the geological, soil, and slope features of occupied sites to predict where else the species may occur. This model indicates that a range of thousands to tens of thousands of hectares of potential habitat exist in south Texas; the largest clusters of potential habitat are in Webb, Jim Hogg, Zapata, and Starr counties. Based on available botanical surveys, we estimate that less than 1 percent of this potential habitat has been surveyed by botanists qualified to identify the species (USFWS, 2023).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

2 (USFWS, 2023)

**Population Narrative:**

The Texas Parks and Wildlife Department (TPWD) Natural Diversity Database (TXNDD) maintains geographic and population data of plant and animal species of conservation concern in Texas. This data is contributed and used by many entities involved in conservation, including TPWD and other state agencies, federal agencies, academic researchers, environmental consultants, non-profit conservation organizations, and private individuals. Data for each species is organized by standard geographical units for populations and habitats called “Element Occurrences” (EOs), which are defined as “areas of land and/or water in which a species or natural community is, or was, present” (NatureServe 2002, p. 1). EOs are displayed as points, lines, and polygons buffered by their estimated geographic precision. The reported populations occur or occurred within, but not necessarily throughout, the buffered EO points, lines, and polygons (see Figure 3). The recommended minimum separation distances between EOs is 1 km (0.6 mi) for gaps of unsuitable habitat or unoccupied suitable habitat. Damude and Poole (1990) and Strong and Williamson (2015) refer to EO 1 as the “five-acre site”, and EO 2 as the “15-acre site”. These EOs, as mapped by TXNDD, occupy 3.1 hectares (ha) (7.7 acres (ac)) and 18.0 ha (44.4 ac), respectively; however, EO 2 is bisected by highway FM 649, which converted about 1.6 ha (4.0 ac) of habitat to pavement and graded right-of-way. Therefore, the total area of these EOs is about 19.5 ha (48.1 ac). The two EOs are separated by 2.05 km (1.27 mi). (USFWS, 2023)

***Threats and Stressors***

**Stressor:** Land use changes
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** We are not aware of any current land use changes within the two known occupied habitats of bushy whitlow-wort since they were first discovered in 1963 and 1987; however, see the discussion of potential wind energy development below. These privately owned properties have been used for livestock grazing for many years. We have no information on the species' palatability to cattle. However, due to its small stature, it offers very little nutritional reward to cattle, particularly when larger palatable plants are relatively abundant. Cattle are not attracted to the barren rock outcrops where the species occurs, so the impact of trampling should be negligible. In any case, the species has persisted in its current locations despite decades of grazing. We conclude that cattle grazing is not a significant threat to the species' survival. The very shallow Zapata and Cuevitas-Randado association soils of occupied populations are underlaid by indurated caliche along steep slopes; since they are not suitable for row crops or other agricultural uses, we do not anticipate habitat losses due to a change in agricultural use. One of the two EOs was bisected by highway FM 649 in 1954; we estimate that the highway construction and ROW destroyed about 1.63 ha (4.03 ac) of habitat. We are not aware of planned highway construction that would affect the occupied habitats. Due to the low population density in rural Jim Hogg County and the distance to population centers, currently there are no projected habitat losses to urban and residential development.

**Stressor:** Few known populations
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Only two EOs of bushy whitlow-wort have been documented, with a combined area of 19.5 ha (48.1 ac). The populations are separated by only 2.1 km (1.3 mi). A single event, such as prolonged drought, or a single development project could easily destroy a large portion of the species' known remaining resources. The close proximity of the two EOs increases this vulnerability. We conclude that the small number of bushy whitlow-wort populations (lack of redundancy) is a current, severe threat to the species. Demographic consequences of small population sizes Small, isolated populations are more vulnerable to catastrophic losses caused by random fluctuations in recruitment (demographic stochasticity) or variations in rainfall or other environmental factors (environmental stochasticity) (USFWS 2016, p. 20). In addition to population size, it is likely that population density also influences population viability, since reproduction requires genetically compatible individuals to be clustered within the forage ranges of the species' pollinators. Surveyors have reported a population size of up to about 2,000 individuals, on single occasions, for each of the two known EOs of bushy whitlow-wort. Compared to the estimated MVP of 1,500 individuals, this might suggest that these populations are relatively resilient. However, on other occasions, surveyors found as few as 4 and 100 individuals at the two EOs. We do not know if these lower numbers represent actual population fluctuations, or if the surveyors were unable to detect live, dormant individuals. Due to the infrequency of censuses, we cannot assess current population sizes or trends. We conclude that the demographic consequences of small population sizes present a potential threat of unknown immediacy, severity, and extent (USFWS, 2023).

**Stressor:** Climate Change
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** The Fifth Assessment Report of the Intergovernmental Panel on Climate Change (IPCC) (IPCC 2013, p. 23) projects the following changes by the end of the 21st century, relative to the 1986 to 2005 averages: • It is virtually certain that most land areas will experience warmer and/or fewer cold days and nights; • it is virtually certain that most land areas will experience warmer and/or more frequent hot days and nights; • it is very likely that the frequency and/or duration of warm spells and heat waves will increase in most land areas; • it is very likely that the frequency, intensity, and/or amount of heavy precipitation events will increase in mid-latitude land masses; and • it is likely that the intensity and/or duration of droughts will increase on a regional to global scale. Similarly, the U.S. Global Climate Research Program (USGCRP) Fourth National Climate Assessment (USGCRP 2017) reports that average annual temperatures from 1986—2016 have increased in the Southern Great Plains (including the range of bushy whitlow-wort) by 0.42° C (0.76° F), compared to the 1901—1960 baseline (USGCRP 2017, Chapter 6, Table 6.1). Average annual temperatures in the Southern Great Plains are projected to increase by 2.65° to 4.69° C (4.78° to 8.44° F), under moderate and high emission scenarios, respectively, by the late 21st century (USGCRP 2017 Chapter 6, Table 6.4). By the end of the 21st century, under the highest emissions scenario, precipitation in Jim Hogg and surrounding counties is projected to decrease from 10 to 20 percent during the winter and spring; summer and fall precipitation changes in this region are projected to be smaller than natural variations (USGCRP 2017 Chapter 7, pp. 15–16 and Figure 7.5). However, the frequency of heavy precipitation events in the Southern Great Plains has increased from 1901 to 2016 and 1948 to 2016 (USGCRP 2017 Chapter 7 pp. 5–9 and Figures 7.2–7.4) and is projected to continue to increase under moderate and high emission scenarios.

***Recovery***

***Conservation Measures and Best Management Practices:***

•

***Additional Threshold Information:***

•

•

**References**

USFWS. 2023. Species status assessment of bushy whitlow-wort (Paronychia congesta Correll). October 2023. (Version 1.0). U.S. Fish and Wildlife Service Southwest Region, Albuquerque, New Mexico. vi + 45 pp. + 2 appendices.

# SPECIES ACCOUNT: *Parvisedum leiocarpum* (Lake County stonecrop)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A low annual herb, generally only 1-3.5 cm tall, with fleshy leaves that fall off the stem by flowering time. Flowers (April-May) are small and yellow. (NatureServe, 2015)

**Taxonomy**

USFWS tracks as Parvisedum leiocarpum (9/93). (NatureServe, 2015)

**Historical Range**

See current range/distribution.

**Current Range**

Known from only a small number of populations within a 10-square-mile area. This species occurs on more or less level sites in shallow depressions that retain water seasonally. Known microhabitats include Northern Basalt Flow and Northern Volcanic Ashflow vernal pools (Sawyer and Keeler-Wolf 1995), low areas in meadows and gravelly flats, and hollows in exposed rocks. A few plants were found on a man-made berm within a flat area that supported a large population. Substrates on which S. leiocarpa occur frequently are of volcanic origin and often are gravelly (Patterson 1986). The species occurs at elevations of 518 to 793 meters (1,700 to 2,600 feet). (USFWS, 2009)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Habitat Type**

Adult: Terrestrial, palustrine (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Vernal pools and margins (NatureServe, 2015)

**Environmental Specificity**

Adult: Very narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Inhabits margins of vernal pools and depressions in bedrock which act as shallow vernal pools and volcanic substrates (NatureServe, 2015).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Decreasing (NatureServe, 2015)

**Population Narrative:**

At least 50% of the known populations have been destroyed in the last 60 years. Decline of 50-70% (NatureServe, 2015). Low resiliency, representation and redundancy are based on the low number of known populations and individuals.

***Threats and Stressors***

**Stressor:** Altered hydrology (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Altered hydrology is listed as a threat to this species (USFWS, 2009).

**Stressor:** Road maintenance/widening (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Road maintenance/widening is listed as a threat to this species (USFWS, 2009).

**Stressor:** Agricultural land conversion (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Agricultural land conversion is listed as a threat to this species (USFWS, 2009).

**Stressor:** Off-highway vehicle use (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Off-highway vehicle use is listed as a threat to this species (USFWS, 2009).

**Stressor:** Trampling by cattle (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Trampling by cattle is listed as a threat to this species (USFWS, 2009).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The final rule finds inadequacies with the Federal Clean Water Act, the California Environmental Quality Act, and the California Endangered Species Act in addressing threats to

this species (USFWS, 2009).

**Stressor:** Likelihood of Stochastic Extinction (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Extinction
**Narrative:** The combination of restricted range, few populations, and highly specific and vulnerable habitat makes this species vulnerable to destruction of all, or a significant part, of any population from random events such as floods or droughts (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Climate change is listed as a possible threat to this species (USFWS, 2009).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 2C

**Delisting Criteria:**
Habitat protection: Accomplish habitat protection that promotes vernal pool ecosystem function sufficient to contribute to population viability of the covered species. Suitable vernal pool habitat within each prioritized core area for the species is protected. Species localities distributed across the species geographic range and genetic range are protected. Protection of the extreme edges of the population protects the genetic differences that occur there. Reintroduction and introductions must be carried out and meet success criteria. Additional localities that are detected (and determined essential for recovery goals) are permanently protected. Habitat protection results in protection of hydrology essential to vernal pool ecosystem function, and monitoring indicates that hydrology that contributes to population viability has been maintained through atleast one multi-year period that includes above average, average, and below average local rainfall as defined above, a multi-year drought, and a minimum of 5 years of post-drought monitoring (USFWS, 2009).

Adaptive habitat management and monitoring. Habitat management and monitoring plans that facilitate maintenance of vernal pool ecosystem function and population viability have been developed and implemented for all habitat protected, as previously discussed in sections 1A-E. Mechanisms are in place to provide for management in perpetuity and long-term monitoring of 1A-E, as previously discussed (funding, personnel, etc.). Monitoring indicates that ecosystem function has been maintained in the areas protected under 1A-D for at least one multi-year period that includes above average, average and below average local rainfall, a multi-year drought, and a minimum of 5 years post drought monitoring. Seed banking actions have been completed for species that would require it as insurance against risk of stochastic extirpations or that will require reintroductions or introductions to contribute to meeting recovery criteria (USFWS, 2009).

Status surveys: Status surveys, 5-year status reviews, and population monitoring show populations within each vernal pool region where the species occur are viable (e.g., evidence of reproduction and recruitment) and have been maintained (stable or increasing) for at least one multi-year period that includes above average, average, and below average rainfall, a multi-year drought and a minimum of 5 years of post drought monitoring. Status surveys, status reviews, and habitat monitoring show that threats identified during and since the listing process have been ameliorated or eliminated. Site-specific threats identified through standardized site assessments and habitat management planning must be ameliorated or eliminated (USFWS, 2009).

Research: Research actions necessary for the recovery and conservation of the covered species have been identified. Research actions on species biology and ecology, habitat management and restoration, and methods to eliminate or ameliorate threats have been completed and incorporated into habitat protection, habitat management and monitoring, and species monitoring plans, and refinement of recovery criteria and actions. Research on genetic structure has been completed and results incorporated into habitat protection plans to ensure that within and among population genetic variation is fully representative by populations protected in the Habitat Protection section of this document as previously described in sections 1A-E. Research necessary to determine appropriate parameters to measure population viability for each species have been completed (USFWS, 2009).

Participation and outreach: Recovery Implementation Team is established and functioning to oversee rangewide recovery efforts. Vernal pool regional working groups are established and functioning to oversee regional recovery efforts. Participation plans for each vernal pool region have been completed and implemented. Vernal pool regional working groups have developed and implemented outreach and incentive programs that develop partnerships contributing to achieving recovery criteria 1-4 (USFWS, 2009).

**Recovery Actions:**

- Protect habitat. Currently none of the known localities of the species are protected. Preservation of Zone 1 core area should be pursued to preserve known localities (USFWS, 2009).
- Control erosion (USFWS, 2009).
- Conduct research at as many of the extant localities as possible (USFWS, 2009).
- Collect seeds for future introduction and/or reintroductions into suitable habitat (USFWS, 2009).
- Formally change the name in the Code of Federal Regulations from Parvisedum leiocarpum to Sedella leiocarpa (USFWS, 2009).
- Correct the downlisting criteria, if necessary, to also apply to the Dry Lake core area (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations that will aid in the recovery and conservation of the Lake County stonecrop. Some of these recommendations have already been discussed in the Recovery Plan (Service 2005, pp. III-5–III93) and the 2009 status review (Service 2009, pp. 18–19) and remain valid. 1. Protect habitat. Currently, none of the known localities of this species are protected.

Preservation of suitable habitat within the Boggs Lake-Clear Lake and Dry Lake Core Areas should be pursued to preserve known localities. 2. Control erosion. Erosion control measures at Manning Flat should be implemented because soil loss is making the habitat unsuitable. 3. Conduct research at as many of the extant localities as possible to implement research recommendations outlined in the 2005 Recovery Plan. The following research should be prioritized: a. Develop a standardized monitoring method to monitor species status and population trends at all known locations. This will improve our understanding of potential threats to the species and will aid in the development of methods to ameliorate these threats. b. Conduct research on the genetic structure of the species to determine if it is affected by breeding system limitations such as low reproductive rate, inbreeding depression, or loss of genetic diversity. 4. Collect seeds for future introduction and/or reintroduction into suitable habitat. 5. Formally change the name in the Code of Federal Regulations from Parvisedum leiocarpum to Sedella leiocarpa. 6. The Recovery Plan describes both down- and de-listing criteria as preliminary that will need periodic reassessment because data was lacking at the time the Recovery Plan was developed. Therefore, reassess both down- and de-listing criteria for the Lake County stonecrop and develop stepdown success parameters, if appropriate, that reflect the species' life history and narrow range to help us better understand the status of the species (USFWS, 2024).

# SPECIES ACCOUNT: *Pedicularis furbishiae* (Furbish lousewort)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Northeast Region (R5) (USFWS, 2015). Reclassified to Threatened June 9, 2023.

**Physical Description**

A perennial herb in the Scrophulariaceae (snapdragon family) that produces 1 or more flowering stems, up to 1 m tall, from a basal rosette of leaves. Leaves are deeply divided and have toothed edges. Yellow, 2-lipped flowers bloom in a spike at the top of the flowering stalk from mid-July to late-August. (NatureServe, 2015)

**Taxonomy**

The genus Pedicularis contains over 600 species, most of which are common in tundra, alpine, and subalpine floras in Asia, Europe and North America (Robart et al. 2015, p. 229). The center of Pedicularis species diversity is in the northern Himalayas, China, and Siberia. The Furbish's lousewort has the most restricted distribution of any species of the genus Pedicularis (Gawler 1983, p. 28). The Furbish's lousewort (Pedicularis furbishiae Sereno Watson 1882) is a member of the broomrape family, Orobanchanceae (formerly from the snapdragon family Scrophulariaceae)(Olmstead et al. 2001). The taxonomic identity of the Furbish's lousewort as a distinct species is unquestioned, but its taxonomic position within the genus Pedicularis is not certain (Macior pers. comm. in Stirrett 1980, p. 21) and has been a topic of considerable conjecture and discussion (Gawler 1983, pp. 28-29, Robart et al. 2015, p. 253). Dr. Peter Nelson at the University of Maine at Fort Kent and Rick Ree at the Field Museum in Chicago are continuing genetic research to identify the "sister species" and document the unique phylogeny of the Furbish lousewort. Dr. Nelson has collected samples at numerous subpopulations in Maine and New Brunswick to evaluate the genetic structure and variation within the Furbish's lousewort metapopulation. Similar to the electrophoretic genetic results published by Waller et al. (1987, entire), preliminary results indicate low genetic variability in the Furbish's lousewort population (P. Nelson email November 11, 2017). Additional results will be available in 2018. (USFWS, 2018)

**Historical Range**

See current range/distribution.

**Current Range**

Endemic to the Saint John River Valley of northern Maine and adjacent New Brunswick. The entire range of Pedicularis furbishiae covers 225 km of the St. John River, extending from a point 1.5 miles upriver of the confluence with the Big Black River in Aroostook County, Maine to the town of Andover, New Brunswick in Canada. (NatureServe, 2015)

**Critical Habitat Designated**

Yes;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (outcrossing) and asexual (USFWS, 1991)

**Dependency on Other Individuals or Species**

Adult: Bombus vagans, a common bumblebee which also forages on other co-flowering species such as red clover, is the exclusive pollinator of Pedicularis furbishiae (Macior 1978a). (USFWS, 1991)

**Breeding Season**

Adult: July to August (USFWS, 1991)

**Reproduction Narrative**

Adult: Pedicularis furbishiae is a herbaceous perennial which takes several years to reach sexual maturity. Reproduction is solely by seed. Louseworts flower from mid-July to mid- August, with seeds dispersing in early September. Recent experiments (Waller et al. 1988) have shown that selfed and outcrossed flowers are equally successful at setting capsules, contradicting Macior's (1978) conclusion that Pedicularis furbishiae is self-incompatible. The success of capsule maturation varies widely among populations and years. On average an inflorescence will produce 7—17 capsules, each averaging 25 seeds (Menges et al. 1985, 1986; Gawler et al. 1986). (USFWS, 1991)

**Habitat Type**

Adult: Palustrine (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Herbaceous wetland, riparian, scrub-scrub wetland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: High soil moisture; flooding is essential for habitat (USFWS, 1991)

**Geographic or Habitat Restraints or Barriers**

Adult: Ice scouring and succession can limit habitat; low vegetative cover (USFWS, 1991)

**Environmental Specificity**

Adult: Narrow. Specialist or community with key requirements common. (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Moderate (USFWS, 1991)

**Habitat Narrative**

Adult: This species inhabits the riverbanks of the Saint John River, mostly in the steep, highly diverse shrub- or forb-dominated zone between open river cobbles and boreal forest. The habitat is notable for the high frequency and the severity of disturbance by ice scour and vertical river bank slumping. (The Saint John River drains one of the largest watersheds in the northeast, yet it has relatively little headwater storage, making it subject to dramatic seasonal and longer-term fluctuations in water level and to severe ice-jams.) The zone in which Pedicularis furbishiae occurs bears the brunt of regular ice scouring - tree establishment does not occur here and vegetation cover tends to be moderate. Plants grow on glacial lacustrine or till deposits. (NatureServe, 2015) Pedicularis furbishiae is a fugitive species, succeeding in early— to mid—successional vegetation, and relying on disturbance to open up new areas for colonization. The growth rate of a lousewort population depends largely on site characteristics, principally soil moisture and time since disturbance. Excluding effects of succession, populations on saturated soils grow most rapidly, those on moist soils grow moderately fast, and those on dry soils grow slowly or even decline (Gawler 1988). (USFWS, 1991; NatureServe, 2015)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seeds appear to be dispersed by wind and water (Waller et al. 1988).

***Population Information and Trends***

**Population Trends:**

Long-term trends suggest declines of 30 to 50%, whereas short-term trends indicate declines of 10 to 30% (NatureServe, 2015)

**Species Trends:**

Declining (NatureServe, 2015)

**Resiliency:**

Narrow endemic species with only two small populations and limited geographical ranges. Count data from surveys over almost two decades indicate both are declining 9-12% annually. Occupancy of shoals has declined in the Conasauga, and fish in both systems have been extirpated or greatly reduced in abundance in the lower reaches of the historic range. Resiliency = low to very low (USFWS, 2018).

**Representation:**

Two declining populations genetically-isolated by Lake Allatoona. Representation = Low to Moderate (USFWS, 2018).

**Redundancy:**

Only two populations are known historically, and neither appears resilient to stochastic or catastrophic events and/or to current anthropogenic stressors. Redundancy = low (USFWS, 2018).

**Number of Populations:**

20 subpopulations distributed across 140 river-miles (USFWS, 2019)

**Population Size:**

~2397 (USFWS, 2018)

**Adaptability:**

Low (inferred from USFWS, 1991)

**Additional Population-level Information:**

All subpopulations at or near lowest recorded numbers since 1980. Two subpopulations good condition, 2 subpopulations fair/good, 3 subpopulations fair, and 8 subpopulations poor condition. Six upriver subpopulations maintaining resiliency and redundancy. Fourteen downriver populations losing resiliency and redundancy; absent from 6 subpopulations. Largest contiguous habitats upriver; smallest, fragmented, eroded habitats downriver. One upriver subpopulation partially protected. One downriver subpopulation partially protected and one New Brunswick site protected. Habitat degradation (erosion, poor riparian buffer) greatest in downriver habitats. (USFWS, 2018)

**Population Narrative:**

Although Furbish's Lousewort is adapted to this highly dynamic riparian habitat, the species is vulnerable to high degrees of the annual ice scouring and flooding. Little genetic variability has been detected in this species. Populations of Furbish's Lousewort have declined since historic times. Long-term population trends suggest declines of 30 to 50%, whereas short-term trends indicate declines of 10 to 30%. The number of stems fluctuate widely with varying hydrological or environmental changes but in Maine have ranged from over 6000 plants to just over 2000 plants over a 25-year period. In New Brunswick the numbers of plants have ranged from 68 to over 1000 plants. Two element occurrences (one historic & one extant) are known in New Brunswick, whereas it is estimated that about three or four extant EOs occur in Maine. Lousewort populations are notoriously difficult to delineate, because the linearity and dynamism of the habitat dictate that populations are rarely discrete units. (NatureServe, 2015)

***Threats and Stressors***

**Stressor:** Alterations in hydrology (USFWS, 1991)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The cycle of intermittent disturbance by floods is crucial to the survival of the species. Damming free—flowing waters of the St. John would not only inundate some populations, but would affect all populations by preventing the ice scour and floods which now shape riverbank vegetation. New Brunswick Power is still pursuing possible modification of the existing dam at Grand Falls, New Brunswick as well as the creation of an additional hydropower facility near Morrill, New Brunswick. Potential and known populations in Canada and the United States from Madawaska to Hamlin would be eliminated by implementation of these projects. (USFWS, 1991)

**Stressor:** Land use (USFWS, 1991)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Aside from the continuing, albeit muffled, potential for dam construction on the St. John, widespread effects on lousewort populations resulting from changing land uses along the river as well as from increased river flows are the major concern at this time. changes in land use on the banks of the St. John River have occurred through the clearing of vegetation, especially trees, for individual houselots, views, and agricultural fields. The removal of trees to the river’s edge eliminates shade conducive to lousewort growth and reproduction, while the subdivision of the riverbank into residential and commercial building lots increases the difficulty of implementing conservation strategies. These land use practices within the St. John River

watershed appear to affect Furbish lousewort habitat and populations. (USFWS, 1991)

**Stressor:** Increased runoff (USFWS, 1991)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In addition, there is evidence that the spring flows of the St. John River have been increasing since the 1940's (Menges and Gawler 1986), possibly due to excess runoff. Increased runoff (Gawler and Menges 1984), perhaps caused by accelerated timber harvesting within the watershed, may exacerbate the disturbance impacts to lousewort habitat. For instance, deforested areas can reduce the water retention capability of the watershed; increased river flows and resultant bank slumping may then eliminate habitat and populations at an artificially high rate. (USFWS, 1991)

**Stressor:** Habitat alteration (USFWS, 1991)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** More localized activities such as direct habitat alteration and the burial of individual plants by the dumping of refuse and slash continue to be minor threats to particular lousewort populations. Causes of habitat degradation associated with shorefront developing include dumping of refuse, slash, and fill; motorized vehicles, vegetation clearing, ATV use along the river bank, personal boat access, and impermeable surfaces that focus runoff. (USFWS, 1991; USFWS, 2007)

**Stressor:** All-terrain vehicles (USFWS, 1991)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Impacts from all—terrain vehicle traffic and bank use by recreationists may become threats as these activities increase in the area. (USFWS, 1991)

**Stressor:** Residential development (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The conversion of farms for residential development, which alters the riparian forest or riverbank vegetation, is an increasing conservation concern. (USFWS, 2007)

**Stressor:** Invasive species (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Competition for invasive species is a threat to the unique riverbank ecosystem in the lower river segments. Phragmites, Japanese knotweed, non-native grasses, and purple loosestrife have all been documented in lousewort habitat. These invasive plant species are linked to human activities such as riverbank clearing, trails, and mowing, and spread of invasive species is one consequence of shorefront development. (USFWS, 2007)

**Stressor:** Forest management (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Forest management in the watershed could increase siltation and run-off (Menges and Gawler 1986). (USFWS, 2007)

**Stressor:** Climate change (USFWS, 2007; USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change is expected to affect the ice regime of northern rivers, including the St. John, by increasing the frequency of severe ice-scour events and patterns os spring ice breakup (Beltaos 1997, Beltaos and Prowse 2001). Beltaos (1999) did a hydroclimatic analysis for the upper St. John River using long-term climate and flow records and documented that a small rise in winter air temperatures over the past 80 years has already resulted in a substantial increase in the number of mild winter days and the amount of winter rainfall- previous rare occurrences in this region. These two factors have augmented river flows, causing increased breakup of ice cover and flow peaks in late winter and the frequency of spring ice jams and flooding. (USFWS, 2007); The Furbish's lousewort is identified as one of Maine's plant species most vulnerable to climate change (Jacobson et al. 2009, p. 33). The species depends on periodic disturbance of the riverbank from ice scour; not too frequent or too infrequent and not too severe (section 2.4). Climate change is expected to affect the ice regime of northern rivers, including the St. John, by increasing the frequency and severity of severe ice-scour and flood events (Beltaos 1997, entire; Beltaos and Prowse 2001, entire; Beltaos and Prowse 2009, entire). In summary, there is evidence suggesting that climate change is indirectly affecting the ice dynamics of the St. John River and these factors have the potential to increase the severity of the spring breakup and increased severity of flooding (Beltaos 2002, entire).We will evaluate climate change as a stressor further in our assessment of future scenarios. (USFWS, 2018)

**Stressor:** Increased frequency of ice jam events (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The increased frequency of ice jam events is a particular concern. The frequency of flooding events on the St. John River has increased since the 1940s (Menges and Gawler 1986). Lousewort biology suggests that a disturbance interval of less than 6 to 10 years would interfere with maturation and seed production (Menges 1990). (USFWS, 2007)

**Stressor:** Development (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Changes in land use on the banks of the St. John River in downriver areas have occurred through the clearing of vegetation, especially trees, for agriculture, individual house lots, roads, and river views. These land use changes within the St. John River valley may have negatively affected some of Furbish's lousewort subpopulations' habitat through removal or

reduction of the forested riparian buffer and subsequent loss of shade critical to lousewort growth and reproduction. Areas cleared of forest and impermeable surfaces associated with development have led to erosion and subsidence of the unconsolidated glacial till soils, and caused slumping and erosion of Furbish's lousewort habitat. We will evaluate development as a stressor further in our assessment of future scenarios. (USFWS, 2018)

***Recovery***

**Reclassification Criteria:**
In light of the recommendation to reclassify the Furbish's lousewort as threatened, downlisting criteria in the 1991 Recovery Plan (USFWS 1991) are now obsolete. (USFWS, 2019)

**Delisting Criteria:**
Criterion 1. The metapopulation is viable, comprising a 30-year median of 4,400 flowering stems or greater, and distributed as follows: Upriver: a 30-year median of2,800 flowering stems or greater in at least 6 subpopulations with at least 3 good and 3 fair subpopulations; Downriver: a 30-year median of 1,600 flowering stems or greater in at least 9 subpopulations with at least 3 good and 6 fair subpopulations. Once the upriver and downriver criteria are reached, the median number of flowering stems for each respective river section will remain stable or increase over a period of at least 30 years (three generations) without augmentation, reintroduction, or hand pollinating of plants. Additionally, in New Brunswick there is a 30-year median of 1,100 plants distributed among at least 5 subpopulations (Resiliency and Redundancy). (USFWS, 2019)

Criterion 2. There is long-term habitat protection for all subpopulations in Maine that provides for the species' needs throughout its life cycle. Long-term habitat protection mechanisms must assure important species' needs: forest overstory shade conditions (about SO-percent sunlight) by protecting or restoring a forested riparian buffer of 250 feet adjacent to suitable habitat; moist soil conditions and seeps by limiting further shoreline erosion and bank slumping, and restoring suitable habitat where it has been damaged from past events; native vegetation that newly germinated Furbish's lousewort plants can parasitize; site conditions without excessive plant competition, especially from tall shrubs and robust herbs; populations of the half-black bumble bee sufficient to assure pollination and subsequent seed production. (USFWS, 2019)

**Recovery Actions:**
- I. Monitor the Furbish's lousewort population and demographics and periodically assess the status of the bumble bee pollinator to document trends. (USFWS, 2019)
- 2. Improve the health and viability of extant subpopulations and restore extirpated subpopulations throughout the historical range. (USFWS, 2019)
- 3. Achieve long-term habitat protection for each subpopulation. (USFWS, 2019)
- 4. Conduct scientific investigations to improve understanding of stressors, viability, propagation, restoration, and genetic needs. (USFWS, 2019)
- 5. Periodically review progress toward achieving recovery criteria and employ strategic conservation and adaptive management to address threats. (USFWS, 2019)
- Contingency recovery strategies will be implemented if the metapopulation in Maine falls below 1,200 flowering stems OR if there are 4 or fewer upriver subpopulations OR if there are 2 or fewer downriver subpopulations OR if seed production is not sufficient to achieve a

stable or increasing metaoooulation. (USFWS, 2019)

- 6. Establish new subpopulations in unoccupied areas having suitable habitat. (USFWS, 2019)
- 7. Store seeds and establish captive populations. (USFWS, 2019)
- 8. Enhance seed production. (USFWS, 2019)
- 9. Work with Canadian partners to implement strategies that prevent extinction. (USFWS, 2019)
- To be considered for delisting in the near future, the Service needs specific information on: 1) the degree of threat from residential development in river segments 2, 3, and 4; 2) the degree of threat from climate change and severe ice jams and flooding; and 3) population viability in the context of a dynamic environment. (USFWS, 2007)
- New recovery criteria should be developed based on current information on population viability and responses to habitat perturbations, specifically related to improving municipal shoreland zoning, addressing habitat restoration caused by catastrophic ice scour events, and controlling invasive species. (USFWS, 2007)
- Efforts to protect lousewort habitat in the lower river reaches should be emphasized. (USFWS, 2007)

Recommendations for Future Actions: Continue to monitor the subpopulations of the species and document population trends. Maintain current long-term habitat protections for subpopulations in Maine. Work with Maine landowners and municipalities to develop conservation easements or fee title opportunities to protect additional subpopulations. Continue to evaluate the effects of climate change and development. (USFWS, 2019)

# SPECIES ACCOUNT: *Pediocactus despainii* (San Rafael cactus)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 09/16/1987; Mountain-Prairie Region (R6) (USFWS, 2016)

**Physical Description**

A small, spiny succulent. Stems can swell to up to 6 dm in height, but during dry or cold weather the plants may not appear above ground at all; the species is easily overlooked except in the spring, when bronze-tinted, yellow to peach-colored flowers are in bloom (NatureServe, 2015).

**Taxonomy**

The plant genus Pediocactus contains nine species (eFloras 2014). Winkler cactus and San Rafael cactus are very closely related with a blending of morphological characteristics where their ranges meet (Porter et al. 1999) (USFWS, 2015).

**Historical Range**

Endemic to south central Utah (USFWS, 2015).

**Current Range**

San Rafael cactus is found exclusively in Emery County, Utah. Overall, the known San Rafael cactus populations are found from Dripping Spring in the north, to Big Ridge South/Keesle Country to the south (approximately 122 km (78.5 mi) north to south), and from Mussentuchit Mine in the west, near the border of Sevier to the Humbug population in the east (approximately 88 km (48.5 mi) east-west) (USFWS, 2015).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: cross-pollination (USFWS, 2015)

**Lifespan**

Adult: 20+ years (USFWS, 2015)

**Breeding Season**

Adult: March - May (USFWS, 2015)

**Key Resources Needed for Breeding**

Adult: Bee pollinators (USFWS, 2015)

**Reproduction Narrative**

Adult: It is reported to have low fruit/seed output (USFWS 2007; NatureServe, 2015). Some monitored cacti lived at least 20 years after tagging, although the age of the cacti at the time of tagging was unknown (Clark et al. 2015). The species reproduces sexually, is self-incompatible; cross pollination is needed to produce viable seeds (Tepedino 2000). Pollinators visiting San Rafael cactus include many species of bees, from multiple families. Flowering occurs from March to May with fruiting from May to June (Heil 1984) (USFWS, 2015).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Semi-arid grassland, desert pavements in pinyon-juniper woodlands (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 4,760-6,820 ft. elevation (USFWS, 2015)

**Environmental Specificity**

Adult: Moderate (inferred from USFWS, 2015)

**Habitat Narrative**

Adult: Inhabits desert pavements of cobble or pebble in pinyon-juniper woodlands (Flora of North America Editorial Committee 2003). Hills, benches and flats, of open, semi-arid grassland with scattered junipers and pinyon pines. (NatureServe, 2015). San Rafael cactus grows in a wide variety of soils, although it may favor fine textured mildly alkaline soils rich in calcium and derived from limestone substrates of the Carmel Formation and the Sinbad member of the Moenkopi formation. It has also been found on shale barrens of the Brushy Basin member of the Morrison, Carmel, Mancos and Dakota geologic formations and in areas of primarily alluvial and colluvium soils. It is found hill tops, and gentle slopes, and most abundantly on sites with a south exposure at elevations of 1450-2080 m (4760-6820 ft.). San Rafael cactus requires intact habitats relatively free of invasive species. This species also requires the presence of native plants which support their pollinators in order to successfully reproduction (USFWS, 2015).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Members of Pediocactus produce dry, dull-colored fruit which are presumed not to be dispersed by birds or rodents, but rather wind or water. Further, dispersal within populations appears to be staggered throughout the growing season from shortly after seeds are produced in June, to fall (NatureServe, 2015).

***Population Information and Trends***

**Population Trends:**

Not available

**Species Trends:**

10 - 30% decline (NatureServe, 2015)

**Number of Populations:**

29 (USFWS, 2024)

**Population Size:**
21,555 (USFWS, 2024)

**Minimum Viable Population Size:**
Unknown; probably 500 individuals per population (USFWS, 2015)

**Adaptability:**
Low (inferred from NatureServe, 2015)

**Population Narrative:**
Little variation exists within populations. The fragile habitat makes the species vulnerable to disturbances. USFWS 2007). The short term population trend is decreasing (10 - 30%) (Butterworth and Porter 2013) (NatureServe, 2015). There are 20 populations of San Rafael cactus, with a total of approximately 8,200 documented individuals (BLM 2012, 2012a, 2013a; Truman 2014, 2015). Based on the most recent survey data, the estimated area of the known populations is approximately 152,971 ha (378,000 ac) (USFWS 2014). The minimum viable population size for this cacti species is unknown. It is likely that population sizes of at least 500 individuals per population are necessary to avoid extirpation (USFWS, 2015). For San Rafael cactus, we recognize has 29 populations with 21,555 plants, including the Blue Bench population that was previously categorized as Winkler cactus (Wang 2018). We used the same three population size categories as Winkler cactus and consider there to be five large populations, 3 medium populations, and 21 small populations (Service 2024). The total population count is much larger than reported in the 2016 draft recovery plan (8,553 plants) because of an expanded survey effort by the BLM and the addition of the Blue Bench population in Sevier County (Service 2024). As with Winkler cactus, known population counts should be considered conservative numbers erring on the low side of actual plant abundance since seedlings and dormant plants are difficult or impossible to detect. It is also difficult to know in any given year whether a plant is dormant or dead (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Recreation (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The majority of the known San Rafael cactus individuals occur near established unpaved roads and are subject to dust effects. Pressures from recreation, including OHV use and biking are extremely high at the two largest known San Rafael cactus populations. All recorded individuals of San Rafael cactus occur on BLM (85 percent) or SITLA (15 percent) land that is open to OHV use on designated routes only. Two heavily used, unofficial OHV recreational areas are located adjacent to or within occupied habitat areas and are impacting individual plants and their habitat. In addition to OHV use, other forms of recreation, including camping and bike riding, exert pressure on some San Rafael cactus populations, particularly the Wedge and Millsite populations (USFWS, 2015).

**Stressor:** Livestock disturbance (USFWS, 2015)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Trampling by livestock has been recognized as a threat to San Rafael cactus since at least 1981, with impacts to cacti documented regularly since that time (Heil et al. 1981; Spector 2013). Grazing is permitted throughout the known range of San Rafael cactus and evidence of livestock has been recorded in every population, although grazing pressure is not equal at every population or every surveyed site within a population. San Rafael cactus occurs on 19 grazing allotments managed by the BLM Price Field office (USFWS, 2015).

**Stressor:** Ungulate disturbance (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Deer prints have been documented within 15 cm (5.9 in) of San Rafael cactus at several sites and can locally be more abundant than livestock tracks but are not as widespread (Spector 2013). For example, in the Millsite/Clawson population, deer disturbance within 15 cm (5.9 in) was found in places at rates over 20 percent, including one survey site with a rate of 95% (BLM 2012); the survey sites are located near an area called Diversion Hollow (BLM 2012; Truman 2014). Deer winter in the area and spring use is high in some parts of the Millsite/Clawson population area. Impacts and disturbance to plants and habitat from wild horses and burros can be very similar to those of cattle and other livestock grazing. Wild horses and burros occur within a portion of San Rafael cactus range in the BLM Price Field Office planning area (BLM 2008a). (USFWS, 2015).

**Stressor:** Energy and mineral exploration and development (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Approximately 86 percent of the total population San Rafael cactus occurs on BLM land that is open to oil and gas leasing either with no additional constraints or subject to minor constraints, including the entirety of the two largest populations (The Wedge and Millsite/Clawson). Previous energy development activity in the Millsite area has destroyed individual plants and occupied habitat (BLM 2008a; Clark 2011). There is a high level of interest in development throughout the range and the majority of the species' occupied habitat is open to leasing. The negative impacts on cactus habitat from oil, gas, and mining development, are well documented (USFWS, 2015).

**Stressor:** Paleontological exploration (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** San Rafael cactus may be subject to some impacts from paleontological exploration and excavation. Emery County is the location of a number of paleontological sites, including the Cleveland-Lloyd Dinosaur Quarry near Price. Paleontological interest in the area has been increasing with recent finds on BLM land (Truman 2014). Disturbance to plants from paleontological activities can include direct injury or mortality of plants situated at an excavation site, effects from dust due to surface disturbance at excavation sites, and impacts from associated activities such as camping near and hiking into sites by paleontological field crews

(USFWS, 2015).

**Stressor:** Invasive plants (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Non-native invasive species are known throughout the ranges of San Rafael cactus, the most common of which are cheatgrass (Bromus tectorum), halogeton (Halogeton glomeratus), and Russian thistle (Salsola tragus). San Rafael cactus inhabits sparsely vegetated areas that are not prone to fire, but the presence of invasive plants can alter local fire regimes (Stoddart et al. 1951; Harper et al. 1996; Brooks and Pyke 2001; Brooks et al. 2003; Duda et al. 2003). Cacti are not adapted to frequent fires in their habitats and are therefore not expected to persist through more frequent and intense fire cycles. In addition, fires may produce intense heat that can kill seeds, thereby reducing seedbank viability (Brooks and Pyke 2001) (USFWS, 2015).

**Stressor:** Collection (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species is highly desired in cactus collections and gardens and are sought by hobby and commercial cactus collectors (Hochstatter 1990; Heil 1984). The fact that this species is difficult to maintain in garden settings stimulates a continual demand for replacement plants as cultivated garden and greenhouse plants die. Cactus collectors are active in the Colorado Plateau, going from the habitat of one species of Pediocactus to the next to collect a complete set of the genus (Heil 1994; 52 FR 32914, September 16, 1987; 63 FR 44587, August 20, 1998) (USFWS, 2015).

**Stressor:** Predation (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The species is susceptible to infestations and mortality of insect larvae, including the flightless cactus borer beetle (Moneilema semipunctatum). The cactus borer beetle larvae enter the plant by eating tunnels, usually at ground level in the stem of the plant and ultimately ingest most of the plant stems’ succulent cortex. Cactus-borer beetle predation can result in 25 to 30 percent mortality in cacti populations, and episodic die offs of significant portions of this species populations due to cactus borer beetles were observed within the past 25 years (Kass 1990; Neese 1987; USFWS 1995; 52 FR 32914, September 16, 1987; 63 FR 44587, August 20, 1998). San Rafael cactus is also predated by weevils. At the Wedge population, 3 percent were found to be infested with weevils which consume the flower buds thereby preventing reproduction. An additional 5 percent were noted to have damage from an unidentified rodent or insect, and several were observed to be infested with the cactus borer beetle (Robinson 2011) (USFWS, 2015).

**Stressor:** Small population size (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Of the known populations of San Rafael cactus, more than half consist of less than 100 recorded individuals and all but three consist of less than 500 individuals (even if the five populations in the McKay flats allotment were shown to be connected, that population would still consist of less than 500 individuals based on current data). This means a majority of populations of this species are moderately to extremely vulnerable to extirpation from known threats and stochastic events. Very little data on genetic diversity within this species exists, and none at all for many of these populations. The loss of any one population could constitute a major loss of genetic diversity for the species (USFWS, 2015).

**Stressor:** Climate change (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** climate change and its impacts to the region are well documented and projected to continue and increase. There was a documented decline of Winkler cactus during the 1999-2003 drought, and the similarity of San Rafael to Winkler cactus suggests a comparable response. (Clark and Clark 2008). Additionally, rare plants have a negative response to drought (Roth 2003, 2004; Van Buren and Harper 2003, 2004), and drought severity and frequency is set to increase due to climate change (IPCC 2007; Karl et al. 2009) (USFWS, 2015).

***Recovery***

**Reclassification Criteria:**
Not available

Recovery Priority Number: 11

**Delisting Criteria:**
1. Based on analysis and modeling implemented under the recovery actions, trends for San Rafael cactus populations are shown to be stable or improving according to the following measures: a) Species presence is maintained at all known San Rafael cactus populations; and b) Within at least three-quarters of the known populations that represent the majority of the total known individuals (and including the Wedge, Millsite/Clawson, and all of the McKay Flats populations) and represent the range of geographical, morphological, and genetic diversity of San Rafael cactus, plant density within occupied habitat is stable or improving over a 20-year period. These populations would be designated as Recovery Populations and this measurement would be based on a standardized, long term monitoring protocol developed by the Recovery Team and managing agencies; and c) Predictive modeling using data from an additional 10-year period (30 years total), collected in accordance with a standardized monitoring protocol, provides an indication of long-term demographic stability as well as a projected survival probability of at least 95 percent over 100 years for the species (USFWS, 2015).

2. Based on best available data, the available habitat base for each recovery population of the species is of sufficient quality and large enough to allow for natural population dynamics, population expansion where needed, and the continued presence of pollinators, with sufficient connectivity to allow for needed gene flow within and, where possible, among populations (USFWS, 2015).

3. Population and habitat management is implemented for all populations of the species in accordance with management plans developed under Recovery Action 1 (Section 3.4). The management plan will include a course of action that addresses the following needs: habitat protection and management, threats abatement, biological and threats monitoring, and reporting and evaluation (USFWS, 2015).

4. Federal land protection through long-term management agreements or plans is achieved for all known San Rafael cactus populations. Protection considerations from grazing impacts, development, mining, oil and gas, and recreation must be included in the management agreements and the protected areas must meet the size and connectivity parameters determined through research to be adequate to sustain those populations. These may include but are not limited to resource management plans, conservation agreements, recreation management plans, and travel management plans (USFWS, 2015).

5. Management agreements or plans in place and being implemented for all San Rafael cactus populations on all federal lands must include measures to address and curtail illegal collection activities. These plans should include criteria for appropriate law enforcement at correct times and places to prevent illegal collection and sales of plants or any plant parts (USFWS, 2015).

6. Adverse population-level effects from herbivory, disease, or predation, if any, are identified, monitored and abated to the extent that at least three quarters of known San Rafael cactus population trends are stable or increasing, as evidenced by demographic monitoring results from studies that have adhered to monitoring protocols developed under Recovery Action 2.4 (Section 3.4). Programs to control excessive herbivory or predation will be developed to adaptively manage each population per criterion P-3, and must take into consideration the degree which climate change may impact disease or herbivory levels in the future (USFWS, 2015).

7. Land protection covering the habitat of all populations for the species and/or statutory and regulatory protections for plants are such that the protections of the ESA are no longer needed to compensate for regulatory inadequacies (USFWS, 2015).

8. A long-term ex-situ conservation program is ongoing for all extant San Rafael cactus populations. This would include seed collection and storage, germination and viability trials, and development of a protocol for successful reproduction under greenhouse conditions. This would help avert the risk of extinction from stochastic events or environmental catastrophes (USFWS, 2015).

9. In conjunction with recovery criterion P-2 (criterion 2), the available habitat base for each of the populations designated under criterion P-1 (criterion 1) is of sufficient quality and large enough to offset the threat of loss or restriction of the species’ pollinators. Effective measurement criteria will be developed through research under Recovery Action 3 (USFWS, 2015).

**Recovery Actions:**

- Protect and conserve known extant Winkler cactus and San Rafael cactus populations and their habitat (USFWS, 2015).

- Survey for additional populations, and monitor all populations in order to apply conservation measures where and when needed (USFWS, 2015).
- Conduct in depth research into the biology, requirements, threat responses, and life histories of both species in order to develop and implement appropriate management practices for the purposes of achieving recovery (USFWS, 2015).
- Promote communication by encouraging and creating dialog regarding these species between managing agencies, land owners, developers, and the public in order to raise awareness and aid recovery (USFWS, 2015).
- Coordinate and work together with all stakeholders to achieve recovery (USFWS, 2015).
- Survey and repeat inventory efforts were completed throughout the range of the species beginning in 1987. These were a responsibility of the Interagency team from 1998 through 2008, which then transferred to individual managing agencies from 2011-2013. Because of these efforts, there is a better understanding of the status and distribution of the species as well as habitat requirements. Although many more occupied sites and populations are now known than at the time of listing, not all suitable habitat has been surveyed. There is currently no comprehensive, funded plan from any of the managing agencies for continued inventory and monitoring of the species (USFWS, 2015).
- A habitat modelling project for the species has been initiated by the USGS, with funding from USFWS and the support of the BLM and CRNP, which will use existing inventory and site data to help determine potential suitable habitat and delineate the range of San Rafael cactus. The model will identify the most influential environmental factors of presence/absence for the species. This will be useful in locating additional sites and populations, as well as helping determine the need for cactus surveys prior to proposed projects that impact potential habitat (USFWS, 2015).
- Seeds of San Rafael cactus have been collected for conservation purposes, most recently in 2013. Seeds are currently stored and maintained at the National Center for Genetic Resource Preservation in Ft. Collins, CO and at Red Butte Garden in Utah. No plants are currently being propagated (USFWS, 2015).

***Conservation Measures and Best Management Practices:***

- Recommended future actions: We recommend rangewide surveys of known populations for Winkler cactus and San Rafael cactus, and that survey results be used to compile a robust, updated population estimate. Additional research that provides a better understanding of current population demographics, population trends, and the impact of and response to the primary threats is vital to evaluating these species' status in the future and to developing updated and meaningful recovery criteria and actions. The designation and management of protected areas that reduce impacts from identified threats may be necessary to facilitate this species' recovery. Additionally, we recommend updating and finalizing the draft recovery plan and specifically reevaluating the recovery goals and criteria based on new population numbers, habitat requirements, connectivity analysis, and recent and upcoming changes in management and conditions that may result in changes to threat intensity and scope (USFWS, 2019)

# SPECIES ACCOUNT: *Penstemon haydenii* (Blowout penstemon)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 09/01/1987; Mountain-Prairie Region (R6) (USFWS, 2016)

**Physical Description**

The blowout penstemon (Penstemon haydenii), a member of the snapdragon family, is a hairless perennial that grows 1 to 2 feet high. The stems are often decumbent, simple, or branched, and very leafy. The stem leaves are linear to lanceolate, entire, 3 to 5 inches long by 1 to 3 inches wide, sessile and clasping. The inflorescence is a compactly crowded thyrse. A thyrse is composed of (1) a main axis of an inflorescence made up of flowers born on stalks of about equal length along an elongated axis that continues to grow during flowering and open in succession from below and (2) secondary and later axes of the inflorescence that terminate in single flowers. Floral bracts are ovate to lanceolate, nearly equaling the flowers. The corolla is milky blue to pale lavender (rarely pink or white) and 1.5 to 2 inches long. The sterile staminode is glabrous and/or hairy. Fruits are 0.5 to 0.6 inch long capsules, acute, with light brown, disc-shaped seeds having winged margins (Heidel 2005, USFWS 1987).

**Current Range**

Blowout penstemon is a regional endemic of the Nebraska Sandhills, the largest sand dune system in North America, located in north central Nebraska (Stokes and Swinehart 1997, Forman et. al 2001). The Nebraska Sandhills is an area of stabilized sand dunes covering 5 million hectares (approximately 12.4 million acres). In 2008, 32 blowout penstemon subpopulations (10 native and 22 introduced) were known to occur in the Sandhills (Stubbendieck 2008). In Wyoming, 3 populations (in addition to 6 subpopulations) of blowout penstemon are located in the Ferris Dunes of northwestern Carbon County, separated from the Nebraska Sandhills by about 175 miles (282 km). The Ferris Dunes cover an area less than 124,000 hectares (50,000 acres). See Figure 1 Geography below.

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: flowers from mid-May to late June in Nebraska

**Reproduction Narrative**

Adult: The species flowers from mid-May to late June in Nebraska. The flowers have a strong, persistent fragrance that lures several kinds of bees and other pollinators. The fruit (capsule) matures and splits in early to mid-August and the seeds either fall near the base of the plant or are transported primarily by wind to other areas within the blowout or outside of the blowout. All healthy flowering plants are thought to produce seed (USFWS 1992). Most blowout penstemon plants begin to bloom at 2 to 3 years of age (Stubbendieck et al. 1993) and have been successfully cultivated in the greenhouse (Flessner and Stubbendieck 1989, 1992).

Flowering in Wyoming occurs later than in Nebraska (late June to early July), probably in response to drier and cooler climatic conditions (Fertig 2001). Each fruit of the blowout penstemon contains an average of 25-35 seeds with as many as 1500 seeds per plant. The seeds are winged presumably to aid in wind dispersal although, given the high degree of herbivory of this plant, some questions have been raised that animals might also be an important avenue of seed dispersal (Heidel 2005). Seeds are released from late August through September. The seeds, potentially remaining dormant in the sand for 20 years, have a thick outer coat and germination is enhanced after some degree of scarification. Axillary root branching may be an adaptation to survive burial by wind-blown sand rather than a common form of reproduction. By digging around individual blowout penstemon plants, Heidel (2005, 2012) did not find evidence of long-distance underground connectivity between adjacent plants.

**Habitat Type**

Adult: Sand dunes

**Environmental Specificity**

Adult: Very Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Characterized as a "primary" blowout species (Pool 1914) on active sand dunes in Nebraska sandhills prairie (Stubbendieck et al. 1989, Kuchler 1964). The term 'blowout' refers to a naturally occurring depression in the Nebraska Sandhills. These depressions are caused when vegetation at the upper slope of a hill is disturbed, typically by fire or grazing animals. The 'blowout' may take as many as ten years to be come a full scale and active blow out. The process is started when sand is deposited from the windward side of the slope to the leeward side, and this process continues until eventually the roots of the surrounding vegetation are exposed and finally ripped up by the force of the wind. Eventually, a crater is created where there is constant wind action, so succession is continually taking place (Stubbendieck et al. 1989). For a detailed description of blowout ecology, see Stubbendieck et al. (1989). Penstemon haydenii occurs within the blowout usually near the leeward side only after the sand has stabilized, and it declines once vegetation is established.All sites have less than 10% basal ground cover (Heidel 1981). Initial colonization of dunes is by Redfieldia flexuosa. Psoralea lanceolata is locally common where P. haydenii is found (Heidel 1981). Other common associates include: Andropogon hallii, Artemisia campestris, Asclepias arenaria, Astragalus longifolia, Calomovilfa longifolia, Cirsium plattensis, Helianthis spp., Hymenopappus corymbosus, Lathyrus polymorphus, Linum sulcatum, Lithospermum incisum, Lygodesmia rostrata, Oenothera serrulata, Oryzopsis hymenoides, Petalostemum villosum, Rume venosus, Tradescantia occidentalis, and Yucca glauca (Heidel 1981; Lichvar 1982). (NatureServe, 2015). Blowout penstemon was first collected along the North Loup River in the Sandhills area of Nebraska by Ferdinand V. Hayden, probably in 1857 (Sutherland 1988). This specimen was without flowers or fruits and was referred to as sharp leaf penstemon, Penstemon acuminatus. Senero Watson originally named and described the species as Penstemon haydeni, based on a collection made by H. L. Webber near the Dismal River in Thomas County, Nebraska in 1891 (Watson 1891). Later, Francis W. Pennell could not locate the original 1857 Hayden specimen, and he substituted the Webber specimen as the type collection (Pennell 1920). Both the Hayden specimen and type specimen were deposited at the Gray Herbarium at Harvard. A second "i" was later added to the specific epithet "haydeni" to make it etymologically correct (Sutherland 1988). The most recent morphological descriptions report a deep taproot and stems which root adventitiously in shifting sand (Great Plains Flora Association 1991). No other populations of blowout penstemon were known outside of Nebraska until 1996. In 1996, the Bureau of Land Management (Frank Blomquist) discovered a small colony of blowout penstemon south of the Ferris Dunes (Fertig 1999). Plant samples were later collected and verified by Dr. Noel Holmgren of the New York Botanical Gardens for verification in 1999. Field identification was subsequently confirmed by additional specimens sent to Dr. James Stubbendieck of the University of Nebraska and Dr. Holmgren. There has been some reason to question whether the populations in Wyoming and Nebraska should be considered members of the same species. Blowout penstemon individuals in Wyoming have divergent flower traits that had not been previously reported (Heidel 2007). At the time of the Five year review, there were still questions as to whether the morphological differences between the Nebraska and Wyoming populations are due to phenotypic plasticity, genetic differences, or a combination of these factors affecting populations. Further consultation with taxonomic experts is ongoing. All known blowout penstemon sites are well-developed blowouts in dune complexes with active sand and accompanying environmental extremes in wind, temperature, evapotranspiration, and soil moisture stress. Blowout penstemon plants are most frequently in microsites that are, or recently have been, zones of sand accumulation. The plant apparently is successional and is a pioneer species that does not persist when a blowout becomes completely vegetated. The species survives burial in sand by sending off shoots at successively higher nodes. It withstands initial erosion and has a rhizomatous system with extensive lateral roots to survive erosion that may uncover much of its root length (USFWS 1987).

***Dispersal/Migration***

***Population Information and Trends***

**Population Narrative:**

Blowout penstemon is a short-lived perennial plant, which requires actively moving sand in blowouts to thrive. It grows from a tap root, initially producing a single stem that often becomes decumbent. The stem roots readily where nodes are buried in the sand. Buds located at the base of the stem break dormancy in the second spring, often producing multi-stemmed plants. These plants typically flower in the second or third year (Kottas 2009), and individual plants live for six to eight years (Stubbendieck et al. 1997). The lavender (or occasionally blue or white) flowers produce two-sided capsules (ovaries) bearing 14 to 35 discoid brown to black seeds (USFWS 1992; Kottas 2009). Seeds have a thick, hard seed coat and germination in the field is typically very low. The seeds are adapted to dispersal by wind, which often distributes seed downwind across the edge of the blowout into the area of sand accumulation. Wind and animals aid in the seed dispersal (Stubbendieck, pers. comm. 2009). Seed numbers are highly variable among years and sites (Kottas 2009). Individual plants may produce approximately 1,400 to 1,500 seeds (Kottas 2009; USFWS 1992), but seed viability can reduce reproductive potential to an average of approximately 530 viable seeds per plant (Kottas 2008). The number of seeds in the seedbank is typically low, due mainly to predation by small mammals at the time of seed rain (Kottas 2009; Stubbendieck, pers. comm. 2009). Kottas (2009) investigated the effects of floral herbivory by insects and fungal infection on seed production and viability. She reported that treatments of plants with insecticide or fungicide did not significantly affect total seed output, weight or viability (Kottas 2009). Consequently, site specific herbivore, granivore and fungal impacts may be important when seed production is low or when the surrounding vegetation invades blowout penstemon habitat, bringing additional herbivory with it (Kottas

2009). The genus Penstemon is endemic to North America. Of 275 species in the Penstemon genus, only the blowout penstemon and one other species are fragrant (Kottas 2009). The common name of the blowout penstemon comes from the blowouts in the Sandhills of Nebraska. Blowouts are round or conical eroded areas, depressions formed in the sand when prevailing northwesterly winds scoop out the sides of the hills (Pool 1914 in Kottas 2009). These eroded areas form on the sides of dunes when vegetative cover is removed or disturbed and wind action further exposes the slopes (Stubbendieck et al. 1989). Blowout penstemon is a pioneer species in these blowouts, frequently found among blowout grass (Redfieldia flexuosa) which is often the first pioneer in a blowout (Kottas 2009). Neither blowout grass nor blowout penstemon persists after other grasses begin to invade the blowout. The amount of suitable, active blowout habitat has declined markedly since settlement of the Sandhills region in the early 20th century (USFWS 2012). In Wyoming, blowout penstemon is found primarily on the rim and lee slopes of blowouts, or the rim and steep faces of sandy slough slopes. These deposits are found at the base of mountains or ridges, which represent topographic barriers. Shifting sand dunes are prevented from becoming fully stabilized and overgrown because of wind and gravity. The dunes may be 60 to 120 feet high at elevations between 5860-7440 feet (Heidel et.al 2007). The blowout penstemon is found in the early stages of plant community development which can be composed of blowout grass, lemon scurfpea, and thickspike wheatgrass or Indian ricegrass (Heidel 2005). The Wyoming sites differ from Nebraska Sandhills in that the populations occur at higher elevations, the mean annual precipitation is lower, and Wyoming has cooler minimum and maximum summer temperatures.

***Threats and Stressors***

**Stressor:**
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing in 1987, the species was known to exist in only six population centers in four counties of the Nebraska Sandhills. Approximately 7000 plants occurred on less than 10 hectares (25 acres). Improved range management practices and fire suppression which promote blowout healing, were a major cause of the species decline in Nebraska and that remains a major threat today. Given the nature of the different habitats occupied by blowout penstemon plants in Nebraska as compared to those in Wyoming, the degree of threat to populations in these two states may differ. When the blowout penstemon was listed as endangered under the Act, only the Nebraska populations were known, therefore only the threats to populations in Nebraska were considered. In Nebraska, despite conservation strategies to increase numbers of plants and populations within the range, two main areas hamper recovery: 1) Continual loss of blowout habitat due to the stabilization of sand dunes (and lack of habitat management) 2) Lack of plans to guide habitat management and a way to include written agreements to implement such habitat management into conservation plans that could protect the species where it primarily occurs (private land). Additional threats identified and discussed in the 5 year review include: drought, overgrazing, ORV use, construction practices, pesticides, and natural outbreaks of the pyralid moth. In Wyoming, populations have basically been preserved in more or less a natural state because of the isolated, currently inaccessible nature of the sites. However, there is potential moderate to significant impacts from future energy development to the species. As with other forms of development, wind energy facilities, have the potential to affect the natural dynamics of a dune system by directly or

indirectly causing changes to the erosion and deposition of sand. Blowout penstemon may be negatively impacted by changes in the dynamics of the dune system (i.e. loss of key habitat attributes, competition, etc.).

**Stressor:** Mining
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Sand mining is currently not occurring in close proximity to any blowout penstemon sites, however more accessible sand deposits in the Rawlins Resource Area are currently being mined. The sand mined from those locations is used for golf courses and road maintenance. Presently, it seems impractical for sand mining to occur near blowout penstemon sites because of their relative isolation, rugged terrain, and limited access. Blowout penstemon populations in Wyoming are located over 7 miles from primary unpaved county roads to the north and east, and at least 15 miles from primary county roads to the west. Future changes in the accessibility to these habitats could affect the profitability and establishment of sand mines near blowout penstemon sites. Other valuable minerals located near the Seminoe Mountains to the south of the blowout penstemon populations include iron, copper, and gold (from Hausel 1989, in Heidel 2012).

**Stressor:** • Water Development
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Near blowout penstemon habitat at Bradley Peak, Bear Mountain, and Junk Hill in Wyoming are excavated ponds, as well as natural ponds and springs used for sources of livestock water. It would not be feasible to develop these water sources as irrigation water for cultivated fields or central pivot irrigation as is done in Nebraska. Nevertheless, further livestock water sources developed near blowout penstemon populations could potentially concentrate livestock near these habitats causing increased grazing or trampling effects to the plants (Heidel 2005).

**Stressor:** • Oil and Gas Leasing
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Oil and gas leasing occurs at the west end of the Bear – Mountain – Junk Hill – Ferris blowout penstemon population. This development includes pumps, pumping stations, and a pipeline corridor (Heidel 2012).

**Stressor:** • Off-Highway Vehicle Use
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Off-highway vehicle (OHV) use has been observed within a blowout penstemon population in Nebraska, and many plants were damaged (USFWS 1992). Hill climbing and associated OHV recreation activities may ensure continued disturbance and erosion of the sand hills and dunes, but driving over and crushing plants may cause severe negative impacts to the plants (USFWS 1992).

**Stressor:** • Changes in Habitat Quality
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Historically, fires removed the protective cover from the soil in the Nebraska Sandhills region resulting in shifting sand dunes and blowouts. Control of prairie fires followed the area's settlement period. Virtual elimination of fire from the Sandhills ecosystem allowed the vegetation to advance into the majority of the eroded areas and to stabilize the sand, resulting in a decline in suitable habitat for the species (USFWS 1992). However, continual summer grazing by cattle during the first half of this century caused enough disturbances to maintain many blowouts. More recently however, the increased use of planned grazing systems (rotational grazing) during the past 30 years has greatly reduced disturbance and has been responsible for decreasing wind erosion. Other advanced range management practices in Nebraska, including techniques to more evenly distribute livestock on rangeland, have been responsible for decreasing blowout penstemon habitat, as well as the numbers of populations, and the numbers of individual plants (USFWS 1992).

**Stressor:** • Livestock Trampling and Grazing
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Sheep previously grazed the allotments occupied by blowout penstemon in Wyoming. Cattle and horses are now commonly found on the rangelands of both Nebraska and Wyoming. The influence of horses on blowout penstemon has not been documented. Cattle, however, have frequently been observed near blowout penstemon plants. Many individual plants have been inspected during and after cattle grazing periods. When adequate other forage is available, cattle occasionally graze a portion of a plant but seldom does this cause major damage to the plant (BLM 2012, USFWS 1992). Under these normal range conditions, the use of high livestock stocking rates as a disturbance factor to maintain habitat for the blowout penstemon is considered beneficial (USFWS 1992). Advanced grazing methods, referred to as "holistic resource management", may further decrease blowout penstemon habitat by reducing active erosion. Techniques which more evenly distribute livestock on rangelands such as "planned grazing systems" or "management intensive grazing" may have been responsible for decreasing blowout penstemon habitat, numbers of populations, and numbers of individual plants in Nebraska (USFWS 1992). The occasional removal of a terminal portion of a shoot of a blowout penstemon plant by a grazing herbivore may be desirable because growth of other shoots is stimulated (USFWS 1992). However, during years of low precipitation, livestock forage may be limited and blowout penstemon plants may be more intensively grazed during those times. In Nebraska during times of limited forage availability, cattle have been observed to closely graze nearly every available blowout penstemon plant. One occurrence of close grazing by cattle may or may not impact blowout penstemon plants, but repeated years of close grazing will severely weaken plants and may be the direct cause of plant death (USFWS 1992) or reduce population numbers. o Cattle trampling of established plants has not been observed to be a problem. Infrequently, cattle will break a blowout penstemon shoot, which poses no threat to the plant (USFWS 1992). Livestock trampling damage is typically not significant to blowout penstemon plants because the plants are sparsely distributed in shifting substrate areas which cattle do not normally frequent. For Wyoming populations, it has been hypothesized that wildlife are the

primary source of blowout penstemon herbivory. Wild ungulates, such as deer and elk, may have a larger grazing impact on blowout penstemon plants than cattle in Wyoming. Fertig (2001) observed stem damage from deer and elk trampling on 10 percent of the population at Bear Mountain and on 60 to 80 percent of the stems at Bradley Peak. The tracks of elk and pronghorn antelope were repeatedly observed near browsed plants during survey efforts in Wyoming (Heidel 2005).

**Stressor:** • Over-collection
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The blowout penstemon is attractive and has been cultivated. Horticultural collecting is a potential threat for this species (USFWS 1987). To date, private and commercial collectors have had little impact on blowout penstemon. It would be an attractive and desirable landscape plant, but most of the plants are in locations which are too remote or inaccessible (USFWS 1992).

**Stressor:** • Pesticide Use
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The direct impact of herbicides on blowout penstemon is not known, although it is highly probable that broadleaf weed killers would negatively influence this plant (USFWS 1992). Herbicide use is thought to be minimally used on sand hills/dune regions due to the sparse cover of its habitat. It is doubtful that ranchers would even inadvertently apply herbicide to blowout penstemon, because most ranchers try to encourage the growth of all vegetation in blowouts. Use of insecticides could negatively impact the pollinators of blowout penstemon. Numerous types of insects may be responsible for pollination; however, it is unlikely that localized insecticide use would completely eliminate insect pollination (Heidel 2005).

**Stressor:** • Encroachment by other plants
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Non-native species in or adjoining blowout penstemon habitat in Wyoming included cheatgrass (Bromus tectorum) and Russian knapweed (Centaurea repens). Russian knapweed (C. repens) recently got introduced at the base of the Bradley Peak population site and could become a major infestation, possibly entering blowout penstemon habitat. Cheatgrass (B. tectorum) is one of the more common non-native species in the Pathfinder population and has been observed to be spreading in some of the Bear Mountain subpopulations (Heidel 2012). Weeds pose may pose threats as competitors. Any herbicides used to control the noxious weeds may pose a threat to the blowout penstemon.

**Stressor:** • Construction Activities
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The area between the Ferris and Seminoe Mountains is an area of particularly high mean turbulent kinetic energy, responsible for sand deposition on steep slip-face slopes

hundreds of feet high. In recent years, there have been wind energy permit applications that encompass blowout penstemon populations. Any alteration of on-site or upwind flow patterns, or related access development and construction, could affect the species and its habitat. There are four separate dead-end roads to occupied habitat, and if there were any road developments between them, it would provide more access to occupied habitat.

**Stressor:** • Vulnerability Based on Small Population Size
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing in 1987, the species was known to exist in only six population centers in four counties of the Nebraska Sandhills. Approximately 7000 plants occurred on less than 10 hectares (25 acres). The small populations known at the time were thought to make the species vulnerable to localized environmental changes. In addition, the species occupies a successional niche in the development and eventual revegetation of blowout habitats. As the vegetation in these areas increases, blowout penstemon undergoes local extirpation. At the time of listing, the species was not only rare, but did not appear vigorous at the known localities in Nebraska, possibly because these blowouts had reached a stage of revegetation that exceeded the optimum habitat conditions for the species. Furthermore, the number of new blowouts was decreasing (USFWS 1987). In Wyoming, 3 populations (in addition to 6 subpopulations). The isolation of these populations from each other, as well as the isolation of these populations from other blowout penstemon populations in Nebraska, makes the Wyoming populations similarly vulnerable to the threat of random stochastic events (such as prolonged drought, introduction of invasive species) that could lead to reduction or loss of these populations.

**Stressor:** • Natural Threats
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Damaging insects and periods of drought may be the greatest natural threats to the survival of this species (USFWS 1992). Prior to the drought of the 1930's, the blowout penstemon was listed as one of the most common species in sand blowouts. Following the drought of the 1930's which severely influenced the vegetation of the Great Plains, the blowout penstemon was thought extinct until it was rediscovered in Nebraska in 1959. At one time, it was thought that a localized drought of a few years duration could eliminate most of the remaining blowout penstemon plants in Nebraska (USFWS 1992). o Destructive insects may be a primary cause of decline in populations (USFWS 1992). Several insects (and arachnids) have been observed feeding on blowout penstemon plants, including spider mites, grasshoppers, and an insect larvae which burrows into the inflorescence. Populations of invertebrates are generally at low levels. However, large numbers of penstemon aphids (Aphis pentstemonicola) were observed on two individual transplanted blowout penstemon plants growing in a blowout near Alliance, Nebraska. Foliage of the infested plants appeared wilted, grayish-green, and stunted. Several seed predators have also been found active on blowout penstemon. The most serious insect threat appears to be the pyralid moth. Larvae of a pyralid moth did extensive damage to one population of blowout penstemon in 1990. Adult female pyralid moths deposit their eggs on blowout penstemon plants. After hatching, the larvae burrow into the stems and are active until reaching the pupal stage. These larvae damage or kill blowout penstemon plants by boring into the crown area below the plant's buds.

**Stressor:** • Disease
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Blowout penstemon plants are also quite susceptible to fungal root rots. Plants infected with these fungi wilt, rot, and usually die (USFWS 1992).

**Stressor:** • Encroachment by Other Plants
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The blowout penstemon is well adapted to the rigorous environment of an actively eroding blowout, but it does not grow in close association with most other plants. It generally grows as widely spaced plants in nearly bare sand indicating that these plants may not have the ability to compete with each other or plants of other species for moisture. Its associate in Nebraska, blowout grass, does not use large amounts of soil moisture. Blowout penstemon populations in Nebraska have been known to rapidly decline as members of new species, primarily sand bluestem (Adropogon hallii) and prairie sandreed (Calamovilfa longifolia) increase and begin to use significant amounts of soil moisture following stabilization of the sand habitat (USFWS 1992).

***Recovery***

**Reclassification Criteria:**
Blowout penstemon will be considered eligible for reclassification to threatened when: 1. a minimum of 10,000 individuals in at least 5 population groups is established; and 2. the 5 populations have the minimum level of protection that will ensure their continued existence.

Recovery Priority Number: 11C

**Delisting Criteria:**
Blowout penstemon will be considered eligible for delisting when: 1. a minimum of 15,000 individuals in at least 10 population groups, each with a minimum population of 300 plants is established; and 2. the 10 populations are demonstrated to be at minimum viable population level s.

**Recovery Actions:**
- 1. Protect and monitor naturally occurring, reintroduced, and introduced populations. 2. Inventory suitable habitat for naturally occurring populations and determine potential reintroduction sites. 3. Conduct research to determine life history, minimum viable population parameters, and management criteria. 4. Establish new populations of blowout penstemon. 5. Establish and implement management plans for each population.

***Conservation Measures and Best Management Practices:***
- RECOMMENDATIONS FOR FUTURE ACTIONS: x Consider revising the recovery plan so that it considers and incorporates the latest information on the species. x Clarify uncertainties regarding the species’ taxonomy in Wyoming (USFWS, 2022).

# SPECIES ACCOUNT: *Pentachaeta lyonii* (Lyon's pentachaeta)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 02/28/1997; Pacific Southwest (R8)

**Physical Description**

An annual herb, 6-48 cm tall, with yellow flower heads that bloom in the spring. Each plant may produce 30 or more flower heads. (NatureServe, 2015)

**Taxonomy**

Pentachaeta lyonii was described by Asa Gray (1886) based on a plant collected by William S. Lyon "near Palos Verdes Mountain" in Los Angeles County. David D. Keck (1958) combined Pentachaeta with Chaetopappa and published the combination Chaetopappa lyonii. This was recognized by Munz and Keck (1959) and Munz (1974). Van Horn (1973) conducted a taxonomic status of Pentachaeta and Chaetopappa and demonstrated that the two genera were distinct in morphological, anatomical features, and breeding systems. This treatment has been followed in current floristic treatments (Raven et a/. 1986, Lane 1993) (USFWS, 1999).

**Historical Range**

See current range/distribution.

**Current Range**

Endemic to coastal southern California, where currently known only from eastern Ventura and western Los Angeles Counties, in the Santa Monica Mountains and western Simi Hills (CNDDB 2008 cited in USFWS 2008). Formerly also known from the Palos Verdes Peninsula and Santa Catalina Island, but now believed historical/extirpated from these areas (CNDDB 2008 cited in USFWS 2008). (NatureServe, 2015)

**Critical Habitat Designated**

Yes; 12/14/2006.

**Legal Description**

On November 14, 2006, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective 12/14/2006) for Pentachaeta lyonii (Lyon's pentachaeta) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes seven critical habitat units (CHUs), in California (71 FR 66374-66423).

**Critical Habitat Designation**

The critical habitat designation for Pentachaeta lyonii includes six CHUs in Ventura, and Los Angeles Counties, California. Approximately 3,396 ac (1,372 ha) fall within the boundaries of the critical habitat designation. The critical habitat units are located in Ventura and Los Angeles Counties, California. Brief descriptions are presented below; detailed coordinates and maps are included in the Final Rule. (USFWS, 2006).

Unit 1: Simi Valley Unit: This unit is located east of Moorpark and west of Simi Valley in Ventura County and consists of 390 ac (157 ha) of private land. This unit is divided into four subunits (subunits 1a, 1b, 1c, and 1d) and mapped from occurrences known at the time of listing. The subunits are in the same geographic area; they are all within 2.5 mi (4000 m) of each other.

Unit 2: Montclef Ridge Unit: This unit is located along Montclef Ridge, northwest of Newbury Park in Ventura County. It consists of 892 ac (361 ha) of local agency land (Lynmere, Wildwood Park, and Mount Clef Ridge) owned and managed by COSCA and Conejo Recreation and Parks District, and 265 ac (107 ha) of private land. This unit is divided into three subunits (subunits 2a, 2b, and 2c) that occur within the same geographic area, and are mapped from occurrences known at the time of listing and one occurrence identified after listing.

Unit 3: Thousand Oaks Unit: This unit is located in Thousand Oaks near Lake Sherwood in Ventura and Los Angeles Counties. It consists of 671 ac (272 ha) of local agency land (COSCA, Las Virgenes Metropolitan Water District, and Mountain Resources Conservation Authority) and 588 ac (238 ha) of private land. This unit is divided into three subunits (Subunits 3a, 3b, 3c (eastern portion), and 3d (western portion)) mapped from occurrences known at the time of listing and two occurrence identified after listing.

Unit 4. Triunfo Canyon Unit: This unit is located in unincorporated Los Angeles County. It consists of 197 ac (80 ha) of local agency land owned by Mountains Recreation and Conservation Authority, and 9 ac (3 ha) of private land. It is mapped from an occurrence known at the time of listing and includes multiple patches within a large, single population complex.

Unit 5: Mullholland Drive Unit: This unit is located in the Santa Monica Mountains in Los Angeles County and consists of 105 ac (42 ha) of Federal land (Santa Monica Mountains National Recreation Area) and 187 ac (75 ha) of private land. It is divided into 4 subunits (Subunites 5a, 5b, 5c, and 5d) mapped from occurrences known at the time of listing and occurrences identified after listing.

Unit 7: Malibu Lake Unit: This unit is located in the Santa Monica Mountains in Los Angeles County and consists of 58 ac (23 ha) of State land (Malibu Creek State Park) and 34 ac (14 ha) of private land. It is mapped from an occurrence known at the time of listing.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Pentachaeta lyonii critical habitat consists of three components (71 FR 66374-66423):

(i) Clay soils of volcanic origin;

(ii) Exposed soils that exhibit a microbiotic crust, which may inhibit invasion by other plant competitors; and

(iii) A mosaic of bare ground (>10%) patches in an area with less than 60 percent cover.

**Special Management Considerations or Protections**

Threats that may require special management are specified in the Final Rule for each Critical Habitat Unit: Unit 1. The invasion of annual grasses and nonnative plants that could crowd out P. lyonii, and grazing, edge effects from urban development, road maintenance, and vehicle traffic, which could result in removal or trampling of plants. Unit 2: The invasion by annual grasses and nonnative plants that could crowd out P. lyonii; recreation, including equestrian activities, foot traffic, and off-road vehicles, which could result in trampling of plants; illegal dumping, urban development, which could result in removal of plants; and edge effects from existing urban development. Unit 3: Edge effects from urban development, removal of plants for urban development or fuel management, invasion by annual grasses and nonnative plants that could crowd out Pentachaeta lyonii, and equestrian and foot traffic that could result in trampling of plants. Unit 4: The invasion by annual grasses and nonnative plants, which could crowd out P. lyonii, fuel management, which could result in removal of plants, and foot traffic, which could result in trampling of plants. Unit 5: The potential for development, which could result in removal of plants; fuel management, which could also result in removal of plants; and invasion by annual grasses and nonnative plants, which could crowd out Pentachaeta lyonii. Unit 7: Recreation activities such as foot traffic, which may result in trampling of plants. (USFWS, 2006)

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollinated (NatureServe, 2015, USFWS, 2006))

**Reproduction Narrative**

Adult: Pentachaeta lyonii is not capable of self-pollination, but is dependent upon insect pollinators for successful seed production (Fotheringham and Keeley 1998). Pollinators of P. lyonii include digger bees, andrenid bees, and megachilid bees (Braken and Verhoeven 1998; Fotheringham and Keeley 1998). These pollinators are polylectic, meaning that they utilize several plant species within an area (Braken and Verhoeven 1998), and a variety of plants are necessary to sustain pollinator populations. Known pollinators of P. lyonii have the ability to pollinate individual plants up to 1,968 ft (600 m) from the pollen source, suggesting that genetic connectivity occurs between populations that are up to 1,968 ft (600 m) apart from each other. (USFWS, 2006). Seeds have deciduous pappus bristles, suggesting that this species is not often dispersed long distances by wind. However, seeds of species in this family (Asteraceae) are also sometimes transported by small seed-eating mammals and birds (Martin et al.1961 cited in USFWS 2008). This species' seeds likely persist in the soil for several years during extended dry spells (Fotheringham and Keeley 1998 cited in USFWS 2008).; Predominantly outcrossing; SEXUAL; BIOTIC; Hymenoptera (NatureServe, 2015).

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species occurs in saddles between hills, on the tops of small knolls, or in flat areas at the base of slopes. Plants are found within small open, grassy sites that intergrade with fire-adapted chaparral and coastal sage scrub; also on road and trail edges. Occupied sites tend to feature a mosaic of bare ground patches in an area with low overall vegetative cover. Tends to occur on exposed, rocky clay soils of volcanic origin that exhibit a microbiotic crust. Does not compete well with dense annual grasses or shrubs; can apparently persist without disturbance if site conditions (e.g. exposed soils with a microbiotic crust) inhibit the growth of plant competitors, otherwise periodic disturbance to remove these competitors may be necessary. 85 - 628 m (USFWS 2008). (NatureServe, 2015)

***Dispersal/Migration***

**Dispersal**

Adult: Wind/mammals (USFWS, 2006)

**Dispersal/Migration Narrative**

Adult: produce on the order of 1,000 seeds. The seeds likely persist in the soil for several years during extended dry spells (Fotheringham and Keeley 1998). Plant seeds are frequently dispersed by a variety of vectors, some which result in short-distance dispersal, and others which result in long-distance dispersal (Cain et al. 2000; Nathan and MullerLandau 2000). The presence of deciduous pappus bristles on the seeds indicates that the plant does not exhibit long-distance dispersal by wind, as do many other species in this family, reducing the likelihood of colonization of new areas and contributing to the limited distribution by this method (Keeley and Baer-Keeley 1992; Fotheringham and Keeley 1998). Longdistance dispersal, however, is likely achieved by transport of seeds by wildlife. Seeds from species within the Asteraceae family are known to be transported by small seed-eating mammals, including ground squirrels (Citellus sp.) pocket mice (Perognathus sp.), kangaroo rats (Dipodomys sp.), and birds, including quail (Lophortyx sp.) (Martin et al. 1961). Small mammals facilitate seed dispersal through consumption and elimination of undigested seed and through seed caching (Cain et al. 2000; Sieg 1987) (USFWS, 2006).

***Population Information and Trends***

**Population Trends:**

Decreasing (NatureServe, 2015)

**Population Growth Rate:**

This species has apparently been extirpated from the southern portion of its historical range (Palos Verdes Peninsula and Santa Catalina Island) (CNDDB 2008 cited in USFWS 2008). Decline of 50-90%  (NatureServe, 2015)

**Number of Populations:**

41 presumed extant (USFWS, 2024)

**Population Size:**

65,000-70,000 plants (NatureServe, 2015)

**Population Narrative:**

This species has apparently been extirpated from the southern portion of its historical range (Palos Verdes Peninsula and Santa Catalina Island) (CNDDB 2008 cited in USFWS 2008). Decline of 50-90% Approximately 65,000-70,000 plants as of most recent counts, but this species is an annual known to exhibit large year-to-year fluctuations in population size, so this particular number may not have much meaning in terms of the species' long-term persistence. Annual fluctuations are believed to occur in response to external factors such as rainfall and competition with other plant species (USFWS 2008). Approximately 32 occurrences are believed extant, with an additional 5 considered historical. At least 3 occurrences have been extirpated. (NatureServe, 2015). Given the likely persistence of soil seed banks, there were 48 total occurrences in 2019 (Service 2019, p. 3) with 7 either extirpated or possibly extirpated (because of likely development), and 41 presumed extant. Of the presumed extant occurrences, 4 were considered declining, 10 were considered increasing or stable, and 27 were in unknown condition. Currently, because of the three additional Santa Catalina Island occurrences, there are 51 occurrences (Figure 1), with 44 presumed extant occurrences. Of these 44 presumed extant occurrences, four appear to be declining, 12 appear to be increasing or stable, and 28 are in unknown condition (Appendix A).

***Threats and Stressors***

**Stressor:** Urban Development (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** At the time of listing, the primary threats to Pentachaeta lyonii were destruction of habitat from urban development. An indirect threat to the species was the influence of urban development on the surrounding environment, which facilitated the introduction of competitive weeds and altered ecosystem processes. Effects of urban development include habitat fragmentation, which reduces gene flow between sites, reduces insect pollinators, and displaces P. lyonii as a result of changes to the structure and composition of pocket grassland communities (i.e., introduction of competitive weeds, changes in local hydrology, and increased gopher activity) (Alberts et al. 1993, Conservation Biology Institute 2000). Gophers are known to till the soil and can facilitate the growth of annual grasses. One site was extirpated in 1993 after the site was burned and non-native annual grasses and gophers became prevalent at the site (CNDDB 2008) (USFWS, 2008).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Inadequacy of existing regulatory mechanisms was identified in the final listing document as a threat in determining endangered status for Pentachaeta lyonii. The species is listed as endangered under the California Endangered Species Act (CESA). Although CESA prohibits "take" of State-listed plants, this appears to be inadequate to protect against the taking of plants via habitat modification or land use change by landowners. After the California Department of Fish and Game (CDFG) notifies a landowner that a State-listed plant grows on his or her property, CDFG Code only requires that the landowner notify CDFG "at least 10 days in advance of changing the land use to allow salvage of such plant" (chapter 10 sec. 1913). Determinations by local lead agencies under the California Environmental Quality Act (CEQA) have resulted in negative impacts to P. lyonii (62 FR 4172). Because the intent of CEQA is to disclose project impacts, proposed mitigation measures do not necessarily guarantee protection and conservation of sustainable populations of P. lyonii (USFWS, 2008).

**Stressor:** Fire (USFWS, 2008)
**Exposure:**
**Response:**

**Consequence:** Loss of habitat
**Narrative:** Despite efforts to suppress fires in coastal southern California, the present fire frequency of every 15 years or less, is substantially higher than it was historically, which is thought to be every 50 to 100 years (Keeley 2006). Over a period of 60 years, most of the Santa Monica Mountains burned an average of three to five times, with an average interval of every 12.4 to 20.7 years (Radtke et al. 1982). This current fire frequency may have negatively impacted Pentachaeta lyonii by displacing chaparral and coastal sage scrub communities with annual invasive grasses that displace P. lyonii. In addition, fire prevention and suppression activities such as spraying fire retardant and discing the soil around urban development remains a threat because it facilitates the growth of annual grasses (USFWS, 2008).

**Stressor:** Human recreation (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat/loss of individuals
**Narrative:** Some light recreation is thought to be compatible and even beneficial to the species. Trails create a zone of compacted soils, and may reduce competition from annual grasses and allow Pentachaeta lyonii to grow. One of the largest populations, with a population of 100,000 plants reported, occurs alongside a popular trail (CNDDB 2008). However, higher intensity uses such as equestrian or vehicle use is a threat to the species. A portion of the population on NPS land was severely reduced after an increase in equestrian use (CNDDB 2008). The remaining portions of the population have been fenced and have shown some signs of recovery (NPS unpublished data 2007) (USFWS, 2008).

**Stressor:** Stochastic extinction (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:** Extinction
**Narrative:** Ten of the 30 known occurrences have greater than 10,000 plants; the remaining populations are small, with several reported at less than 1,000 plants (CNNDB 2008; Appendix A). The small populations are vulnerable to extirpation by demographic, environmental, and genetic stochasticity, and natural catastrophes (Shaffer 1981). Demographic stochasticity is random variability in survival or reproduction among individuals within a population (Shaffer 1981), and could play a role in the extirpation of small populations of Pentachaeta lyonii. Environmental stochasticity refers to annual variation in birth and death rates in response to weather, disease, competition, predation, or other factors external to the population (Shaffer 1981). This could play a role in extirpations of small populations because the species exhibits large annual fluctuations in population size, probably in response to external factors such as rainfall and competition with other plant species. Genetic stochasticity results from changes in gene frequencies due to founder effect, random fixation, or inbreeding (Shaffer 1981). The low levels of genetic variation among and within populations (Arias et al. no date) could impair the species' ability to adapt to changes in the environment or contribute to inbreeding depression (i.e., loss of reproductive fitness or vigor). Natural catastrophes such as fire, landslide, or prolonged drought could result in extirpation of populations (Shaffer 1981). The entire range of P. lyonii occurs within a distance of 24 km (15 mi); therefore, all populations would be expected to experience similar rainfall patterns or could be affected by a single fire (USFWS, 2008).

**Stressor:** Climate change (USFWS, 2008)

**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Hayhoe et al. 2004, Cayan et al. 2005, Intergovernmental Panel on Climate Change (IPCC) 2007). Recently, the potential impacts of climate change on the flora of California were discussed by Loarie et al. 2008). Based on modeling, they predicted that species' distributions will shift in response to climate change, specifically that the species will "move" or disperse to higher elevations and northward, depending on the ability of each species to do so. Species diversity will also shift in response to these changes with a general trend of diversity increases shifting towards the coast and northwards with these areas becoming de facto future refugia. The Santa Monica Mountains is expected to increase in diversity becoming one of these potential future refugia (Loarie et al. 2008). These increases in species diversity in the refugia, due to climate change, have the potential to result "…in new species mixes, with consequent novel patterns of competition and other biotic interactions…" to the species present (Loarie et al. 2008) with unknown consequences to the species present. We recognize that climate change is an important issue with potential effects to listed species and their habitats. While we lack adequate information to make specific and accurate predictions regarding how climate change, in combination with other factors such as small population size, will affect Pentachaeta lyonii, small ranged species, such as Pentachaeta lyonii, are more vulnerable to extinction due to these changing conditions (Pimm and Raven 2000, Loarie et al. 2008) (USFWS, 2008).

***Recovery***

**Reclassification Criteria:**
1. When 10 populations of 10,000 or more plants, from the 30 current sites (see Table 2 of the Recovery Plan), are fully protected and self-sustaining (as demonstrated through monitoring) (USFWS, 1999)

2. When the populations from Reclassification Critieron 1 are managed to control threats such as alien plants (USFWS, 1999)

3. When the populations from Reclassification Criterion 1 are self-sustaining over a minimum of 15 years (or longer, if data suggest large population fluctuations). (USFWS, 1999)

Recovery Priority Number: 11C

**Delisting Criteria:**
1. When 20 populations of 10,000 or more plants, from the 30 current sites (see Table 2 of the Recovery Plan), are fully protected and self-sustaining (as demonstrated through monitoring) (USFWS, 1999)

2. When the populations from Delisting Critieron 1 are managed to control threats such as alien plants (USFWS, 1999)

3. When the populations from Delisting Criterion 1 are self-sustaining over a minimum of 15 years (or longer, if data suggest large population fluctuations). (USFWS, 1999)

**Recovery Actions:**

- Protect and secure populations and habitat on unprotected lands. Habitat for the listed plants must be protected and secured in perpetuity, from identified threats of loss. Methods for securing lands include permanent conservation easements established through land use decisions, in-fee purchase, gifts of easement, or fee interest by property owner (USFWS, 1999).
- Manage and monitor protected areas. The process of evaluating past and current management and making adjustments as needed is termed “adaptive management.” Public and private conservation lands should be adaptively managed to maximize their potential to support listed species and their habitats. (USFWS, 1999)
- Survey historic locations and other potential habitat where species may occur, Surveys of the potential albeit limited, habitat within the species range should be done. Several California Natural Diversity Database occurrence records for the listed species are represented only by observations. Information on population status, threats, and abundance is also needed for these sites. Information gathered from the additional details will be used to provide lead agencies to determine protective land use designation for the listed plant species . Data gathered will assist in determining the range of site characteristics, population vigor, and species viability to help establish minimum population standards for rare plant reserves, and consequently, for recovery. (USFWS, 1999)
- Conduct biological and ecological research to define life history strategies and population dynamics to guide recovery/conservation efforts. A better understanding of the population dynamics and identification of ecological factors that may be affecting those dynamics are needed to develop appropriate management plans to recover the plant species. (USFWS, 1999).
- Develop outreach plans to conserve the species. Outreach is an important component of implementing this recovery plan. This plan should be developed to enhance the public’s understanding of issues related to conservation and recovery of the listed species. Participation from both public and private entities should be encouraged for the establishment of conservation plans for the listed species. (USFWS, 1999)
- Recommendations for Future Actions from 2019 5-Year Review: • Increase monitoring of within and among mainland occurrences for better understanding of population trends. • Monitor the Santa Catalina Island occurrence for better understanding of population numbers, trends, and geographic extents. • Collect additional seed for banking from both mainland and Santa Catalina Island occurrences. • Augment existing occurrences when possible. • Search for additional suitable outplanting locations on protected lands and establish new occurrences. (USFWS, 2019)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Explore private land acquisition to conserve Lyon’s pentachaeta occurrences and habitat. Work with private, local, state, and federal partners to identify and leverage funding. 2. Monitor mainland occurrences, especially larger occurrences, for better understanding of population trends. 3. Manage the habitat for the species on Santa Catalina Island to provide protected suitable habitat. This should include removal or effective exclusion of deer and bison, and appropriate landscape recovery efforts. 4. Monitor the Santa Catalina Island occurrences for better understanding of occurrence sizes, trends, and geographic extents. 5. Collect additional seed and increase the number of occurrences represented in conservation seed banks, especially for Santa Catalina Island. 6. When possible, augment existing occurrences with seed derived from within those occurrences. 7. Search for additional suitable mainland outplanting locations on protected lands and establish new occurrences. (USFWS, 2024)

# SPECIES ACCOUNT: *Phacelia argentea* (Sand dune phacelia)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened

**Physical Description**

Sand dune phacelia is an herbaceous flowering perennial with many branching stems arising from a flattened mat. The 1-2 inch (2.5 - 5 centimeter) long, deeply veined leaves are covered with long silvery hairs, and are either entire or with two basal lobes. White flowers include five stamens with rounded heads and are generally present from May through August. Fruits are produced from June through August, with seeds dropping onto the adjacent sand at maturity (USFWS, 2021).

**Taxonomy**

Sand dune phacelia was first described and determined to be a distinct species in 1916 (Nelson and MacBride 1916, p. 34). The plant described (i.e., the type specimen) was collected in 1884 from what was described as a sandy seashore at Chetco, in Curry County, Oregon. Its accepted taxonomy (ITIS 2020) is as follows: Kingdom: Plantae Phylum: Anthophyta Class: Magnoliopsida Superorder: Asteranae Order: Boraginales Family: Boraginaceae (formerly Hydrophyllaceae). Genus: Phacelia Species: argentea

**Current Range**

California, Oregon.  Sand dune phacelia is documented to occur from about 5 miles (8 kilometers) north of Bandon, Oregon, south to Crescent City, California (Figure 1: Distribution map of Phacelia argentea). Whether the species was ever present or abundant elsewhere is unknown. In 1933, sand dune phacelia was reportedly collected from one location in Clatsop County, on Oregon's northern coast (ODA 2020, no pagination), and in 1991, a specimen was reported from Mendocino County, California (Calflora 2020, no pagination). The Mendocino, California location has not been confirmed by the Service and the location that it was reported from does not appear to be suitable habitat (L. Goldsmith 2020, pers. comm.). Other than these two occurrences, sand dune phacelia populations have been reported only from Coos and Curry Counties in Oregon, and Del Norte County in California (USFWS, 2021).

**Critical Habitat Designated**

Yes; 9/21/2023.

**Legal Description**

We, the U.S. Fish and Wildlife Service (Service), list the sand dune phacelia (Phacelia argentea), a plant species from coastal southern Oregon and northern California, as a threatened species with a rule issued under section 4(d) of the Endangered Species Act of 1973, as amended (Act). We also designate critical habitat for the species under the Act. In total, approximately 180.8 acres (73.2 hectares) within 13 units in Coos and Curry Counties in Oregon, and Del Norte County in California, fall within the boundaries of the critical habitat designation. This rule extends the protections of the Act to this species and its designated critical habitat.

**Critical Habitat Designation**

Critical habitat units are depicted for Coos and Curry Counties, Oregon, and Del Norte County, California

**Primary Constituent Elements/Physical or Biological Features**

Within these areas, the physical or biological features essential to the conservation of the sand dune phacelia consist of the following components:

(i) Sandy coastal dune habitat above the high tide line that provides a high light environment, room for growth, and adequate moisture.

(ii) A sufficiently abundant pollinator community (which may include leafcutter bees and bumble bees) for pollination and reproduction.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features which are essential to the conservation of the species and which may require special management considerations or protection. In the case of the sand dune phacelia, these essential features include sandy dune habitat with high light exposure and adequate moisture and unvegetated space, as well as a sufficiently large and diverse pollinator community, and a minimum of 25 reproductively mature sand dune phacelia plants within dispersal distance of one another to sustain a population. These features essential to sand dune phacelia conservation may require special management considerations or protection to reduce the threat of invasive species encroachment, and to withstand climate change effects such as drought and sea level rise. In addition, localized stressors related to recreational activity, such as off-road vehicle use and pedestrian or equestrian trampling, may also need to be mitigated by special management practices to maintain the sandy open dune habitat that sand dune phacelia populations require. Management activities that could ameliorate these threats include, but are not limited to: (1) Habitat restoration activities in sand dune habitat that include the removal of invasive species such as nonnative European beachgrass and gorse, or native successional species such as shore pine; (2) efforts to restore a diverse and abundant pollinator community, such as through restricting land management practices that harm pollinator species, or through support of a diverse native nectar plant community; (3) access restrictions and enforcement for off-road vehicle use in areas occupied by the sand dune phacelia; and (4) recreational restrictions to prevent damage to sandy coastal dune habitat and the pollinator communities that support the species by pedestrians or equestrians. These management activities will protect the physical or biological features essential for the conservation of the sand dune phacelia by providing native sandy dune habitat that allows for sand dune phacelia population growth and expansion, supporting the pollinator community that enables sand dune phacelia reproduction, protecting sand dune phacelia populations from trampling and crushing, and maintaining an adequate number of sand dune phacelia individuals necessary to sustain viable populations.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Cross-pollination

**Lifespan**

Adult: Unknown

**Breeding Season**

Adult: bloom in late April and May, with flowers persisting through August (USFWS, 2021).

**Reproduction Narrative**

Adult: Reproductively mature plants begin to bloom in late April and May, with flowers persisting through August (Meinke 1982, p. 282) (Figure 3). Sand dune phacelia appears to be largely incapable of significant self-pollination (Meinke 2016, p. 3), relying upon pollination by leafcutter bees (Anthidium palliventre), bumblebees (Bombus spp.), and honeybees (Apis melifera; Rittenhouse 1995, p. 8). Ants (Formica spp.) and beetles (unidentified spp.) were also reported by Rittenhouse as potentially pollinating sand dune phacelia as they travel from plant to plant. Meinke (2016, p. 3) found that sand dune phacelia plants can produce large crops of fertile seeds, and that typical populations usually include several large plants that carry the burden of sexual reproduction and recruitment, producing thousands of seeds over a growing season (USFWS, 2021).

**Habitat Type**

Adult: Terrestrial

**Dependencies on Specific Environmental Elements**

Adult: Dunes/coastal bluffs (10-40 ft elevation)

**Geographic or Habitat Restraints or Barriers**

Adult: Coastal

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2021)

**Habitat Narrative**

Adult: Sand dune phacelia occurs on the open sand above the high tide line, further inland on semi-stabilized and open dunes, and on coastal bluffs (Kalt 2008, p. 2). It has been described as occurring at elevations ranging from 10-40 feet (33 to 131 meters) and on slopes less than 30 percent comprised of sand or (rarely) gravel (USFWS, 2021).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not likely to disperse and colonize new areas without human intervention (USFWS, 2021)

***Population Information and Trends***

**Population Trends:**

Declining. 16 of the 22 populations (63 percent) for which we estimated a trend are declining (Tables 3, 4) (Brown 2020 database). Downward trends are most often associated with low habitat condition (12 populations, or 54 percent), and 68 percent of all populations are in low condition overall when considering all three parameters (habitat, abundance, and trend). Given the preponderance of sand dune phacelia populations in currently low condition, resiliency is low rangewide for most populations (USFWS, 2021).

**Resiliency:**

Seventeen of 25 extant populations (68 percent) are considered low in abundance, with 12 populations (48 percent) containing fewer than 25 individuals (USFWS 2021, pp. 38, 41). Based on what we know about historical abundance, 16 of the 22 populations (73 percent) for which we estimated a trend are declining. Downward trends are most often associated with low habitat condition (12 of 22 populations, or 54 percent), and 68 percent of all populations are in low condition overall when considering all 3 parameters (habitat, abundance, and trend). Given the preponderance of sand dune phacelia populations in currently low condition, resiliency is low rangewide for most populations (USFWS, 2023).

**Representation:**

Representation units were delineated by dividing the rangewide population into logical breaks based on geography and State boundaries. There are nine populations in the Oregon North Unit, six in the Oregon South Unit, and ten in California (Figure 1). Overall current condition is ranked as low in 55 percent of the populations in Oregon North, 67 percent of the populations in Oregon South, and 78 percent of the populations in California. Currently, populations of sand dune phacelia are patchy and dispersed, often isolated by large tracts of habitat made unsuitable by human development or invasive species and are thus unlikely to be able to colonize new areas. The lack of connectivity between populations may result in reduced gene flow and genetic diversity, rendering the species less able to adapt to novel conditions. Further, the lack of available and unoccupied suitable habitat leaves less opportunity for an adaptable species to exploit new resources outside of the area it currently occupies. Thus, ecological diversity is generally low for this highly specialized species, and the limited availability of suitable habitat limits the potential for this species to adapt to environmental changes (adaptive capacity). However, the species currently retains representation with multiple populations in all three representation units, even if those populations are small and resiliency is low (USFWS, 2023).

**Redundancy:**

There are currently approximately 33,858 naturally occurring sand dune phacelia plants existing in 25 extant populations along approximately 100 miles (161 kilometers) of coastline. However, 71 percent of these plants occur in Oregon on private land at the northernmost extent of the range. Of the remaining 14 sites in Oregon, almost all are in public ownership (mostly on OPRD lands), with two on BLM lands. In California, all 10 of the sites include some public land, with a few sites also containing portions of private lands. In Oregon, 60 percent of extant populations are considered in low condition. In California, 80 percent are considered in low condition. Rangewide, 12 of the 25 extant populations have fewer than 25 individuals. Our analysis of redundancy concludes that although most populations exhibit low resiliency, it is unlikely that a single catastrophic event could eliminate all extant populations. Populations are well distributed throughout all representation units, with the highest-condition populations located at either end of the species’ range (USFWS, 2023).

**Number of Populations:**

25 Extant Populations (USFWS, 2021).

**Population Size:**

Populations range in size from ~33,858 (USFWS, 2023)

**Minimum Viable Population Size:**

Unknown (USFWS, 2021)

**Population Narrative:**

Populations delineated as spatially explicit by ORBIC and the California Natural Diversity Database (CNDBB) were used as the analytic units for this assessment (see Methodology, Chapter V). Spatially explicit populations of sand dune phacelia are defined differently in Oregon and California. In California, individual plant mats that are separated by a 0.25-mile (0.4-kilometer) interval are considered separate populations, whereas in Oregon the threshold for distinct populations is 0.30 miles (0.48 kilometers). Beyond these limits, gene flow is considered improbable.  Sand dune phacelia is documented to occur from about 5 miles (8 kilometers) north of Bandon, Oregon, south to Crescent City, California (Figure 1: Distribution map of Phacelia argentea). Whether the species was ever present or abundant elsewhere is unknown. In 1933, sand dune phacelia was reportedly collected from one location in Clatsop County, on Oregon's northern coast (ODA 2020, no pagination), and in 1991, a specimen was reported from Mendocino County, California (Calflora 2020, no pagination). The Mendocino, California location has not been confirmed by the Service and the location that it was reported from does not appear to be suitable habitat (L. Goldsmith 2020, pers. comm.). Other than these two occurrences, sand dune phacelia populations have been reported only from Coos and Curry Counties in Oregon, and Del Norte County in California (USFWS, 2021).  Sand dune phacelia is documented to occur from about 5 miles (8 kilometers) north of Bandon, Oregon, south to Crescent City, California (Figure 1: Distribution map of Phacelia argentea). Whether the species was ever present or abundant elsewhere is unknown. In 1933, sand dune phacelia was reportedly collected from one location in Clatsop County, on Oregon's northern coast (ODA 2020, no pagination), and in 1991, a specimen was reported from Mendocino County, California (Calflora 2020, no pagination). The Mendocino, California location has not been confirmed by the Service and the location that it was reported from does not appear to be suitable habitat (L. Goldsmith 2020, pers. comm.). Other than these two occurrences, sand dune phacelia populations have been reported only from Coos and Curry Counties in Oregon, and Del Norte County in California (USFWS, 2021).

***Threats and Stressors***

**Stressor:** Invasive Plants
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasive, introduced plant species are reportedly one of the most influential stressors to sand dune phacelia and its habitat (Kalt 2008, p. 7; Rodenkirk 2019, p. 6). European beachgrass, gorse, and other invasive plant species outcompete sand dune phacelia throughout its range (Rodenkirk 2019, p. 6). Introduced to the Pacific Northwest region of the United States and California in the 1800s, European beachgrass is an aggressive, perennial, rhizomatous grass. It was extensively planted to stabilize sand and build dunes parallel to the ocean shore in an effort to protect infrastructure from the effects of ocean storms and tides (Hacker et al 2011, p.

2; ODFW 2016a, pp. 6-7). Prior to the introduction of European beachgrass, the dunes of the Oregon and northern California coasts rose gradually from the beach and sand moved in patterns reflecting the prevailing wind directions. Dunes ran perpendicular to the coast, and the plant community was comprised of native plants adapted to shifting sand. Colonizing European beachgrass captured sand with its deep roots and spreading shoots, forming dense monocultures of grass that outcompeted many native dune species, including sand dune phacelia, for growing space, sunlight, and moisture (Rittenhouse 1996, p. 3). The steep, heavily vegetated foredunes seen today along much of the Oregon, and to a lesser extent California, coastlines are the result of European beachgrass colonization (Rittenhouse 1995, p. 9; Zarnetske et al. 2010, pp. 1-2). Dune stabilization by European beachgrass also facilitates the establishment and succession of native trees and shrubs that proliferate in the absence of natural disturbance regimes, thereby resulting in the conversion, and ultimate loss, of native dune habitat.

**Stressor:** Human Activity (Recreation)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Legal and illegal off-highway vehicle (OHV) use can damage or kill sand dune phacelia. While widely perceived as a threat (Kalt 2008, p. 9; Brown 2020 database; Rodenkirk 2019, p. 6), documented impacts from OHVs are limited to individuals at a small number of sites throughout its range, most notably in California (Imper, 1987, p. 1; Gedik 2009, p. 7; Tolowa Dune Stewards 2013, p. 18; Jacobs 2019, pp. 15, 102). Rittenhouse (1995, p. 9) described the impact of OHV use to be minimal and localized in Oregon, and while he noted some damage to individuals at two sites (Lost Lake and Ophir Dunes), he and Kalt (2008, p. 9) reported that most OHV use occurs in areas unoccupied by sand dune phacelia. Rodenkirk (2019, p. 22) speculated that illegal OHV use may have contributed to the decline of the population at Fourmile, and Forys (2020, pers. comm.) expressed concern that illegal OHV use may be impeding the recovery of sand dune phacelia at the Lake Tolowa Restoration and East Dead Lake sites. Jerabek (2020a, pers. comm.) concurred, and described OHV use as an ongoing and pervasive issue for the California populations. Legal vehicle use may also impact sand dune phacelia where roads bisect populations, or populations which are located on beaches that are designated as open to motorized vehicle use (Brown 2020 database). Trampling by pedestrians and equestrians is noted as a concern throughout the range of sand dune phacelia.

**Stressor:** Private Land Development/Management (Coastal Development)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Coastal development activities that may affect sand dune phacelia include the maintenance and construction of roads, airports, utilities, and buildings.

**Stressor:** Livestock Grazing
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Negative effects of livestock grazing on sand dune phacelia are undocumented. Livestock grazing does occasionally occur throughout the range of sand dune phacelia on private lands; however it usually occurs on well-stabilized (i.e., vegetated) dunes and coastal meadows,

which are not ideal sand dune phacelia habitat. Rodenkirk (2019, p. 22) speculated that grazing may have actually benefitted sand dune phacelia at the Fourmile site by reducing competition from invasive species. A nearby population occurring on a grazed, private ranch was presumed to be doing well, but no data were presented to substantiate this claim, or upon which to draw a correlation (Kalt 2008, p. 10). Furthermore, grazing was not listed as a threat by Brown (2020 database) for any of the populations surveyed. Therefore, we did not include livestock grazing as a threat influencing the current and future conditions of sand dune phacelia populations.

**Stressor:** Overutilization
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Because of its attractive foliage, illegal removal for horticultural purposes has been cited as a threat to sand dune phacelia (Rodenkirk 2019, p. 6; ODA 2020, no pagination). We could find no information with which to validate this claim, or assess its impacts on sand dune phacelia populations, thus we did not consider overutilization as a threat influencing the current and future conditions of sand dune phacelia populations.

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 8

***Conservation Measures and Best Management Practices:***

•

# SPECIES ACCOUNT: *Phacelia insularis ssp. insularis* (Island phacelia)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

An annual herb, usually about 1.5 dm tall. Small lavender to violet, bell-shaped flowers bloom in March and April. (NatureServe, 2015)

**Taxonomy**

The summary and table of the July 31, 1997 notice in the Federal Register (in which the USFWS determines this taxon as endangered) lists the taxon as Phacelia insularis SSP. insularis; in the text the taxon is referred to as a subspecies and as a variety. The treatment the notice appears to follow is Wilken et al. (1993; in Hickman) which treats the taxon as a variety. (NatureServe, 2015)

**Historical Range**

Endemic to the California Channel Islands and, at the time of listing in 1997, a single population on Santa Rosa Island was the only known population of the species. By the time the recovery plan was published in 2000, island phacelia was known to occur in five localities: the one on Santa Rosa Island at Carrington Point and the four on San Miguel Island (see Santa Rosa Island and San Miguel Island maps, pp. 15-16). Both islands occur on lands managed by Channel Islands National Park (Park). The Santa Rosa Island population occupies about 15 acres (6 hectares (ha)) based on its maximum observed extent in 1998. The San Miguel Island populations range from about 0.02 to 0.86 acres (0.01 to 0.35 ha). These figures are from USGS surveys made in April and May, 1998, when the largest number of plants were observed (McEachern in litt. 2007b). Surveys since 1998 have not seen such extensive numbers of plants in those same areas; however, a seed bank likely still exists (McEachern in litt. 2007b). (USFWS, 2008)

**Current Range**

This variety occurred only in Santa Rosa and San Miguel Islands, Santa Barbara county, California. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

Adult: Currently, little life history information is available for this species. This annual flower blooms from March through April (USFWS, 2000).

**Habitat Type**

Adult: Sandy valley and foothill grassland communities, bluffs, dunes, dominated by alien grasses with some scattered native bunchgrasses, shrubs, and herbs; at or near sea level (partly based on Calif. Nat. Diversity Database, May/1998 report). (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Sandy valley and foothill grassland communities, bluffs, dunes, dominated by alien grasses with some scattered native bunchgrasses, shrubs, and herbs; at or near sea level (partly based on Calif. Nat. Diversity Database, May/1998 report). (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Sandy valley and foothill grassland communities, bluffs, dunes, dominated by alien grasses with some scattered native bunchgrasses, shrubs, and herbs; at or near sea level (partly based on Calif. Nat. Diversity Database, May/1998 report). (NatureServe, 2015)

**Environmental Specificity**

Adult: Moderate (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Sandy valley and foothill grassland communities, bluffs, dunes, dominated by alien grasses with some scattered native bunchgrasses, shrubs, and herbs; at or near sea level (partly based on Calif. Nat. Diversity Database, May/1998 report). (NatureServe, 2015). The plant is found on stabilized sand dunes at 50–200 meters elevation. It occurs in non-native annual grassland, usually in bare openings within the grass thatch. (USFWS, 2025)

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

6 EOs (USFWS, 2021)

**Population Narrative:**

USFWS reports a population of 31 plants from Santa Rosa Island in 1994. No populations have been relocated in San Miguel Island. As of 2001, no populations exist. The California Natural Diversity Database (May/1998) reports four occurrences, none of which have been observed in the last 20 years; but USFWS (1997) reports that Sarah Chaney found one small population in 1994 in Santa Rosa Island. (NatureServe, 2015). Low redundancy, representation and resiliency are inferred based on low population numbers and low number of individuals.

***Threats and Stressors***

**Stressor:** Predation (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Some progress has been made toward eliminating non-native animals from Santa Rosa Island since the time of listing. We believe the removal of pigs by 1993, removal of cattle by

1998, and smaller populations of deer and elk since 1998 have reduced browsing pressure on island phacelia. Although habitat conditions on Santa Rosa Island and San Miguel Island show the effects of long-term grazing, the USGS believes that at the landscape level, conditions are improving (McEachern in litt. 2007b). In fact, browsing by an animal is rarely seen, although predation does occur from mice that are known to harvest the fruits (McEachern in litt. 2007b) (USFWS, 2008).

**Stressor:** Non-native plants (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Invasion of habitats by non-native annual grasses, especially ripgut brome, continues to impact the species, particularly germination. Non-native annual grasses and the litter they produce also appear to inhibit successful establishment of phacelia seedlings in field experiments (McEachern in litt. 2007b, Levine et al. 2007) (USFWS, 2008).

**Stressor:** Small population size (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:** Loss of genetic variability/extinction
**Narrative:** At the time of listing, island phacelia was threatened by the risk of stochastic extinction due to small population size and limited distribution (62 FR 40954). The conservation biology literature commonly notes the vulnerability of taxa known from one or very few locations and/or from small and highly variable populations (e.g., Shaffer 1981, 1987; Primack 2006; Groom et al. 2006). In particular, the small size of each population makes it difficult for this species to persist while sustaining the impacts of soil damage and habitat alteration from non-native species. The species remains vulnerable to extirpation due to its small population size, high inter-annual variability in plant numbers, limited distribution, and low survival rate (USFWS, 2008).

**Stressor:** Climate change (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Island phacelia may be particularly threatened by climate change because its geographic distribution is so narrow and its current range is unlikely to overlap regions that would be climatically favorable in the future (Levine et al. 2007). This is particularly acute for species on islands because they are unable to disperse to more favorable habitat as the environment changes. Because of this, Levine et al. (2007) suggest that the persistence of many rare species depends on how populations respond to climate change in their current locations (USFWS, 2008).

***Recovery***

**Reclassification Criteria:**
1. Discover or establish 10 populations per island (San Miguel and Santa Rosa) (USFWS, 2021)

2. Maintain stable populations for a period of 15 years that includes the normal precipitation cycle. (USFWS, 2021)

3. Seed stored in CPC cooperating facilities. (USFWS, 2021)

4. Seed germination and propagation techniques understood. (USFWS, 2021)

5. Successful outplanting techniques developed (USFWS, 2021)

6. Life history research conducted. (USFWS, 2021)

7. Weed management plan developed and implemented. (USFWS, 2021)

8. If declining, determine cause and reverse trend. (USFWS, 2021)

Recovery Priority: 6.

**Delisting Criteria:**
Discover or establish five additional populations per island (USFWS, 2008).

No decline after downlisting for 10 years (USFWS, 2008).

All potential habitat surveyed. (USFWS, 2021)

**Recovery Actions:**
- Reclassification Criteria: Although surveys in historical and other suitable habitat have been conducted, additional populations have not been found and no reintroduced populations have been established on Santa Rosa Island. Therefore, this criterion has not been met. We believe this criterion may be possible on San Miguel Island because, although these plants have every specific habitat requirements, there are several places on the island where suitable habitat conditions exist and the plant now occurs (McEachern, in litt. 2007a). However, this criterion is not appropriate with respect to the recovery of the species on Santa Rosa Island because suitable habitats appear to be extremely rare on the island. Suitable habitat may be available on Carrington Point; otherwise, suitable habitat on the island appears to be limited. Therefore, a more realistic goal would be to establish one additional population on Santa Rosa Island. Results of restoration field experiments over time would help establish whether or not the goal of one more population is feasible (McEachern, in litt. 2007a). Delisting Criteria: This criterion has not been met. We believe this criterion may be possible on San Miguel Island where three populations exist now but it is not realistic with respect to the recovery of the species on Santa Rosa Island for the same reasons described in downlisting criterion #1 above (USFWS, 2008).
- Reclassification Criteria: Delisting Criteria: This criterion has not been met. Although we believe the intent of this criterion is appropriate, we think it should be refined to focus on long-term trends, rather than a short-term, absolute decline, once additional information about the life history of the species and the species' response to recovery actions are better understood. Factor B is not relevant to this species. Factor D is relevant but is not addressed in the recovery criteria (USFWS, 2008).

- Reclassification criteria: A precipitation cycle includes periods of drought and wet years, with annual rainfall starting at 100 to 135 percent of average, dropping below 65 percent of average, and returning to at least average (Service 2000). Because the species has not been listed for a minimum of 15 years, this criterion has not been met. We believe this criterion is adequate and appropriate with respect to the recovery of the species (USFWS, 2008).
- The USGS-BRD and NPS should seek additional funding to continue field surveys and monitoring, demographic monitoring, population viability analyses, and further investigations into recovery projects (USFWS, 2008).
- The Service should work cooperatively with NPS and USGS-BRD to refine the generalized downlisting criteria to take into consideration new information. Attaining the recovery objective of securing several populations containing a minimum of 2,000 plants each is unrealistic for this species (USFWS, 2008).
- The Service should work cooperatively with NPS and USGS-BRD to refine delisting criteria to emphasize long-term population growth trends rather than short-term gains or declines (USFWS, 2008).
- The USGS-BRD and NPS should investigate the community-level factors that influence population abundance, distribution, and demographic trends (USFWS, 2008).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Continue monitoring the Santa Rosa Island occurrence of Phacelia insularis var. insularis and establish regular surveys on both Santa Rosa and San Miguel Islands. 2. Better define suitable germination and growth microhabitat for Phacelia insularis var. insularis, especially in relationship to non-native Bromus diandrus competition and thatch accumulation, and if needed determine how to manage Bromus diandrus. 3. Determine efficient methods to reduce Bromus diandrus thatch without harming Phacelia insularis var. insularis individuals. 4. Control non-native Malva psuedolavatera in the Carrington Point area on Santa Rosa Island. 5. Improve the completeness of coverage of Phacelia insularis var. insularis in conservation seed banks, with more occurrences over more years. (USFWS, 2021)
- RECOMMENDATIONS FOR FUTURE ACTIONS: The following list carries over recommendations from the previous 5-year review (Service 2021), and adds an additional one (Recommendation 5). 1. Continue monitoring the Santa Rosa Island occurrence of island phacelia and establish regular surveys on both Santa Rosa and San Miguel Islands to document changes in distribution and abundance. 2. Better define suitable germination and growth microhabitat for island phacelia, especially in relationship to non-native grass Bromus diandrus competition and thatch accumulation, and if needed determine how to manage Bromus diandrus. 3. Determine efficient methods to reduce Bromus diandrus thatch without harming island phacelia seeds or plants. 4. Control non-native Malva multiflora in the Carrington Point area on Santa Rosa Island. 5. Monitor the effects of increased backcountry visitor use on island phacelia, and on the possible increase of non-native plants that could negatively affect the island phacelia. 6. Improve the completeness of coverage of island phacelia in conservation seed banks, with more occurrences over more years. (USFWS, 2025)

# SPECIES ACCOUNT: *Phacelia submutica* (DeBeque phacelia)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 08/26/2011; Mountain-Prairie Region (R6) (USFWS, 2016)

**Physical Description**

Annual plant, stems 2-8 cm long, often branched at the base, mostly prostrate, leaves hairy, oblong or egg-shaped, flowers crowded, petals 3.5-4.5 mm long, white or cream colored becoming yellowish with age, stamens not protruding beyond the petals. (NatureServe, 2015)

**Taxonomy**

Phacelia submutica was first described by Howell based on specimens collected from the town of DeBeque, Mesa County, Colorado, in 1911 and 1912 (Howell 1944, pp. 370– 371Halse (1981, pp. 121, 129, 130) reduced it to varietal status as P. scopulina var. submutica. This has been challenged as incorrect by O'Kane (1987, p. 2), who claimed Halse used inadequate collection materials, and that P. submutica is geographically isolated from P. scopulina (O'Kane 1987, p. 2; 1988, p. 462). Phacelia submutica is recognized at the species rank by current floristic treatments in Weber and Wittmann (1992, p. 98; 2001, p. 203) and by the Director of the Biota of North America Program (Kartesz 2008, pers. comm.). While the Integrated Taxonomic Information System (2001) database cites John Kartesz as the expert source for this species, it is not updated with his currently accepted name for the species: Phacelia submutica (Kartesz 2008, pers. comm.). Phacelia is included in the Hydrophyllaceae (waterleaf family). Recent molecular data suggest that this family should be combined in an expanded Boraginaceae (borage family). There are conflicting views on the configuration of this larger Boraginaceae and the lead author of the family treatment for the upcoming Flora of North America has chosen to retain the Hydrophyllaceae. Therefore, we will retain Phacelia in the Hydrophyllaceae family for this proposal (USFWS, 2010).

**Current Range**

Phacelia submutica is endemic to Colorado and known only from Garfield and Mesa counties. Estimated range is 356 square kilometers, calculated in GIS by drawing a minimum convex polygon around the known occurrences.

**Critical Habitat Designated**

Yes; 8/13/2012.

**Legal Description**

On August 13, 2012, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Phacelia submutica (DeBeque phacelia) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes four critical habitat units (CHUs), in Colorado (77 FR 48356-48415).

**Critical Habitat Designation**

The critical habitat designation for Phacelia submutica includes nine CHUs in Garfield and Mesa Counties, Colorado. This species critical habitat encompasses approximately 25,484 acres (ac) (10,313 hectares (ha)) (77 FR 48356-48415).

Unit 1, the Sulphur Gulch Unit, consists of 1,046 ac (423 ha) of federally owned land. The Unit is located approximately 7.7 mi (12.5 km) southwest of the town of DeBeque in Mesa County, Colorado. This Unit is managed by BLM, through the Grand Junction Field Office. This Unit is currently occupied. This Unit currently has all the physical and biological features essential to the conservation of the species including barren clay badlands with less than 20 percent plant/vegetation cover, suitable elevational ranges of 5,480 to 6,320 ft (1,670 to 1,926 m), appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. All lands within this Unit are leased as grazing allotments, and less than 1 percent is managed as an active pipeline ROW by the BLM. While these lands currently have the physical and biological features essential to the conservation of Phacelia submutica, because of a lack of cohesive management and protections, special management will be required to maintain these features in this Unit. Threats to Phacelia submutica and its habitat in this Unit include energy development, recreation (especially OHV use), domestic and wild ungulate grazing and use, and nonnative invasive species, such as Bromus tectorum.

Unit 2, the Pyramid Rock Unit, is the largest Unit we are designating and consists of 17,321 ac (7,010 ha) of federally and privately owned lands in Mesa and Garfield Counties, Colorado. This Unit is approximately 1.6 mi (2.6 km) west of the town of DeBeque. The eastern boundary borders Roan Creek, and Dry Fork Creek runs through the northern quarter of the Unit. Eighty-nine percent is managed by BLM through the Grand Junction Field Office, and 11 percent is under private ownership. Three percent of this Unit is within the Pyramid Rock Natural Area and Pyramid Rock ACEC that was designated, in part, to protect Phacelia submutica, as discussed in the proposed (75 FR 35739) and final listing rules (76 FR 45054). This Unit is currently occupied. This Unit currently has all the physical and biological features essential to the conservation of the species including barren clay badlands with less than 20 percent plant/vegetation cover, suitable elevational ranges of 4,960 to 6,840 ft (1,512 to 2,085 m), the appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. Ninety-four percent of this Unit is managed as a grazing allotment on BLM and private lands. Additionally, 11 percent of this Unit is managed as an active pipeline ROW. While these lands currently have the physical and biological features essential to the conservation of Phacelia submutica, because of a lack of cohesive management and protections, special management will be required to maintain these features in this Unit. Threats to Phacelia submutica and its habitat in this Unit include energy development, recreation (especially OHV use), livestock and wild ungulate grazing and use, and nonnative invasive species including Bromus tectorum and Halogeton glomeratus. The Westwide Energy corridor runs through this Unit. The corridor covers almost 10 percent of this Unit (Service 2011c, p. 9).

Unit 3, the Roan Creek Unit, consists of 54 ac (22 ha) of federally and privately owned lands in Garfield County, Colorado. The Unit is located 3.3 mi (5.4 km) north of the town of DeBeque and for 1.7 mi (2.7 km) along both sides of County Road 299. Ninety-seven percent of this Unit is privately owned. Three percent of this Unit is managed by BLM through the Grand Junction Field Office. This Unit is currently occupied. This Unit currently has all the physical and biological features essential to the conservation of the species including barren clay badlands with less than 20 percent cover, suitable elevational ranges of 5,320 to 5,420 ft (1,622 to 1,652 m), the appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. The entire Unit is within a grazing allotment. While these lands currently have the physical and biological features essential to the conservation of Phacelia submutica, because of a lack of cohesive management and protections, special management will be required to maintain these features in this Unit. Threats to Phacelia submutica and its habitat in this Unit include recreation (especially OHV use), livestock and wild ungulate grazing and use, nonnative invasive species including Bromus tectorum and Halogeton glomeratus, and a lack of protections on private lands.

Unit 4, the DeBeque Unit, consists of 530 ac (215 ha) of Federal and private lands in Mesa County, Colorado. This Unit is located 0.25 mi (0.4 km) north of DeBeque between Roan Creek Road and Cemetery Road. Seventy-six percent of this Unit is managed by BLM through the Grand Junction Field Office. This Unit is currently occupied. This Unit currently has all the physical and biological features essential to the conservation of the species including barren clay badlands with less than 20 percent plant/vegetation cover, suitable elevational ranges of 5,180 to 5,400 ft (1,579 to 1,646 m), the appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. While these lands currently have the physical and biological features essential to the conservation of Phacelia submutica, because of a lack of cohesive management and protections, special management will be required to maintain these features in this Unit. Threats to Phacelia submutica and its habitat in this Unit include energy development, residential development, recreation (especially OHV use), livestock and wild ungulate grazing and use, and nonnative invasive species including Bromus tectorum and Halogeton glomeratus. Since 24 percent of the Unit is privately owned and borders the north of the town of DeBeque, this Unit is threatened by potential urban or agricultural development. The Westwide Energy corridor runs through this Unit. The corridor covers almost 66 percent of this Unit (Service 2011c, p. 9).

Unit 5, the Mount Logan Unit, consists of 277 ac (112 ha) of Federal and private lands in Garfield County, Colorado. The Unit is located 2.7 mi (4.4 km) north, northeast of the town of DeBeque, Colorado, and 0.5 mi (0.8 km) west of Interstate 70. Eighty-eight percent of this Unit is managed by BLM through the Grand Junction Field Office. The remainder of this Unit is privately owned. This Unit is currently occupied. This Unit currently has all the physical and biological features essential to the conservation of the species including barren clay badlands with less than 20 percent plant/vegetation cover, suitable elevational ranges of 4,960 to 5,575 ft (1,512 to 1,699 m), the appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. Eighty-eight percent of this Unit is managed as a grazing allotment by BLM, and 53 percent is managed as an active pipeline ROW. An access road runs through the Unit connecting several oil wells and associated infrastructure. While these lands currently have the physical and biological features essential to the conservation of Phacelia submutica, because of a lack of cohesive management and protections, special management will be required to maintain these features in this Unit. Threats to Phacelia submutica and its habitat in this Unit include energy development, recreation (especially OHV use), livestock and wild ungulate grazing and use, and nonnative invasive species, including Bromus tectorum and Halogeton glomeratus.

Unit 6, the Ashmead Draw Unit, consists of 1,276 ac (516 ha) of Federal and private lands in Mesa County, Colorado. The Unit is located 1.5 mi (2.5 km) southeast of the town of DeBeque, Colorado, and east of 45.5 Road (DeBeque Cut-off Road). Eighty-seven percent of this Unit is managed by BLM through the Grand Junction Field Office, the remainder is private lands. This Unit is currently occupied. We slightly increased the size of this Unit from our proposed critical habitat designation in our notice of availability (77 FR 18162) to include sites that were revisited and more accurately mapped during the spring of 2011 (Service 2011e, pp. 1-3). This Unit currently has all the physical and biological features essential to the conservation of the species including barren clay badlands with less than 20 percent plant/vegetation cover, suitable elevational ranges of 4,940 to 5,808 ft (1,506 to 1,770 m), the appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. A network of access roads runs through the Unit. Eighty-eight percent of this Unit is within a BLM grazing allotment, and 84 percent is within the Grand Junction Field Office's designated energy corridor. Thirty percent of the Unit is managed as an active pipeline ROW. While these lands currently have the physical and biological features essential to the conservation of Phacelia submutica, because of a lack of cohesive management and protections, special management will be required to maintain these features in this Unit. Threats to Phacelia submutica and its habitat in this Unit include energy development, recreation (especially OHV use), livestock and wild ungulate grazing and use, and nonnative invasive species, including Bromus tectorum and Halogeton glomeratus. The Westwide Energy corridor runs through this Unit. The entire Unit is within the Westwide Energy corridor, and 88 percent is within several grazing allotments.

Unit 7, the Baugh Reservoir Unit, consists of 430 ac (174 ha) of Federal and private lands in Mesa County, Colorado. The Unit is located 6 mi (10 km) south of DeBeque, Colorado, near Kimball Mesa and Horse Canyon Road. Thirty-nine percent is managed by BLM through the Grand Junction Field Office, and the remaining 61 percent is on private lands. This Unit is currently occupied. We slightly increased the size of this Unit from our proposed critical habitat designation in our notice of availability (77 FR 18162) to include sites that were revisited and more accurately mapped during the spring of 2011 (Service 2011e, pp. 5-8). This Unit currently has all the physical and biological features essential to the conservation of the species, including barren clay badlands with less than 20 percent plant/vegetation cover, a suitable elevational range of 5,400 to 5,700 ft (1,646 to 1,737 m), the appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. An access road runs through the Unit, close to the occurrence of Phacelia submutica. While these lands currently have the physical and biological features essential to the conservation of P. submutica, because of a lack of cohesive management and protections, special management will be required to maintain these features in this Unit. Threats to Phacelia submutica and its habitat in this Unit include energy development, recreation, livestock and wild ungulate grazing and use, and nonnative invasive species including Bromus tectorum and Halogeton glomeratus. The Westwide Energy corridor runs through this Unit. The entire Unit is within the Westwide Energy corridor and one grazing allotment.

Unit 8, the Horsethief Mountain Unit, consists of 4,209 ac (1,703 ha) of Federal and private lands in Mesa County, Colorado. It is located approximately 3.5 mi (5.6 km) southeast of DeBeque, Colorado, and along the eastern side of Sunnyside Road (V Road). Thirty-four percent is managed by BLM through the Grand Junction Field Office, 29 percent by the White River National Forest, 23 percent by the Grand Mesa Uncompahgre National Forest, and 14 percent is on private lands. This Unit is currently occupied. This Unit currently has all the physical and biological features essential to the conservation of the species, including barren clay badlands with less than 20 percent plant/vegetation cover, a suitable elevational range of 5,320 to 6,720 ft (1,622 to 2,048 m), the appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. While these lands currently have the physical and biological features essential to the conservation of Phacelia submutica, because of a lack of cohesive management and protections, special management will be required to maintain these features in this Unit. A portion of the site on USFS lands is within a proposed Research Natural Area. Threats to Phacelia submutica and its habitat in this Unit include energy development, recreation (especially OHV use), livestock and wild ungulate grazing and use, and nonnative invasive species, including Bromus tectorum and Halogeton glomeratus.

Unit 9, the Anderson Gulch Unit, consists of 341 ac (138 ha) of State and private lands in Mesa County, Colorado. It is located 11 mi (17 km) southeast of DeBeque, Colorado, and 3.5 mi (5.5 km) north of the town of Molina, Colorado. Within the Unit, 56 percent of the lands are managed by CDOW, within the Plateau Creek State Wildlife Area, and 44 percent is private. This Unit is currently occupied. We slightly increased the size of this Unit from our proposed critical habitat designation in our notice of availability (77 FR 18162) to include sites that were revisited and more accurately mapped during the spring of 2011 (CNHP 2012b, spatial data). This Unit currently has all the physical and biological features essential to the conservation of the species, including barren clay badlands with less than 20 percent plant/vegetation cover, a suitable elevational range of 5,860 to 6,040 ft (1,786 to 1,841 m), the appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. Forty-two percent of the Unit is a pending pipeline ROW. While these lands currently have the physical and biological features essential to the conservation of Phacelia submutica, special management may be required to maintain these features in this Unit. Threats to Phacelia submutica and its habitat in this Unit include energy development, recreation (especially from OHV use), livestock and wild ungulate grazing and use, and nonnative invasive species, including Bromus tectorum and Halogeton glomeratus.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Phacelia submutica critical habitat consists of five components (77 FR 48356-48415):

(i) Suitable soils and geology. (A) Atwell Gulch and Shire members of the Wasatch formation. (B) Within these larger formations, small areas (from 10 to 1,000 ft\2\ (1 to 100 m\2\)) on colorful exposures of chocolate to purplish brown, light to dark charcoal gray, and tan clay soils. These small areas are slightly different in texture and color than the similar surrounding soils. Occupied sites are characterized by alkaline (pH range from 7 to 8.9) soils with higher clay content than similar nearby unoccupied soils. (C) Clay soils that shrink and swell dramatically upon drying and wetting and are likely important in the maintenance of the seed bank.

(ii) Topography. Moderately steep slopes, benches, and ridge tops adjacent to valley floors. Occupied slopes range from 2 to 42 degrees with an average of 14 degrees.

(iii) Elevation and climate. (A) Elevations from 4,600 ft (1,400 m) to 7,450 ft (2,275 m). (B) Climatic conditions similar to those around DeBeque, Colorado, including suitable precipitation and temperatures. Annual fluctuations in moisture (and probably temperature) greatly influences the number of Phacelia submutica individuals that grow in a given year and are thus able to set seed and replenish the seed bank.

(iv) Plant community. (A) Small (from 10 to 1,000 ft\2\ (1 to 100 m\2\)) barren areas with less than 20 percent plant cover in the actual barren areas. (B) Presence of appropriate associated species that can include (but are not limited to) the natives Grindelia fastigiata, Eriogonum gordonii, Monolepis nuttalliana, and Oenothera caespitosa. Some presence, or even domination by, invasive nonnative species, such as Bromus tectorum, may occur, as Phacelia submutica may still be found there. (C) Appropriate plant communities within the greater pinyon-juniper woodlands that include: (1) Clay badlands within the mixed salt desert scrub; or (2) Clay badlands within big sagebrush shrublands.

(v) Maintenance of the seed bank and appropriate disturbance levels. (A) Within suitable soil and geologies (see paragraph (2)(i) of this entry), undisturbed areas where seed banks are left undamaged. (B) Areas with light disturbance when dry and no disturbance when wet.

**Special Management Considerations or Protections**

The features essential to the conservation of this species (plant community and competitive ability, elevation, topography, soils, climate, reproduction and seed bank, and disturbance regime) may require special management considerations or protection to reduce threats. Specifically, the clay soils on which Phacelia submutica are found are relatively stable when dry but are extremely vulnerable to disturbances when wet. The current range of P. submutica is subject to human-caused modifications from natural gas exploration and production with associated expansion of pipelines, roads, and utilities; development within the Westwide Energy Corridor; increased access to the habitat by OHVs; soil and seed disturbance by livestock and other human-caused disturbances; nonnative invasive species including Bromus tectorum and Halogeton glomeratus (halogeton); and inadequacy of existing regulatory mechanisms (76 FR 45054). Special management considerations or protections are required within critical habitat areas to address these threats. Management activities that could ameliorate these threats include (but are not limited to): Development of regulations and agreements to balance conservation with energy development and minimize its effects in areas where the species resides; the establishment of additional protection areas that provide greater protections for the species; minimization of OHV use; placement of roads and utility lines away from the species and its habitat; minimization of livestock use or other human-caused disturbances that disturb the soil or seeds; and the minimization of habitat fragmentation. These management activities would protect the PCEs for the species by preventing the loss of habitat and individuals, protecting the plant's habitat and soils, and managing for appropriate levels of disturbance. Criteria Used To Identify Critical Habitat As required by section 4(b)(2) of the Act, we used the best scientific data available to designate critical habitat. We reviewed available information pertaining to the habitat requirements of this species. In accordance with the Act and its implementing regulation at 50 CFR 424.12(e), we considered whether designating additional areas-- outside those currently occupied as well as those occupied at the time of listing--are necessary to ensure the conservation of the species. We are designating critical habitat in areas within the geographical area occupied by Ipomopsis polyantha, Penstemon debilis, and Phacelia submutica at the time of listing in 2011. We also are designating specific areas outside the geographical area occupied by I. polyantha and P. debilis at the time of listing because we have determined that such areas are essential for the conservation of the species. All units are designated based on sufficient elements of physical and biological features being present to support Ipomopsis polyantha, Penstemon debilis, and Phacelia submutica life-history processes. Small populations and plant species with limited distributions, like those of Ipomopsis polyantha and Penstemon debilis, are vulnerable to relatively minor environmental disturbances (Given 1994, pp. 66-76; Frankham 2005, pp. 135-136), and are subject to the loss of genetic diversity from genetic drift, the random loss of genes, and inbreeding (Ellstrand and Elam 1993, pp. 217-237; Leimu et al. 2006, pp. 942-952). Plant populations with lowered genetic diversity are more prone to local extinction (Barrett and Kohn 1991, pp. 4, 28). Smaller plant populations generally have lower genetic diversity, and lower genetic diversity may in turn lead to even smaller populations by decreasing the species' ability to adapt, thereby increasing the probability of population extinction (Newman and Pilson 1997, p. 360; Palstra and Ruzzante 2008, pp. 3428-3447). Because of the dangers associated with small populations or limited distributions, the recovery of many rare plant species includes the creation of new sites or reintroductions to ameliorate these effects. Genetic analysis of Ipomopsis polyantha has not been conducted; therefore, we do not understand the genetic diversity of this species. Given the species' limited extent and presence in only two populations, we expect the species may be suffering from low genetic diversity, or could in the future. Genetic research on Penstemon debilis, based on neutral genetic markers, has found that there is more genetic diversity in larger populations than smaller populations, that the northeastern populations are more closely related to one another than to the southwestern populations, that inbreeding is common within each population, and that genetic diversity for the species is low when compared with other species of plants with similar life-history traits (Wolfe 2010, p. 1). The plant is partially clonal, which likely explains the lowered genetic diversity and further reduces the actual population size. Small population sizes with few individuals are a problem for this species, as supported by this research. When designating critical habitat for a species, we consider future recovery efforts and conservation of the species. Realizing that the current occupied habitat is not enough for the conservation and recovery of Ipomopsis polyantha and Penstemon debilis, we worked with species' experts to identify unoccupied habitat essential for the conservation of these two species. The justification for why unoccupied habitat is essential to the conservation of these species and methodology used to identify the best unoccupied areas for consideration for inclusion is described below. Habitat fragmentation can have negative effects on biological populations, especially rare plants, and affect survival and recovery (Aguilar et al. 2006, pp. 968-980; Aguilar et al. 2008, pp. 5177-5188; Potts et al. 2010, pp. 345-352). Fragments are often not of sufficient size to support the natural diversity prevalent in an area, and thus exhibit a decline in biodiversity (Fahrig 2003, pp. 487-515). Fragmentation effects are especially prevalent in systems where multiple generations have elapsed since the fragmentation occurred (Aguilar et al. 2008, p. 5177). Habitat fragmentation has been shown to disrupt plant-pollinator interactions and predator-prey interactions (Steffan-Dewenter and Tscharntke 1999, p. 432-440; Aguilar et al. 2006, pp. 968-980; Eckert et al. 2010, pp. 35-43), alter seed germination percentages (Menges 1991, pp. 158-164), affect recruitment (Santos and Telleria 1997, pp. 181-187; Quesada et al. 2003, pp. 400-406), and result in lowered fruit set (Burd 1994, pp. 83-139; Cunningham 2000, pp. 1149-1152; Eckert et al. 2010, p. 38). In general, habitat fragmentation causes habitat loss, habitat degradation, habitat isolation, changes in species composition, changes in species interactions, increased edge effects, and reduced habitat connectivity (Fahrig 2003, pp. 487-515; Fisher and Lindenmayer 2007, pp. 265-280). These effects are more prevalent in arid ecosystems with low native vegetation cover (Fisher and Lindenmayer 2007, p. 272). Habitat fragments are often functionally smaller than they appear because edge effects (such as increased nonnative invasive species or wind speeds) impact the available habitat within the fragment (Lienert and Fischer 2003, p. 597). Shaffer and Stein (2000) identify a methodology for conserving imperiled species known as the three Rs: Representation, resiliency, and redundancy. Representation, or preserving some of everything, means conserving not just a species but its associated plant communities, pollinators, and pollinator habitats. Resiliency and redundancy ensure there is enough of a species so it can survive into the future. Resiliency means ensuring that the habitat is adequate for a species and its representative components. Redundancy ensures an adequate number of sites and individuals. This methodology has been widely accepted as a reasonable conservation strategy (Tear et al. 2005, p. 841). We have addressed representation through our PCEs for each species (as discussed above) and by providing habitat for pollinators of Ipomopsis polyantha and Penstemon debilis (as discussed further under ``Ipomopsis polyantha'' below). For Phacelia submutica, we believe that the occupied habitat provides for both resiliency and redundancy and that with conservation of these areas, the species should be conserved and sustained into the future. For I. polyantha, there are only two known populations, both with few or no protections in place (low resiliency). For adequate resiliency, we believe it is necessary for the conservation and recovery of I. polyantha that additional populations with further protections be established. Therefore, we have identified two unoccupied areas as designated CHUs for I. polyantha. For P. debilis, there are only approximately 4,000 known individuals (low redundancy), all within 2 concentrated areas (low resiliency). For adequate redundancy and resiliency, we believe it is necessary for conservation and recovery that additional populations of P. debilis be established. Therefore, we have identified two unoccupied areas as designated CHUs for P. debilis.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollinated/Asexual (USFWS, 2013)

**Lifespan**

Adult: One year (USFWS, 2013)

**Breeding Season**

Adult: DeBeque phacelia plants flower between late April and late June and set seed from midMay through late June (USFWS, 2013).

**Reproduction Narrative**

Adult: DeBeque phacelia plants flower between late April and late June and set seed from midMay through late June. Preliminary evidence on the pollination biology of the species indicates that insect pollinators are not necessary for reproduction (Langton and Schupp 2012a). Yearly germination is variable depending on precipitation patterns and can fluctuate widely (Burt and Spackman 1995). For example, DeBeque phacelia numbers at Horsethief Mountain fluctuated from 1,700 plants in 1986, to 50 in 1992, up to 1,070 in 2003, and down to only a few from 2006 to 2008 (Colorado Natural Heritage Program (CNHP) 2010) (Figure 1). This strategy of maintaining seed dormancy through unfavorable conditions is common among annual plant species of arid environments (Anderson et al. 2012; Baskin and Baskin 1998). Maintenance of a large seed bank is also vital to the persistence of these species through unpredictable and long periods of drought (Anderson et al. 2012). No information is currently available on the density and longevity of the species’ seed bank, nor the environmental conditions required to break seed dormancy, but studies are under way (Langton and Schupp 2012b) (USFWS, 2013).

**Habitat Type**

Adult: Ridge tops (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Xeric ridge tops (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (NatureServe, 2015)

**Site Fidelity**

Adult: High (NatureServe, 2015)

**Habitat Narrative**

Adult: DeBeque phacelia is a rare annual narrow endemic forb found on clay soils of the Wasatch Formation in Mesa and Garfield Counties, Colorado. It is found on slopes that average 14 degrees and elevation bands between 5,026 and 6,424 feet (1,532 and 1,958 meters). It has a short-lived annual growing season, April through June, with seeds germinating in March (Langton 2015, p. 66). DeBeque phacelia seeds do not have the required mechanisms to facilitate horizontal dispersal; therefore, seeds scatter directly beneath the mother plant, known as gravity dispersal, between July and September (Langton 2015, entire). Upon drying, cracks form in the shrink-swell soils this plant prefers, which allow a space for seeds that fall, and upon wet conditions, the cracks close and provide a seed bank. Seeds contained in these seed banks can remain dormant for at least 6 years (Langton 2015, p. 77). DeBeque phacelia requires specific environmental conditions to break seed dormancy; it is currently unknown exactly what those conditions are, but they likely involve a mix of temperature and precipitation. Additionally, DeBeque phacelia uses only self-fertilization for reproduction (Langton 2015, p. 11), which limits its genetic diversity (USFWS, 2024).

***Dispersal/Migration***

**Dispersal**

Adult: Low (USFWS, 2010)

**Dispersal/Migration Narrative**

Adult: Numbers of flowering plants fluctuate, but they do not disperse seeds beyond the existing patches of unique soil that are separated from one another by a few yards or several miles (Ewing 2008b, map) (USFWS, 2010).

***Population Information and Trends***

**Population Trends:**

Unknown (NatureServe, 2015)

**Number of Populations:**

26 (USFWS, 2024)

**Population Size:**

10,000 - 100,000 individuals (NatureServe, 2015)

**Additional Population-level Information:**

To discern the nuances in conditions that occur across the range of the species and in the stressors that are influencing these conditions, we analyzed the resiliency, redundancy, and representation of DeBeque phacelia in five analytical units (AUs) (Figure 1). Boundaries for these AUs incorporate all known suitable and occupied habitats and are delineated by natural geological features (e.g., soil type) and a generalization of management boundaries. The 5 AUs are delineated around 26 known element occurrence (EO) areas, as defined by the Colorado Natural Heritage Program (CNHP 2020, entire). EOs are occupied or previously occupied habitat that contributes or potentially contributes to the persistence of the species at a location (CNHP 2020, entire). Our SSA report (Service 2022, entire) includes 25 EOs; however, since completion of the SSA report, we received updated information from CNHP that included an additional EO. Therefore, we are using the current information indicating 26 EOs in this document, and future updates to the SSA report will incorporate this new information. The addition of this newest EO did not change the delineation of the 5 AUs described in the SSA. (USFWS, 2024)

**Population Narrative:**

Vulnerable to changes in habitat conditions, especially surface disturbances such as trampling of soil. An annual species whose population size varies widely from year to year. Because Phacelia submutica is adapted to a very specific geologic substrate and habitat type, a range extension is unlikely. Approximately 35,000-40,000 individuals have been documented within 21 of the 22 occurrences. However, this species is a seed-banking annual with numbers of visible plants varying drastically from year to year. There are 22 principal occurrences documented in the Colorado Natural Heritage Program database. Six of the occurrences have not been observed in over 20 years (as of 2012). The USFS Conservation Assessment documents 40 occurrences (Ladyman 2003). It is likely that this discrepancy in the total number of occurrences is because some of the sites reported by Ladyman are represented in the Heritage database as portions of other occurrences and not reported separately (NatureServe, 2015). Low resileinct, representation and redundancy are based on the low number of known populations, the relatively narrow geographic area this species inhabits and the variability in numbers from year to year. Across its limited range DeBeque phacelia currently has multiple individuals occurring in 25 separate EOs spread across five AUs (Service 2022, pp. 4–5). Redundancy for narrow endemic species is inherently limited; however, DeBeque phacelia plants are distributed broadly across the range of the species in the five defined AUs, providing redundancy throughout its small geographic range, especially given that the only plausible catastrophic event is prolonged extreme drought (Service 2022, p. 33). DeBeque phacelia's broad distribution and multiple moderately resilient AUs contribute to its ability to withstand catastrophic events. Additionally, BLM's ACECs reduce the influence of the stressors of OHV use and oil and gas development in 63 percent of the species' currently occupied range; approximately 359 acres of occupied DeBeque phacelia habitat and nine of the 25 DeBeque phacelia EOs occur within BLM ACECs. A BLM ACEC is a designation that highlights an area where special management attention is needed to protect important historical, cultural, and scenic values, protect fish and wildlife, or protect other natural resources. One of the eight EOs in the South Shale Ridge AU is located in the Pyramid Rock ACEC, which is intended specifically for the preservation of habitat for plant species, including DeBeque phacelia. This area is fenced and closed to livestock use; motorized, mechanized, and equestrian use; and hiking (BLM 2015, p. 31). It is unlikely that any of the ACEC designations will be withdrawn in the foreseeable future (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Oil and gas development (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Increasing oil and gas development in the Piceance Basin is a significant concern in the recovery of the species. About 95 percent of occupied habitat is on BLM lands leased for energy extraction (Service 2012). Ongoing energy development activities include well pad and road construction, installation of pipelines, and construction of associated buildings, holding tanks, and other facilities. Oil and gas pipelines and well pads are present within thirteen EOs (Service 2012). Several pipelines and pipeline right-of-ways already exist within 20 ft (6 m) of DeBeque phacelia EOs (Lincoln 2008, pers. comm.; Service 2012). Roads used for energy extraction bisect and cross the edges of eleven EOs (Service 2012) (USFWS, 2013).

**Stressor:** Utility and Energy Corridors: (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Utility and energy corridors provide pathways for future pipelines and electrical transmission lines. A portion of the designated Westwide Energy Corridor crosses 22,404 ac (9,066.6 ha) of BLM land within the range of DeBeque phacelia (see Figure 3) (Service 2012). Eight of the 20 EOs and 13 percent of critical habitat are within the Westwide Energy Corridor (Service 2012). Continued development of pipeline and transmission lines within the energy corridor is likely to affect DeBeque phacelia and its habitat (USFWS, 2013).

**Stressor:** Livestock Use and Trampling (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Potential threats related to livestock, deer, and elk use include the direct effects from trampling, and the indirect effects of habitat degradation. Ninety percent of DeBeque phacelia EOs are under management by the BLM as a grazing allotment (Service 2011a). Livestock trampling has occurred or is a threat at 14 EOs (CNHP 2010). Livestock can easily trespass from BLM or private grazing allotments onto USFS property where grazing is not allowed. This has been documented at two occurrences, one obtaining frequent disturbance from its proximity to a pond (Langton 2012). No research or monitoring has been conducted to evaluate the effects of livestock, deer, or elk use on DeBeque phacelia. However, the deleterious effects of livestock on western arid ecosystems are well documented (Milchunas et al. 1992; Jones 2000). Some of the adverse effects from livestock include changes in water infiltration due to soil compaction (Jones 2000, Table 1); changes to the physical and structural properties of soils (Kinlock and Friedel 2002); disturbance to soil microbiotic crusts (Evans and Belnap 1999; Jones 2000); subsequent nonnative invasive plant invasions (Parker et al. 2006); and soil erosion from hoof action (Jones 2000). Effects from livestock grazing to DeBeque phacelia and its habitat are occurring will likely continue (USFWS, 2013)

**Stressor:** Off-Highway Vehicle Use (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Off-highway-vehicle (OHV) use occurs on lands throughout the range of DeBeque phacelia. OHV recreation has damaged plants and habitat at seven EOs (CNHP 2012). On Federal lands, vehicles stray from designated roads to climb clay barrens for recreational purposes (Johnston 2012; Mayo 2008d). OHV trespass has even been documented within the Pyramid Rock Natural Area and BLM Area of Critical Environmental Concern (ACEC). The ACEC is fenced with post and cable, and an information sign is posted near an access point. The visible effects of OHV recreation within DeBeque phacelia habitat has been seen to persist for several years (Johnston 2012). Surface disturbances from OHV recreation cause accelerated erosion, fugitive dust production, soil compaction, sedimentation, and potentially irreversible changes to soil physical properties and chemistry (Iverson et al. 1981; Pagliali et al. 2003). Additionally, these changes in the soil environment can affect ecosystem function (DeFalco 2009. OHV use is expected to increase in the region with the construction of additional roadways for energy development and the increasing popularity of OHV recreation. With OHV recreation within the range of the species, direct losses of plants and the seed bank, as well as indirect affects to the species and its habitat will continue to occur (USFWS, 2013).

**Stressor:** Invasive Nonnative Plants (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The threat from invasive nonnative plant species (weeds) is a growing concern in the recovery of DeBeque phacelia. Weeds have been documented at 15 EOs (CNHP 2012a). Disturbances such as roads, grading, and livestock grazing generally introduce and spread exotic species (Gelbard and Belnap 2003). Weeds invade and alter all types of plant communities, sometimes resulting in nonnative plant monocultures that support little wildlife or native plants (D’Antonio and Vitousek 1992; Olson 1999; Mooney and Cleland 2001). Many experts believe that, following habitat destruction, nonnative invasive plants are the next greatest threat to biodiversity (Randall 1996). Nonnative invasive plants alter different ecosystem attributes including geomorphology, fire regime, hydrology, microclimate, nutrient cycling, and productivity (Dukes and Mooney 2004). Species known to occur within DeBeque phacelia habitat include cheatgrass (Bromus tectorum), bur buttercup (Ranunculus testiculatus), and annual wheatgrass (Eremopyrum triticeum). These weeds are prevalent on public and private lands within the range of the DeBeque phacelia. Recent data suggest that weed cover in DeBeque phacelia sites is related to distance from roads, while the number of flowers was found to be higher at distances away from roads (BioLogic 2011). The control of weeds on public lands, especially around well pads, utility corridors, and roads, may also pose a danger to DeBeque phacelia. For example, herbicide drift from well pad spraying has led to the mortality of Colorado hookless cacti near DeBeque (Perkins 2012, pers. comm.) (USFWS, 2013).

**Stressor:** Water Reservoirs (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat

**Narrative:** Two water reservoir projects known as Roan Creek and Sulphur Gulch were proposed within potential and occupied habitat of DeBeque phacelia (Bray and Drager 2008, pers. comm.; Grand River Consulting Corporation 2009). The proposals were withdrawn and are not imminent. However, the sites have been identified as potential reservoir locations that could be developed within 20 years if warranted by increased demands for water. Increased demands are likely, depending on the oil shale market, urban development in Colorado, and less (or altered) precipitation due to climate change. If developed, construction and inundation of these reservoirs would permanently destroy DeBeque phacelia plants and habitat within the project areas (USFWS, 2013).

**Stressor:** The Inadequacy of Existing Regulatory Mechanisms (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat/loss of individuals
**Narrative:** Removal, damage, or destruction of plants on private lands is not prohibited under the Endangered Species Act (Act). We are not aware of any state, county, city, or local laws, ordinances or zoning that provide for the protection or conservation of DeBeque phacelia or its habitat. Though no state regulations protect rare plants in Colorado, the Colorado Natural Areas Program manages a State Natural Area on BLM land protecting 510.9 ac (206.7 ha) of the species' habitat within the Pyramid Rock population. This agreement between Colorado Natural Areas Program and the BLM can; however, be terminated with a 90-day written notice by either party. Additional habitat on state land includes 7.5 ac (3 ha) of the Anderson Gulch population. This population contains the only "A"- ranked Elemental Occurrence (CNHP 2012a) meaning it has excellent estimated viability/ecological integrity. The majority of this population (90 percent) is within the Piceance Creek State Wildlife Area and is managed by Colorado Parks and Wildlife (USFWS, 2013).

**Stressor:** Climate Change and Drought (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** According to the Intergovernmental Panel on Climate Change (IPCC), "Warming of the climate system in recent decades is unequivocal, as is now evident from observations of increases in global average air and ocean temperatures, widespread melting of snow and ice, and rising global sea level" (IPCC 2007). Research indicates that warming is occurring more rapidly in the southwest region of the United States that elsewhere in the country with an increase of 1.5°F (0.8°C) since 1979 (Karl et al. 2009). Additionally in the west, the onset of spring has been advancing since the 1970's (Cayan et al. 2001). Annual temperature is predicted to increase approximately 2.2°C (4°F) in the southwest by 2050, with summers warming more than winters (Ray et al. 2008). Effects of climate change include persistent or prolonged drought conditions, changes in the vegetative community including increased invasions by weeds (Everard et al. 2010). Climate change is likely to affect many rare plant species because seed germination, seed dormancy, and persistence of the seed bank are all directly dependent on precipitation and temperature patterns (Levine et al. 2008). However, we do not understand how these changes may affect the long-term persistence of DeBeque phacelia because no information is available on the ecology of the species. Improved localized projections and precipitation models are also needed to better understand the threat of climate change to the species. The potential impacts of climate change will be significant at a global scale and we expect the predicted increased

drought conditions to affect the recovery of DeBeque phacelia (USFWS, 2013).

***Recovery***

**Reclassification Criteria:**
The preliminary plan lists three basic steps for recovery: 1: Protect and maintain all extant populations (USFWS, 2013).

2. Prevent of minimize habitat disturbing threats (USFWS, 2013).

Develop and implement rangewide monitoring (USFWS, 2013).

Recovery Priority Number: 14C

**Delisting Criteria:**
Recovery Criterion 1: Presence of DeBeque phacelia is maintained within at least 20 EOs across 5 analytical units (AUs). (USFWS, 2024).

Recovery Criterion 2: In at least 13 EOs, the number of aboveground plants remains at or above 500 individuals during years where aboveground growth is observed at known occurrences of DeBeque phacelia over a 15-year period. (USFWS, 2024)

Recovery Criterion 3: Maintain habitat quality, as measured by low (less than 20 percent) vegetative cover and high soil functional integrity, within known occupied habitat for DeBeque phacelia across all 5 analytical units (AUs) over a 15-year period. (USFWS, 2024)

Recovery Criterion 4: Maintain or improve existing regulatory mechanisms and associated protective measures for the 9 EOs within currently designated ACECs. For EOs on Federal lands outside of these ACECs, new or amended land management designations may include adequate protective measures for DeBeque phacelia and its habitat to reduce or ameliorate threats associated with soil disturbance and non-native, invasive plant species. On lands outside of Federal management, additional protective measures may include formal land management designations, management agreements, conservation agreements, easements, or other conservation plans or mechanisms. (USFWS, 2024)

Recovery Criterion 5: All AUs are represented in an ex-situ seed collection that is managed according to the Center for Plant Conservation guidelines (Guerrant et al. 2004, entire). The ex-situ seed collection should contain existing levels of genetic diversity (representation) of DeBeque phacelia across the species' range. (USFWS, 2024)

**Recovery Actions:**
- Protection of Extant Populations and Habitat: Establish and implement protective measures for all known populations (USFWS, 2013).
- Threats Abatement: Implement protective measures such as fencing, controlled management of livestock use, nonnative species control and additional measures to avoid or minimize impacts to the species and its habitat (USFWS, 2013).
- Threats Abatement: Coordinate with land managers, project proponents, and other partners early in the planning process to limit direct and indirect effects of oil and gas development,

grazing, OHV recreation, weeds, and additional threats that arise (USFWS, 2013).

- Threats Abatement: Work with land management agencies and other partners to formally establish land management designations to provide for long-term protection of populations and habitat (USFWS, 2013).
- Threats Abatement: Ensure that additional oil and gas leases avoid or take into consideration occupied and suitable habitat (USFWS, 2013).
- Threats Abatement: Consider installing livestock exclosures for both protection and monitoring purposes (USFWS, 2013).
- Surveys and Monitoring: Complete a comprehensive survey throughout the species' range, including areas designated as "potential habitat". Survey results should provide an accurate population estimate and allow us to identify core population areas so we can more effectively protect the species (USFWS, 2013).
- Surveys and Monitoring: Establish a survey protocol to identify areas of suitable habitat during years in which few above-ground plants are found. This protocol must take into account an evaluation of habitat components that support DeBeque phacelia (USFWS, 2013).
- Surveys and Monitoring: Establish a long-term monitoring plan to document rangewide population demographics and trends, and quantify the affects from threats. An adaptive management approach that uses feedback from implemented, site-specific recovery tasks should be integrated into the plan to inform recovery activities (USFWS, 2013).
- Surveys and Monitoring: Gain permission from landowners to survey for DeBeque phacelia on private lands with potential habitat (USFWS, 2013).
- Research: Continue research into DeBeque phacelia life history and ecology, including pollination biology, seed bank density, seed bank longevity, seed germination ecology, and habitat and soil requirements (USFWS< 2013).
- Research: Study population genetics and demographics (USFWS, 2013).
- Research: Conduct a population viability analysis (USFWS, 2013).
- Research: Conduct investigations that project DeBeque phacelia vulnerability and response to climate change (USFWS, 2013).
- Research: Improve our understanding of livestock and native ungulate grazing impacts (USFWS, 2013).
- Research: Monitor changes in invasive species prevalence and conduct research on impacts to DeBeque phacelia (USFWS, 2013).
- Research: Continue to refine a survey protocol for delineating suitable habitat (USFWS, 2013).
- Research: Continue to analyze the effects of dispersed oil and gas development and roads (USFWS, 2013).
- Seed Banking: Store genetic material in the form of seed in an appropriate repository to provide a back-up supply of genetic stock that represents as much of the available genetic diversity within the species as possible (USFWS, 2013).
- Priority 1 Actions: 1. Conduct primary research to fill information gaps on DeBeque phacelia ecology and inform development of monitoring methods (Criteria 1, 2, 3, and 4). 2. Develop standardized methodology for data collection and analysis to monitor all DeBeque phacelia EOs across all 5 AUs (Criteria 1, 2, 3, and 4). 3. Maintain or augment all extant DeBeque phacelia populations (EOs) on Federal and State lands in all five AUs (Criteria 1, 2, 3, and 4). 4. Develop ex-situ (off-site) collections of seeds to preserve DeBeque phacelia genetic diversity (representation) and provide the capability to augment existing populations, if

necessary (Criterion 5). (USFWS, 2024)

- Priority 2 Actions: 5. Survey for additional populations of DeBeque phacelia (Criteria 1 and 2). (USFWS, 2024)
- Priority 3 Actions: 6. If there is a population decline or loss (e.g., based on the results of Recovery Actions 1 and 2), develop and implement a range-wide strategy for population augmentation, or if necessary, re-introductions (Criteria 1, 2, and 3). (USFWS, 2024)

# SPECIES ACCOUNT: *Phlox hirsuta* (Yreka phlox)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

Cespitose perennial subshrub from a stout, woody base. Stems stout, to 1.5dm tall. Herbage copiously hirsute with long, jointed hairs. Leaves crowded Blooms April-June. (NatureServe, 2015)

**Taxonomy**

Elias Nelson (1899) described P. hirsuta based on a collection made by Edward L. Greene in 1876. A complete nomenclatural history can be found in Appendix 1 of the Recovery Plan for Phlox hirsuta (Yreka Phlox) (U.S. Fish and Wildlife Service 2006). No changes in taxonomy have occurred since the time of listing (USFWS, 2007).

**Historical Range**

Phlox hirsuta is known to occur at five locations, which are referred to as the “China Hill,” “Soap Creek Ridge,” “Cracker Gulch,” “Greenhorn Creek,” and “Jackson Street” occurrences. In addition, the locality information from a single 1930 collection indicates a possible historical location in the vicinity of Etna or in the vicinity of Echo Mill, near Soap Creek Ridge (California Department of Fish and Game 1986; J. Molter in litt. 2001; Appendix 1, prepared by F. Lang in U.S. Fish and Wildlife Service 2006). A P. hirsuta location or occurrence is defined as a group of at least 200 individual plants that is separated from any other P. hirsuta locality by at least 0.40 kilometer (0.25 mile). (USFWS, 2007)

**Current Range**

In and near the towns of Yreka and Etna in Siskiyou County, northern California (USFWS 1995). Range extent is approximately 34 sq mi. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Reclassification Criteria:**

Recovery Priority Number: 2C

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Future actions will focus on securing and permanently protecting four (up to six) Yreka phlox occurrences and ameliorating ongoing threats of invasive weeds. Work has been initiated on each of the actions listed below. • Funding is needed to purchase, or establish conservation easements on, Cracker Gulch, the northern portion of Soap Creek Ridge, and Greenhorn Creek Occurrence properties from willing sellers who have indicated their strong interest in conserving Yreka phlox habitat in perpetuity. • Complete the cooperative agreement with the Siskiyou Land Trust to approach Greenhorn Creek property owners who might wish to establish conservation agreements or easements on several additional scattered properties where Yreka phlox occurs. • Continue to cooperate with the City of Yreka and the County to protect populations from off-road vehicle trespass and invasive non-native weed infestation. • Collect and accession seeds from each Yreka phlox occurrence at the Rae Selling Berry Seed Bank and California Botanic Garden. • Consult, through section 7 of the Endangered Species Act, with the Klamath National Forest on the effects to Yreka phlox of the 2022 McKinney Fire suppression actions, especially with respect to the introduction of non-native invasive weeds on contingency fire lines (USFWS, 2024).

# SPECIES ACCOUNT: *Phlox nivalis ssp. texensis* (Texas trailing phlox)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 09/30/1991; Southwest Region (Region 2) (USFWS, 2016)

**Physical Description**

The Texas trailing phlox is an evergreen perennial that forms clumps (but seldom mats). The plants are herbaceous or subshruby. Stems tend to spread along the ground surface, and are erect only for the terminal 2—15 centimeters (0.8-5.9 in). Leaves are needlelike to lanceolate, densely packed on the stem (producing an appearance somewhat like a juniper seedling), usually less than 1.5 cm (0.6 inch) long, and more or less glandular pubescent. Older stems have smaller and darker green leaves, and typically lie directly on the ground surface. Young stems produce the flowers, are more or less erect, and have longer, slightly wider, and lighter—green leaves. Inflorescences are 3-12 flowered cymes, terminal on (typically) the tallest stems. The calyx is tubular with five sepals, which are fused for most of their length. The corolla is rotate, with a tube approximately 1.5 centimeters (0.6 inch) long. The five petals, each about 1 centimeter (0.4 inch) long, are pink to magenta in color, and darker near the throat. Petals are reported to be white in some individuals. Pistils have three styles, and the ovule is usually single. Fruits are achene— like, and apparently indehiscent (this character description of the fruit differs from previously published summaries). Flowering occurs from March to May. (USFWS, 1994)

**Taxonomy**

Texas trailing phlox belongs to the family Polemoniaceae, which includes such plants as sweet William, Jacob's ladder, Texas plume, and phlox. Texas trailing phlox is one of two subspecies recognized in P. nivalis. The nominal subspecies (ssp. nivalis) occurs in pine/oak barrens or scrub on the Coastal Plain or Piedmont, from Alabama to Florida and north to Virginia. Flowers of this subspecies are typically white or pale pink, with plants of forma roseiflora having deep rose or magenta flowers (Fernald 1970). According to Wherry (1955), the major difference between the two subspecies is the presence of minute glandular hairs on texensis, and their absence on nivalis. Currently, the nearest known populations of ssp. nivalis to those of texensis are located more than 1000 kilometers (600 miles) eastward in northern Florida. Wherry included Phlox nivalis in series Subulatae, along with Phlox subulata and Phlox oklahomensis. Both of the latter species have gross morphological features similar to that of P. nivalis, but Bogler (1992) expressed the opinion that, based on Texas specimens, fl. nivalis is most similar to P. oklahomensis. Populations of P. oklahomensis found in Texas are disjunct from the main range of P. oklahomensis (located further north in Oklahoma), lying approximately equidistant between it and range of P. nivalis ssp. texensis. (USFWS, 1994)

**Historical Range**

Although its historic range includes Hardin, Polk, and Tyler Counties of Texas, the Texas trailing phlox is presently known from only two sites in southeast Texas. (USFWS, 1994)

**Current Range**

Endemic to the Pineywoods of the West Gulf Coastal Plain of east Texas. Texas trailing phlox is presently known from only two sites, one each in Tyler and Hardin counties, Texas. (USFWS, 1994; NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Asexual (vegetative) and sexual (outcrossing) (USFWS, 1994)

**Breeding Season**

Adult: Flowering generally occurs between late March and early April (Ajilvsgi 1979, Poole et al. 2007, U.S. National Park Service (USNPS) 2015), sometimes extending into May depending on precipitation and management (i.e. prescribed burning). (USFWS, 2018)

**Other Reproductive Information**

Adult: Flies, bees, and butterflies have been observed at flowers. Based on the plant's floral structure, butterflies are the most likely pollinators. (USFWS, 1994)

**Reproduction Narrative**

Adult: Flies, bees, and butterflies have been observed at flowers. Based on the plant's floral structure, butterflies are the most likely pollinators. Typically, no more than one seed is produced per flower and, based on limited field observation, fruit set is low. An individual plant may have 3 to 50+ flowers and primarily depending on number of flowers. Its low population numbers are likely due to a combination of anthropogenic factors and a naturally low reproductive rate. (USFWS, 1994); Little is known about the reproduction of the Texas trailing phlox. Their populations are small and consist of a few scattered, inconspicuous individuals (Mahler 1980). This could make asexual reproduction very important for recruitment (Parker and Warnock 1993) but this frequency is unknown. Texas trailing phlox is mostly an outcrossing species pollinated by moths and butterflies (Bogler 1992). However, it is not known whether flowers are obligate or facultative outcrossers (Maxey and Warnock 1996, USFWS 1995). Pollinators include carpenter bees (M. Quinn, pers. comm. 2008), Nessus sphinx moth (Amphion floridensis) (G. Grant, pers. comm. 2017), and Tiger swallowtail butterfly (Papilio glaucus) (G. Grant, pers. comm. 2014). Other bees and butterflies, as well as flies could also serve as pollinators (USFWS 1995, Maxey and Warnock 1996, TPWD 1997). Poole et al. (2000) noted that there is the potential of large terrestrial arthropods to act as pollinators. Also, seed and seedling biology (seed maturation, dormancy, seed viability) are largely unknown for the Texas trailing phlox. We lack information about seed dispersal; however, dehiscence could play a role in local dispersal. (USFWS, 2018)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Forest/woodland, savanna, shrubland/chaparral, woodland - hardwood (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Texas trailing phlox occurs in southeast Texas in the southern portion of the Pineywoods vegetational area. Within the range of Texas trailing phlox, annual precipitation averages 125 cm (49 in), with no pronounced summer drought. The average frost—free period is 244 days (Bogler 1992), from early March through mid-December (Larkin and Bomar 1983). Elevation ranges from 9 to 75 meters (30-240 feet), and topography is nearly level. This species prefers deep, sandy soils in fire-maintained openings in upland longleaf pine (Pinus palustris) savannahs or post oak-bluejack oak (Quercus stellata-Q. incana) woodlands. Field studies suggest that sandy surface soil, coupled with moisture-bearing clays or sandy-clay soils at depths of 0.5-2 meters (1.6-6.6 feet), provide the best soil structure for Texas trailing phlox. Overstory cover at sites of Texas trailing phlox occurrence typically ranges from 25-75 percent. Understory and shrub cover is less than 25 percent at most plant sites, but ranges up to nearly 100 percent at some. However, the best growth of Texas trailing phlox is seen at the lower percentages of understory and shrub cover. The degree of ground cover associated with optimum growth of Texas trailing phlox appears to be 25-75 percent. Litter depth is generally 3-5 cm (1.2-2.0 in), and coverage is usually 75-100 percent. The most common canopy trees associated with Texas trailing phlox are Pinus palustris, P. elliottii, R. taeda, Ouercus incana, Q. falcata, and Q. stellata and Carva texana. (USFWS, 1994; NatureServe, 2015)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available.

***Population Information and Trends***

**Population Trends:**

Long-term trends indicate a decline of 30 to 70%, whereas short-term trends suggest a relatively stable population (NatureServe, 2015)

**Resiliency:**

Populations were considered to have high resiliency when they: contained at least 600 individuals, exhibited plant separation less than 2 kilometers (1.24 miles), contained canopy cover between 5-25 percent, limited shrub layer cover to 10-25 percent, maintained litter depths of 3-5 centimeters, and received an annual precipitation rate of 48-60 inches (121.9-152.4 centimeters). Frequent fire exposure (every 1-2 years) serves as a critical component to sustaining healthy individual plants within the longleaf pine ecosystem, as well as other native vegetation associated with the Pineywoods. Using all of these factors, seven extant populations were ranked either low or moderate in current resiliency (USFWS, 2020).

**Representation:**

We lacked genetic studies specific to Texas trailing phlox examining variability within and among its' populations. Further genetic analysis of Texas trailing phlox could determine to what extent, if any, the impact of range contraction contributes to the loss of the genetic variability. Due to an absence of genetic information informing our measure of representation, we used ecological diversity as a surrogate for genetic diversity. We assumed no ecological or niche diversity at any of the specific sites therefore, the representation of Texas trailing phlox is extremely low (USFWS, 2020).

**Redundancy:**

For the Texas trailing phlox, we measured redundancy as an adequate number of resilient populations that provided an exchange of genetic material and foraging opportunities for pollinators. Due to the low or moderate resilience rankings of most populations, the few number of extant populations, and that these populations are distributed throughout a restricted range, we estimated that both connectivity for pollinating species and exchange of genetic material is limited. Therefore, we rank the overall redundancy of Texas trailing phlox as low (USFWS, 2020)

**Number of Populations:**

7 (USFWS, 2018)

**Population Size:**

<750 individuals (NatureServe, 2015)

**Population Narrative:**

Long-term trends indicate a decline of 30 to 70%, whereas short-term trends suggest a relatively stable population. Although its historic range includes Hardin, Polk, and Tyler Counties of Texas, the Texas trailing phlox is presently known from only two sites in southeast Texas. Although nineteen collections of Texas trailing phlox are reported in historical records, these appear to originate from only six definable population systems, however, only two are extant populations. Reintroductions are being attempted in areas where there were historic populations. (NatureServe, 2015); When the species was listed as endangered in 1995, there were only 2 known populations in southeast Texas, one in Hardin County (the type locality) and another from Tyler County. Since then, 17 populations were observed in Hardin, Polk, and Tyler counties, however, these are considered extirpated. The USFWS Recovery Plan (1995) provides a definition of a “population” and a “plant”. Based on this definition, the USFWS recognizes that there are 7 known extant populations in Hardin, Polk, and Tyler counties that include: 1) Sunflower road (Element of Occurrence (EO) 17) and Big Thicket National Preserve (BTNP), Big Sandy Creek reintroduction; 2) Farm-to-Market 1276 right-of-way (EO 21); 3) Campbell Units (EO 22 and 23); 4) The Nature Conservancy, Roy E. Larsen Sandylands Sanctuary (EOs 3, 5, 13); 5) Resource Management Services (EO 9); 6) Hancock Timber (introduced); and 7) BTNP, Turkey Creek reintroduction. Land ownership includes private, public, and state lands. (USFWS, 2018). These extant EO ID’s remain owned and managed by TNC Sanctuary staff. The EO ID was last surveyed for Texas trailing phlox in 2023. Prior to that, the Sanctuary staff conducted a thorough assessment of extant populations in 2019, surveying 68 sites (61 previously recorded and 7 new sites) counting 304 plants (W. Ledbetter, pers. comm. 2019). Dr. C. Edwards and Dr. G. Yatskievych conducted a thorough genetic analysis of the Texas trailing phlox (Edwards 2022, entire) which included sampling from known Sanctuary plants. More information about their research is detailed in the Conservation Measures section of this review. Edwards, Yatskievych, TNC, and the Service visited these EO ID’s between March 30 and April 1, 2021, and found 300+ individual plants (S. Benedict, pers. comm. 2021) at 31 global positioning position (GPS) locations (Strong 2023, redacted site info excel sheet). A site assessment was not completed in 2022; however, in April and May of 2023, TNC staff counted 255 plants across the management units (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Habitat loss (USFWS, 1994)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat loss has been caused by housing development; land—clearing and site preparation for pine plantations and pasture; encroachment of a closed canopy forest onto formerly open forest or savanna due to fire suppression; exposure to herbicides; and activities associated with pipeline, powerline, railroad, and highway construction. (USFWS, 1994)

**Stressor:** Human activities (USFWS, 1994; NatureServe, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Factors adversely affecting the habitat of Texas trailing phlox, combined with other potentially adverse activities such as off-road vehicle use, illegal dumping, burning of debris, and commercial take of plants, may continue to restrict the species to critically low population levels. Current threats include continued habitat loss due to canopy closure/encroachment of hardwood trees and soil disturbances associated with human activities. (USFWS, 1994; NatureServe, 2015)

**Stressor:** Clearcuts (NatureServe, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Much of this taxon's habitat had been clearcut and converted to slash-pine plantations, urbanized, and/or altered by fire suppression. (NatureServe, 2015)

***Recovery***

**Reclassification Criteria:**
1. At least 12 self-sustaining populations, distributed across the known geographic range of Hardin, Polk, and Tyler counties, Texas, are established. There should be at least three populations located in each county in order to provide adequate representation. The remaining three populations can be distributed in any fashion among the available habitat across the geographic range. A population will be considered self-sustaining if it reaches and maintains a population number of at least 600 reproductive individual plants. A population is considered a group of plants separated by a distance of at least 2 kilometers (km) (1.2 miles (mi)) from any other Texas trailing phlox plants, as to promote healthy populations of pollinators and the exchange of genetic material. A “plant” is defined as a cluster of Texas trailing phlox stems with no above-ground connection to other groups of stems, and separated by a distance of at least 5 decimeters (dm) (1.6 feet (ft)). Habitat will be of sufficient quality as defined by Maxey and Warnock (1996), that it promotes the success of Texas trailing phlox. The numbers of plants and populations must be verified through adequate monitoring. Populations can include both natural and ex-situ (introduction and reintroduction) efforts. To be considered under this criterion, the habitats of Texas trailing phlox must be managed in a manner that promotes the

continued survival of the subspecies. Management can include, but is not limited to, prescribed burning and/or restoration of longleaf pine habitat. (USFWS, 2019)

2. Sufficient, documented protection measures and management plans have been established for these 12 self-sustaining populations. Long-term, binding agreements that aim to conserve and protect the subspecies, and its habitat, are preferred. Private lands should be a priority focus for these agreements; however, protected areas can and should include lands owned by federal, state, or local government agencies. (USFWS, 2019)

Recovery Priority Number: 3

**Delisting Criteria:**
1. To secure redundancy of the subspecies into the foreseeable future, we conclude that more populations would be needed for delisting. Therefore, at least 15 populations distributed across the known geographic range of Hardin, Polk, and Tyler counties, Texas, have been established. At least four populations should be located in each of the counties in order to provide representation of the potential genetic and ecological diversity of the subspecies. The remaining three populations can be distributed in any fashion among the available habitat within the range. A population will be considered self-sustaining if it reaches and maintains a population number of at least 600 reproductive individual plants. Ex-situ efforts should be focused within the known geographic range unless habitat suitability mapping proves otherwise. Habitat will be of sufficient quality, as defined by Maxey and Warnock (1996), that it promotes the success of Texas trailing phlox. (USFWS, 2019)

2. Monitoring efforts indicate that the MVP level of 600 reproductive plants at each population has remained stable or has increased over a monitoring time period of 30 years. Monitoring must be routine in order to gauge subspecies' viability. Site-specific management plans should be aligned with landscape scale strategies to attain optimal habitat quality conditions that promotes the Texas trailing phlox. (USFWS, 2019)

**Recovery Actions:**
- Monitor, protect, and manage existing populations. (USFWS, 1994)
- Locate or establish additional populations of sufficient number to meet downlisting criteria. (USFWS, 1994)
- Obtain biological data necessary to refine downlisting criteria. (USFWS, 1994)
- Characterize suitable habitat of plant and determine the management regime needed to preserve suitable habitat. (USFWS, 1994)
- Determine limiting factors on reproduction. (USFWS, 1994)
- Establish captive populations to protect genetic integrity. (USFWS, 1994)
- 1) Conduct Genetics Investigations: Conduct studies to determine genetic diversity of the Texas trailing phlox. Conduct studies to determine the genetic relatedness between individual plants within a population. Determine relatedness between populations across the species geographic range. Determine the relationship between Texas trailing phlox plants to Phlox oklahomensis, found in Texas, and to Phlox nivalis, found in Louisiana. Use this new genetic information to re-evaluate the criteria used in the Texas trailing phlox Recovery Plan to define a population and an individual plant. (USFWS, 2018)

- 2) Promote Landowner Stewardship and Outreach: Encourage awareness of Texas trailing phlox, its management needs within longleaf pine savanna habitat, and its habitat structure/composition. Develop outreach resources for landowners and land managers. Provide technical support for management, surveys, monitoring, and conservation efforts. Provide financial support for management and/or leverage funds for restoration and recovery efforts. (USFWS, 2018)
- 3) Monitor Extant Populations: Continue to monitor extant populations of Texas trailing phlox to assess species viability, habitat conditions, and management needs. Continue management on sites and acquire long-term conservation easements, where feasible, or conservation agreements. (USFWS, 2018)
- 4) Survey for New Populations: Develop a habitat suitability map to assist in identifying new parcels of land for surveying, restoration, and ex-situ opportunities. Outreach to new landowners and land managers. Conduct surveys of potential Texas trailing phlox habitat, with landowner permission, throughout species' known geographic range. (USFWS, 2018)
- 5) Revisit Historic Populations: Use herbarium records, field data, and expert input to determine and revisit sites presumed to be extirpated. Coordinate with landowners and land managers to access sites. Educate landowners and land managers about the Texas trailing phlox and its habitat. Conduct surveys of suitable areas with permission. Submit data to TPWD's Texas Natural Diversity Database. (USFWS, 2018)
- 6) Actively Manage Habitat: Develop management plans with landowners and land managers with the primary goal of restoring or maintaining longleaf pine savanna habitat for Texas trailing phlox. Investigate plant response to management practices (prescribed burning, mowing, thinning), conducted in various frequency and intensity schemes. (USFWS, 2018)
- 7) Develop Reintroduction Plan: Develop a Controlled Propagation and Reintroduction Plan (per USFWS policy). Limit reintroduction work to the known geographic range of the species (Hardin, Tyler, Polk counties). Coordinate with the Center for Plant Conservation Institutions' guidelines for augmentation procedures. (USFWS, 2018)
- 8) Conduct Essential Life History Studies: Investigate pollinating species of Texas trailing phlox and promote pollinator conservation. Conduct seed biology (seed maturation, fecundity, seedbank) and seedling studies (longevity of plant, mortality). Encourage collaboration, ingenuity, financial support, and technical support between partners and the USFWS to conduct these studies. (USFWS, 2018)
- Conservation measures are not available.

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Future actions to aid in the recovery of the Texas trailing phlox should focus on implementation of the following recovery actions: 1.2 Provide immediate protection for existing habitat areas. Most of the extant populations outside of the TNC Sanctuary are declining in abundance and most are on private lands. Long-term mechanisms such as cooperative agreements for conserving and protecting genetically important populations is essential and should be explored with landowners and land managers. 1.3 Contact landowners and land managers of all Texas trailing phlox sites. Changes in landowner/land managers at several of the sites, many of which are privately owned, have occurred. Contact with the new owners at the Tyler County reintroduction site were made in June 2023 and a potential site visit was discussed for fall 2023. Each land steward should be made aware of the ecologic and genetic importance of the Texas trailing phlox. The Service should seek out opportunities to build and strengthen relationships with new land stewards and continue to work with and foster existing partnerships. 1.4 Work with landowners to develop and implement compatible management for Texas trailing phlox. Assist and/or develop management plans with land stewards with the primary goal of restoring and maintaining longleaf pine savanna habitat for the species. Investigate plant response to management practices (prescribed burning, mowing, thinning), conducted in various frequency and intensity schemes. Encourage collaboration, ingenuity, and financial and technical support between partners and the Service to conduct on the ground management and track the response of these management actions. 1.4.3. Continue to seek landowner assistance with monitoring activities. Continue to actively engage with land stewards at extant sites to monitor and understand conservation needs. Verifying the status of the EO ID records considered to be unverified or historic are a priority. 1.5 Monitor Extant Populations. Continue to monitor extant populations, assessing species' viability, habitat conditions, management needs, and potential threats. 2.1 Search for new populations in suitable East Texas habitat. Develop a habitat suitability map to assist in identifying new parcels of land appropriate for surveying, restoration, and ex-situ opportunities. Using updated habitat suitability mapping and information, the Service should seek out and conduct searches for additional populations of Texas trailing phlox across its range. 3. Implement captive propagation program. Ensure collection of seed and/or plant material from populations where threats remain high, abundance is low, and/or genetic analysis suggested distinctiveness. Work with local Center for Plant Conservation partner to follow collection and storing procedures. 5. Investigate the reproductive biology of Texas trailing phlox including pollination (5.2) seed biology (5.3), and seedling studies (5.5). Conduct essential life history studies, but not limited to the abovementioned topics, should new biological needs arise for the species. Encourage collaboration between the Service, partners, and land stewards to foster ingenuity, financial and technical support to conduct such studies. 6. Investigate the response of Texas trailing phlox to various management techniques and types of disturbance. Assist in the development and implementation of studies aimed at investigating plant response to different types of management, conducted in various seasons, frequency, and intensity. Provide updates to land stewards and partners to better manage the Texas trailing phlox and its habitat throughout the range. Ensure that findings are made available to the public and other potential managers of longleaf pine savanna habitats. 8. Develop Reintroduction Plan. Develop a Controlled Propagation and Reintroduction Plan (per USFWS policy). Limit reintroduction work to the known geographic range of the species (Hardin, Tyler, Polk counties). 9. Implement public education efforts. Encourage awareness of Texas trailing phlox, its management needs within the longleaf pine savanna habitat, and its habitat structure/composition. Develop outreach resources for land stewards. Provide technical support for management, surveys, monitoring, and conservation efforts. Provide financial support for management and/or leverage funds for restoration and recovery efforts (USFWS, 2023).

# SPECIES ACCOUNT: *Physaria douglasii ssp. tuplashensis* (White Bluffs bladderpod)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 05/23/2013; Pacific Region (R1) (USFWS, 2016)

**Physical Description**

White Bluffs bladderpod is a low growing, herbaceous, perennial plant with a sturdy tap root and a dense rosette of broad gray-green pubescent leaves (WDNR 2010). The subspecies produces showy yellow flowers (USFWS, 2013a).

**Taxonomy**

Although specimens of this taxon were originally collected from a population in 1883, the plant material was in poor condition, no definitive identification could be made, and the plant was not recognized as a species at that time. The population was rediscovered in 1994, and was described and published as a species, Lesquerella tuplashensis, by Rollins et al. (1996, pp. 319–322). Based on molecular, morphological, phenological, reproductive, and ecological data, the conclusions in AlShehbaz and O'Kane (2002, p. 322) and Caplow et al. (2006, pp. 8–10) combining the genera Lesquerella and Physaria and reducing the species Lesquerella tuplashensis to Physaria douglasii subsp. tuplashensis, provide the most consistent and compelling information available to date (USFWS, 2013a).

**Historical Range**

In 1996, White Bluffs bladderpod was only known from a single population that occurred along the upper edge of the White Bluffs of the Columbia River in Franklin County, Washington (USFWS, 2013a). It is endemic to a small band about 17 km long by about 10 meters wide (NatureServe, 2015).

**Current Range**

White Bluffs bladderpod is still known only from the single population that occurs along the upper edge of the White Bluffs of the Columbia River, Franklin County, Washington (USFWS, 2013a). Extensive searches of suitable substrate elsewhere in Washington have been conducted but no other plants have been found (USFWS, 2004; NatureServe, 2015). – In the late 1990s the subspecies was described as occupying a narrow area 17 to 20-km long on the slopes and top of the White Bluffs. When the listing rule was revised, it was determined that the occupied area had likely shrunk due to threats and habitat changes in the southern part of the range (USFWS 2013b, p. 76998). The recent and current range of White Bluffs bladderpod is uncertain because there has not been a complete survey since 1997, only the northern part of the distribution is monitored. The northern part continues to be occupied but the status of the southern part is unknown. However, Refuges' outplanting efforts from 2013 to 2015 have resulted in at least a temporary range expansion within the Monument. As of 2020, the plants in the outplanting area were still successfully reproducing. The establishment of a self-sustaining population there could be essential to the continuation of the subspecies should there be catastrophic landslides where the main population occurs. (USFWS, 2020)

**Critical Habitat Designated**

Yes; 4/23/2013.

**Legal Description**

On April 23, 2013, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Physaria douglasii ssp. tuplashensis (White Bluffs bladderpod) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in Washington (78 FR 76995-77005; 78 FR 24008-24032).

**Critical Habitat Designation**

The critical habitat designation for Physaria douglasii ssp. tuplashensis includes one CHU in Franklin County, Washington. This species critical habitat encompasses approximately 2,033.4 acres (ac) (822.9 hectares (ha)) (78 FR 76995-77005; 78 FR 24008-24032).

White Bluffs bladderpod is only known from a single population that occurs in a narrow band approximately 10 m (33 ft) wide by 17 km (10.6 mi) long, at the upper edge of the White Bluffs of the Hanford Reach. The subspecies only occurs at the upper surface areas of a near-vertical exposure of paleosol (ancient, buried soil whose composition may reflect a climate significantly different from the climate now prevalent in an area). This surface material overlies several hundred feet of easily eroded sediments of the Ringold Geologic Formation, a sedimentary formation made up of soft Pleistocene lacustrine deposits of clay, gravel, sand, and silt (Newcomb 1958, p. 328). The upper part of the Ringold Formation is a heavily calcified and silicified cap layer that exists to a depth of at least 4.6 m (15 ft). This layer is geologically referred to as ‘‘caliche,’’ although it lacks the nitrate constituents found in true caliche. The caliche-like layer is a resistant caprock underlying a 275–305 m (900–1,000 ft) plateau extending north and east from the White Bluffs (Newcomb 1958, p. 330). The entire population of White Bluffs bladderpod is down-slope of irrigated agricultural land, and is being impacted to differing degrees by landslides induced by water-seepage (see Factor A). The potential for landslide is greatest in the southern portion of the subspecies’ distribution where irrigated lands are closer to, or directly adjacent to, the bluffs (Lindsey 1997, p. 12). In addition, field investigations have determined that Lesquerella (now Physaria) plants can be outcompeted by nonnative, weedy plant species associated with irrigation projects and other disturbance (TNC 1998, p. 5). Therefore, based on the information above, we identify the weathered cliffs at approximately 210–275 m (700–900 ft) above sea level of the White Bluffs of the Ringold Formation exposed by natural erosion as a physical and biological feature essential to the conservation for White Bluffs bladderpod. The habitat includes the adjacent cliff breaks, moderate to gentle slopes (<100 percent slope) to the toe of slope, and flat or gently sloping cliff tops with exposed alkaline paleosols. This habitat is stable with a minimal amount of landslide occurrence. This critical habitat unit was mapped using Universal Transverse Mercator, Zone 11, North American Datum 1983 (UTM NAD 83) coordinates. These coordinates establish the vertices of the unit boundaries. The map in this entry, as modified by any accompanying regulatory text, establish the boundaries of the critical habitat designation. The coordinates or plot points or both on which the map is based are available to the public at the field office internet site (http:// www.fws.gov/wafwo/HanfordPlants/ FLFCH.html), http:// www.regulations.gov at Docket No. FWS–R1–ES–2013–0012, and at the Service’s Washington Fish and Wildlife Office. You may obtain field office location information by contacting one of the Service regional offices, the addresses of which are listed at 50 CFR 2.2.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Physaria douglasii ssp. tuplashensis critical habitat consists of five components (78 FR 76995-77005; 78 FR 24008-24032):

(i) Weathered alkaline paleosols and mixed soils overlying the Ringold Formation. These soils occur within and around the exposed caliche-like cap deposits associated with the White Bluffs of the Ringold Formation, which contain a high percentage of calcium carbonate. These features occur between 210–275 m (700–900 ft) in elevation.

(ii) Sparsely vegetated habitat (less than 10–15 percent total cover), containing low amounts of nonnative or invasive plant species (less than 1 percent cover).

(iii) The presence of insect pollinator species.

(iv) The presence of native shrub steppe habitat within the effective pollinator distance (300 m (approximately 980 ft)).

(v) The presence of stable bluff formations with minimal landslide occurrence.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and that may require special management considerations or protection. All areas designated as critical habitat as described below may require some level of management to address the current and future threats to the physical and biological features essential to the conservation of Umtanum desert buckwheat. In all of the described units, special management may be required to ensure that the habitat is able to provide for the biological needs of the species. Further studies leading to an enhancement or reintroduction plan may be necessary to increase population size and prepare for recovery postwildfire. More research is needed to determine habitats most suitable for expansion of the current population. In summary, special management considerations or protections should address activities that would be most likely to result in the loss of Umtanum desert buckwheat plants or the disturbance, compaction, or other negative impacts to the species’ habitat. These activities could include, but are not limited to, recreational activities and associated infrastructure, off-road vehicle activity, dispersed recreation, wildfire, and wildfire suppression activities. Special management considerations or protection will conserve the primary constituent elements for the species. Management activities that could ameliorate these threats include, but are not limited to, the fire management plan that has been completed for the Hanford installation (DOE 2011, p. 93) and recently revised to incorporate more detailed management objectives and standards. Though not intended to specifically address Umtanum desert buckwheat, implementation of this plan will contribute to the protection of the primary constituent elements (and physical or biological features) by: (1) Using a map of ‘‘sensitive resources’’ on the site during implementation, including the location of Umtanum desert buckwheat habitat; (2) requiring a biologist to assist the command staff in protecting these environments during wildfire suppression efforts; and (3) restricting public access to the entire Umtanum desert buckwheat site, including the pollinator use area. Public access without security clearance is currently prohibited at the Umtanum desert buckwheat site, reducing the risk of trampling or crushing the plants by ORV use. Special management to protect the designated critical habitat areas and the features essential to the conservation of Umtanum desert buckwheat from the effects of the current wildfire regime may include preventing or restricting the establishment of invasive, nonnative plant species, post-wildfire restoration with native plant species, and reducing the likelihood of wildfires affecting the population and nearby plant community components. These actions may be achieved by detailed fire management planning by the DOE, including rapid response and mutual support agreements between the DOE, the Monument, the U.S. Department of the Army, Bureau of Land Management, and the Washington Department of Fish and Wildlife for wildfire control. These agreements should contain sufficient detail to identify actions by all partners necessary to protect habitat for Umtanum desert buckwheat from fire escaping from other ownerships.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (inferred from USFWS, 2013a)

**Lifespan**

Adult: 4 - 5 years (USFWS, 2013a)

**Breeding Season**

Adult: May - July (USFWS, 2013a)

**Reproduction Narrative**

Adult: In a presentation of preliminary life history studies, Dunwiddie et al. (2002, p. 7) reported that most individuals reach reproductive condition in their first or second year, most adult plants flower every year, and the lifespan of this short-lived subspecies is probably 4 to 5 years. Flowers are produced in May, June, and July (USFWS, 2013a).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Cliff, shrubland/chaparral (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 900 - 1,000 ft. elevation (USFWS, 2013a)

**Environmental Specificity**

Adult: Very narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Found on a dry, barren, vertical exposure of caliche (a hard, highly alkaline, highly calcalcareous substrate) capping a bluff (Hallock 2002; Washington Natural Heritage 2002). The environmental specificity is very narrow; it is known only from one extensive rock formation (the White Bluffs of the Columbia River), where the plants occur in a highly alkaline caliche-type cemented paleosol that caps several hundred feet of easily eroded alkaline lacustrine sediments

(USFWS, 2004). Terrestrial habitat is characterized as cliff or shrubland/chaparral (NatureServe, 2015). The uppermost part of the Ringold Formation is a heavily calcified and silicified cap layer to a depth of at least 4.6 m (15 ft.). This layer is commonly called ''caliche'' although in this case, it lacks the nitrate constituents found in true caliche. The ''caliche'' layer is a resistant caprock underlying the approximately 274–304 m (900–1,000 ft.) elevation (above sea level) plateau extending north and east from the White Bluffs (Newcomb 1958, p. 330) (USFWS, 2013a).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Number of Populations:**

1 (USFWS, 2020)

**Population Size:**

2,529 to 58,472 (USFWS, 2020)

**Population Narrative:**

The White Bluffs bladderpod population continues to fluctuate greatly among years, with an overall trend of consistently going up and down over time. The monitored portion of the population has ranged from an estimated 2,529 to 58,472 flowering plants since 2013. The size of the entire White Bluffs bladderpod population is uncertain because monitoring occurs only along permanent transects in an area totaling 3.7-km long in the northern part of the subspecies' range. A population viability analysis has not been done and therefore a minimum viable population size has not been estimated. It was suggested that there should be at least 10,500 reproductive individuals in the monitored portion for the population to be considered viable (Caplow 2003, p. 3-3) but as recently as 2015 and 2016 this threshold was not met. Therefore, small population size may continue to be a threat. (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Irrigation (NatureServe, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** About one-third of the population is located near or adjacent to irrigated land, where excess groundwater seepage has triggered mass-slope failures (landslides) in the past that obliterate the narrow blufftop soil band in which these plants are found; Lesquerella tuplashensis has not been found in areas disturbed by these landslides (USFWS 2004). Recent incorporation of the area into a national monument/national wildlife refuge may increase capabilities to mitigate this threat somewhat; however, irrigation-dependent farming continues in the area (NatureServe, 2015).

**Stressor:** Pesticide use (NatureServe, 2015)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Pollinators may be affected by use of agricultural pesticides nearby (USFWS, 2004; NatureServe, 2015).

**Stressor:** Invasive species (NatureServe, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Yellow star thistle (Centaurea solstitialis), a highly invasive exotic weed, has been documented in the vicinity (USFWS 2003 & 2004). A seed-predator insect has also been noted in recent years (USFWS, 2004), but it is not known if this is a natural phenomenon or an exotic species introduction (NatureServe, 2015). Cheatgrass is an introduced annual grass that is widely distributed in the western United States, and has been documented in the White Bluffs bladderpod population. Cheatgrass can outcompete native plants for water and nutrients in the early spring, since it is actively growing when native plants are initiating growth. It also completes its reproductive process and becomes senescent before most native plants (Pellant 1996, p. 1–2) (USFWS, 2013b).

**Stressor:** Off-road vehicles (NatureServe, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Off-road vehicles, including mountain bikes, have increased disturbance and erosion, and destroyed individual plants (F. Caplow, pers. comm. cited in USFWS 2003 & 2004) (NatureServe, 2015).

**Stressor:** Fire (USFWS, 2013b)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire is considered to be a threat to White Bluffs bladderpod, although the decline in population numbers after the 2007 fire indicated the population estimate was still within the known range of variability. Fire events tend to be large and unpredictable in the Hanford Reach (see Table 3) and can potentially affect large numbers of plants and significant areas of pollinator habitat. In addition, wildfire also impacts pollinator communities by directly causing mortality, altering habitat, and reducing native plant species diversity (USFWS, 2013b).

**Stressor:** Predation (USFWS, 2013b)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since 1996, some predation by larval insects on developing fruits of White Bluffs bladderpod has been observed. Larvae of a species of Cecidomyiid fly have been observed infesting and destroying flowering buds, and an unidentified insect species has been documented boring small holes into young seed capsules and feeding on developing ovules. However, the overall effect of these insect species on the plants or population is not known (TNC 1998, p. 5). Although insect predation may be a potential threat to White Bluffs bladderpod, more thorough

investigations are necessary to determine its significance to seed production (USFWS, 2013b).

**Stressor:** Utility lines (USFWS, 2020)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since the listing rule, one highly localized and largely temporary potential threat emerged. A 115 kilovolt electrical transmission line (Benton-Othello) crosses the White Bluffs in an area where the subspecies occurs. The line, owned by Avista Utilities (hereafter, Avista), was rebuilt from 2019-2020. Direct (e.g., uprooting plants, crushing plants) and indirect (e.g., increased likelihood of fire or non-native plants) impacts to bladderpod were expected (U.S. Department of Energy 2019, p. 44). Within the subspecies' critical habitat, the estimated disturbance was 0.02 ac permanently and 2.37 ac temporarily. The actual disturbance was less than estimated. Construction techniques were altered to reduce impacts in critical habitat; for example, spoil that would normally be placed in the right-of-way was instead hauled away (U.S. Department of Energy 2019, p. 13). Avista developed a site-specific restoration plan that specifies how damage to the habitat and vegetation will be avoided, minimized, and mitigated (U.S. Department of Energy 2019, p. 16). The Service reviewed a draft of the plan. Revegetation will begin in late 2020 and continue into 2021, with weed control to occur for several years. All disturbed areas not needed for future operation and maintenance of the line will be revegetated with native species (USFWS 2018a, pp. 4-5). Avista will monitor these areas for 5 years to ensure success criteria have been met; if not met, additional restoration and monitoring will occur (U.S. Department of Energy 2019, p. 16). (USFWS, 2020)

***Recovery***

**Reclassification Criteria:**
Not available - this species does not have a recovery plan.

Recovery Priority Number: 6C

**Delisting Criteria:**
1) Discover or establish at least one additional population of White Bluffs bladderpod within the Monument or, if possible, on nearby protected lands. These populations will be capable of adapting to changing environmental conditions and be of sufficient size and distribution to withstand stochastic events, such that extinction is highly unlikely (USFWS, 2022).

2) Manage and improve sufficient habitat to support populations wherever they occur (USFWS, 2022).

**Recovery Actions:**
- 1. Monitor population status, trend, and distribution (USFWS, 2022).
- 2. Conduct scientific research to improve understanding of the subspecies' life history, autecology, and limiting factors (USFWS, 2022).
- 3. Protect, conserve, and enhance habitat (reduce or eliminate Factor A threats) (USFWS, 2022).
- 4. Determine the minimum viable population size for White Bluffs bladderpod and the number and distribution of populations needed for long-term viability (USFWS, 2022).

- 5. If needed, increase population size and distribution (reduce or eliminate Factor E threats) (USFWS, 2022).
- 6. Promote outreach and cooperation with partners and stakeholders (USFWS, 2022).

# SPECIES ACCOUNT: *Physaria filiformis* (Missouri bladderpod)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 01/08/1987; Great Lakes-Big Rivers Region (R3) (USFWS, 2015)

**Physical Description**

The Missouri bladderpod is a winter annual, up to 2.5 dm tall, which produces yellow flowers which are especially showy against the plant's silvery stems and foliage. The plants flower, set seed, and die in early spring; the seeds germinate in autumn and overwinter as rosettes. (NatureServe, 2015)

**Taxonomy**

Previously known as Lesquerella filiformis (USFWS, 2008)

**Historical Range**

In addition to its current range, the bladderpod is believed to be extirpated in Jasper and Lawrence counties, Missouri. (USFWS, 1987)

**Current Range**

The Missouri bladderpod currently occurs in four counties in Missouri and five counties in Arkansas and the species is distributed on limestone glades in Southwest Missouri, dolomite glades in northern Arkansas (a report for Missouri on a dolomitic glade has not been confirmed, George Yatskievych, pers. comm. Aug. 11, 2014), and shale glades in the Ouachita Mountains in central Arkansas (Witsell, 2008). (USFWS, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual; self-incompatible (USFWS, 2015)

**Lifespan**

Adult: Less than one year (USFWS, 1988)

**Dependency on Other Individuals or Species**

Adult: Numerous insect species as pollinators (USFWS, 2015)

**Reproduction Narrative**

Adult: The Missouri bladderpod is a winter annual, germinating in the fall and overwintering in the form of basal rosettes. Plants send up flowering stems in late April and flower, fruit and senesce by the end of June. Seeds lie dormant on the limestone glades through the summer and germinate in the fall, starting the life cycle over again. There is considerable variation in these life history details from year to year. (USFWS, 1988) This bladderpod is an obligate outcrosser, being dependent upon several species of pollinators for pollination and fruit set. No less than 38 species of insects in four orders, visited Missouri bladderpod plants (Edens-Meier et al., 2011). (USFWS, 2015)

**Habitat Type**

Adult: Unglaciated prairie areas (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Limestone and dolomitic glades or grazed pastures (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Limestone, dolomitic, or shale substrate (USFWS, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from USFWS, 2015)

**Environmental Specificity**

Adult: Narrow/specialist on specific soils (inferred from USFWS, 2015)

**Site Fidelity**

Adult: High (USFWS, 2015)

**Habitat Narrative**

Adult: The Missouri bladderpod is most commonly found in open limestone glades, barrens, and outcrops within unglaciated prairie areas. It occasionally occurs in dolomitic glades, and is known from one site on a shale substrate. It is often associated with grazed pastures. Cedar invasion of glade sites is common. (NatureServe, 2015; USFWS, 2015)

***Dispersal/Migration***

**Dispersal**

Adult: Low (USFWS, 1988)

**Dispersal/Migration Narrative**

Adult: Seeds are mainly dispersed by falling from dried capsules although some dispersal occurs by seeds being washed downhill by rainwater runoff. (USFWS, 1988)

***Population Information and Trends***

**Population Trends:**

Increasing (USFWS, 2015). Unknown. Inferred from information (USFWS, 2020)

**Species Trends:**

Increasing (USFWS, 2015). Unknown. Inferred from information (USFWS, 2020)

**Population Growth Rate:**

Increasing, but annually variable (USFWS, 2015)

**Number of Populations:**

55 total extant. 51 extant in Missouri and 4 in Arkansas (USFWS, 2025).

**Population Size:**

10,000 to >1,000,000 individuals (NatureServe, 2015)

**Adaptability:**

Somewhat compatible with residential development and grazing. (NatureServe, 2015)

**Population Narrative:**

When listed, the Missouri bladderpod was not yet known from Arkansas and there were only 11 known populations in Missouri (USFWS, 2003). As of 2015, the species is known from 66 sites in four counties in Missouri and 10 sites in five counties in Arkansas (USFWS, 2003); Rhonda Rimer, pers. comm. Mar.10, 2014, Jan. 14, 2015; Cindy Osborne, pers. comm., Aug. 13, 2014). While the total number of populations now far exceeds the number when listed, an assessment as to whether or not they are self-sustaining is problematic because populations of Physaria filiformis can vary widely from year to year depending on different climatic and edaphic factors and in response to various management practices. For example, Young (2013) monitored populations of Physaria filiformis over a 25-year period on the largest bladderpod site on the Wilson Creek National Battlefield in Missouri and demonstrated that plants fluctuated from a few thousand in 1990, to 261,000+ in 1991, to a few thousand in 1992, to zero in 1993 and 1994, and then rebounded to highs of between 30,000+ and 137,000+ in 1995, and between 42,000+ and 114,000+ in 2011. Similar results have been noted in other areas (USFWS, 2003). While some of the currently known bladderpod sites exceed one-half acre in size, many are much smaller and the distributions of some populations are limited due to the availability of suitable glade habitat. (USFWS, 2015). While populations on managed glades are stable or increasing, data suggest that populations that receive no management are declining. During 2015 and 2016 surveys, Edwards et al. (2019, p. 18) found that P. filiformis was absent or only represented by a single individual in 11 of 25 populations surveyed, and many of these populations showed further decline in 2017. A review of 19 glades surveyed by MDC between 2006 and 2019 demonstrated that seven glades (37%) have stable populations, four have declining populations (21%), and eight are presumed extirpated (42%) (Rhonda Rimer, MDC, Nov. 12, 2019, Dec. 18, 2019, pers. comm.). More than half of Missouri sites have not been surveyed since 2005 and their status is unknown (USFWS, 2020). We received survey data and monitoring reports from MDC and ANHC with updated information regarding the species' status and current threats in the time since we conducted the last 5-year review. Three new sites have been documented since the last review. Results of these efforts indicate that managed populations in Missouri and Arkansas are stable and that unmanaged populations may be declining rapidly. No new threats have been documented since the last 5-year review. As described above, the recovery criteria outlined in the recovery plan has not been met. Eleven of 30 self-sustaining populations occur on public land; however, four of these occur in the Ouachita Mountains and may be reclassified as a different species in the future. Fourteen populations either occur on protected land or privately owned land but are being managed by a conservation agency. The exclusion of populations in the Ouachita Mountains would reduce the number of protected populations range-wide from 14 to 10. (USFWS, 2020) . For purposes of this analysis, the terms "sites," "occurrences," and "populations" have been used interchangeably in Arkansas and Missouri natural heritage databases or in published literature. Seven new populations of Missouri bladderpod have been discovered in Missouri and one in Arkansas since the last 5-year review (Rimer, pers. comm. 5

Sep. 2024). Currently, there are 75 sites of Missouri bladderpod in Missouri and 8 in Arkansas (Soteropoulos 2023). One of the sites in Missouri at the Nathan Boone State Historic Site was a result of seed dispersal from an adjacent site in 2020-2021 (Crabtree, pers. comm. 28 Sep. 2024). Of the 75 naturally occurring, known sites in Missouri, 24 (32%) of these sites are extirpated or likely extirpated (Rimer, pers. comm. 5 Sep. 2024). Since the last 5-year review, approximately 21 of the known sites in Missouri were monitored (~ 28%). Leis (2023) monitored sites on the Wilson Creek National Battlefield and used a gridbased survey approach (Young et al. 2008) to monitor 10 known Missouri bladderpod sites and established a midpoint of population estimates. Leis noted that bladderpod numbers increased following dormant season burns. Soteropoulos (2023) monitored all known sites of Missouri bladderpod in Arkansas and noted that some populations were the largest ever recorded in the state, and some of the increases were due to clearing of competing vegetation or prescribed fires (Soteropoulos 2023; Benton, pers. comm. 20 Sep. 2024). Based on Edwards et al. (2021), Edwards et al. (2023), and Kallison et al. (submitted for publication August 2024), populations of Physaria sp. on shale glades in the Ouachita Mountains represent a new species. A manuscript on the new species (Physaria ouachitensis E.R. Hallison & C.E. Edwards) was submitted to Systematic Botany and is currently under review (Edwards, pers. comm. Sep. 19, 2024). Given probable approval, the new species in the Ouachita Mountains would remove four populations from the overall range of the species (see further discussion in section 4). Prior to 2023 it would have been three sites, but Benton discovered one new site in Garland County in 2023 on a shale substrate (Benton, pers. comm. 20 Sep. 2024). Approval of the new species would also remove one natural community from the range of P. filiformis. Of the 51 extant sites in Missouri, 23 (45%) are in public ownership (Rimer, pers. comm. 9 Sep. 2024). Assuming the bladderpod that occurs on shale glades in the Ouachita Mountains is accepted as a new species, only two sites with Missouri bladderpod in Arkansas would be in public ownership [Blue Springs Recreation Area in Northwest Arkansas- Beaver Lake North and Beaver Lake South (Soteropoulos 2023)]. Therefore, 25 of the currently known 55 (~45%) sites for P. filiformis rangewide are in public ownership. While some of the currently known Missouri bladderpod sites exceed one-half acre in size, many are much smaller, and the distributions of some populations are limited due to the availability of suitable glade habitat. There are populations that would increase if various management actions were undertaken [e.g., removal of woody vegetation, especially red cedar; control of invasive brome (Bromus spp.) grasses] but the original recovery goal of one-half acre of size was based on limited data on only 11 sites when the recovery plan was completed in 1988. Recovery criteria could be updated and revised to address the current knowledge of the species' life history requirements, distribution, and new information on management actions that can benefit the species and address known threats. Given information obtained since the recovery plan was approved in 1988 regarding variations in areal coverage of some bladderpod sites, the habitat size criterion may not benefit recovery. (USFWS, 2025)

***Threats and Stressors***

**Stressor:** Human disturbance and collection (USFWS, 1987)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The low number of individual plants make the species vulnerable to collecting and other human disturbance. Two of the populations are within the Wilson's Creek National Battlefield, where a system of interpretive trails extends through the sites. These populations

receive some disturbance from the more than 124,000 annual visitors to the Battlefield site, but Morgan (1983) concluded that disturbance may help maintain the Lesquerella filiformis populations. In addition, wildflower collectors may reduce populations in more accessible sites. As Steyermark (1963) pointed out, this plant with handsome yellow flowers makes a desirable addition to rock gardens and may be vulnerable to overcollecting. (USFWS, 1987)

**Stressor:** Lack of management research (USFWS, 1987)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Research is needed to determine proper management techniques for maintenance of the species, especially at disturbed sites. (USFWS, 1987) Consistent glade management maintains suitable habitat for P. filiformis and is considered vital to the survival and recovery of populations in Arkansas and Missouri. Removal of Eastern red cedar (Juniperus virginiana), prescribed fire, and control of exotic species allow for the persistence and expansion of populations. Many privately owned glades in Missouri are not being managed to promote the persistence of this plant species, and surveys indicate generally low numbers of P. filiformis. With a few exceptions, glades on private lands are over-shaded by encroaching Eastern red cedar, intensively grazed, densely covered by grasses and forbs, and not managed with fire (Christine Edwards, MOBOT, Nov. 12, 2019, pers. comm.). Although restoration efforts increase abundance of P. filiformis, implementation of those efforts on privately-owned glades is challenging (Rhonda Rimer, MDC, November 12, 2019, pers. comm.). Similar to Missouri, glade habitat in Arkansas has become degraded at several locations due to lack of management. (USFWS, 2020)

**Stressor:** Right-of-way maintenance (USFWS, 1987)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Three populations of Lesquerella filiformis occur in Dade County within Missouri highway rights-of-way. Two of these populations extend onto private land. Because of yearly right-of-way treatments, there is a threat of destruction to these populations. Cooperation with the State Department of Highways and Transportation is necessary in order to provide these sites additional protection from accidental mowing or chemical treatment. (USFWS, 1987)

**Stressor:** Seed destruction (USFWS, 1987)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Seed predation by insects and fungal infection of developing capsules have been reported by Morgan (1983). It is not known whether the ensuing loss of reproductive capacity constitutes a significant threat to the species. (USFWS, 1987)

**Stressor:** Competition from native and exotic plants (USFWS, 2003; 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Shortly after listing, the Service (1988) documented the presence of exotic plant species, such as Bromus tectorum (a cheat grass), in bladderpod habitat as a significant threat,

and this was further supported by observations by Hickey (1988, 2000) and Thomas (1996, 1998). (USFWS, 2003) Witsell (2008) and Eulinger and Skinner (2007) noted that encroachment by Eastern red cedar onto glades causes habitat degradation and this threat will need to be continually monitored. (USFWS, 2015)

**Stressor:** Development (USFWS, 2003)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Hickey (1988, 2000) and Thomas (1996) identified development, especially land-use changes resulting from urban expansion, as a major threat to the species. (USFWS, 2003)

**Stressor:** Climate change (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change may lead to increased frequency and duration of droughts (Rind et al., 1990; Seager et al., 2007; Rahel and Olden, 2008). Climate warming may increase the virulence of nonnative parasites and increased drought conditions may favor the establishment and spread of nonnative species (Rahel and Olden 2008). Extended droughts and an increase in soil and air temperatures could negatively impact seed set, germination, and overall fitness of Physaria filiformis. (USFWS, 2015)

***Recovery***

**Reclassification Criteria:**
The bladderpod has already been reclassified from endangered to threatened based on discovery of new populations and reduced threats to large existing populations. (USFWS, 2003)

Recovery Priority Number: 8

**Delisting Criteria:**
The Missouri bladderpod may be considered for delisting when there are thirty scattered, self-sustaining populations of Lesquerella filiformis that are maintained and protected. Fifteen of the thirty populations must be in secure ownership, occupy a minimum of one-half acre of habitat each, and show self-sustaining populations for at least seven years. (USFWS, 1988)

**Recovery Actions:**
- Existing populations need to be protected and managed. (USFWS, 1988)
- Suitable habitat needs to be surveyed for new populations. (USFWS, 1988)
- Populations need continuing monitoring; autecological and management research is needed on the species. (USFWS, 1988)
- Management programs need to be developed and then initiated on protected sites. (USFWS, 1988)
- New populations need to be established on public land. (USFWS, 1988)
- Programs need to be developed to enhance public awareness and support for conservation of the species. (USFWS, 1988)

- The establishment of measurable recovery criteria that address threats to the species should be developed and implemented before possible delisting is recommended. (USFWS, 2015)
- A revision of the 1998 Missouri Bladderpod Recovery Plan is needed to develop measurable delisting criteria that reflect remaining threats to the species and to incorporate new information that has been obtained in the last 26 years. Development of such a plan should be done in cooperation with the appropriate experts and stakeholders in Missouri and Arkansas. (USFWS, 2015)
- Missouri bladderpod numbers and the results of ongoing conservation efforts need to be regularly monitored to assess recovery and ongoing management efforts. It may be appropriate to identify priority populations in Missouri and Arkansas for monitoring. Monitoring efforts should include populations that occur on the three different substrate types. (USFWS, 2015)
- Studies need to be initiated on the potential impacts of climate change on the Missouri bladderpod and its habitat. The species could be impacted from droughts and accompanying problems associated with climate change; further research is warranted. (USFWS, 2015)
- Physaria filiformis would benefit from additional genetic studies that evaluate genetic diversity across the range of the species, especially given the now known large geographic gaps between populations in southwest Missouri and scattered populations in Arkansas and the occurrence on three different soil substrates. (USFWS, 2015)
- Outreach efforts need to be made to private landowners in Missouri and Arkansas regarding best management practices that will maintain, and where necessary restore bladderpod habitat. (USFWS, 2015)
- Ongoing survey efforts should continue to search for new populations, especially in Arkansas. (USFWS, 2015)
- Viable sites should be protected and properly managed in all the outlying clusters within the species' range. (USFWS, 2015)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: The Service provides the following recommendations: 1. Revise the recovery plan to include measurable delisting criteria that appropriately reflect remaining threats to the species and new information that has been obtained in the last 31 years. The plan should define "self-sustaining" and identify how often populations should be monitored within a 7-year period to meet that definition. Development of such a plan should be done in cooperation with the appropriate experts and conservation partners in Missouri and Arkansas. 2. Monitor populations and use results to assess efficacy to further recovery efforts. Recovery criteria cannot be met unless ≥30 populations are monitored. 3. Assess the status of populations in Missouri that have not been surveyed since 2010. Examine what proportion of unmanaged, extant populations in Missouri are threatened by overgrazing, encroaching Eastern red cedar and invasive grass and forb species, as well as changing land use practices that may result in extirpation of populations. 4. Implement a simple, standardized survey to count or estimate the number of plants present in Missouri and Arkansas populations. 5. Conduct outreach efforts with private landowners in Missouri and Arkansas regarding best management practices to maintain, and where necessary, restore habitat for Missouri bladderpod. 6. Collect data to evaluate whether or not application of herbicide spraying to populations along rights of way and roadways in Arkansas negatively affect P. filiformis. 7. Implement management practices such as prescribed burning and removing Eastern red cedar and non-native plant species within glades. Develop and implement additional management plans in Missouri and Arkansas to maintain habitat on private and public lands to further recovery efforts for this plant species. 8. Protect and manage more of the populations that occur on privately owned land through an appropriate combination of financial incentives, acquisition, easements, and logistical support. 9. Continue to protect and manage at least one population within each distinct genetic group and two populations from the genetically distinct group that occur in Sharp and Izard Counties, Arkansas. 10. Conduct a morphological study to determine if populations located in the Ouachita Mountain in Arkansas are a different species. (USFWS, 2020)

- RECOMMENDATIONS FOR FUTURE ACTIONS: The Service provides the following recommendations: 1. Edwards et al. (2021) recommended the collection of seed from genetic clusters they identified. A threatened and endangered species seed bank proposal has been submitted to MDC's Science Branch by the Missouri Botanical Garden that will help ensure that the range-wide genetic diversity is represented in ex-situ conservation (Malissa Briggler, State Botanist, MDC, pers. comm. 10 Oct. 2024). 2. Based on genetics results outlined by Edwards et al. (2021), ongoing monitoring should be undertaken at a minimum of the six genetic clusters identified in Arkansas and Missouri. Due to the number of extant sites in Missouri and Arkansas, and a general lack of personnel, there will likely be a need to prioritize what sites are monitored. Simple presence/absence monitoring may be insufficient to assess the status of Missouri bladderpod in Arkansas and Missouri, especially sites with high genetic diversity as determined by Edwards et al. (2021). Monitoring as outlined by Young et al. (2008) and Leis (2023), or a program supported and coordinated among Federal and State agencies in Missouri and Arkansas, should be implemented. The need for an increased level of monitoring at priority sites notwithstanding, only 28% of known sites in Missouri were surveyed between 2020 and 2024 (Rimer, pers. comm. 5 Sep. 2024). At least presence/absence monitoring should be conducted on Missouri sites that have not been visited in several years. 3. In Arkansas, Soteropoulos (2023) determined that there was "considerable habitat in Arkansas suitable for the species that remains under-surveyed and under-inventoried," and Benton (pers. comm. 20 Sep. 2024) reported that surveys in un-inventoried habitat are planned for the spring of 2025. Consequently, we recommended enhanced survey effort in suitable habitat in Arkansas. 4. Because Missouri bladderpod is a conservation-reliant species as described above, private land-owner incentive programs could be investigated that ensure long-term conservation of Missouri bladderpod while providing financial benefits to landowners. Possible landowner incentive programs include: a Recovery Credit System and a Conservation Award System (Wilkins et al. 2009; Kreuter 2017); conservation management agreements (Scott et al. 2005; Bocetti et al. 2012); credit marketing (Wolfe et al. 2017); and conservation banking for multiple species (Evans et al. 2016). One of the more innovative approaches has been the development of a Covenant Program for Environmentally Endangered Lands in Florida that provided as much as a 90% reduction in property taxes for private landowners who signed up in the program (Giannini and Heinen 2014). 5. Conduct an analysis of the projected impact of future residential and commercial development on existing bladderpod habitat. In Missouri, populations in Christian and Greene counties are projected to significantly increase between 2000 and 2030 (Missouri Economic and Resource Report 2024). Because some of our largest populations have historically occurred in these two counties (MDC Natural Heritage Database 2024), residential and commercial development on private property could eliminate bladderpod habitat. 6. Conduct an analysis on changes in suitability of glade habitat in Missouri and Arkansas. Young et al. (2009) provided startling photos depicting changes in bladderpod habitat on Bloody Hill Glade of Wilson's Creek National Battlefield between 1936 and 2003. Similar analyses of potential bladderpod habitat may reveal that areas now completely enclosed due to canopy closure from red cedar encroachment were historically more open as noted by Nelson (2005). The identification of such areas could be identified as priority areas for restoration efforts using clearing and prescribed fire. 7. Conduct outreach efforts with private landowners in

Missouri and Arkansas regarding best management practices to maintain, and where necessary, restore habitat for Missouri bladderpod. Provide technical assistance and cooperatively work with private landowners in restoration efforts. 8. Evaluate whether herbicide spraying along rights of way and roadways in Missouri and Arkansas negatively affects Missouri bladderpod. 9. Continue to protect and manage at least one population within each distinct genetic group and two populations from the genetically distinct group that occur in Sharp and Izard Counties, Arkansas as recommended by Edwards et al. (2021). 10. Based on genetic analyses of Edwards et al. (2021), Missouri bladderpod on COE land in northwest Arkansas is experiencing a genetic bottleneck. Consideration should be given to the possibility of increasing the genetic diversity of northwest Arkansas plants by supplementing existing populations with seeds from the most geographically proximal site in Arkansas or Missouri. Such augmentations will require close coordination among Missouri and Arkansas natural heritage botanists, U.S. Army Corps of Engineers personnel, USFWS staff, and geneticists from the Missouri Botanical Garden. 11. Conduct an analysis on which environmental variables affect yearly demographic trends in Missouri bladderpod and incorporate that information into a future SSA. (USFWS, 2025)

# SPECIES ACCOUNT: *Pinguicula ionantha* (Godfrey's butterwort)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 8/11/1993; Southeast Region (R4)

**Physical Description**

Pinguicula ionantha has a rosette of fleshy, oblong, bright green leaves that are rounded at their tips, with only the edges rolled upward. The rosette is about 15 cm (6 in) across. The upper surfaces of the leaves are covered with short glandular hairs that capture insects. The flowers are on leafless stalks (scapes) about 10-15 cm (4-6 in) tail. When a flower is fully open, its corolla is about 2 cm (almost 1 in) across. The five corolla lobes are pale violet to white. The throat of the corolla and the corolla tube are deeper violet with dark violet veins. The corolla has a spur 4-5 mm (0.2 in) long that is yellow to olive (Godfrey and Stripling 1961, Godfrey and Wooten 1981). (USFWS, 1994)

**Taxonomy**

Pinguicula ionantha Godfrey (Godfrey’s butterwort or violet-flowered butterwort) is a member of the bladderwort family (Lentibulariaceae), a small family of carnivorous plants closely related to the snapdragon family (Scrophulariaceae) (USFWS, 1994). Pinguicula L., the second most diverse genus of the carnivorous Lentibulariaceae, is monophyletic and composed of about 85 to 100 species native to Europe, North America, Asia, and South and Central Americas (Cieslax et al. 2005, Degtjareva et al. 2006). Six species can be found in Florida, of which P. ionantha Godfrey is endemic (Gluch 2005). All Florida species belong to the section or subgenus Isoloba (Fleischmann 2021, Cieslax et al. 2005, Gluch 2005). We are not aware of any changes to the taxonomy of this entity, and it is still considered valid by the Service and the scientific community (USFWS, 2023).

**Historical Range**

See current range/distribution.

**Current Range**

Endemic to the central panhandle region of Florida with reported occurrences in Bay, Calhoun, Franklin, Gulf, Liberty, and Wakulla counties (USFWS, 2018).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Food/Nutrient Narrative**

Adult: Pinguicula L., the second most diverse genus of the carnivorous Lentibulariace is monophyletic and composed of about 85 to 100 species native to Europe, North America, Asia, South and Central America, and southern Mexico (Cieslax et al. 2005, Degtjareva et al. 2006). Members of this genus use sticky, glandular leaves to trap and digest insects (USFWS, 2009). It is unclear what benefit the plant derives from this carnivory.

**Breeding Season**

Adult: The flowers rise from late February to April according to temperatures (USFWS, 2009).

**Reproduction Narrative**

Adult: Pinguicola ionantha has a rosette of fleshy, bright green-yellow leaves of up to 15 cm across that can be characterized by upward rolled leaf edged. The plants stay in rosette form all year. The flowers rise from late February to April according to temperatures. The flowers, borne on stalks of about 10 to15 cm in height, are about two centimeters across and possess five pale violet to white petals all of same shape corolla. The throat of the corolla and the corolla tube are deeper violet with dark violet veins. A yellow to olive spur 4 to 5 mm long is present on the corolla and the palate is yellow with a purple base and covered with yellow hairs (Godfrey and Stripling 1961, Godfrey and Wooten 1981) (USFWS, 2009). SEXUAL; ABIOTIC; Wind; (NatureServe, 2015)

**Habitat Type**

Adult: Bos/long leaf pine savannas (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred form NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred form NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits open, acidic soils of seepage bogs on gentle slopes, deep quagmire bogs, ditches, and depressions in grassy pine flatwoods and grassy savannas, often occurring in shallow standing water. "Pinguicula ionantha occurs in herb bog habitats embedded in longleaf pine savannas. Specifically, it is found between a lower elevation habitat dominated by pond cypress (Taxodium ascendens) overstory and a slightly higher elevation pine flatwoods dominated by an overstory of longleaf pine (Pinus palustris) (USFWS 2009) (NatureServe, 2015). High ecological integrity of the community and site fidelity and low tolerance ranges are inferred based on the species specific habitat needs.

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: No information found.

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2018)

**Species Trends:**

Unknown (USFWS, 2018)

**Population Growth Rate:**

It is estimated that between 85 and 98% of herb bog/savanna habitats have been lost (Folkerts 1982 cited by Kesler et al. 2008). Decline of >70% (NatureServe, 2015)

**Number of Populations:**

~66. (approximately 54 occurrences on public lands and an additional 12 on private lands) (USFWS, 2023).

**Population Size:**

2500 - 100,000 individuals (NatureServe, 2015)

**Additional Population-level Information:**

Previously, 83 historical sites were documented between 1956 and 2009 (FNAI 2008). Based on information provided by FNAI (2017) and FWCC (2018) and recent surveys, the number of sites has increased to 92; technically representing 66 EOs. About 10,558 plants were present at 21of the 23 EOs revisited in 2015 (Molano-Flores et al. 2014). A total of 52 sites were visited in 2006, 2008, and 2009 surveys: 33 sites were revisited by Kesler and Trusty (2008) during April 2006, and 19 sites were visited by Negrón-Ortiz during 2008 and 2009 surveys. Plants were present at 24 (46%) of these sites. Searches did not locate plants at 22 (42%) of the previously recorded sites. Additionally, high water or a dense woody midstory prevented access to six previously recorded sites in Gulf and Franklin counties (Kesler and Trusty 2008, Negrón-Ortiz, 2008 surveys). This species appears to be increasing in number of populations on public lands. However, overall trends in both abundance of individuals within each population and the total number of populations through the species range remain unknown. (USFWS, 2018)

**Population Narrative:**

Current survey information indicates an increase in the number of populations. Survey information shows 22 (33%) of the 66 EOs appear to be extirpated due to development and/or habitat modification. However, since surveys were conducted irregularly and based on either presence/absence and/or qualitative visual estimate (Jenkins et al. 2007); with most sites visited only once; and the actual counts of plants rarely provided, a comprehensive population survey is needed in order to better assess the current status of this species. Studies have demonstrated variation among the number of plants necessary for a population to survive risks of extinction (Given 1994, Matthies et al. 2004, Menges 1990). Matthies et al. (2004) study of 379 populations of eight threatened plant species in northern Germany demonstrated that very small populations face a considerable risk of extinction, while the risk for populations with more than 1000 individuals was very small. Because most of the P. ionantha populations have less than 1000 individuals, any impact to existing populations (specifically sites outside the ANF) could cause extirpation of these populations. Furthermore, the relatively low level of genetic diversity associated with this species is a concern as it may impair fitness and evolutionary adaptability in a changing environment (Zaya et. al 2016). (USFWS, 2018). Godfrey’s butterwort is a carnivorous plant presently located in six Florida panhandle counties. The species’ populations primarily found on Apalachicola National Forest and Tate’s Hell State Forest. There are approximately 54 occurrences on public lands and an additional 12 on private lands. Most of the P. ionantha populations have less than 1000 individuals, therefore any impact to existing populations (specifically sites outside the Apalachicola National Forest) could cause loss of these populations (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Logging and Pulpwood Production (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Privately owned forests managed (clearcutting, mechanical site preparation, and bedding) for commercial timber production, is a primary threat to P. ionantha habitat. An active paper mill located in Panama City (Bay County) receives timber from thousands of acres of pine plantation. The commercial timber industry in North Florida became well established in the 1850's (FNAI 2005). It started in Franklin County in the 1870's and continued to be a prominent industry until the mid-1990's (Howell and Hartsell 1995). The Timberland Company had close to a million acres in timber production in the eastern region of the Panhandle and they plan to continue to commercially harvest and replant off-site pine species. The Company also owned a paper mill in Port St. Joe until it was sold and shut down in 1999. In 2013, the Timberland Company sold more than 380,000 acres of its land to AgReserves, Inc.. The land sold included timberlands in Bay, Calhoun, Franklin, Gadsden, Gulf, Jefferson, Leon, Liberty and Wakulla counties. Within Gulf County, AgReserves, Inc. has repurposed timberlands into pasture lands for cattle (A. North, FDEP, 2/6/2018, pers. comm.). (USFWS, 2018)

**Stressor:** Coastal real estate and road development (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Urban development continues to threaten Godfrey's butterwort. The Timberland Company is one of the largest private landowners in Florida, and one of the largest real estate operating companies in the Southeast. The Company develops both residential and commercial properties along roadways and near or within business districts in the region. More than a third of Florida's land is projected to be developed by 2070 along with a grow of about 33.7 million residents–almost 15 million more people than in 2010 (University of Florida GeoPlan Center 2017). Many P. ionantha locations are found along U.S. and state roads. Construction activity may directly kill individual plants or convert habitat to unsuitable habitat; widening may convert native habitat to managed road side; and culvert modification may change drainage patterns, which may change seasonal hydrology. Evidence suggests past road improvements have resulted in localized extirpation of Godfrey's butterwort in ANF (Kesler and Trusty 2008). Therefore, because they contribute to habitat loss, road widening and new roads continue to pose a threat to the species. (USFWS, 2018)

**Stressor:** Fire suppression (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Suppression of fire during the growing season continues to threaten the pineland and savanna's flora, as fire is an important factor in the maintenance of flatwoods (Abrahamson and Hartnett 1990). Fire influences community structure and composition (Abrahamson and Hartnett 1990), and with insufficient frequency in longleaf pine communities, a woody midstory quickly

develops (Glitzenstein et al. 1995), negatively affecting the understory diversity. Several studies have shown that frequent, low intensity prescribed fire regimes are important for maintenance of flatwoods diversity (Hiers et al. 2007). Therefore, frequent prescribed burnings, i.e., < 3 yr interval, are needed to maintain optimal habitat for P. ionantha populations (Kesler et al. 2008). At present, the Apalachicola National Forest utilizes a 3- to 5-yr interval burn rotation (2-4 yr burn rotation at the burn units with P. ionantha, J. Drake, USFS, 02/21/2018, pers. comm.); Box-R WMA and SJBSBP utilize 2- to 3-yr interval; and Lathrop Bayou applies prescribed fire on a 2- to 7-yr interval. Thus, fire suppression continues to threaten to P. ionantha habitat and population numbers. Lack of fire, and subsequent growth of shrubs (particularly encroachment of Cyrilla racemiflora L., commonly known as swamp titi) and saplings in the understory, in addition to shading by planted pines, inhibits this species emergence (Negrón-Ortiz, 2008, pers. observ.; FNAI 2008, Kesler et al. 2008). Declining fire frequency reduces P. ionantha abundance in areas where it was previously observed in large quantities (FNAI 2008). Emergence of this species is prolific within one year of the fire event (Kesler and Trusty 2008). (USFWS, 2018)

**Stressor:** Over collection (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** This factor is a threat, but the magnitude has been reduced. Butterworts are widely cultivated, grown and sold by plant enthusiasts and nurseries. Pinguicula ionantha was overcollected in the 1970s (58 FR 37440). Many thousands of plants propagated by tissue culture were sold without permits, but the plant is no longer commercially available in large quantities (D'Amato, California carnivores). In order to implement conservation measures and regulations, the Service granted a permit (TE061005-1) to the International Carnivorous Plant Society (ICPS) in 2003, which allows the society to sell seeds of endangered and threatened carnivorous plants only within the USA. Some restrictions apply to this permit (see http://www.carnivorousplants.org/conservation/policies); in addition, an annual report is required stipulating their selling activities. Collecting guidelines for live plants and seeds were developed by the ICPS: 1) they do not recommend collecting live plants unless it is for scientific purposes such as herbaria, the species has never been introduced to cultivation, or because a variant (a taxon exhibiting slight differences in form); 2) they will not accept field collected seed of listed plants, only seeds from cultivated plants will be accepted if they are donated in accordance with all relevant laws. The Nurseries Stock Restrictions manual summarizes the entry status of regulated plant material capable of or intended for propagation (USDA 2010). (USFWS, 2018)

**Stressor:** Hurricanes (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Saltwater inundation from storm surges caused by hurricanes represents a threat. Kesler and Trusty (2008) monitored one population in Franklin County, which was flooded during Hurricane Francis in 2004. In 2005, they observed that the plant number declined from about 100 to two individuals. (USFWS, 2018)

**Stressor:** Sea Level Rise (USFWS, 2018)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Sea level rise (SLR) as a result of climate change is a growing concern for much of Florida's coastline and the endemic species that occur there because about 10% of Florida is less than 1 meter above current sea level. Being endemic to Florida, Godfrey's butterwort is threatened by climate change. Using the NOAA Sea Level Rise and Coastal Flooding Impacts Viewer (https://coast.noaa.gov/slr/), the projections indicated potential impacts to six known P. ionantha EOs (Bay Co.: 1 EO; Franklin Co.: 5 EOs) by intrusion of saltwater beginning at one foot SLR. (USFWS, 2018)

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Section 7(b)(4) and 7(b)(2) of the Endangered Species Act (Act) generally do not apply to listed plant species. However, limited protection of listed plants from take is provided to the extent that the Act prohibits the removal and reduction to possession of Federally listed threatened and endangered plants or the malicious damage of such plants on areas under Federal jurisdiction, or the destruction of endangered plants on non-Federal areas in violation of State law or regulations or in the course of any violation of a State criminal trespass law. Seeds of both threatened and endangered species found on Federal land are regulated under the Act. However, the seeds of threatened species are not regulated if they come from cultivated plants (7 CFR 319.37.2, USDA 2008). Since P. ionantha is a threatened species, growers can obtain and sell seeds from other growers. Several populations of P. ionantha occur on private timberland and ROWs. While the Act requires Federal agencies to carry out programs for the conservation of endangered and threatened species, no such programs are stipulated for private landowners. The Act does not provide for protection of plants on private lands as long as the activity is permissible under state/local laws. The State requires permission of private landowners for collecting of State-listed plants from their property. Pinguicula ionantha is protected under Florida State Law, chapter 581.185: Preservation of native flora of Florida, which includes preventions of take, transport, and the sale of the plants listed under the State Law. The rule Chap. 5B-40, Florida Administrative Code, contains the "Regulated Plant Index" (5B-40.0055) and lists endangered, threatened, and commercially exploited plant species for Florida; defines the categories; lists instances where permits may be issued; and describes penalties for violations (Coile and Garland 2003). Bay County Comprehensive plan, under chapter 6, provides restrictions, constraints and requirements to protect and preserve designated habitat conservation areas for rare, threatened, or endangered species, and wetlands (http://baycountyfl.gov/276/Planning-Zoning). Calhoun, Gulf, Franklin, and Liberty Counties do not have such regulations. Highway ROW maintenance activities are not always reviewed for threatened and endangered species impact. However, if there is an activity (e.g., construction, mowing, or maintenance projects) affecting protected species, then the Service can recommend consultation to the FDOT under section 7 of the Act. The FDOT routinely consults with the Service on all major road construction activities. (USFWS, 2018)

***Recovery***

**Reclassification Criteria:**
Not relevant. (USFWS, 1994)

Recovery Priority Number: 8C

**Delisting Criteria:**
1. When 15 populations are adequately protected and managed throughout its historic range. Existing public land (mainly the Apalachicola National Forest) does not suffice for recovery). (USFWS, 1994)

**Recovery Actions:**
- Manage ROW Continue fostering conservation practices for utility and highway Right-of-Ways with the Forest Service, FDOT, and USFWS; a ROW Best Management Practices plan should be developed and implemented. (USFWS, 2018)
- Develop a stand-alone plan for managing listed plants at the Apalachicola National Forest and THSF, and integrate it to their Management Plan. (USFWS, 2018)
- Conduct a long-term study using 15 populations distributed throughout the species' historical range for 10 years to determine whether the observed declines in abundance reflect acceptable stochasticity or if they are indicative of dangerously declining populations. This study could use the sites from Kesler and Trusty (2008) study, and will address the delisting criterion. (USFWS, 2018)
- Since habitat loss and degradation are leading causes of endangerment for P. ionantha, designating habitat that is critical for survival and recovery is recommended. (USFWS, 2018)
- Complete a comprehensive census (e.g., the total number of individuals, number of flowering vs. non-flowering plants, and whether seedling recruitment is occurring) throughout the present distribution including all the historical locations to determine the species' status. (USFWS, 2018)
- Conduct surveys/inventories on potentially new sites. This action can include the use of aerials and species distribution modeling methods to initially determine potential sites, with subsequent field inventory of the site using a consistent, statistically valid, repeatable inventory method. If new populations are discovered, protection should be sought, and identify sites for reintroductions such as areas that will not be affected by SLR and future development (USFWS, 2018)
- Establish (or continue) frequent growing-season fire regimes (i.e., 2-3 yr interval) on selected areas such as Apalachicola National Forest, SJBSBP, THSF, and Tyndall AFB to maintain optimal conditions of P. ionantha populations. Re-visit sites shortly after a burn event, and mark and count individual plants. Populations tend to be more evident after a fire event. (USFWS, 2018)
- Garden propagation and reintroduction. An ex-situ plant collection should be actively pursued and implemented with a botanical garden. (USFWS, 2018)
- Investigate if there is a soil seed bank persistence of P. ionantha seeds throughout the species geographic range. (USFWS, 2018)
- Conduct population biology studies at Apalachicola National Forest. Compare the demographic performance of P. ionantha in pinelands and road habitats. Survey for seedling recruitment and survival of tagged individuals (plant height and reproduction) for a period of 3-5 years in or near roadside populations of SR 65 and pinelands. (USFWS, 2018)
- The recovery plan should be updated to define objective measurable criteria and better address the five listing factors.(USFWS, 2018)
- 1. Manage ROW

- 2. Since habitat loss and degradation are leading causes of endangerment for P. ionantha, designating habitat that is critical for survival and recovery is recommended (USFWS, 2009).
- 3. Evaluate the current species status (USFWS, 2009).
- 4. Conduct surveys/inventories on potentially new sites. This action can include the use of species distribution modeling methods to initially determine potential sites, with subsequent validation or inspection of the sites (USFWS, 2009).
- 5. Establish frequent growing-season fire regimes (i.e. 2-3 yr interval) on selected areas such as Tate's Hell State Forest, St. Joseph State Buffer Preserve, and ANF to maintain optimal conditions of P. ionantha populations. Re-visit sites shortly after burn event and mark individual plants. Populations tend to be more evident after a fire event (USFWS, 2009).
- 6. Garden propagation and reintroduction. An ex-situ plant collection should be actively pursued and implemented with a botanical garden. Studies on the viability of dry-stored seeds, the timing of the germination, and whether a persistent seed bank is present should be addressed (USFWS, 2009).
- 7. Conduct population studies at ANF (USFWS, 2009).
- 8. Conduct systematic studies to examine the current taxonomic classification (USFWS, 2009).
- 9. Conduct pollination studies (USFWS, 2009).
- 10. The recovery plan should be updated to define objective measurable criteria and better address the five listing factors (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIVITIES 1. Address the delisting criterion, 'adequately protect and manage 15 populations distributed throughout the species' historical range for 10 years'. This study could use the sites from Kesler and Trusty (2008) established plots. a. Continue the long-term monitoring ANF, Tyndall, and LB sites, and set up plots in SJSBP and THSF. b. As sea levels rise, seawater intrusion increases in duration, frequency, and spatial extent. To assess the effect of salinity on P. ionantha, sites where intrusion of salt water occurs should be considered for long-term monitoring. 2. Conduct surveys/inventories on potentially new sites. a. Calhoun and Wakulla counties. Historically, P. ionantha was documented in Wakulla and Calhoun. Therefore, surveys are strongly recommended in these counties within the habitat types or vegetation communities associated with the species. b. This action can include the use of aerials and species distribution modeling methods to initially determine potential sites, with subsequent field inventory of the site using a consistent, statistically valid, repeatable inventory method. If new populations are discovered, protection should be sought. 3. Manage ROW Continue fostering conservation practices for utility and highway ROWs with the Forest Service, FDOT, and USFWS; a ROW Best Management Practices plan should be developed and implemented. 4. Develop a stand-alone plan for managing listed plants at the ANF and THSF, and integrate it to their Management Plan. 5. Since habitat loss and degradation are leading causes of endangerment for P. ionantha, designating habitat that is critical for survival and recovery is recommended. 6. Complete a comprehensive census (e.g., the total number of individuals, number of flowering vs. non-flowering plants, and whether seedling recruitment is occurring) throughout the present distribution including all the historical locations to determine the species' status. 7. Establish (or continue) frequent growing-season fire regimes (i.e., <4 yr interval) on selected areas such as ANF, SJBSBP, THSF, and Tyndall to maintain optimal conditions of P. ionantha populations. Re-visit sites shortly after a burn event, and mark and count individual plants. Populations tend to be more evident after a fire event. 8. Garden propagation and reintroduction. An ex-situ plant collection should be actively pursued and implemented with a botanical garden. In February 2016, 238 plants were removed from the F-22 Munitions Storage Complex on Tyndall AFB prior to new bunker construction and relocated to a wet prairie at Tyndall AFB. Post-transplanting monitoring is ongoing since 2017. 9. Investigate if there is a soil seed bank persistence of P. ionantha seeds throughout the species geographic range. The following studies were inconclusive; therefore, better observations are needed to clarify the type of seed bank present in this species. A few points from these studies: • The lack of a persistent seed bank was suggested by Kesler et al. (2008), as they observed a 430-day delay in the population growth response of P. ionantha to dormant season fires. • Molano-Flores et al. (2014) found the emergence of two Pinguicula seedlings from soil collections, but identification to species was not possible because seedlings did not reach the flowering stage during the study. • Molano-Flores et al. (2021) subsequent seed germination and seed bank studies on multiple populations of P. ionantha, P. lutea, and P. planifolia suggest: o transplanting seedlings is not recommended unless moisture and humidity are retained, and root disturbance is minimized. o sprouted seeds of P. ionantha with emerging cotyledon, previously soaked in gibberellic acid solution and rinsed with distilled water, were transplanted to a soilless mixture but did not survive o 6 months post-collection seeds kept in cold storage for about 5 months have high potential for germination o viability potential of seeds in the seed burial trail was at least 2 months (that was the duration of their study) 10. Conduct population biology studies at ANF Survey for seedling recruitment and survival of tagged individuals (plant height and reproduction) for a period of 3-5 years in or near roadside populations of SR 65 and pinelands (USFWS, 2023).

# SPECIES ACCOUNT: *Pityopsis ruthii* (Ruth's golden aster)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015) 7/18/1985

**Physical Description**

A perennial herb, 1-3 dm tall. The stems are leafy with grass-like leaves. Bright yellow flower heads bloom in late summer and fall (NatureServe, 2015).

**Taxonomy**

Past taxonomic treatments of Ruth’s golden aster, and golden asters in general, have involved frequent shifting of species among genera. Small (1897) described the species as Chrysopsis ruthii but subsequently transferred it to the genus Pityopsis (Small 1933), a genus characterized as those golden asters with graminiform (grass-like) leaves. This concept was rejected by Fernald (1942) who described the recognition of Pityopsis as “hardly worthwhile” and retained the species in Chrysopsis. Later, Shinners (1951) included Chrysopsis in his concept of the genus Heterotheca. His treatment generally was accepted by Harms (1969), who published the combination Heterotheca ruthii, and by Bowers (1972b) and Cronquist (1980). Dress (1953), in his study of the eastern Chrysopsis, continued to follow Small’s 1933 nomenclature (except in the case of the Pityopsis graminifolia complex). Semple (1977), Semple et al. (1980), and Semple and Bowers (1985) reaffirmed Heterotheca, Chryopsis, and Pityopsis as distinct genera. Semple’s work is widely accepted, and Ruth’s golden aster will be referred to here as Pityopsis ruthii (Small) Small. It is instructive to note that no student of the genus has questioned the validity of the species, only the proper generic designation (USFWS, 1990).

**Historical Range**

See current range/distribution.

**Current Range**

Known only to occur along short reaches of the Ocoee and Hiwassee River, Polk County, Tennessee (USFWS, 2018).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

Adult: Reproduction in natural populations is attributed to stem regeneration or tillering of the subaerial root-rhizome crown (Wofford and Smith 1980). This agrees with White (1977), who stated that the chief method of reproduction is by existing rhizomes. White observed no seedlings in the field and concluded that P. ruthii has difficulty becoming established on the phyllite boulders. His comparison of plants from the Hiwassee River population with those grown for his greenhouse studies showed an average of 50 achenes and 58 achenes per flowering head, respectively. Typically, 18 percent of those achenes from the wild population were filled (i.e., viable) compared to 19 percent from the greenhouse populations. Although White (1977) presented no figures on percentage germination of the filled achenes he sowed during his greenhouse study, he indicated that 62 percent of the P. ruthii seedlings resulting from the 960 filled achenes sown survived their first 3 weeks. It is suggested that a combination of wind and nonselective foraging by insects could account for the low percentage of filled achenes (Wofford and Smith 1980). No studies of pollinators or of pollination in P. ruthii have been performed. However, in the field, Bowers (1972a) noted several kinds of bees visiting the flowers of various members of the section Pityopsis (including P. ruthii), and in the greenhouse he observed occasional visits by flies to the flowers of the same species. He determined that members of the section Pityopsis are obligate outcrossers and that self-fertilization and apomixis seldom, if ever, occur. He also concluded that wind is of little importance in pollination. White (1977), while collecting soil samples in the field, observed numerous ant colonies sharing the same crevices with P. ruthii. He suggested there may be a relationship between the presence of the ants and the establishment of P. ruthii but made no further investigation of this potential relationship. Production of low numbers of viable seeds could easily contribute to difficulties in the establishment of new plants. Ineffective dispersal methods also could be a contributing factor. While Wofford and Smith (1980) stated that “age class determinations indicate only mature individuals are present,” there was evidence that regeneration from seeds is occurring. In an ongoing study of P. ruthii, Collins and Gunn (1986) observed one subpopulation on the Hiwassee River comprising 1,149 individual plants. Relative to other subpopulations measured in 1986 and 1987, a greater preponderance of those plants were small and single-stemmed and were not located near enough other larger plants to have come from rhizomes. The same subpopulation was measured the next year (Collins and Gunn 1987), and 307 fewer individuals were found, perhaps the victims of stress from severe drought. Apparently many of the absent individuals were the small, single-stemmed plants recorded the prior year. It is possible that many of those plants were young seedlings, not yet vigorous enough to withstand the extreme conditions at the time. Furthermore, a great many more individuals not producing flowering heads were seen than were found by Wofford and Smith (1980). The extent and significance of predation upon P. ruthii are not known. White (1977) observed predation by the larvae of three moth species on plants in the greenhouse. In the field, Collins and Gunn (1986) also have observed insect larvae apparently feeding on the achenes in the maturing heads of some plants (USFWS, 1990).

**Habitat Type**

Adult: The species is restricted to outcrops of phyllite (rarely greywacke) within 5.7 km (3.5 mi) and 4.6 km (2.9 mi) reaches of the Hiwassee and Ocoee Rivers, respectively (USFWS, 2018).

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (NatureServe, 2015)

**Site Fidelity**

Adult: High (NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits soil-filled cracks in phyllite boulders along river banks and in rivers, within 5.7 km (3.5 mi) and 4.6 km (2.9 mi) reaches of the Hiwassee and Ocoee Rivers, respectively (USFWS, 2018). Shade intolerant but adapted to annual high water flows; requires periodic flooding and scouring to remove competing vegetation (NatureServe, 2015). High ecological integrity of the community and site fidelity along with low tolerance ranges are noted based on the species specific habitat requirements and the relatively low number of populations (NatureServe, 2015).

***Dispersal/Migration***

**Motility/Mobility**

Adult: Low (inferred from USFWS, 1990)

**Dispersal**

Adult: Low (inferred from USFWS, 1990)

**Dispersal/Migration Narrative**

Adult: No study of fruit dispersal has been made, but the pappus is disposed to dissemination by wind. According to Wofford and Smith (1980), dispersal also is achieved by water. They regarded effective dispersal as rare, based on the paucity of observations of seedlings in nature, but provided no supportive data (USFWS, 1990). Low mobility and dispersal are inferred based on rare effective dispersal of the species.

***Population Information and Trends***

**Population Trends:**

Stable to decreasing (USFWS, 2018)

**Species Trends:**

Decreasing (USFWS, 2018)

**Number of Populations:**

2 (USFWS, 2023)

**Population Size:**

~100,000 total individuals (USFWS, 2023)

**Population Narrative:**

As of 2017, the population from the Ocoee River was relatively stable from 2011 through 2017 ranging from a low of 1,140 during 2011 to a high of 1,299 individuals in 2015. As of 2017, there were 1,232 individuals, an overall increase of 82 individuals (7.2 percent) compared to the baseline census in 2011. Data collection on the Hiwassee River has occurred at a total of 57 sites, but only 27 sites have been counted annually. These 27 sites account for more than 90 percent of all plants counted in each year from 2011 through 2017, thus are representative of trends for the population on this river. Data from the Hiwassee demonstrate that a period of increase occurred from 2011 through 2014, followed by decreases through 2017. Using data from the 27 sites counted annually, as of 2017 there has been a decrease of 1,676 individuals (17.6 percent) compared to the 2011 baseline and a decrease of 4,125 individuals (34.5 percent) since 2014, when the population peaked (USFWS, 2018). A study from 2013 showed moderate genetic diversity in three populations sampled and a study from 2018 determined that gene flow levels among populations within each river were sufficient to reduce risk of divergence due to genetic drift. The species is restricted to two populations located along short reaches of the Hiwassee and Ocoee rivers, in Polk County, Tennessee. Available data indicate that the Ocoee River population has increased by approximately 20 percent since 2011, to a total of 1,388 individuals in 2022. While it is the larger of the two populations, the species abundance in the Hiwassee River population has decreased by approximately 10 percent since 2011, to a total of 8,968 individuals in 2022 (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Encroachment of competing vegetation (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** There are concerns about the loss of habitat in the Hiwassee drainage to encroachment of competing herbaceous and woody vegetation. A Biological Assessment prepared by TVA (2002) discussed the threat posed to the Hiwassee population by vegetation encroachment onto the phyllite boulders due to altered flows in the river below Apalachia Dam since its construction in 1943. They identified this threat as the cause for the observed decline of P. ruthii since monitoring began in 1986. Several lines of evidence support this conclusion, including the general declining trend in the Hiwassee population since monitoring began, the finding of Thomson and Schwarz (2006) that all Hiwassee populations suffered mean negative growth rates except for one plot from which vegetation had been removed in the past, and Cruzan's (2000) observation that vegetative cover in the Hiwassee floodplain has increased approximately 50 percent since the late 1940s (USFWS, 2012). Continued ecroachment and habitat reduction contributes to decreases in P. ruthii in some sites. As abundance decreases, pollinator attraction could decrease, potentially creating a negative feedback loop reducing reproductive output and contributing to further declines (USFWS, 2018).

**Stressor:** Altered flow regimes (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Altered flow regimes (due to the Apalchia dam) and encroachment of competing vegetation into suitable habitat in the Hiwassee drainage remain the greatest active threats for P. ruthii. Because the process of vegetation encroachment has occurred over a period of several decades, riparian communities have become established on the phyllite boulders to the extent that periodic high flows alone would not be enough to remove this threat and restore P. ruthii habitat (USFWS, 2012). Maintenance work in 2015-2016 on the Apalachia powerhouse and switchyard caused elevated flows for 132 days in the Hiwassee River where P. ruthii occurs and a decline in this population was observed. Drought conditions also occurred during part of 2016, which could also account for the decline in the observed Ocoee River population (USFWS, 2018).

**Stressor:** Recreation (USFWS, 2012)
**Exposure:**
**Response:**

**Consequence:** Loss of individual plants
**Narrative:** The development of a whitewater recreation facility on the Ocoee River and hosting of whitewater events during the 1996 Olympics elevated concerns about recreation-related impacts to P. ruthii, both from whitewater paddlers and spectators. The USFS-CNF recommended corrective measures to reduce recreation-related impacts at two sites (Doublesuck and Tablesaw) where they were found to be greatest (Herrig and Wyrick 1996). The threat of trampling by spectators at the Tablesaw site was reduced by the extension of a guardrail on the nearby highway, eliminating parking access in close vicinity to this population. However, no billboard or kiosk has been constructed at the access point for paddlers upstream of Doublesuck, to inform paddlers of the presence of P. ruthii and biologically sensitive areas near particular whitewater features (USFWS, 2012). No adverse effects from whitewater recreationists or observers have been reported since 2015 (USFWS, 2018).

**Stressor:** Road construction (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The Tennessee Department of Transportation is currently analyzing transportation alternatives for Corridor K, which passes through the Ocoee River Gorge and based on a preliminary map of targeted spot improvements, some of the road construction would occur along US HWY 64 where it parallels sites on the Ocoee River that P. ruthii occupies. A Section 7 consultation has not been completed and therefore the potential for adverse effects to P. ruthii that could result from implementing the Targeted Approach have not been analyzed (USFWS, 2018).

**Stressor:** Disease or predation (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Five potential invertebrate herbivores have been observed on P. ruthii in situ and ex situ plants and can damage flower buds and developing seeds (USFWS, 2018).

**Stressor:** Hybridization (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The potential for hybridization to occur between Heterotheca ruthii (=P. ruthii) and H. graminifolia (=P. graminifolia var. latifolia) was first documented by Bowers (1972), in a cross that produced only two seeds, one of which germinated and died within a week. Moore et al. (2016) report that P.A. Wadl (unpublished data) produced viable offspring from controlled crosses between these species. Recent evidence (Boggess 2013, Hatmaker et al. 2018, P. Wadl 2018, pers. comm.) indicates that wild hybrids may be formed where these two species co-occur. Hybridization could present a threat to reproductive output and genetic variation (USFWS, 2018).

**Stressor:** Climate change (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Using NatureServe's Climate Change Vulnerability Index (CCVI) to assess P. ruthii's predicted exposure to climate change, the species was ranged as highly to extremely vulnerable indicating that abundance and/or range extent or are either likely to decrease significantly (highly vulnerable), or extremely likely to substantially decrease or disappear (extremely vulnerable), by 2050 (Young et al., 2015)(USFWS, 2018). Drought experienced in 2016 and 2017 contributed to declines of this species and very likely reduced seedling establishment given that seedling emergence has been observed to occur beginning in November (USFWS, 2018).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 5C

**Delisting Criteria:**
The Ocoee River population, under the criteria described in or to be established by implementation of Task 7, is deemed recovered and the rate of natural succession on the phyllite boulders on the Hiwassee River is determined to not be detrimental to the survival of P. ruthii (USFWS, 1990).

The Hiwassee River population, under the criteria described in or to be established by implementation of Task 6, is deemed recovered and Tasks 7.2, 7.3, 7.4, and 7.6 are accomplished for the Ocoee River population.

Pityopsis ruthii shall be considered recovered when the full set of recovery goals (Tasks 6 and 7) for each population is fulfilled (USFWS, 1990).

**Recovery Actions:**
- 1. Maintain formal agreements among the appropriate concerned agencies on the preservation of Pityopsis ruthii.
- 2. Maintain permanent plots.
- 3. Determine what is necessary for effective and successful achene dispersal. seed germination, and seedling establishment. 3.1 Study achene dispersal. 3.2 Determine life history. seed germination, and seedling establishment requirements. 3.3 Determine the role of interspecific and intraspecific competition.
- 4. Determine what constitutes suitable habitat.
- 5. Search for Pityopsis ruthii on other rivers.
- 6. Determine and implement for the Hiwassee River population the management necessary for long-term reproduction, maintenance, and vigor. 6.1 Determine and compare Past and present stream flow regimes. 6.2 Determine the nature and role of natural succession on the phyllite boulders. 6.3 Determine whether or not the population is self-sustaining. 6.4 Establish P. ruthii on unoccupied suitable habitat. 6.5 Establish a cultivated population of plants descended from the Hiwassee River population and provide for long-term seed storage. 6.6 Determine feasibility and/or necessity of water releases and hand-clearing of phyllite boulders (USFWS, 1990).
- 7. Determine and implement for the Ocoee River population the management necessary for long-term reproduction, maintenance, and vigor. 7.1 Study the relationship of the river to P. ruthii. 7.2 Determine impacts of river recreational users and implement required

management actions. 7.3 Ensure that highway construction will not damage or destroy plants or suitable habitat. 7.4 Determine whether the population is self-sustaining. 7.5 Establish P. ruthii on unoccupied suitable habitat. 7.6 Establish a cultivated population of plants descended from the Ocoee River population and provide for long-term seed storage (USFWS, 1990).

- 8. Variability in population trends among sites in the Hiwassee River suggests that demographic monitoring of selected sites would be useful in understanding which life history stages are most affected by threats to the species and its habitat. Demographic monitoring will be necessary for evaluating effectiveness of any future efforts to reintroduce the species into suitable unoccupied habitat (USFWS, 2018).
- 9. Future restoration projects should explore effects of planting season and importance of mycorrhizal associations on establishment, survival, growth, and reproduction of introduced plants. Additionally, if restoration into suitable habitat is to be successful, multiple outplantings over time likely will be necessary at any given site (USFWS, 2018).
- 10. For each mapped location on the Hiwassee River, record data on apparent vulnerability to vegetation encroachment, including observations on substrate composition (e.g., bedrock, boulder, cobble, gravel, degree of sediment deposition), landform and aspect. Use these data to map risk of local extinction and assess whether and where management is needed to control vegetation encroachment (USFWS, 2018).
- 11. Incorporate observations on presence and relative abundance of Pityopsis graminifolia var. latifolia at monitoring sites, to document locations where potential threat of hybridization is greatest (USFWS, 2018).
- 12. Coordinate with TDOT to avoid potential adverse effects to P. ruthii from road construction activities on US HWY 64 (USFWS, 2018).
- The primary actions needed to move P. ruthii towards a status at which downlisting or delisting could be considered, include: 1. Determining effective methods for controlling vegetation encroachment and restoring degraded habitat in the Hiwassee drainage (USFWS, 2012).
- 2. Implementing a vegetation control and habitat restoration program to restore suitable habitat conditions across the occupied range in the Hiwassee drainage. For long-term prevention of repeated vegetation encroachment, altering flows to provide sufficient frequency and duration of scouring of phyllite boulders will likely be necessary (USFWS, 2012).
- 3. Analyzing and comparing contemporary flow regimes (i.e., since 1943) on the Hiwassee River to pre-impoundment flow regimes (USFWS, 2012).
- 4. Conducting future surveys of P. ruthii populations in the Hiwassee drainage in order to assess (1) the degree to which suitable habitat for the species declines due to vegetation encroachment and (2) whether the species' linear distribution along the Hiwassee River changes over time (USFWS, 2012).
- 5. Developing effective reintroduction methods for establishing P. ruthii in suitable habitat, in order to fulfill recovery tasks 6.4 and 7.5 (USFWS, 2012).
- 6. Ensuring that recommendations for controlling whitewater recreation-related threats to the Ocoee population are implemented (USFWS, 2012).
- 7. Continuing long-term monitoring effort that has been implemented by TVA, USFS-CNF, and TDEC (USFWS, 2012).
- 8. Continuing annual meetings of the RCWG to coordinate recovery efforts (USFWS, 2012).

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES Recovery Activities In the absence of river flows sufficient to regulate vegetation encroachment in many sites where Pityopsis ruthii occurs along the Hiwassee River, it could be necessary to develop effective approaches for mechanical or chemical control to prevent the species' displacement from some sites where this threat of encroaching vegetation is most aggressive. It would likely be infeasible to conduct such intensive management at the scale of the entire occupied reach, owing to the remoteness of the area and other environmental considerations (e.g., presence of endangered mussel species and designated critical habitat in this reach of the Hiwassee River). A management plan identifying the areas under the greatest threat and that guides incremental habitat restoration over a period of several years, however, may need to be developed in order to advance recovery of the species at a biologically meaningful scale. Additionally, flow prescriptions could be developed to regulate vegetation encroachment and enhance P. ruthii habitat, as discussed below. Monitoring and Research Activities The 2012 and 2018 5-year status reviews for Pityopsis ruthii discussed at length how a better understanding of artificially regulated river flows in the Hiwassee River and their influence on P. ruthii population growth could inform the development and implementation of more ecologically compatible flow prescriptions. The presumed importance of river flows that inundate occupied P. ruthii habitats at a frequency sufficient to regulate encroachment of competing herbaceous and woody vegetation are discussed in the species recovery plan, which calls for an analysis of contemporary and historical flow regimes to understand how flow alterations have contributed to changes in riparian vegetation conditions and availability of suitable sites for P. ruthii. Hydrological reference conditions for the Hiwassee River, however, are unavailable prior to the closing of Apalachia Dam. An alternative approach for understanding how flows interact with vegetation and suitable sites for P. ruthii would be to adapt a methodology used for assessing effects of river flows on another species in the family Asteraceae, beautiful Barbara's buttons (Marshallia pulchra) (Tracey and Simmerman 2021). These methods could be adapted to investigate relationships between discharge, depth and duration of inundation, and response of P. ruthii and the associated vegetation community to compare these dynamics for the Hiwassee River to the Ocoee River, where conditions have supported population increase for more than a decade of monitoring. With a better understanding of the relationship between river flows, habitat inundation, and P. ruthii population responses in both river systems, it might be possible to prescribe a flow regime that would support population growth in the Hiwassee River population. A collaborative effort leveraging the authorities and resources of multiple partners, such as the U.S. Fish and Wildlife Service, Tennessee Valley Authority (TVA), American Whitewater Association, US Forest Service, and Tennessee State Parks, could potentially take on such an investigation to advance the status of the species (USFWS, 2023).

# SPECIES ACCOUNT: *Plagiobothrys hirtus* (rough popcornflower)

***Species Taxonomic and Listing Information***

**Commonly-used Acronym:** Plhi

**Listing Status:** Endangered; Pacific Region (R1) (USFWS, 2016)

**Physical Description**

Rough popcornflower plants are between 7 centimeters (cm) (2.75 inches [in]) to 60 cm (23.6 in) tall, with narrow, simple hairy-margined bright-green leaves along hairy stems. The non-fragrant flowers consist of five fused petals, are trumpet-shaped, mostly white with yellow centers, and positioned in a hairy calyx. The flowers are helicoid in development and occur on paired coiled inflorescences. Each flower produces four tan to black-colored, one-seeded nutlets, which loosely adhere to the receptacle, until they drop. These nutlets will germinate readily (Amsberry and Meinke 2002, p. 24). However, due to fruit abortion or lack of pollination, flowers with fewer than four nutlets are often observed. As in most members of the Boraginaceae family, anthers are included and epipetalous (having stamens attached to the inner corolla surfaces. Rough popcornflower can be either an annual or a short-lived perennial. Rough popcornflower exhibits two distinct growth forms in the northern and southern portions of its range in Douglas County. In the northern part of its range near Yoncalla, the plants are more robust, slightly taller, and predominantly perennial (Figure 1). Here rough popcornflower has the ability to produce adventitious roots that easily establish in the moist soil of their wetland habitats. In the southern part of the range, 25.8 kilometers [km] (16 miles [mi]) south of the Yoncalla population, from the general area of Sutherlin to Wilbur, the population include annual plants, often in clusters, with a few sporadic perennial plants. The rough popcornflower and fragrant popcornflower (P. figuratus) are found in similar wetland habitat in northern Douglas County. Both are members of the subgenus Allocarya (Peck 1961, p. 66), and are quite similar in appearance. Rough popcornflower differs from fragrant popcornflower in that the entire plant is larger and has less fragrant flowers, hairier stems and fruits, more robust stems, and blooms several weeks later. The larger rough popcornflower plants grow with more arched stems as well. A stout, hairy (on the upper part of the stems) annual, 3-6 dm tall, with long, narrow leaves and white flowers. Blooms primarily from mid to late June. (NatureServe, 2015)

**Taxonomy**

Allocarya hirta Greene was the original scientific name applied to the species in 1888. Since then, the species has undergone a number of taxonomic re-arrangements, including Allocarya scouleri var. hirta, Allocarya calycosa, and Plagiobothrys scouleri var. hirtus. Since the 1961 edition of Plants of Oregon, it has remained Plagiobothrys hirtus (Peck 1961, p. 661), and this classification is recognized as valid by the U.S. Department of Agriculture Plants Database (U.S. Department of Agriculture 2018, website) and the Integrated Taxonomic Information System (Integrated Taxonomic Information System 2019, website).

**Historical Range**

Rough popcornflower is found only in northern Douglas County, Oregon, occurring at low elevations (100 and 230 meters (m) [328 to 755 feet [ft]) within the Umpqua River basin, distributed in the Elk Creek, Umpqua River, and Lower North Umpqua River watersheds.

**Current Range**

Rough popcornflower has been documented at 23 populations historically; 18 are extant and 5 are extirpated. Five of the known populations occur on private land and lack monitoring access. Despite this, the species is estimated to have greater than 883,154 mature, reproductive individuals across its range. Of the 18 extant populations, 1 is very large (700,000 plants), 10 are relatively large (5,000-70,000 plants), 4 are medium (1,000-4,999 plants), and 3 are small (less than 1,000 plants). While smaller populations, in general, are more vulnerable to extirpation from stochastic events and genetic drift than larger populations (Szczecińska et al. 2016, p. 17; Ma et al. 2013, p. 805), the majority of rough popcornflower populations support more than 5,000 individuals and we believe are less susceptible to stochastic events and genetic issues.

**Critical Habitat Designated**

No;

**Legal Description**

NA

***Life History***

**Food/Nutrient Resources**

**Competition**

Adult: Competes with both invasive and native plants

**Food/Nutrient Narrative**

Adult: water availabilty is dependent on annual weather patterns and heavy clay soils

**Reproductive Strategy**

Adult: r strategy, species relies on outcrossing but can self if necessary

**Reproduction Narrative**

Adult: Popcornflower can be a perennial, growing to 70 cm tall (27.5 inches), with dozens of flowering stems and hundreds of flowers, or can be a diminutive annual with only a few flowers (Amsberry and Meinke 2001). At Popcorn Swale Preserve, rough popcornflower generally reaches peak growth and flowering by mid-June. By July 1, many plants have dropped seed and are senescing. By July 15, rough popcornflower generally appears gray-brown and crispy although a rare flower or two may be found low to the ground in moister, shaded areas. Although most plants are dormant by mid-July, perhaps around 1% of individuals may still be green and actively growing and flowering. Rough popcornflower, like most borages, can potentially produce four nutlets per flower. In most sites, copious numbers of mature seeds were observed from mid-June through early September, but plants in a few wetter habitats delayed seed maturation until the beginning of August. The number of seeds produced by individual plants is largely controlled by the number of flowers produced, and correspondingly, large plants produce more flowers (USFWS, 2016). Pollination biology of rough popcornflower is not well documented but we are not currently considering lack of pollination or seed production a stressor, but are more concerned with connectivity and habitat quality since pollination is dependent of habitat corridors of an adequate variety of native and non-native plants (habitat quality). We know that the typical high seed set indicates that pollination is highly successful since the flowers are visited by a diverse group of generalist pollinators, and that pollination is not currently a limiting factor for this species. Connectivity and habitat quality is essential to ensure that genetic exchange is taking place within and among populations by these pollinators (U.S. Fish and Wildlife Service 2003, p. 54). (USFWS, 2021b)

**Habitat Type**

Adult: River valley wetlands (USFWS, 2016)

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from USFWS, 2016)

**Environmental Specificity**

Adult: Very narrow to narrow. (Natureserve, 2015)

**Habitat Narrative**

Adult: Rough popcornflower is a plant closely associated with seasonally wet, relatively level, open habitats in Douglas County formed from poor draining clay-loam soils, concentrated in the Sutherlin Creek basin in Oregon. These wet habitats are unique to the Sutherlin area and correspond to a particular type of soil series known as Conser silty clay-loam. The majority of rough popcornflower populations largely correspond to Conser soils, which is a poorly draining silty clay-loam series soil. To a lesser extent, the species occurs on clay or loam soils including Bashaw clay, Brand silty clay loam, Curtin clay, Dixonville silty clay loam, Nonpareil loam, Oakland clay-loam, Packard silty loam, Philomath-Dixonville complex, Sibold clay, and Waldo silty clay loam soil types. Rough popcornflower habitat corresponds to emergent wetlands within seasonally wet meadows or prairie, seasonally-ponding mudflats, and Oregon ash (Fraxinus latifolia) swale openings dominated by native wetland-associated herbs and graminoids in valley lowlands where the ground is moist well into the summer season. The species appears to be adapted to early seral succession habitat so it does not often occur under dense shade. Native perennial plant species commonly associated with rough popcornflower habitat include Oregon ash, dense sedge (Carex densa), green-sheathed sedge (C. feta), one-sided sedge (C. unilateralis), spreading rush (Juncus patens), pointed rush (J. oxymeris), common rush (J. effusus), tufted hairgrass (Deschampsia cespitosa), great white camas (Camassia leichtlinii), rush-leaved coyote thistle (Eryngium petiolatum), Willamette gumweed (Grindelia integrifolia), and western mannagrass (Glyceria occidentalis). Native annuals commonly associated with rough popcornflower include American sloughgrass (Beckmannia syzigachne), skullcap speedwell (Veronica scutellata), Cascade calicoflower (Downingia yina), and Douglas meadowfoam (Limnanthes douglasii). Common invasive plant associates in rough popcornflower habitat include trees (e.g. European pear [Pyrus communis]); shrubs (e.g. Armenian blackberry [Rubus armeniacus] and English hawthorn [Crataegus monogyna]); herbaceous plants (e,g. meadow knapweed [Centaurea moncktonii], teasel [Dipsacus fullonum], Canada thistle [Cirsium arvense], pennyroyal [Mentha pulegium], and curly dock [Rumex crispus]); and graminoids (e.g. reed canarygrass [Phalaris arundinacea] and tall fescue [Schedonorus arundinaceous]). Pennyroyal and tall fescue are nearly always present in or around rough popcornflower habitat. Rough popcornflower appears to be a species that requires early seral habitat and is not associated with habitat under dense tree or shrub canopies. Grazing helps to control invasive and native plant competitors and provides a measure of disturbance that maintains the preferable more-early seral and open habitat conditions for rough popcornflower. Flooding, fire, and native ungulate grazing, also likely played a large role in the development and maintenance of habitat for the plant (U.S. Fish and Wildlife Service 2000, p. 3867). When such natural disturbance events are lacking, active management is necessary to control competing vegetation and maintain requisite conditions for this plant to compete with naturally occurring and non-native plant species. An increase in abundance of Oregon ash or spreading rush can result in a loss of rough popcornflower habitat without mowing, grazing, or fire to restore habitat suitability (USFWS 2021).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Has increased from 8 populations at the time of listing to 18 populations. (USFWS 2021).

**Resiliency:**

We assessed habitat conditions for rough popcornflower in terms of habitat area, population size, habitat quality, connectivity, management, protection, reproduction, abundance of insect pollinators, and rainfall. Of the 18 total rough popcornflower populations, 11 had a higher probability of persistence, 3 had a moderate probability of persistence, and 4 had a low expected persistence over the next 30 years. (USFWS 2021)

**Representation:**

An abundance of insect pollinators and habitat connectivity leads to genetic diversity by the process of cross-pollination between patches within a population. There is a need to maintain the genetic variation between populations as their potential genetic and life history attributes may buffer the species to adapt to environmental changes over time. At this time, we do not know the degree of genetic variation among rough popcornflower populations and whether connectivity and active genetic exchange is occurring across populations and within patches or within populations. Most rough popcornflower populations are not isolated from one another by over 2.0 km (1.24 miles) and it is assumed that gene flow occurs among the majority of the population. (USFWS 2021)

**Redundancy:**

Rough popcornflower requires multiple resilient populations distributed throughout its range to provide for redundancy. The more populations, and the wider the distribution of those populations, the more redundancy the species will exhibit. Redundancy reduces the risk that a large portion of the species' range will be negatively affected by a catastrophic natural or anthropogenic event at a given point in time. (USFWS 2021)

**Population Growth Rate:**

From 7,000 individuals at the time of listing has increased to a total population estimate of over 883,154 individuals. (USFWS 2021).

**Number of Populations:**

18 are extant and 5 are extirpated. (USFWS 2021)

**Population Size:**

883,154 individuals (USFWS 2021)

**Minimum Viable Population Size:**

Although a minimum viable population hasn't been determined, based on studies by Lande (1995) and Lynch et al. (1995) we have recommended the recovery level population size for rough popcornflower as 5,000 plants per population. This figure is based on the authors' suggestion that in most cases, 5,000 individuals in a population, is necessary to maintain above normal levels of potentially adaptive genetic variability under a balance between mutation and random genetic drift. Without a Population Viability Analysis (PVA) to indicate what an optimal abundance level should be, using our best professional judgement, we consider a population with over 5,000 mature plants to be in high condition, over 1,000 plants to be in medium condition, and under 200 plants to be in low condition.

**Adaptability:**

We have no documentation of rough popcornflower's adaptability. Maintaining representation in the form of genetic or ecological diversity will provide rough popcornflower the capacity to adapt to future environmental changes.

**Population Narrative:**

Rough popcornflower has been documented at 23 populations historically; 18 are extant and 5 are extirpated. All known populations (naturally occurring and reintroductions) occur in Douglas County, OR. Five of the known populations occur on private land and lack monitoring access. Despite this, the species is estimated to have greater than 883,154 mature, reproductive individuals across its range. Of the 18 extant populations, 1 is very large (700,000 plants), 10 are relatively large (5,000-70,000 plants), 4 are medium (1,000-4,999 plants), and 3 are small (less than 1,000 plants). The majority of rough popcornflower populations support more than 5,000 individuals and we believe are less susceptible to stochastic events and genetic issues. Through extensive surveys and augmentation and introduction efforts, the 7,000 individuals within 8 populations known at the time of listing has increased to 18 populations, with a total population estimate of over 883,154 individuals. The bulk of this estimate includes a single extensive rough popcornflower population south of Sutherlin, which has not been adequately censused but may have as many as 700,000 individuals.

***Threats and Stressors***

**Stressor:** Competition (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Stressors to rough popcornflower habitat include encroachment by Oregon ash and European pear, Armenian blackberry and English hawthorn, pennyroyal, teasel, Canada thistle, curly dock, spreading rush and reed canarygrass), which compete for moisture, light, and space. Pennyroyal is nearly always present in rough popcornflower habitat and is an ever-present competitor. (USFWS, 2021, p. 17).

**Stressor:** Development (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat

**Narrative:** Development was described as a serious stressor to rough popcornflower. In addition, habitat can become degraded by both channelization (e.g. ditching) and filling of wetland habitat.(USFWS,2021, p. 17)

**Stressor:** Agriculture (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The species appears to be adapted to early seral succession habitat and cannot compete with later successional vegetation such as Oregon ash, rushes, and tall fescue for light, moisture, and space. Stressors to rough popcornflower habitat include encroachment by Oregon ash and European pear, Armenian blackberry and English hawthorn, pennyroyal, teasel, Canada thistle, curly dock, spreading rush and reed canarygrass), which compete for moisture, light, and space. Pennyroyal is nearly always present in rough popcornflower habitat and is an ever-present competitor.

**Stressor:** Fire suppression (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Fire suppression resulting in encroaching native oaks and ash trees that shade popcornflower and reduced gene flow due to habitat fragmentation are considered to be other threat factors (USFWS 2010).

**Stressor:** Urban and Rural Development (USFWS, 2021b)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Urban and Rural Development. The final listing decision (U.S. Fish and Wildlife Service 2010, p. 3869) described how rough popcornflower populations had become fragmented due to draining and filling of wetlands from properties being developed, primarily in the city of Sutherlin area. For example, between 1995 and 2002, four rough popcornflower populations were either heavily impacted or lost due to urban development, mostly prior to the species' listing. Currently, we consider urban development in the general vicinity of Sutherlin (within and just beyond the Urban Growth Boundary) as a threat to four populations (Hawthorne, Southside Swale, Sutherlin East, and Stearns Lane). However, 11 of the 18 populations (151,195 of 883,154 total plants) throughout the species' range are under Federal, State, municipal, or land trust protections providing for the long-term persistence of these populations. At other privately owned populations on rural pasturelands (Horsepasture 2, Nonpareil), long-term persistence has been documented for over 30 years. Additionally, developers, State and Federal wetland regulators, and city and county governments are doing an increasingly better job of recognizing rough popcornflower habitat and avoiding and minimizing (or mitigating) development impacts. Because the majority of the population is protected and the species is benefitting from increased awareness, the threat posed by development has been significantly diminished. Nine rough popcornflower populations occur on Federal, State and Municipal owned lands, where management of the species is directed by species-specific management plans and regulations (Table 2). Rough popcornflower is distributed across properties with a mix of ownership (Table 2) and land use practices. These land use practices on privately owned land may or may not be

consistent with rough popcornflower conservation. For example, while some landowners mow rough popcornflower during its growing period, seed with non-native pasture grass, and use selective herbicides to promote hay or agricultural crops (i.e., practices that can be detrimental to the species), other landowners are interested in conserving the species, mow, and graze when competition with invasive non-native species is problematic for the species. As discussed above in the Habitat section, some forms of land use practice can be beneficial to the species. The fact that lands are held in private ownership in and of itself does not constitute a threat to the species. In fact, three of the largest rough popcornflower populations occur on private lands where the property is not specifically managed to benefit the species (Table 2). Of the 18 extant rough popcornflower populations, 4 with greater than 5,000 individuals occur partially or wholly on private lands which are grazed beneficially for the species. At the time of listing, only five populations of rough popcornflower were protected from detrimental land-use activities. Since listing, significant progress has been made in protecting and managing sites supporting rough popcornflower. Because 12 of the 18 of the populations are now considered protected or on adequately managed land, the threat from development activities is no longer as severe. (USFWS, 2021b)

**Stressor:** SMALL POPULATION SIZE (USFWS, 2021b)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The final listing rule (U.S. Fish and Wildlife Service 2000, pp. 3869-3870) described the distribution of the rough popcornflower as 17 small patches (approximating 7,000 plants) which were threatened by natural (i.e., flood) and / or anthropogenic (e.g., herbicide treatment) events. At the time, the species' small population size was considered a threat because a single natural or man-made event could have the potential to extirpate a small rough popcornflower patch. Although small populations occur that are still vulnerable to extirpation, there are now multiple, large populations of rough popcornflower occurring in patches larger than those at the time of listing, providing added resilience to the species. In addition, at the time of listing there were concerns that a small, isolated population might not be able to sustain adequate genetic variation, or that reproduction may be impaired (see Fertilization, below). There was also a concern that a lack of connectivity between isolated patches and populations would limit pollinator-mediated gene flow. Since then, these concerns have since been alleviated to a significant extent. At the time of listing, the limited number of individuals and populations was considered a threat. Today, eight of the 18 populations are dispersed over a much larger area (over 500 m2 [5382 ft2 ]) than in the past and are likely large enough to withstand a single random natural or anthropogenic event. However, the Hawthorne, Stearns Lane, and Ford's Pond populations are located in small discrete areas and are vulnerable. Even so, these small populations are broadly distributed and the likelihood of large-scale event affecting them collectively is unlikely. Overall, while this species' relatively small population is still of some concern, it is much less vulnerable than when it was listed. (USFWS, 2021b)

**Stressor:** HERBIVORY (USFWS, 2021b)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbivory by Columbian white-tailed deer (Odocoileus virginianus leucuruswas), black-tailed deer (Odocoileus hemionus columbianus), assorted rodents, and livestock, particularly

sheep, has occasionally been documented and could be a threat to rough popcornflower (U.S. Fish and Wildlife Service 2000, p. 3871). Densities of white-tailed and black-tailed deer are high in much of the Sutherlin Creek area and generally overlap with the distribution of rough popcornflower. Deer herbivory was evident following introduction of rough popcornflower to a wetland mitigation site (U.S. Fish and Wildlife Service 2020, p. 2) and some evidence of sheep herbivory has been documented (U.S. Fish and Wildlife Service 2000, p. 3871). Despite the densities of deer, herbivory does not appear to be causing widespread damage to most rough popcornflower populations. (USFWS, 2021b)

**Stressor:** INVASIVE PLANT ENCROACHMENT (USFWS, 2021b)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Non-native invasive plants are a primary threat to the establishment of rough popcornflower due to their encroachment of habitat and elimination of bare-ground, which popcornflower seeds require to germinate. Invasive pennyroyal is present at many rough popcornflower sites and controlling this species requires constant effort and is a management priority at the NBHMA, TNC Popcorn Swale Preserve, and Red Rock Park populations. Similarly, teasel and Canada thistle control requires constant effort at the NBHMA, Yoncalla South and the TNC Popcorn Swale Preserve populations. Reed canary grass covered over 70 percent of the Red Rock Park rough popcornflower site for several years and required three years of repeated manual weeding efforts and herbicide treatments to reduce this invasive plant to manageable levels. As discussed above, rough popcornflower is conservation reliant in that some form of active management is necessary to maintain habitat in an early-successional condition. For example, prescribed fire, mowing, manual weeding, and herbicide treatment may be required to help maintain many of the rough popcornflower populations into the future (U.S. Fish and Wildlife Service 2010, p. 27). This is exemplified by the active management practices and population response at multiple locations (see Appendices 2 and 3). Invasive plants appears to be less of a concern on private lands because livestock grazing controls invasive plant growth (citation). Strategic grazing by livestock, in terms of seasonal grazing periods and intensity, when closely monitored, can benefit rough popcornflower populations by reducing plant competition and creating open ground that facilitates seed germination and enables population expansion (U.S. Fish and Wildlife Service 2020, p. 2). Competition with invasive plants is an ongoing threat to rough popcornflower. However, investments in weed control and lessons learned in how to combat invasive species has resulted in flourishing populations. A continued commitment will be needed to maintain these populations (see Appendices 3 and 4). While invasive plants remain a threat to rough popcornflower, this threat can be successfully managed. (USFWS, 2021b)

**Stressor:** FIRE (USFWS, 2021b)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, fire was considered a necessary natural event key to the formation and maintenance of rough popcornflower habitat (U.S. Fish and Wildlife Service 2000, p. 3867). In late September 2003, an accidental fire occurred at the Soggy Bottoms meadow within the BLM's NBHMA and burned across the introduced rough popcornflower population. The intensity of the fire was moderate but did not sterilize the soil's organic layers. Following the burn, staff noted that individual rough popcornflower plants were much larger, robust, and the

population increased from 1,193 plants in July 2003 to 1,869 plants in July 2004. However, by 2009 the population had been reduced to 15 individuals. The BLM and the Service attributed the rapid population decline to factors other than the burn, including changes in water flow and increased erosion due to stream channelization at the site that affected the hydrology of the site. While the effects of fire in rough popcornflower habitat restoration are still unknown (U.S. Fish and Wildlife Service 2010, p. 27), the fire at North Bank/Soggy Bottoms suggest that low to moderate intensity fire can have short-term beneficial effects to the species. (USFWS, 2021b)

**Stressor:** CLIMATE CHANGE (USFWS, 2021b)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The likely impacts of climate change on rough popcornflower's ecological processes are closely connected to availability of water. Due to their shallow and ephemeral nature, wet swales in southwestern Oregon are particularly sensitive to increases in evaporation or reductions in rainfall. Strong climate variability is likely to persist in the Pacific Northwest, owing in part to the year-to-year and decade-to-decade climate variability associated with the Pacific Ocean (May et al. 2019, p. 1039). Periods of prolonged drought are projected to intersperse with years featuring heavy rainfall driven by powerful atmospheric rivers and strong El Niño winters (May et al. 2019. p. 1039). Even modest increases in warming could result in more runoff in winter and less in spring and summer, more winter flooding, and drier summer soils, thereby altering the seasonality and duration of wetland hydration (Field et al. 2017, p. 18). Climate change is expected to lead to increased variability in precipitation and to an increased loss of soil moisture due to evaporation and transpiration (Field et al. 2017, p. 18), which may exacerbate effects due to drought. Drought-mediated decreases in water depth and inundation periods could increase the frequency at which wetlands dry before rough popcornflower has completed their flowering and fruiting stages. Climate change could also cause temperatures to exceed those suitable for growth of the species (U.S. Fish and Wildlife Service 2010, p. 28). The expected negative effects of climate change on rough popcornflower include heavier winter rains and limited spring moisture, which would result in decreased fruit production. (USFWS, 2021b)

**Stressor:** Herbicide use
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The species is likely affected by common herbicides. We have no knowledge the species is affected by Malathion or other general contaminants.

***Recovery***

**Reclassification Criteria:**
Criterion 1. At least 9 reserves, containing a minimum of 5,000 plants each, are protected and managed to assure their long-term survival. A reserve may be composed of one or more patches of rough popcornflower located within 1 km (0.6 mi) of each other. Criterion 2. A minimum of 500 m2 (5,382 ft2) is occupied by the rough popcornflower within each reserve. Occupied habitat should be determined by using a GPS device to delineate patches of plant, with the GPS data then uploaded into a GIS program to calculate total area. The maximum allowable location error is +/- 3 m (9.8 ft). For patches too small to be delineated accurately, a

GPS point location should be recorded along with a measurement of the occupied area. Criterion 3. A minimum of nine reserves, each meeting the requirements in Downlisting Criteria 1 and 2, are distributed with at least one reserve each in the Calapooya Creek and Yoncalla Creek recovery units, and a minimum of five reserves in the Sutherlin Creek recovery unit. The remaining two required reserves may be located within any of the natural recovery units, or elsewhere within the Lower North Umpqua River (1710030111), Calapooya Creek 6 (1710030301), and Elk Creek (1710030303) Hydrologic Unit Code 10 watersheds containing the recovery units. Criterion 4. Over a 5-year period with a minimum of 3 individual years of monitoring, demographic data indicate that at least seven of the nine reserves have average population numbers that are stable or increasing, without decreasing trends lasting more than 2 years.

Recovery Priority Number: 8C

**Delisting Criteria:**
Criterion 1. At least 9 reserves will have established management plans or conservation agreements that include requirements for periodic monitoring and habitat maintenance. Habitat maintenance must prioritize the removal of woody vegetation and non-native invasive plants. Criterion 2. Seed accessions need to be collected from all 9 reserves and submitted for long-term storage at a local seed bank repository, with a minimum of 15,000 seeds per reserve stored for use in future augmentations or to re-establish each source population should one ever be extirpated. Criterion 3. Over a 10-year period with a minimum of 7 years of monitoring, demographic data indicate that populations in at least seven of the 9 recovery reserves have average population numbers that are stable or increasing, without decreasing trends lasting more than 2 years.

**Recovery Actions:**

- Recovery Measures for Popcornflower: Evaluate the status of all existing populations. Conduct surveys to search for new populations. Rough popcornflower populations will have reserve status if protected and meet recovery criteria of 5,000 plants. Currently we consider 12 of 18 populations protected. Protect habitat to be included in reserves Provide educational opportunities for landowners/managers/general public Use of existing authorities and applicable regulations Evaluate techniques to reduce competition Evaluate techniques to reduce impacts of woody succession Implement control measures: Implement appropriate management to reduce competition and control woody plant succession Collect seeds from extant sites Produce and establish transplants Monitor existing populations Identify ecologically appropriate habitat Protect population introduction sites Produce and establish transplants Manage populations to promote viability Monitor new populations to determine viability Rank populations. Collect and bank seeds Evaluate population genetic diversity Evaluate pollinator availability Provide outreach services for reserve owners and the general public Evaluate the status of Plagiobothrys hirtus Inventories for new and known populations of popcornflower were conducted throughout the species range in 2005 and 2014 by ODA (K. Amsberry, Oregon Department of Agriculture, pers. comm. 2014). Documentation of the distribution and abundance of popcornflower began in 1995 and has continued annually at most sites in most years; the exceptions are 2001 for BLM populations and 2008 to 2011 for TNC populations (USFWS, 2016).

***Conservation Measures and Best Management Practices:***

- Recommendations: • Recommend downlisting to threatened. • In cooperation with partners, continue to manage rough popcornflower, utilizing best management practices for this conservation-reliant species. • Enhance protection for, and augment, existing populations in the Calapooya Recovery Unit by ensuring protection through formal conservation agreements, management plans or publicly established reserves for the Nonpareil and other populations in this Recovery Unit. • Reintroduce rough popcornflower into suitable habitat, particularly in locations that will contribute to meeting recovery criteria. • Continue to pursue protected/reserve status of wetland and wet-swale habitat conditions benefitting rough popcornflower. (USFWS, 2021a)
- Vegetation Control Mowing is a management tool utilized in rough popcornflower habitat to control competing native plant species and invasive species as well as to prepare for outplanting efforts. The Red Rock Park, Wilbur Mitigation Site, the Southside Swale, and the ODOT Yoncalla South populations are regularly mowed and rough popcornflower populations have expanded. A late summer and fall mowing at Red Rock Park was instrumental in combatting pennyroyal growth throughout much of the site and resulted in the largest ever plant count at this location (U.S. Fish and Wildlife Service 2020, p. 2) (Table 2). The Service funds mowing at the Southside Swale and the TNC Popcorn Swale Preserve to control native graminoids, non-native grass, and pennyroyal. In the last 15 years, the Service funded various non-native invasive plant and native vegetation management at four rough popcornflower populations (Southside Swale, Red Rock Park, TNC Popcorn Swale Preserve, and Orenco Ponds). The initial results were promising for the four sites, which saw increased population numbers. Non-native and native tree thinning conducted in 2004, at the TNC Popcorn Swale Preserve resulted in the highest number of rough popcornflower plants recorded for the preserve (three years post-treatment). Unfortunately, over time and without further vegetation management, the native and non-native plants (spreading rush and pennyroyal) responded more aggressively than rough popcornflower and encroached on much of the habitat formerly occupied by the plant, leading to an overall population decline. The population is slowly rebounding and TNC has plans to mow the property annually, with the expectation that plants will spread into previously occupied habitat. There is no planning to utilize grazing or prescribed burns for vegetation control at this time. Fencing Fencing can protect populations from anthropogenic disturbance. The Sutherlin Red Rock Park rough popcornflower population was regularly affected by horse trampling and used horse bedding was tossed into the wetland area supporting rough popcornflower. The plants were often smothered while competing with aggressive grass and pennyroyal. Since the area was enclosed with fencing and signed with information about rough popcornflower, the plants are no longer subject to trampling and no longer smothered with the bedding and thus are able to grow in denser patches, compete better with the grass and pennyroyal, and occupy more space than prior to fencing. Introductions and Augmentation In 1998, before the species was listed, rough popcornflower plants were introduced to three locations on BLM managed lands. Two of the populations were successful and are still extant. Rough popcornflower was also introduced to the Orenco Ponds mitigation site in 2011 on a parcel owned by Douglas County and at a privately held mitigation site in 2001 (ODOT Wilbur Mitigation Site). Rough popcornflower was also successfully augmented at the Douglas SWCD property, the ODOT Wilbur Mitigation Site, and a second ODOT mitigation site (Del Rio Mitigation Site). In 2016, a new population was introduced to the NBHMA (Soggy Bottoms Sister) and is a recovery level population (i.e., greater than 5,000 plants) (J. Brown, pers. comm. 2020). Stakeholder workshops Five stakeholder meetings occurred between 2004 and 2016, at which population and species needs, recovery targets, and habitat conservation were discussed. At the most recent meeting, the agencies and landowners indicated that the species was making significant progress in recovery. Conservation Agreements Collaboration among stakeholders plays an important role in species management. For example, a Management

Plan between the Service, City of Sutherlin, ODA, and Douglas SWCD was finalized to protect and maintain the populations on Sutherlin and Douglas SWCD properties in 2007. For information specific to each reserve and other populations of rough popcornflower, see Appendices 2 and 3.

# SPECIES ACCOUNT: *Plagiobothrys strictus* (Calistoga allocarya)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

An annual herb, 1-4 dm tall. White flowers appear March-April in a slender, curved inflorescence. (NatureServe, 2015)

**Historical Range**

Historically, three populations of Plagiobothrys strictus were documented within a 3-kilometer (2-mile) radius of Calistoga, Napa County, California. Prior to listing one population had been extirpated due to urbanization and agricultural land conversion (California Native Plant Society 2008a). (USFWS, 2010)

**Current Range**

The range extent covers a small area in Napa County, near Calistoga. The total range is only about 14 sq mi. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

Adult: Plagiobothrys strictus is an annual herb in the Boraginaceae (borage family) (USFWS, 2010).

**Habitat Type**

Adult: Vernal pools (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (NatureServe, 2015)

**Site Fidelity**

Adult: High (NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits geyser- and hot spring-fed vernal pools and swales in meadows at 90-160 m elevation. Soils are clay or gravelly-clay loams. These pools contain high concentrations of boron and sulfates - substances that are toxic to most plants. Associated species include the rare Napa blue grass (Poa napensis). (NatureServe, 2015)

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Decreasing (NatureServe, 2015)

**Population Growth Rate:**

Decline of 30-50% (NatureServe, 2015)

**Number of Populations:**

1 (USFWS, 2023)

**Population Size:**

297,963 plants (USFWS, 2023)

**Adaptability:**

Highly vulnerable due to annual habit and location in wetlands. (NatureServe, 2015)

**Population Narrative:**

Highly vulnerable due to annual habit and location in wetlands. Decline of 30-50% .Population size of this annual fluctuates from year to year. In some good years, as many as 6000 plants were reported. There are only 2 extant EO's ;there is a third, historical EO. (NatureServe, 2015). Low resiliency, representation and redundancy are based on the low number of known populations and individuals. Historically, there were only three known populations of both the Calistoga allocarya and the Napa bluegrass. The three populations of Calistoga allocarya were documented within a 3- kilometer (2-mile) radius of the city of Calistoga in Napa County, California; however, prior to listing one of the populations was extirpated due to urbanization and agricultural land conversion (Service 1997, pp. 55792, 55799). At the time of listing and our 2010 status review, there were two extant occurrences of Calistoga allocarya: one within a property that contains Myrtledale Hot Springs (hereafter referred to as the hot spring property) and the other on a property where the former Calistoga glider airport is located (hereafter referred to as the airport property) (Service 1997, p. 55792; Service 2010, p. 4). The combined area of the two remaining populations is less than 80 square meters (900 square feet) (CNPS 1990 as cited in Service 1997, p. 55792). The three historical occurrences of Napa bluegrass were also entirely within Napa County: two were on the hot spring property and the third was on the airport property (Service 2010, p. 4). Prior to listing, one of the Napa bluegrass populations on the hot spring property was extirpated (Department 1989, p. 2), and at the time of listing, two populations of Napa bluegrass, one at the hot spring property and one at the airport property, remained (Service 1997, p. 55799). The total area occupied by Napa bluegrass was estimated to be slightly greater than 100 square meters (1,100 square feet). In 1994, near the time of listing, the population of Calistoga allocarya at the airport property had approximately 5,000 plants within 180 square meters (2,000 square feet) (J. Ruygt 1996 as cited in Service 2010, p. 5). Surveys carried out prior to the last status review in 2009 estimated the airport property population size at between 3,310 and 5,000 individual plants (Service 2010, p. 6). Since the 2010 status review, the population of Calistoga allocarya at the airport property has been surveyed annually from 2013–2022, except for 2020 due to Covid restrictions (WyrickBrownworth et al. 2021, p. 3) (see specific counts in Table 1, below). The number of plants counted during these annual surveys is heavily influenced by the survey methods. Surveys consisting of weekly walk-throughs of the property from early spring to early summer (January – May) are preferable as identification of individuals is difficult later in the summer when the plants have already senesced and lost their flowerheads. In 2019, the total population for Calistoga allocarya equated to 297,963 plants within the airport property (Wyrick-Brownworth et al. 2021, p. 6). (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Commerical/Residential Development (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The two Plagiobothrys strictus and Poa napensis populations exist on private land and could be developed. The airport property will be required by the City of Calistoga to be evaluated under the California Environmental Quality Act for the environmental effects to these species, and the evaluation reviewed by the California Department of Fish and Game, if and when any development should ever be proposed. According to the City of Calistoga Zoning Map, one property is zoned as Rural-residential and the former airport property is zoned Commercialairport (City of Calistoga 2003). Given that both species' population sizes are very small and restricted to two locations, development of these parcels could lead to the extinction of both species. The occurrences of the two species on the second private parcel (Myrtledale Hot Springs) in the City of Calistoga had been proposed for a new hospital (USFWS, 2010).

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** the California and Federal Endangered Species Acts are the primary State and Federal laws, respectively, that provide protection for this species since its listing as endangered in 1997. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent its status under the Act. Therefore, we continue to believe other laws and regulations have limited ability to protect the species in absence of the Endangered Species Act (USFWS, 2010).

**Stressor:** Human activities (USFWS, 201)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Poa napensis individuals within the Myrtledale Hot Springs population could be lost to trampling should the number of hikers increase to the hot spring, the paved road is widened, or the property owner decides to alter the landscape causing the alteration of hydrology. Because the most recent observation of six Poa napensis individuals was in 2007 and conducted from

outside the property boundary (Occurrence #1, CNDDB 2009b), the risk of human activities may be even greater since a more accurate count of individuals does not exist currently. The former Calistoga airport parcel could be mowed or its hydrology could be altered presenting unknown magnitude of risk to the populations of either species since neither population has been thoroughly surveyed since 1996 (P. napensis Occurrence #3 and Plagiobothrys strictus Occurrence #3, CNDDB 2009a) (USFWS, 2010).

**Stressor:** Restricted Habitat, Range, and Few Numbers of Populations (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of geneitc variability/extinction
**Narrative:** Species in natural habitats face threats both from deterministic facts such as habitat loss, overexploitation, pollution, introduced species, and stochastic events associated with small population size. Such events may be of a demographic genetic or environmental nature, including catastrophes (World Conservation Monitoring Centre 1992). The estimated population size for Plagiobothrys strictus was over 5,000 individuals in 1994 (Occurrence # 3, CNDDB 2009a) and six plants in 2007 as observed from the edge of the second property boundary for Poa napensis (Occurrence #1, CNDDB 2009b). Both species' populations could be susceptible to extirpation from random events due to their restricted range. Increased homozygosity resulting from genetic drift and inbreeding may lead to a loss of fitness (ability of individuals to survive and reproduce) in small populations (Menges 1991; Ellstrand and Elam 1993)

**Stressor:** Invasive plant species (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Competition from invasive plant species poses a potential threat to both species. Exotic and/or invasive, weedy plant species reduce native plant diversity and diminish the habitat suitability for native species; this is particularly the case in sensitive habitats (G. Cooley, California Department of Fish and Game, pers. comm. 2008). The consistent pattern of heavy growth of nonnative grasses when not controlled by grazing or other management can 'smother' native plants, resulting in the subsequent crowding out, outcompeting, or overshadowing of native annuals. A common consequence of such heavy annual grass growth is development of thatch, which adds to the strong smothering effect by inhibiting annuals' germination and growth (Weiss et al. 2007) (USFWS, 2010).

**Stressor:** Climate Change and Drought (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** A modeling study completed by Loarie et al. (2008) provides an evaluation of potential trends to California's floristic communities under climate change scenarios. In general, plant diversity will shift in two divergent directions: along the coast and northwards at higher elevations; and southwards at higher elevations of the Sierra Nevada. The models suggest that climate change has the potential to break up local floras, resulting in new species combinations, with new patterns of competition and biotic interactions (Loarie et al. 2008). Based on these modeling results, Plagiobothrys strictus and Poa napensis plants could be unable to shift their range because of their isolated, small populations, whose growth depend upon particular

hydrological regimes, and the limited available, suitable habitat surrounding the two private parcels (USFWS, 2010).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 5C

**Recovery Actions:**

- No final recovery plan has been completed for these species (USFWS, 2010).
- Work with the landowners, the California Department of Fish and Game, the City of Calistoga, and California Native Plant Society to ensure the protection of all known populations of Plagiobothrys strictus and Poa napensis (USFWS, 2010).
- Work with the landowners, the California Department of Fish and Game, the City of Calistoga, and California Native Plant Society to ameliorate or eliminate any threats to Plagiobothrys strictus and Poa napensis from hydrological changes and from competition from nonnative plants (USFWS, 2010).
- Collect seeds from both species from both parcel sites and store them in Center for Plant Conservation certified botanic gardens to guard against extirpation of populations from chance catastrophic events (USFWS, 2010).
- Follow conservation measures and policies as stated in the 2007 Napa County General Plan Update (USFWS, 2010).
- Follow conservation measures and policies as stated in the 2003 City of Calistoga General Plan for sensitive plant species (USFWS, 2010).
- Conduct a population assessment for each species and continue monitoring over the next 5 years (USFWS, 2010).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of Calistoga allocarya and Napa bluegrass. Some of these recommendations were discussed in the last status review (Service 2010, p. 16) and remain valid. 1. Partner with private landowners, the California Department of Fish and Wildlife, the City of Calistoga, and the California Native Plant Society to ensure protection of all known populations of Calistoga allocarya and Napa bluegrass. 2. Work with the California Department of Fish and Wildlife, the City of Calistoga, and the California Native Plant Society to ameliorate or eliminate any threats to Calistoga allocarya and Napa bluegrass from hydrological changes and competition from invasive plants. 3. Collect seeds from both populations of both species and store them in Center for Plant Conservation certified botanic gardens to guard against extirpation from chance catastrophic events. 4. Follow policy CON-17 and associated conservation measures as stated in the Napa County General Plan to “Preserve and protect native grasslands, serpentine grasslands, mixed serpentine chaparral, and other sensitive biotic communities and habitats of limited distribution” (Napa County Department of Conservation, Development, and Planning 2009, p. CON-28). 5. Follow policies P1.1-3 and P1.1-4 and associated actions as stated in the Open Space and Conservation Element (Updated 2012) of the City of Calistoga General Plan to continue “efforts to identify and map biological resources on the gliderport property [airport property], which provides an important and unique habitat area within the city limits” and “explore the possibility of designating parcels as Natural Resource Preservation

Areas in areas of the city known to contain sensitive and unique species, in order to protect these resources” (City of Calistoga 2012, p. OSC-23). 6. Conduct a population assessment for each species and continue monitoring annually (USFWS, 2023)

# SPECIES ACCOUNT: *Pogogyne nudiuscula* (Otay mesa-mint)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A small aromatic annual to 3 dm tall. Leaves are dark green, opposite, ovate to oblong and hairless. There are both axillary flowers and flowers at the top of the plant. The flowers are two-lipped, lavender and 11-14mm long. The fruit consists of small nutlets. Blooming is May-July. (NatureServe, 2015)

**Taxonomy**

Pogogyne nudiuscula is an annual herb in the mint family (Lamiaceae). As was mentioned in the description for Pogogyne abramsii, Howell (1931) considered all Pogogyne populations on Otay Mesa to be Pogogyne nudiuscula. Many of the older herbarium specimens that might be from the central mesas are labeled as Pogogyne nudiuscula, but are likely Pogogyne abramsii. Howell considered Pogogyne nudiuscula to be diagnosable from Pogogyne abramsii by having a glabrous (smooth) calyx and bract with a different morphology. This distinction is supported by current work (Jokerst 1993; McMillan unpublished data 1995), and the species is also diagnosable by usually having at least six flowers per node on the stem (USFWS, 1998).

**Historical Range**

Historically P. nudiuscula was found beyond Otay Mesa and occurred at 10 locations in southern San Diego County (Appendix 1). Herbarium records indicate that P. nudiuscula historically occurred further north near University Heights, Balboa Park, and Mission Valley (CNDDB 2010, Element Occurrence (EOs) 4, 9, and 10, respectively). Also, P. nudiuscula occurred in Mexico at the eastern edge of the city of Tijuana; however, it was believed to be extirpated from its Mexican locations prior to listing (Bauder and McMillan 1998, p. 65; USFWS 1993, p. 41385). Currently, P. nudiuscula is found at three locations on Otay Mesa: Otay Mesa West, Otay Mesa East, and Otay Mesa Northeast (Appendix 1). (USFWS, 2010)

**Current Range**

San Diego County, California; adjacent Baja California, Mexico. The range extent covers approximately 370 sq mi. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollinated (NatureServe, 2015)

**Reproduction Narrative**

Adult: The family is primarily bee pollinated (Proctor & Yeo, 1973, p. 219).; (NatureServe, 2015). There is little documented information regarding pollination and seed dispersal mechanisms of P. nudiuscula. Observations in the field suggest that native syrphid flies (Syrphidae) and bee flies (Bombyliidae) are the most common pollinators (S. McMillan, EDAW pers. comm. 2010). Eurasian honeybees (Apidae) have also been seen pollinating P. nudiuscula (McMillan, pers. comm. 2010). Research on the similar species Pogogyne abramsii show that it is self-fertile but has greater seed set when cross-pollinated (Schiller et al. 2000, p. 393); further research is necessary to determine if this is the case for P. nudiuscula (USFWS, 2010).

**Habitat Type**

Adult: Vernal pools (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist

**Habitat Narrative**

Adult: Vernal pools (Smith & Berg, 1988). Moist flats in chaparral and coastal sage scrub (Munz, 1959). (NatureServe, 2015)

***Dispersal/Migration***

**Dispersal**

Adult: Moderate (USFWS, 2010)

**Dispersal/Migration Narrative**

Adult: Zedler and Black (1992, p. 4) found that Pogogyne abramsii seeds germinated and grew from pellets of brush rabbits (Sylvilagus bachmani) and Audubon’s cottontail rabbits (S. auduboni) that were collected from vernal pools on Del Mar Mesa and Miramar Mesa. Zedler and Black (1992, p. 2) postulated that rabbit movement may be a potential vector for seed dispersal and genetic mixing of vernal pool obligate species including P. abramsii. They concluded that rabbit dispersal explains the “anamolous occurrence of vernal pool plants in newly excavated artificial pools (1992, p. 8).” Additionally, P. abramsii seeds float, which may result in limited dispersal opportunities when pools interconnect or lakes fill their basins in years of greater than average precipitation (Scheidlinger 1981, p. 54). It is possible that these dispersal mechanisms also apply to P. nudiuscula; however, data do not exist to support this assumption (USFWS, 2010).

***Population Information and Trends***

**Population Trends:**

Decreasing (NatureServe, 2015)

**Number of Populations:**

17 known and 2 questionable (USFWS, 2021)

**Population Size:**

1000 - 2500 individuals (NatureServe, 2015)

**Population Narrative:**

This wetland annual endemic is highly vulnerable. The long term trend is one of very rapid decline. Decline of >90% Population numbers for this annual are mostly unknown. CNDDB records only record a total of 1700 plants from all currenly known vernal pools. This is likely wildly off from reality. Of 9 EOs, at least five may be extirpated, and all but a few are severely threatened. (NatureServe, 2015). Based on current updates, there are 24 Pogogyne nudiuscula locations (Figure 2, Table 1): 17 are extant, 2 are presumed extant, 3 are historically extirpated, and 2 have questionable identification. (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Urban development (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Planned and ongoing development projects throughout Pogogyne nudiuscula's range were described as a primary threat in the listing rule (USFWS 1993, p. 41387). Urban development may result in: (1) the loss or damage of vernal pools by filling, grading, discing, leveling, and other activities; and (2) destruction of watersheds and the hydrology that support vernal pools; (3) isolation of vernal pools; (4) fragmentation of vernal pool systems. Destruction of watersheds and disruption of hydrological systems can create further impacts by creating barriers to dispersal, such that pollination and reproductive output may be inhibited (Schiller et al. 2000, p. 395). Potential means of seed dispersal (e.g., rabbits, floating seeds) (Zedler and Black 1992, p. 2) may also be impacted. Whenever development impacts vernal pools in a complex, some degree of fragmentation occurs within and among complexes. Because P. nudiuscula has specific habitat requirements (e.g., soil type, water depth), habitat degradation and alteration likely result in population decline (USFWS, 2010).

**Stressor:** Road projects (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Road projects are a type of development that pose a threat to Pogogyne nudiuscula habitat at Otay Mesa West, Otay Mesa South, and Otay Mesa Northeast (Appendix 1). First, the listing rule identified State Route 125 construction on Otay Mesa as a project that could impact P. nudiuscula habitat. This project was completed and directly impacted vernal pool basins on the Otay Mesa Northeast occurrence (i.e., J29–30); however, vernal pools containing P. nudiuscula were avoided in one pool and seeds were collected and used to reestablish populations within their mitigation site which encompass J29–30 (Wynn, pers. obs. 2010). Second, the construction associated with Interstate 905 and Otay Mesa Road (J14) did not directly impact P. nudiuscula; however, indirect impacts in the future in the form of edge effects (see below) are possible. Third, State Route 11 (associated with a new U.S./Mexico border crossing) is planned southeast of State Route 125 on Otay Mesa. Though habitat is present, P. nudiuscula was not detected and Caltrans anticipates future potential edge effects to vernal pools if they are discovered in the area (USDOT and Caltrans 2008, p. 3.20-11–3.20-15). Edge effects to Pogogyne nudiuscula are evident as a result of road widening projects, creating outer bands of habitat distant from the center but immediately proximal to a different type of habitat, thus providing a different species composition and abundance divergent from the interior of the habitat (Forman and Gordon

1986, p. 108). These edges may allow P. nudiuscula to be in closer proximity to disturbed areas, which may facilitate the incursion of invasive, nonnative plants that can outcompete P. nudiuscula for space (see also Factor E discussion). Edge effects degrade extant interior habitat and create an island of the protected habitat/reserve through isolation and decrease the effective size and serviceability of a conservation area (Diamond and May 1976, pp. 228–252). Characteristics of habitat islands include less resistant habitat, more disturbed habitat, areas more susceptible to invasive species, areas with native species less resistant to disturbance, and higher seed immigration (Meyers and Bazely 2003, pp. 34-50). Further development of the roads mentioned above and surrounding areas would exacerbate these impacts (USFWS, 2010).

**Stressor:** Alteration of watershed (Hydrology) (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Although altered hydrology continues to be a threat to the species, the Service has been successful in ensuring implementation of measures to reduce this threat through section 7 consultations. For example, best management practices reduce the amount of runoff entering vernal pool watersheds, and restoration projects are designed to minimize water draining off impervious surfaces into vernal pool watersheds. However, the specific impact runoff has on Pogogyne nudiuscula is unknown because site specific monitoring has not been conducted. Preserved pools should be monitored for these runoff impacts to identify remediation where feasible and prevent further damage to vernal pool systems (USFWS, 2010).

**Stressor:** Compaction of erosion of soil (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Recent studies suggest that trampling associated with limited livestock grazing in the watershed may benefit some vernal pool species by increasing the inundation period of the pools through reduction of vegetation (particularly nonnative grass) in the watershed and compaction of the soil, which reduces infiltration (Marty 2005, p. 1630). Grazing may also increase the duration of vernal pool inundation by altering soil properties and modifying the rate of evapotranspiration from plants, thus counteracting the potential decrease in precipitation brought about by climate change to some degree (Pyke and Marty 2005, p. 1623). However, it is unknown if Pogogyne nudiuscula or vernal pool habitat in San Diego County benefit from low levels of trampling (USFWS, 2010)

**Stressor:** Off-Highway Vehicles (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Since listing, OHV continues to threaten Pogogyne nudiuscula, especially from recreational and Border Patrol activities (see Appendix 1). Installation and maintenance of fencing and signage are needed to help protect P. nudiuscula habitat from these impacts (USFWS, 2010).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2010)
**Exposure:**

**Response:**
**Consequence:** Loss of habitat
**Narrative:** Since listing in 1993, the Act is the primary law that provides protection for Pogogyne nudiuscula on Federal lands or in instances where there is a Federal nexus. Nearly all occurrences of P. nudiuscula are conserved under the San Diego's MSCP; however, coverage for this species and six other vernal pool species was removed from the City of San Diego Subarea Plan in April 2010. The Service accepted the City's relinquishment of coverage for vernal pool species; thus, P. nudiuscula is no longer a covered species under the subarea plan. However, the City of San Diego is currently working with the Service to revise and improve the management plan for P. nudiuscula under the MSCP. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent its status under the Act. However, once a revised subarea plan is completed that provides coverage for P. nudiuscula, the Act will likely provide the most effective protection for the species (USFWS, 2010).

**Stressor:** Competition with invasive, nonnative plants (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Depending upon conditions, certain invasive, nonnative plants (such as the grasses discussed above) may replace Pogogyne nudiuscula. Therefore, we consider invasive, nonnative plants to be a continuing rangewide threat to all extant occurrences of P. nudiuscula (USFWS, 2010).

**Stressor:** Human access and disturbance effects (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Protective fencing is used in several conserved areas to protect vernal pool complexes and has been successful in significantly decreasing the impact of trampling and OHV use in the J29–30 vernal pool complex at Otay Mesa Northeast and J2 N/W/S vernal pool complex at Otay Mesa West (City of San Diego 1997, p. 299, 316). Though implementing this protective measure has lessened the impacts of human access and disturbance, such effects still threaten Pogogyne nudiuscula occurrences. The J32 complex in the Otay Mesa West occurrence may be the most severely impacted by trampling due to foot traffic by immigrants, transients, Border Patrol, and OHV use (City of San Diego 1997, p. 236). Fencing was installed and stolen (City of San Diego 1997, p. 236) indicating that monitoring is critical in reducing the impacts of human access and disturbance (USFWS, 2010).

**Stressor:** Fire and fire suppression activity (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Fire and fire suppression have been identified as a current potential threat at three of the four occurrences (vernal pool complexes J2, J2 N/W/S, J28, J14, and J29–30), with the exception of the Otay Mesa East occurrence. These areas may serve as a staging area in the event of a fire if defensible structures are developed in the vicinity (City of San Diego 1997) (USFWS, 2011).

**Stressor:** Drought and climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to particular species, including Pogogyne nudiuscula or sites at this time. However, it is likely that impacts from existing threats could increase and new threats may arise. Sharing information between scientists, land managers, and decision makers will increase our ability to address and manage these threats (USFWS, 2010).

**Stressor:** Small population size (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Lack of geneitc variability/extinction
**Narrative:** Since listing, Pogogyne nudiuscula's range has decreased and there have been no new occurrences of the species. Therefore, restricted range and small population size continue to threaten P. nudiuscula at all of its occurrences (USFWS, 2010).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 2C

**Delisting Criteria:**
All the existing vernal pools and their watersheds identified in Appendix F and G of the Recovery Plan should be secured from further loss and degradation in a configuration that maintains habitat function and viability (as determined by prescribed research tasks) (USFWS, 2010).

Secured vernal pools must be enhanced or restored such that population levels of existing species are stabilized or increased (USFWS, 2010.

Population trends must be shown to be stable or increasing for a minimum of 10 consecutive years prior to consideration for reclassification (USFWS, 2010).

In the interest of ensuring these criteria are clearly articulated, we are amending the following clarification to the existing recovery plan. This amendment does not represent a revision of the delisting criteria, it simply provides more specific terminology. Delisting for the species covered by the 1998 recovery plan may be considered when the downlisting criteria have been met and: 1. All 74 geographic areas and associated vernal pool complexes as identified in Appendices F and G of the 1998 Recovery Plan under each of the specific management areas are protected and managed to ensure long-term viability. 2. The U.S. Fish and Wildlife Service must determine that the following factors are no longer present, or continue to adversely affect, Eryngium aristulatum var. parishii, Pogogyne abramsii, Pogogyne nudiuscula, Orcuttia californica, and the Riverside and San Diego fairy shrimp: ( 1) the present or threatened destruction, modification, or curtailment of their habitat range; (2) over utilization for commercial, recreational, scientific, or educational purposes; (3) disease or predation; (4) the inadequacy of existing regulatory mechanisms; and ( 5) other natural and manmade factors affecting their continued existence (50 CFR 424.11). 3. Population trends for all seven taxa continue to be stable or increasing for 10 consecutive years after threats have been sufficiently ameliorated or managed ( completion of delisting criterion 2) prior to consideration for delisting. (USFWS, 2019)

**Recovery Actions:**

- This recovery criterion does not explicitly address any of the threat factors identified in the five factor analysis in the listing rule or in the above discussion. Moreover, achievement of this criterion as written is complicated by the fact that some pool basins within the complexes identified in Appendices F and G have been developed or preserved in accordance with provisions of regional HCPs since the completion of the Recovery Plan. However, working toward the goals in this criterion will reduce the threats discussed above under Factors A and E. Securing vernal pool complexes physically, legally, and ecologically would reduce threats posed by development (e.g., habitat loss and alterations of hydrology) and discussed under Factor A and E above. As discussed in Factor A, all of the extant occurrences of Pogogyne nudiuscula, are partially or completely conserved and those that are only partial conserved have been mitigated in another area of suitable habitat (Appendix 1). These protections generally extend to direct loss and not necessarily indirect loss of habitat through degradation. These lands are under conservation easements or protected in perpetuity, conserved through mitigation, or have some sort of protection from development (Appendix 1). Pools within these areas meet the criterion in the Recovery Plan as “secured legally” from further habitat loss. In the Recovery Plan, Appendix F lists the vernal pool occurrences that are necessary to stabilize the proposed and listed vernal pool species (USFWS 1998, p. F1). Appendix G of the Recovery Plan lists vernal pool occurrences identified as necessary to secure in order to reclassify the proposed and listed vernal pool species (USFWS 1998, p. G1). Appendix G broadly lists complex J (undescribed) and J–3 and J–22. Pogogyne nudiuscula is found throughout the J complex and portions of this complex have been conserved partially or fully and other areas have been extirpated and mitigated. Although some of these occurrences are considered secure from development, they are not all guaranteed monitoring or maintenance in perpetuity. Although it is not possible to specifically identify every complex in Appendices F and G of the Recovery Plan, development and impacts on complexes listed in Appendices F and G that contain P. nudiuscula should be avoided. Additionally, the Service is working towards conserving these complexes (USFWS, 2010.
- This criterion does not directly address any of the threats discussed above in the five-factor analysis. Rather, it uses a measure of stability that is not easily assessed for Pogogyne nudiuscula. As discussed in the abundance section of this 5-year review, the population numbers for P. nudiuscula are not easily measured. Because methods of measurement are not standardized and P. nudiuscula does not germinate every year, population abundance is not a good indicator for the species. However, restoration and management do provide a measure of protection against threats to the species. Additionally, the CFWO issues biological opinions associated with consultations under section 7 of the Act for Pogogyne nudiuscula. These opinions detail avoidance and minimization measures to prevent jeopardizing the species’ continued existence and can include restoration of P. nudiuscula habitat. Many of these opinions lead to successful restoration and protected populations of P. nudiuscula. Some pools are being restored and therefore meet the outlined goals of Criterion 3 in the Recovery Plan (USFWS, 2010).

- This criterion does not directly address any threats outlined in the five-factor analysis. In order to stabilize or increase the population, threats would have to be reduced. Reducing the threats discussed above in Factors A and E would help us provide the conditions needed to work toward the goal in this criterion, but vernal pool habitat has been reduced by human-induced conversion (Bauder and McMillan 1998, p. 66). As yet, however, it is difficult to assess the abundance of Pogogyne nudiuscula in the absence of standardized sampling methods and population trends for vernal pool annuals are often difficult to detect. Therefore, we are unable to address this criterion (USFWS, 2010).
- Support continued conservation, management, and monitoring of vernal pool habitat that supports Pogogyne nudiuscula, including monitoring of restored/enhanced habitat to determine if vernal pool restoration projects continue to be viable through time (e.g., artificial clay layer remains stable and supports adequate ponding) (USFWS, 2010).
- Work with the Otay Mesa Water District to address inundation of pools in J26 from the Otay Mesa water pump. Implement measures to ensure that water does not flow over the road and into the pools (USFWS, 2010).
- Conduct research to determine life history traits most vulnerable to threats discussed in the five factor analysis (USFWS, 2010).
- Develop a dynamic, threats based, species-specific recovery plan based on analysis of current knowledge of the species (USFWS, 2010).
- Establish a seed bank for Pogogyne nudiuscula according to Center for Plant Conservation guidelines (USFWS, 2010).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The recommended actions listed below were identified in the 2010 status review (USFWS 2010, p. 29). The actions were intended to reduce threats to Pogogyne nudiuscula and provide information to better understand the biological and physical factors limiting the population growth and distribution. We recognize that conservation of P. nudiuscula will require cooperation and coordination with partners to minimize impacts from current threats, aid future restoration, and maximize effectiveness of limited funding. We continue to believe the actions described in 2010 are relevant to the conservation of P. nudiuscula. 1. Support continued conservation and management of vernal pool habitat that supports Pogogyne nudiuscula, with emphasis on complexes that are not currently conserved and those within the Stockpen soil association. 2. Develop and implement a long-term monitoring program to describe population trends to better understand the resiliency of the different vernal pool complexes, including monitoring of restored and enhanced habitat to determine if vernal pool restoration projects continue to be viable through time (e.g., artificial clay layer remains stable and supports adequate ponding). 3. Identify a new conservation easement holder and land manager for the J26 complex. 4. Conduct research to determine life history traits most vulnerable to threats discussed in the five-factor analysis. 5. Develop a dynamic, threats based, species-specific recovery plan based on analysis of current knowledge of the species. (USFWS, 2021)

# SPECIES ACCOUNT: *Polygala lewtonii* (Lewton's polygala)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 5/27/1993; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

Polygala lewtonii is a relatively short-lived (5 to 10 year) perennial herb. Each plant produces one to several annual stems, which are spreading, upward-curving or erect, and are often branched. The leaves are small, sessile, rather succulent, broader toward the tip, and are borne upright, tending to overlap along the stem, like shingles. The normally opening flowers are in erect, loosely flowered racemes about 1.5 cm (Wunderlin et al. 1981) or 3.3 cm (Weekley 1996) long. The flowers are about 0.5 cm long and bright pink (Wunderlin et al. 1981) or purplish-red (Ward and Godfrey 1979). Two of the five sepals are enlarged and wing-like, between which the largest of the three petals forms a keel that ends in a tuft of finger-like projections (Ward and Godfrey 1979). The plant also produces two types of small, cleistogamous (non-sexual) flowers (L. Miller, Ocala NF, personal communication 1996,Weekley 1996). This species is closely related to the widespread P. polygama, which forms larger clumps and has a longer root, narrower leaves, and differently shaped wing sepals. It also has short branches that hug the ground, bearing inconspicuous self-pollinating flowers. (USFWS, 1999)

**Taxonomy**

This small herb was first collected near Frostproof, Florida by F. L. Lewton in 1894, and was named by J.K. Small (1898). The status of P. lewtonii as a distinct species was affirmed by Blake (1924) and James (1957). There have been no other taxonomic treatments of this species. (USFWS, 1999)

**Historical Range**

See current range.

**Current Range**

Lewton’s polygala occurs in sandhill (high pine) vegetation and Florida scrub of the Lake Wales and Mount Dora ridges in Highlands, Polk, Osceola, Orange, Lake, and Marion Counties of central Florida. (USFWS, 1999)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollination/self-fertilization

**Lifespan**

Adult: relatively short-lived (5-10 year) (USFWS, 2019)

**Other Reproductive Information**

Adult: Lewton's polygala is amphicarpic, producing flowers and fruits above and below ground at different times (Menges and Weekley 2002). Lewton's polygala is one of only a few dozen amphicarpic angiosperms known worldwide. Amphicarpy is viewed as an adaptation for reproduction in uncertain habitats, for example, producing seeds underground where they have better chances of surviving fire (Cheplick and Quinn 1982) and are protected from herbivory (Menges and Weekley 2003). While self-fertilization occurs in Lewton's polygala, it appears to be a less-reliable mechanism for seed production than insect pollination. (USFWS, 2019)

**Reproduction Narrative**

Adult: Confusion has existed about whether P. lewtonii has cleistogamous flowers (James 1957, Wunderlin et al. 1981, Ward and Godfrey 1979, FWS 1996). More recently, Weekley (1996) and Miller (Ocala NF, personal communication 1996) confirmed the presence of two types of cleistogamous flowers. The first are solitary flowers in the axils of the lower leaves and the second are few-flowered racemes on underground rhizomes that are usually 5 to 15 cm long (Weekley 1996). Polygala lewtonii blooms from February to May with chasmogamous flowers dominating from February to April. Chasmogamous flowers have an average of four to six racemes per plant, though one extreme individual had 30 racemes (Weekley 1996). Each raceme has 20 to 25 flowers 85 to 100 percent of these set fruit. This high percentage of fruit set suggests that flowers self-pollinate when insect pollinators are not present. (USFWS, 1999).

**Habitat Type**

Adult: high pine and turkey oak barrens and transitional areas (USFWS, 1999)

**Environmental Specificity**

Adult: Narrow (USFWS, 1999)

**Habitat Narrative**

Adult: Polygala lewtonii is not strictly a scrub species and is found in widely scattered populations that frequently occur in transitional habitats between high pine and turkey oak barrens. P. lewtonii also occurs in both habitats (Wunderlin et al. 1981, Christman 1988). P. lewtonii depends on fire to maintain its habitat. It is found in sunny openings and often colonizes disturbed sites, such as roadsides and fire lanes. P. lewtonii’s preference for transitional habitats between high pine and turkey oak barrens suggests a preference for a burn frequency that is less frequent than high pine, but more frequent than turkey oak barrens. (USFWS, 1999)

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

32 known occurrences (USFWS, 2021)

**Population Narrative:**

Lewton’s polygala is a perennial herb occurring in sandhill and scrub communities on the Lake Wales and Mount Dora Ridges in central Florida. Currently, there are an estimated 32 extant populations, though most are of unknown status due to lack of recent surveys, and 19 known or possibly extirpated populations (Table 1). Of the 32 extant populations, only 1 is stable to increasing, 6 are stable, 2 are declining, and 23 have an unknown status (Table 1). Although demographic and abundance data have been collected at 6 populations for approximately 20 years (Rosner-Katz 2020; Menges et al. 2021; Noland 2021), information on natural recruitment and age distribution is lacking for almost all populations, and trends cannot be determined. (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species is restricted to xeric scrub habitats in one or more of the interior Central Florida counties of Polk, Highlands, Hendry, Osceola, and Lake, where habitat destruction from development continues to occur and development pressure remains high. Areal extent of post-Columbian xeric upland habitat loss on the Lake Wales Ridge is estimated to exceed 85 percent (Weekley et al. 2008a). Increasing pressure from population growth is likely to result in further loss of these habitats going forward. Carr and Zwick (2016) analyzed existing land use and landscape patterns to identify areas (including central Florida) most likely for development to accommodate a growing human population. They suggests that Florida's 2070 population will be early 15 millionpersons greater than in 2010, for an estimated total of 33,721,828. Using these figures, they estimated relative losses to agriculture, open space, and conservation to other land uses. If trends continue, they estimate 34 percent of land will be developed by 2070, up from 19 percent in 2010. At the same time, conservation lands will increase less than 1 percent (from 9,269,000 acres in 2010 to 9,525,000 acres by 2070). Overall, loss of habitat to development, primarily on private lands, will likely continue in Central Florida, eliminating populations and reducing the area of suitable habitat for these species. Therefore, habitat on protected lands are critical for the recovery of this scrub plants. (USFWS, 2019)

**Stressor:** Lack of adequate fire management
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire is necessary to maintain the scrub habitats upon which this species depends. Historically, lightning-induced fires were a vital component in maintaining native vegetation within the scrub community. Fire suppression started on a regional scale on the Central Florida ridges about 80 years ago. Due to the extent of residential and agricultural development throughout Central Florida, fire has all but disappeared from the region as a widespread, natural phenomenon. Prescribed fire is a crucial management component for maintenance of all scrub habitats. Because of the difficulties of applying prescribed fire on an ever-increasing urban landscape, imperiled species on unmanaged sites will almost certainly disappear over time (Turner et al. 2006). In managed areas, prescribed fire is essential to manage habitats and restore or maintain suitable conditions for scrub species. (USFWS, 2019)

**Stressor:** Limited geographic range
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** This species occurs occur within a relatively limited geographic range in Central Florida. The limited geographic range in combination with the loss of habitat has resulted in a highly fragmented landscape where the remaining scrub areas and their residing species have become more and more isolated from each other, thereby making resiliency, redundancy, and representation more challenging to achieve. The effects of habitat fragmentation on species richness have been exhaustively studied (MacArthur and Wilson 1967, Diamond 1975, 1978; Simberloff and Abele 1976, 1982; Zimmerman and Bierregaard 1986). For most taxonomic groups, large habitat patches in close proximity to each other provide for the greatest species diversity and minimize extinction probabilities. On the contrary, small patches that are isolated are less likely to preserve species that would otherwise be common in the mosaic of communities that existed before isolation. Since at least the Pleistocene, Florida scrub has been characterized by an insular, discontinuous distribution, but the degree of habitat fragmentation seen today is unprecedented and certainly will contribute to increases in extinction rates among scrub-dependent plants and animals. (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**
1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations and sites needed to assure 20 to 90 percent probability of persistence for 100 years (USFWS, 1999)

2. When these sites, within the historic range of P. lewtonii, are adequately protected from further habitat loss, degradation, and fragmentation (USFWS, 1999)

3. When these sites are managed to maintain the seral stages of high pine and xeric oak scrub to sup port P. lewtonii (USFWS, 1999)

4. When monitoring programs demonstrate that these sites support the appropriate numbers of self-sustaining populations, and those populations are stable throughout the historic range of the species. (USFWS, 1999)

**Delisting Criteria:**
1. At least 40 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)

2. Populations (as defined in criterion 1) in yellow sand scrub or sand hill habitats are distributed across the known range of the species. (USFWS, 2019)

3. Populations are protected and managed via a conservation mechanism to a degree that enough suitable habitat is present for the species to remain viable for the foreseeable future. (USFWS, 2019)

**Recovery Actions:**
- Determine current distribution and status of P. lewtonii. This species' distribution is somewhat questionable since individuals are easily overlooked. A thorough survey is needed to determine the distribution for this species. (USFWS, 1999)

- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, has become isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Conduct research on life history characteristics. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species, more specific biological information is needed. (USFWS, 1999)
- Monitor existing populations of P. lewtonii. (USFWS, 1999)
- Provide public information about P. lewtonii. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. Care is needed, though, to avoid revealing specific locality information about P. lewtonii. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of P. lewtonii and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS A detailed discussion of recovery actions and criteria are presented in the Recovery Plan and amendment (Service 1999 and 2019, respectively). During this status review new and/or targeted potential recovery activities were identified and are included below. Recovery Activities • Conduct habitat restoration efforts at possibly extirpated sites on managed lands since Lewton’s polygala has a persistent soil seed bank and can reappear after fire/restoration. Lewton’s polygala 5-Year Review • Work with State, Federal, and non-profit partners to ensure adequate fire management is achieved at sites that support Lewton’s polygala. • Work with private landowners to acquire or conserve extant populations and restore sandhill and scrub habitat on these sites. • Strengthen ex situ conservation measures, including ensuring representation of Lewton’s polygala at the National Center for Genetic Resources Preservation in Fort Collins, Colorado. Monitoring/Research Activities • Determine the condition of populations on private land whose status is currently unknown. • Expand level 3 (demographic) monitoring to more populations, such as ONF, Tiger Creek Preserve, and Bok Tower Gardens Pine Ridge Preserve, (as recommended by Menges et al. 2019) to determine trends and produce a population viability analysis. • Develop a standard methodology for monitoring Lewton’s polygala on conservation lands. • Initiate large-scale level 1 (distribution) and 2 (population size/condition) monitoring of Lewton’s polygala throughout the geographic range, including sites across a spectrum of time-since-fire and management regimes. • Compare germination rates of aboveground to belowground seeds and investigate the limitations to germination of aboveground seeds. • Determine the status of pollinator populations. (USFWS, 2021)

# SPECIES ACCOUNT: *Polygala smallii* (Tiny polygala)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 8/19/1985; Southeast Region (R4)

**Physical Description**

Tiny polygala is an erect short-lived herbaceous species. Most plants germinate and die within one year. It forms a rosette and grows no more than 8 cm tall (Kennedy 1998). It has one to four, short, usually unbranched stems, and a well-developed, scented taproot. Its leaves are oblanceolate to lanceolate, from 1.5 to 5 cm long and 0.2 to 1.4 cm broad and occur in a basal rosette. The inflorescence is a cylindric raceme from 0.4 to 7 cm long and 0.5 to 1.8 cm thick and usually surpassed by the basal leaves (Kennedy 1998) The flowers have both functional stamens and pistils (perfect) and are not radially symmetrical (zygomorphic). The calyx has five sepals. The lateral pair is decurrent, large and petaloid. The corolla is a greenish-yellow color with three petals. The fruit is a thin-walled, two-celled capsule that splits down the center of the compartment. The seed is 1.2 to 1.4 mm long, with sparse rather short, stiff, appressed hairs (strigose). It also has a pair of aril-like outgrowths about half the length of the capsule (Gann and Bradley 1995, Smith and Ward 1976). (USFWS, 1999)

**Taxonomy**

J.K. Small first described tiny polygala as Polygala arenicola (Small 1905; type specimen at New York Botanical Garden, Small #1276). The specific epithet was later found to be invalid due to its prior use in 1903 by Gurke in describing another species of Polygala from southeast Africa (Smith and Ward 1976). In 1933, Small revived the segregate genus Pilostaxis Raf., and renamed tiny polygala Pilostaxis arenicola (Small) Small. The genus Pilostaxis has since fallen out of use, but represents the series Decurrentes, a natural group of seven species of Polygala found only in the southeastern U.S. (Smith and Ward 1976). Long and Lakela (1971) considered tiny polygala to be conspecific with Polygala nana (Michx.) DC., a species widely distributed in the southeastern U.S., but in 1976, Smith and Ward defended the specific status of tiny polygala, recognizing distinct characters of the seeds, lateral sepals, flower color, and leaves, and proposed Polygala smallii Smith and Ward as a nomen novum. Synonyms: Polygala arenicola Small, non Gurke; Pilostaxis arenicola (Small) Small; Polygala nana auct., non (Michx.) DC. (USFWS, 1999)

**Historical Range**

See Current Range. The historic distribution of tiny polygala to the north is uncertain; it possibly ranged as far north as central Brevard County, Florida. (USFWS, 1999)

**Current Range**

This species is known to occur on the Atlantic Coastal Ridge of southeast Florida, in Miami-Dade, Palm Beach, St. Lucie, and Martin Counties. (USFWS, 2019)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: ~ 180 days

**Other Reproductive Information**

Adult: Pollination in tiny polygala has not been observed in 2.5 years of monitoring (Kennedy 1998), or in 3 years of monthly life history monitoring (DERM 1994). Zomlefer (1991) reports that self-pollination may occur in species of Polygala which have a tuft of hairs on the sterile apical lobe of the stigma. These hairs catch pollen when the anthers dehisce, and, as the flower develops, these hairs may touch the receptive lobes of the stigma, transferring pollen. Tiny polygala has these hairs (Smith and Ward 1976) and may be selfpollinating. (USFWS, 1999)

**Reproduction Narrative**

Adult: Tiny polygala seedlings can be observed from late October through April, but are most typically seen from December to February (DERM 1996). Populations in Miami-Dade County appear to have two germination periods, a short one in June and a longer one between September and January (Kennedy 1998). Thus, seedlings can be germinating for 6 months out of the year, resulting in plants maturing at different times of the year, and overlapping generations within years. In populations, flowers appear throughour the year with a peak during summer. Also, seeds are produced year-round. Approximately one year following appearance of seedlings, plants show a marked reduction in condition, apparently allocating resources to flowering instead of growth or self-maintenance. By July, approximately 18 months after the first seedlings are observed, remaining plants senesce and die (DERM 1994). (USFWS, 1999)

**Habitat Type**

Adult: pine rockland, scrub, high pine, and open coastal spoil (USFWS, 1999)

**Habitat Vegetation or Surface Water Classification**

Adult: Terrestrial

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 1999)

**Habitat Narrative**

Adult: Tiny polygala occurs in four distinct habitats with similar characteristics: pine rockland, scrub, high pine, and open coastal spoil (Gann and Bradley 1995). All of these habitats are pyrogenic-extremely dry and prone to periodic natural fire. Pine rocklands historically burned every 2 to 15 years (Snyder et al. 1991). Sand pine scrub and sandhill burn less frequently, possibly every 10 to 50 years. (USFWS, 1999)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Tiny polygala seeds have paired, fleshy outgrowths, a typical adaptation to ant dispersal. ostermeijer (1989) reports that a similar species Polygala vulgaris L. is a specialist in ant dispersal. Also, ants have been observed carrying tiny polygala seeds to their nests on several occasions in Miami-Dade County (K. Bradley, Institute for Regional Conservation, personal communication 1996). The seeds have a bilobed aril attached to the caruncle. This bilobed aril was suggested by some to be an elaisome, a structure that contains lipids that are attractive to ants. Kennedy (1998) reports observing ants going into the flowers and removing and transporting seeds by the arils. After applying Sudan IV stain to the arils, she determined that they do not contain lipids; rather the arils appear to be hollow sacs. It is unclear why the ants are moving the seeds. (USFWS, 1999)

**Additional Life History Information**

Adult: Polygala smallii seeds are able to float in water for extended periods (over three weeks) (Kennedy 1998). The hairs on the seed coat appear to provide most of the buoyancy by trapping air. Since many of the sites where tiny polygala occurs are riparian or riverine and the seeds are buoyant, water may be the primary means of dispersal. After Hurricane Andrew, tiny polygala was found growing in areas where the soil was turned over or disturbed (ie. around uprooted fallen trees). A response to soil turnover may indicate a good seed bank. The seed banks probably occur in more habitat types than previously thought. (USFWS< 1999)

***Population Information and Trends***

**Number of Populations:**

6 (USFWS, 2021)

**Population Narrative:**

Polygala smallii is extant on a total of nine sites in Miami-Dade, Palm Beach, St. Lucie, and Martin Counties, with the highest density of sites located in southern Miami-Dade County (Wendelberger and Frances 2004; Woodmansee et al. 2007; Maschinski, pers. comm. 2010; Florida Natural Areas Inventory [FNAI] 2010a; Lange, pers. comm. 2017; Possley, pers. comm. 2017a). Clusters of sites are separated by an average of 38 miles (61 km). Eight of nine known occurrences are on publicly owned lands, and all the sites are currently being managed for conservation of P. smallii. The species is known to have been extirpated from at least five historical locations, including three in Miami-Dade County and single populations in Broward and St. Lucie Counties. Five sites are known from Miami-Dade County. These include the publicly owned Zoo Miami and adjacent U.S. Coast Guard (USCG) property, both located within the 2,100-acre Richmond pinelands (Lange, pers. comm. 2017; Possley, pers. comm. 2017). Possley pers. comm. (2017a) indicates the P. smallii population size within Zoo Miami has fluctuated from 13 to over 1,000 individuals in the past decade. The USCG site contains the largest population, which was estimated at over 10,000 plants during a 2008 survey (Lange, pers. comm. 2017; Possley, pers. comm. 2017a); no recent estimates are available for the species at this site. The three remaining P. smallii sites within Miami-Dade County each retain populations of ten individuals or less (Lange, pers. comm. 2017; Possley, pers. comm. 2017a). In Palm Beach County, the P. smallii abundance at two known locations fluctuates dramatically from year to year (Woodmansee et al. 2007). At Jupiter Ridge Natural Area, P. smallii abundance has fluctuated from 86 (2005) to 8 (2017) (Buck, pers. comm. 2017). The Limestone Creek Natural Area population has ranged from 3 to 60 since being discovered in 2002, with 5 encountered during 2017 (Woodmansee et al. 2007; Shearer, pers. comm. 2017). In southern Martin County, P. smallii is known to occur in Jonathan Dickinson State Park (JDSP). Surveys of the site have recorded between 6 and 64 individuals (Woodmansee et al. 2007; FNAI 2010a). Woodmansee et al. (2007) indicated that while the species appears to be in decline at JDSP, it is expected that plant numbers will increase in the long run, provided fires are administered. In St.

Lucie County, a small population (14 plants) of P. smallii occurs at the privately owned Lynn University (Woodmansee et al. 2007). (USFWS, 2019). Tiny polygala is currently known to occur in small populations located on tracts of suitable pine rockland and scrub habitat, mostly within publicly owned lands. Its limited distribution renders tiny polygala vulnerable to random natural or human-induced effects, including fire suppression and invasive exotic species. The most recent surveys for the species indicate that plants remain on ten sites within six populations (Table 1; Woodmansee et al. 2007; FNAI 2019; Black Finch 2020; Possley 2020; Rogers 2020; Rossmanith 2020; Shearer 2020; Law 2021). The majority of known tiny polygala populations occur on publicly owned lands that are managed for conservation. The one remaining population on private lands is managed for conservation under an HCP (Coral Reef Commons in the Richmond Pineland Complex; Service 2017). (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Habitat loss and fragmentation
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The pine rockland community of south Florida is critically imperiled globally (FNAI 2010b). In Miami-Dade County, development and agriculture have reduced pine rockland habitat by 90 percent. Continued habitat loss (Factor A) and fragmentation threaten the existence of this species, and less than 1 percent of the original acreage of pine rockland habitat remains outside of Everglades National Park (Herndon 1998). Populations on private sites remain threatened with destruction or habitat modification due to improper or lack of management (Factors A and E). (USFWS, 2019)

**Stressor:** Indequacy of existing regulatory mechanisms
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Currently, regulatory mechanisms (Factor D) provide limited protections for this species. The Florida Department of Agriculture and Consumer Services designated these species as endangered under Chapter 5B-40, Florida Administrative Code. This law regulates the taking, transport, and sale of listed plants. This law does not prohibit private property owners from destroying listed plants, nor does it require them to manage habitats to maintain populations. The Natural Forest Communities (NFC) program was established by Miami-Dade County to encourage but not require private landowners to protect forested lands by making it necessary to apply for a permit with the County prior to working in designated NFCs (i.e., pinelands, hammocks). (USFWS, 2019)

**Stressor:** Inadequate fire management
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire suppression continues to affect Amorpha crenulata(Factor E). Historically, frequent (approximately twice per decade), lightning-induced fires were a vital component in maintaining native vegetation and ecosystem functioning within south Florida pine rocklands. A period of just 10 years without fire may result in a marked decrease in the number of herbaceous

species due to the effects of shading and litter accumulation (FNAI 2010b). The majority of extant populations of this species is affected by some degree of inadequate fire management, with the primary threat being shading by hardwoods (Bradley and Gann 1999; Bradley and Gann 2005). (USFWS, 2019)

**Stressor:** Nonnative invasive plants
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasion by exotic plant species continue to affect Amorpha crenulata (Factor E). Nonnative invasive plants compete with native plants for space, light, water, and nutrients, and make habitat conditions unsuitable for this species, which prefers open conditions (Factor E). Bradley and Gann (1999) indicated that the control of nonnative plants is one of the most important conservation actions for the pine rockland species and a critical part of habitat maintenance. Nonnative plants have significantly affected pine rocklands and negatively impacted all occurrences of this species to some degree (Bradley and Gann 1999; Bradley 2006; Bradley and Saha 2009; Bradley and van der Heiden 2013). (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**
Not developed (USFWS, 1999; USFWS, 2010)

Recovery Priority Number: 5C

**Delisting Criteria:**
1. Existing natural populations achieve and maintain a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (addresses Factors A and E) (USFWS, 2019)

2. A network of 6 new populations are either discovered or reintroduced that exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (addresses Factors A and E) (USFWS, 2019)

3. All populations (criteria 1 and 2) are protected by a conservation mechanism. (addresses Factors A, D, and E) (USFWS, 2019)

4. Threats have been reduced or eliminated to the degree that this species will remain viable for the foreseeable future. (addresses Factors A, D, and E) (USFWS, 2019)

**Recovery Actions:**
- Conduct surveys to determine distribution and status of Polygala smallii. Pine rocklands have been thoroughly surveyed in Miami-Dade County. Additional surveys in the historic range of this plant should be performed in the scrub, sandhill, and open coastal spoil of Broward, Palm Beach, Martin, and St. Lucie counties. Fire eliminates litter concealing species, it may kill seeds in the litter or soil surface, or it may enable seeds in the seed bank to germinate. For that reason, suitable habitats which did not contain listed species when unmanaged should be resurveyed after fire events. (USFWS, 1999)

- Protect and enhance existing populations. It is imperative for the recovery of this species that populations not be lost. (USFWS, 1999)
- Collect biological information important to species recovery. Determine population size and viability of all populations. Investigate the genetic relationship of distinct Polygala populations. (USFWS, 1999)
- Develop standardized monitoring. Collect existing and historical data, and place in a central location. Convene a meeting of all researchers. Monitor status and success of all populations; change management practices if so indicated.Monitor reintroduction success and modify procedures as necessary. (USFWS, 1999)
- Continue to provide public information about scrub, sandhill, and open coastal spoil habitat and its unique flora. (USFWS, 1999)
- Habitat-Level Recovery Actions: Continue to protect existing pine rockland, scrub, sandhill, and open coastal spoil plant habitats. Restore areas to suitable habitat. Research additional habitat relationships. Monitor sites with pine restoration programs to determine success. Continue implementation of the fire education program and modify as necessary, any fire management education program that has been developed. (USFWS, 1999)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • Implement, continue, or increase habitat restoration efforts (exotic species removal and prescribed fire) at all sites with tiny polygala. • Survey extirpated sites and sites with unknown status annually to monitor for potential reappearance. • Continue to monitor extant populations annually. • Examine extant populations in Palm Beach, Martin, and St. Lucie Counties to determine if they are P. smallii or P. nana. • Conduct a comparative taxonomic study of P. smallii and P. nana using a multi-data approach (e.g., morphology, genetics, geography, ecological factors, etc.). • Survey potential habitat on privately owned sites if landowners will allow access. • If additional sites with tiny polygala are discovered, pursue conservation agreements and/or acquire land. Implement appropriate management for habitat restoration, particularly on sites with former tiny polygala populations. Any opportunities for purchase of properties with tiny polygala or better management under conservation easement should be pursued. • Additional partnerships should be promoted to share information, conduct collaborative research on pine rockland and scrub habitat conservation, and provide land managers and the interested public with information about the ecosystem, threats, recovery actions, and associated rare biota. • Expand work on ex situ propagation and seed banks. • Conduct reintroduction feasibility studies and identify potential recipient sites. • Conduct additional demographic research including population assessments and tracking of habitat changes through time. Monitoring should assess population declines or increases and examine growth and establishment rates. • Conduct genetic studies to examine diversity among sites which may be declining due to isolation and reduced genetic drift. • Conduct research to evaluate reproductive biology. • Conduct research to examine the effects of growing season burns versus non-growing season burns on flowering, seed set, and establishment. • Conduct studies to examine the cyclic occurrence of tiny polygala and determine if select fire-return intervals can reestablish the species to historical locations. (USFWS, 2021)

# SPECIES ACCOUNT: *Polygonella basiramia* (Wireweed)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 2/20/1987; Southeast Region (R4)

**Physical Description**

P. basiramia is a short-lived, perennial herb ( Hawkes, University of Pennsylvania, personal communication 1995). When vegetative, the plant consists entirely of basal, compressed stems with narrow, alternate leaves. Ocreae, the sheaths formed at stem nodes, are ciliate. Stems and leaves range in color from green to dark red; red coloration in the stems and leaves appears to be associated with individuals more exposed to sunlight and with older vegetative parts (although even seedlings are often red). As basal stems elongate, plants develop 1 to 46 slender, flowering, spike-like panicles as tall as 0.8 m (Hawkes and Menges 1995). This species is gynodioecious and plants have either only female flowers or hermaphroditic flowers. Individual flowers are small, white to slightly pink with 5 sepals (no petals), pink pistils, and black anthers. The gynoecium consists of 3 united carpels, 1-ovuled, ovary superior. Flowering occurs from the top spikelet downward on each stem. The fruit is a three-sided achene 1 to 3 mm in length. (USFWS, 1999) Wireweed Polygonella basiramia (= ciliata var. b.) (Small) Nesom and Bates Page 4-1149 Federal Status: Endangered (January 21, 1987) Critical Habitat: None Designated Florida Status: Endangered Figure 1. County distribution of wireweed. Recovery Plan Status: Revision (May 18, 1999) Geographic Coverage: Rangewide

**Taxonomy**

Originally named Delopyrum basiramia by Small in 1924 (Nesom and Bates 1984), this species was later thought to be a variety of Polygonella ciliata by Horton (1963). In 1984 Nesom and Bates recognized P. basiramia as a separate species. This species is commonly known as hairy or tufted wireweed. Polygonella basiramia is most closely related to P. ciliata and P. gracilis (Lewis and Crawford 1995). P. basiramia and P. ciliata are believed to have originated from P. gracilis, but whether they did so independently or from a single intermediate ancestral species is unknown. (USFWS, 1999)

**Historical Range**

See current range.

**Current Range**

Lake Wales, Winter Haven, and Bombing Range ridges in central peninsular Florida. It ranges from Lake Pierce in Polk County southward to Venus near the southern tip of the Lake Wales Ridge in Highlands County (USFWS, 1999)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: short-lived (average 0.31 years) (USFWS, 2019)

**Breeding Season**

Adult: September to December (USFWS, 1999)

**Other Reproductive Information**

Adult: Wireweed is an obligate seeder: no adult plants survive fire, and all post-fire recruits derive from seed. Flowering begins in September and achenes are produced in late November and early December. Because flowering is sequential, beginning at the top of each spike-like panicle and moving downwards, flowers and achenes are present at the same time mid-autumn. Achenes drop readily from the plant and most fall by mid-January. (USFWS, 2019)

**Reproduction Narrative**

Adult: Polygonella basiramia is gynodioecious, with individual plants producing either pistillate (female) or perfect flowers (both sexes in a single flower). The ratio of female to hermaphroditic plants is 1:1 at Archbold Biological Station (Hawkes and Menges 1995). Pollinators of P. basiramia include small halictid bees, Perdita polygonellae (a bee specific to the genus Polygonella), Eumenidae wasps, and potentially Glabellula spp. (Bombyliidae) (M. Deyrup, Archbold Biological Station, personal communication 1995). Seed production by female plants greatly exceeds that of perfect plants, with an average of 217.8 seeds per stem for females, but only 32.1 for perfect plants. P. basiramia is an obligate seeder which means that no adult plants survive a fire event and all new growth is from seedlings. On a population level, the number of seeds produced by P. basiramia in one reproductive season is more than 30 times the average plant density, sufficient to replace existing populations if only 3 percent of seeds were able to germinate and survive. (USFWS, 1999)

**Habitat Type**

Adult: scrub/scrubby flatwoods

**Environmental Specificity**

Adult: Narrow (USFWS, 1999)

**Habitat Narrative**

Adult: Polygonella basiramia is most commonly found in rosemary scrub, also known as rosemary phase of sand pine scrub (Abrahamson et al. 1984, Menges and Kohfeldt 1995). At Archbold Biological Station, rosemary scrubs are found only on the higher ridges and knolls at 40 to 50 m in elevation, and are largely restricted to St. Lucie and Archbold soil types (Abrahamson et al. 1984), both well drained white sands (Carter et al. 1989). Outside Archbold Biological Station, rosemary scrubs are generally found on white sands and higher elevations (Hawkes, University of Pennsylvania, personal communication 1998). The fire cycle in rosemary scrub can range from 10 to as long as 100 years (Johnson 1982, Myers 1990). Polygonella basiramia occupies open spaces or gaps between shrubs and can be found in abundance along sandy fire lanes, which provide similar habitat. (USFWS, 1999)

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Declining (inferred) (USFWS, 2019)

**Number of Populations:**

Based on FNAI data (2021) there were 65 EORs of wireweed considered extant and 4 EORs that were possibly extirpated (USFWS, 2021)

**Population Size:**

>1,000,000 total (USFWS, 2021)

**Population Narrative:**

The last FNAI Element Tracking Summary (FNAI 2015) reported 71 extant occurrences, 47 of which were on managed lands. This was a significant decrease (approximately 40 percent) from the 119 reported occurrences in the last 5-year status review (Service 2010d). At a larger scale, regional persistence of this species is dependent on landscape features and disturbance effects on metapopulation dynamics. Fire may expand or create the open sand gaps within a shrub matrix that support wireweed, but fire also kills established plants. Patchy fires may provide a balance, both creating suitable habitats and providing a fine-grained spatial landscape structure so wireweed can colonize those habitats. (USFWS, 2019). Wireweed occurs at nearly all (18 of 19) of the units of the Lake Wales Ridge Wildlife and Environmental Areas (LWRWEAs) (Menges et al. 2019): four areas at Avon Park Air Force Range (APAFR), three units of Lake Wales Ridge State Forest (LWRSF), three state parks (Highlands Hammock, Lake June in Winter, and Allen David Broussard Catfish Creek Preserve), two areas owned by The Nature Conservancy (Saddle Blanket Lakes, Tiger Creek Preserve), two tracts at Lake Wales Ridge National Wildlife Refuge, land owned by the Southwest Florida Water Management District, and at ABS. According to FNAI (2021), most occurrences (44 of 69 or 64 percent) are on protected areas, with 17 on LWRWEAs and many others on the LWRSF and various state parks (Table 1). Wireweed is a short-lived perennial plant, with widely varying population sizes (Bridges 2018). Population sizes vary annually and seasonally (Maliakal-Witt 2004). Because this species lacks a persistent seed bank, wireweed population recovery often experiences a delay for a few years after fire (which kills individual plants) until seeds disperse into the site (Book 2019). Most EORs (FNAI 2021; Table 1) do not specify the size of the occurrence, but those that do, range widely including populations in the thousands (Table 1). Christman (2006) reported about 1,082,433 plants throughout all occurrences evaluated, with the largest occurrence at 32,959 plants and the smallest consisting of one plant. More recent survey data (2014 to 2017) from APAFR (four EORs over nearly 1,500 acres) documented over 218,000 plants in four EORs (Bridges 2018). These surveys also documented an increase in the population sizes of wireweed over the last few years of surveys attributed to increased prescribed fire and hurricane damage opening overgrown areas (Bridges 2018). Bridges (2018) compared data collected from APAFR to Christman (2006) and estimated that APAFR accounted for about a third of known plants for wireweed and considered APAFR a “major stronghold” for the species. Population trends The recently reported 69 EORs (FNAI 2021) were a decline from the 119 extant EORs reported in the previous 5-year review (Service 2010), largely due to changes in FNAI definitions. Since 2010, FNAI has increased the area used to define an EOR. Due to insufficient research and monitoring of wireweed, there are insufficient data to evaluate the trends in populations. Detailed demographic data on individual populations (Level 3 monitoring, sensu Menges and Gordon 1996) was collected nearly two decades ago (Maliakal-Witt 2004) but has not been applied to questions of individual population persistence. Given the species’ life history (many populations, plants killed by fire, no persistent seed bank, and need for dispersal into burned areas), metapopulation analyses would be more appropriate than individual population viability analyses. FNAI ranks the viability (EORANK) of the EORs based on the size of the EOR general condition of the EOR, and the condition of the landscape surrounding the EOR. Based on FNAI data (2021) there were 65 EORs of wireweed considered extant and 4 EORs that were possibly extirpated (X?) (Table 1). A total of 35 EORs were considered viable (EORANK of A, AB, B, BC, or C), 5 EORs classified with uncertain viability (EORANK of BD or E), and 29 EORs were considered non-viable (EORANK of D, D?, H, X?) (Table 1, Figure 1). Of the 35 viable EORs, 30 (86 percent) occurred on protected lands (sites with habitat management or conservation mechanism) (Table 1, Figure 1). In contrast, the 29 non-viable EORs had few occurrences (9 EORs or 31 percent) on protected lands (Table 1, Figure 1). All 5 of the EORs with uncertain viability occurred on protected lands (Table 1, Figure 1). There is a need for surveys to determine the viability of these EORs. (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species is restricted to xeric scrub habitats in one or more of the interior Central Florida counties of Polk, Highlands, Hendry, Osceola, and Lake, where habitat destruction from development continues to occur and development pressure remains high. Areal extent of post-Columbian xeric upland habitat loss on the Lake Wales Ridge is estimated to exceed 85 percent (Weekley et al. 2008a). Increasing pressure from population growth is likely to result in further loss of these habitats going forward. Carr and Zwick (2016) analyzed existing land use and landscape patterns to identify areas (including central Florida) most likely for development to accommodate a growing human population. They suggests that Florida's 2070 population will be early 15 millionpersons greater than in 2010, for an estimated total of 33,721,828. Using these figures, they estimated relative losses to agriculture, open space, and conservation to other land uses. If trends continue, they estimate 34 percent of land will be developed by 2070, up from 19 percent in 2010. At the same time, conservation lands will increase less than 1 percent (from 9,269,000 acres in 2010 to 9,525,000 acres by 2070). Overall, loss of habitat to development, primarily on private lands, will likely continue in Central Florida, eliminating populations and reducing the area of suitable habitat for these species. Therefore, habitat on protected lands are critical for the recovery of this scrub plants. (USFWS, 2019)

**Stressor:** Lack of adequate fire management
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire is necessary to maintain the scrub habitats upon which this species depends. Historically, lightning-induced fires were a vital component in maintaining native vegetation within the scrub community. Fire suppression started on a regional scale on the Central Florida ridges about 80 years ago. Due to the extent of residential and agricultural development throughout Central Florida, fire has all but disappeared from the region as a widespread, natural phenomenon. Prescribed fire is a crucial management component for maintenance of all scrub habitats. Because of the difficulties of applying prescribed fire on an ever-increasing urban landscape, imperiled species on unmanaged sites will almost certainly disappear over time

(Turner et al. 2006). In managed areas, prescribed fire is essential to manage habitats and restore or maintain suitable conditions for scrub species. (USFWS, 2019)

**Stressor:** Limited geographic range.
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species occurs occur within a relatively limited geographic range in Central Florida. The limited geographic range in combination with the loss of habitat has resulted in a highly fragmented landscape where the remaining scrub areas and their residing species have become more and more isolated from each other, thereby making resiliency, redundancy, and representation more challenging to achieve. The effects of habitat fragmentation on species richness have been exhaustively studied (MacArthur and Wilson 1967, Diamond 1975, 1978; Simberloff and Abele 1976, 1982; Zimmerman and Bierregaard 1986). For most taxonomic groups, large habitat patches in close proximity to each other provide for the greatest species diversity and minimize extinction probabilities. On the contrary, small patches that are isolated are less likely to preserve species that would otherwise be common in the mosaic of communities that existed before isolation. Since at least the Pleistocene, Florida scrub has been characterized by an insular, discontinuous distribution, but the degree of habitat fragmentation seen today is unprecedented and certainly will contribute to increases in extinction rates among scrub-dependent plants and animals. (USFWS, 2019)

**Stressor:** Climate Change (USFWS, 2021)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** There is currently no evidence of negative impacts to wireweed from climate change factors, but this could change in the future as Florida is vulnerable to changes in rainfall and temperatures expected due to climate change. While the strong influence of ocean currents make projecting regional climate in Florida difficult (Kirtman et al. 2017), estimates project that Florida's average annual temperatures will increase approximately 1.5 to 5.5°F (0.8 to 3.1°C) by 2050 and from 2.3 to 11.5°F (1.1 to 6.4°C) by 2100. The degree of change depends on the greenhouse gas emission rates and the region in Florida (Runkle et al. 2017). In addition, it is predicted that for Central Florida summer rainfall (wet season) will decrease up to 5 percent by 2050 (Runkle et al. 2017). Wireweed vital rates are sensitive to winter and spring rainfall (Maliakal-Witt 2004). Higher temperatures and changes in precipitation patterns could alter relative humidity levels and evapotranspiration rates, leading to the potential for more frequent and intense droughts and wildfire events. Scrub and sandhill species, in general, can tolerate drought conditions, but it is unclear how this anticipated future threat will fully affect species like wireweed or the ability to implement prescribed fire (Kupfer et al. 2020). In addition to changes in precipitation and temperatures patterns, there are also anticipated changes to the severity of tropical storms and hurricanes. Sweet et al. (2017) predicted a 20 percent increase in both rainfall rates and wind speeds near the center of storms due, in part, to higher sea surface temperatures. Sea-level rise is another anticipated consequence of climate change in Florida. Sea level rise will not cause direct impacts to the Central Florida ridges as is anticipated for coastal and low elevation areas. However, as sea level rises in coastal regions, development is likely to move inland, further increasing the threat of development in the higher elevation areas, such as the LWR (Volk et al. 2017). (USFWS, 2021)

**Stressor:** Non-native plant species (USFWS, 2021)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Bahia grass (Paspalum notatum), cogon grass (Imperata cylindrica), and natal grass (Rhynchelytrum repens) invade scrub habitats and have negative effects through direct competition and by altering fire behavior. These species occur at numerous sites supporting wireweed. Because of wireweed's small stature and its preference for open conditions, exotic grasses are likely to have a serious negative effect on wireweed where they co-occur. At some protected site (USFWS, 2021).

**Stressor:** Off-road vehicles (ORVs) (USFWS, 2021)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** ORV impacts have occurred to natural areas on the LWR and throughout Central Florida (Schultz et al. 1999). ORVs crush, uproot, and tear plants as they drive over them. Although most managed sites restrict ORV use where wireweed occurs, ORVs are a potential threat on unprotected sites. (USFWS, 2021)

**Stressor:** Ex situ measures (USFWS, 2021)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Wireweed is lacking ex situ conservation measures for which imperiled and rare plants need. Bok Tower Gardens does not have wireweed in its' Center for Plant Conservation's National Collection of Endangered Species. However, wireweed may not be an ideal candidate for ex situ measures. Its short life span will create problems holding plants in a botanical garden setting. Seeds are stored at the National Center for Genetic Resources Preservation in Fort Collins, Colorado. Seeds tend to germinate immediately and may not store well over long periods (although this has not been investigated). (USFWS, 2021)

***Recovery***

**Reclassification Criteria:**
1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations and sites needed to assure 20 to 90 percent probability of persistence for 100 years (USFWS, 1999)

2. When these sites, within the historic range of P. basiramia, are adequately protected from further habitat loss, degradation, and fragmentation (USFWS, 1999)

3. When these sites are managed to maintain the rosemary phase of xeric oak scrub communities to support P. basiramia (USFWS, 1999)

4. When monitoring programs demonstrate that populations of P. basiramia on these sites support the appropriate numbers of self-sustaining populations, and those populations are

stable throughout the historic range of the species. Individuals growing opportunistically in unnatural areas, for example fire lanes, should be excluded from consideration when determining the status of this species. (USFWS, 1999)

Recovery Priority Number: 2

**Delisting Criteria:**
1. At least 40 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)

2. Populations (as defined in criterion 1) in rosemary scrub or scrubby flatwoods habitats are distributed across the known range of the species. (USFWS, 2019)

3. Populations are protected and managed via a conservation mechanism to a degree that enough suitable habitat is present for the species to remain viable for the foreseeable future. (USFWS, 2019)

**Recovery Actions:**
- Determine current distribution status of Polygonella basiramia. This species' distribution is somewhat questionable for taxonomic reasons. A thorough survey is needed to determine the distribution for this species. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Conduct research on life history characteristics. Though much of the basic biology and ecology of this species is understood, to effectively recover this species additional biological information is needed. (USFWS, 1999)
- Monitor existing populations of Polygonella basiramia. (USFWS, 1999)
- Provide public information about P. basiramia. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. (USFWS, 1999)
- Habitat-level Recovery Actions: Prevent degradation of existing habitat. Restore areas to suitable habitat. Conduct habitat-level research projects. Monitor habitat/ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)

# SPECIES ACCOUNT: *Polygonella myriophylla* (Sandlace)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 5/27/1993; Southeast Region (R4)

**Physical Description**

Polygonella myriophylla is a sprawling shrub that looks somewhat like the ornamental creeping juniper (Juniperus horizontalis). Its many branches zigzag along the ground and root at the nodes, forming low mats. The lower parts of the creeping branches have bark that cracks and partly separates in long, flat, interlacing strips. The short lateral branches end in flowering racemes. P. myriophylla has the sheathing leaf stipules (ocreae and ocreolae) typical of the jointweed family. The leaves are needle-like and are from 0.3 to 10.0 mm long. The small, white or cream colored flowers have white petallike sepals up to 3.4 mm long (Kral 1983). (USFWS, 1999)

**Taxonomy**

Sandlace is one of 11 species of North American Polygonella and one of three species of Polygonella that occur in scrub habitat in south Florida (Lewis and Crawford 1995). The sandlace was first collected in the early 1920s and was subsequently identified and named by Small (1924) as Dentoceras myriophylla. Horton (1963) combined two of Small’s genera with the genus Polygonella. P. myriophylla has been commonly called sandlace (Christman 1988), Small’s jointweed and woody wireweed (Wunderlin 1982). (USFWS, 1999)

**Historical Range**

See current range/distribution.

**Current Range**

In the Florida Counties of Orange, Osceola, Polk (Lake Wales Ridge), and Highlands (Lake Wales Ridge). (USFWS, 1999)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual; Vegetative (USFWS, 2019)

**Other Reproductive Information**

Adult: Sandlace reproduces sexually and vegetatively through the rooting of prostrate branches. Sandlace is killed by fire and will recolonize burned areas by seedling recruitment or clonal growth. Most obligate seeders in Florida scrub and sandhill, including both herbs (e.g., Highlands scrub hypericum, snakeroot, Lewton's polygala) and sub-shrubs (e.g., several species in the genus Dicerandra), recover quickly post-fire via seedling recruitment and often show dramatic aboveground population booms. In sandlace's preferred habitats, recommended FRIs range from 8 to 16 years for xeric scrubby flatwoods to 15 to 30 years for Florida rosemary scrub (Menges 2007). (USFWS, 2019)

**Reproduction Narrative**

Adult: Weekley and Menges (2003) confirmed that sandlace does not resprout after fire, but recolonizes burned areas from seed arriving from unburned areas, and perhaps by spreading from unburned areas. Pollinators of sandlace are genus-specific bees and likely a few varieties of wasps. Little is known about seed production and germination for this species, but seedlings do not survive in the vicinity of the mature plants, which are allelopathic, meaning they produce chemicals that inhibit the growth and survival of other nearby plants (Weidenhamer et al.1989). The major allelochemicals are gallic acid and hydroquinone (Weidenhamer and Romeo 2004).

**Habitat Type**

Adult: Scrub

**Environmental Specificity**

Adult: Narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Sandlace occupies open, sandy areas within the scrub vegetation, and it appears to require fire or other disturbances that create or maintain these sandy gaps. This species is killed by fire, and reoccupies burned sites from seed (Pedro Quintana-Ascencio, University of Central Florida, pers. comm. 2004). Its abundance can easily be overestimated, because it tends to colonize disturbed areas along easily accessible road cuts and rights-of-way.

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2019)

**Number of Populations:**

2 extant occurrences (USFWS, 2021)

**Population Size:**

~1.5 million (USFWS, 2021)

**Population Narrative:**

The previous FNAI Element Tracking Summary (FNAI 2015) reported 72 extant occurrences, 39 of which occurred on managed land. Thirty-three of 72 extant sandlace occurrences were located on private property where they had no protection from development and were unlikely to be appropriately managed. This was a significant decrease (approximately 36 percent) from the previous 5-year status review, which reported 113 extant occurrences. (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species is restricted to xeric scrub habitats in one or more of the interior Central Florida counties of Polk, Highlands, Hendry, Osceola, and Lake, where habitat destruction from development continues to occur and development pressure remains high. Areal extent of post-Columbian xeric upland habitat loss on the Lake Wales Ridge is estimated to exceed 85 percent (Weekley et al. 2008a). Increasing pressure from population growth is likely to result in further loss of these habitats going forward. Carr and Zwick (2016) analyzed existing land use and landscape patterns to identify areas (including central Florida) most likely for development to accommodate a growing human population. They suggests that Florida's 2070 population will be early 15 millionpersons greater than in 2010, for an estimated total of 33,721,828. Using these figures, they estimated relative losses to agriculture, open space, and conservation to other land uses. If trends continue, they estimate 34 percent of land will be developed by 2070, up from 19 percent in 2010. At the same time, conservation lands will increase less than 1 percent (from 9,269,000 acres in 2010 to 9,525,000 acres by 2070). Overall, loss of habitat to development, primarily on private lands, will likely continue in Central Florida, eliminating populations and reducing the area of suitable habitat for these species. Therefore, habitat on protected lands are critical for the recovery of this scrub plants. (USFWS, 2019)

**Stressor:** Lack of adequate fire management
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire is necessary to maintain the scrub habitats upon which this species depends. Historically, lightning-induced fires were a vital component in maintaining native vegetation within the scrub community. Fire suppression started on a regional scale on the Central Florida ridges about 80 years ago. Due to the extent of residential and agricultural development throughout Central Florida, fire has all but disappeared from the region as a widespread, natural phenomenon. Prescribed fire is a crucial management component for maintenance of all scrub habitats. Because of the difficulties of applying prescribed fire on an ever-increasing urban landscape, imperiled species on unmanaged sites will almost certainly disappear over time (Turner et al. 2006). In managed areas, prescribed fire is essential to manage habitats and restore or maintain suitable conditions for scrub species. (USFWS, 2019)

**Stressor:** Limited geographic range
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species occurs occur within a relatively limited geographic range in Central Florida. The limited geographic range in combination with the loss of habitat has resulted in a highly fragmented landscape where the remaining scrub areas and their residing species have become more and more isolated from each other, thereby making resiliency, redundancy, and representation more challenging to achieve. The effects of habitat fragmentation on species richness have been exhaustively studied (MacArthur and Wilson 1967, Diamond 1975, 1978; Simberloff and Abele 1976, 1982; Zimmerman and Bierregaard 1986). For most taxonomic groups, large habitat patches in close proximity to each other provide for the greatest species diversity and minimize extinction probabilities. On the contrary, small patches that are isolated

are less likely to preserve species that would otherwise be common in the mosaic of communities that existed before isolation. Since at least the Pleistocene, Florida scrub has been characterized by an insular, discontinuous distribution, but the degree of habitat fragmentation seen today is unprecedented and certainly will contribute to increases in extinction rates among scrub-dependent plants and animals. (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**

1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations and sites needed to assure 20 to 90 percent probability of persistence for 100 years (USFWS, 1999)

2. When these sites, within the historic range of P. myriophylla, are adequately protected from further habitat loss, degradation, and fragmentation (USFWS, 1999)

3. When these sites are managed to maintain the seral stage of xeric oak scrub communities to support P. myriophylla (USFWS, 1999)

4. When monitoring programs demonstrate that populations of P. myriophylla on these sites support the appropriate numbers of self-sustaining populations, and those populations are stable throughout the historic range of the species. (USFWS, 1999)

**Delisting Criteria:**

1. At least 40 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)

2. Populations (as defined in criterion 1) in yellow sand scrub or sand hill habitats are distributed across the known range of the species. (USFWS, 2019)

3. Populations are protected and managed via a conservation mechanism to a degree that enough suitable habitat is present for the species to remain viable for the foreseeable future. (USFWS, 2019)

**Recovery Actions:**

- Determine current distribution of P. myriophylla. A thorough survey is needed to determine the distribution for this species. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Conduct research on life history characteristics. Though much of the basic biology and ecology of this species is understood, to recover this species more specific biological information is needed. (USFWS, 1999)
- Monitor existing populations of P. myriophylla. (USFWS, 1999)
- Provide public information about P. myriophylla. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native

Plant Society, and private landowners be appropriately informed about this species. Care is needed, though, to avoid revealing specific locality information about where P. myriophylla is found. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of P. myriophylla and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations that will aid in the recovery and conservation of the white-rayed pentachaeta. Some of these recommendations have already been discussed in our previous status review (Service 2010, p. 28): 1. Conduct surveys at known occurrences at least every five years to determine population trends and habitat changes. 2. Collect information on habitat preferences in order to facilitate the search for suitable habitat for outplanting. Data to be collected should include associated plant communities, soil types, soil nutrients, pollinators, and hydrology of the currently occupied habitat as well as the historically occupied sites. Conditions at currently occupied sites may not represent the habitat that supported the species at historic locations, particularly for white-rayed pentachaeta, which had a far greater range historically and likely more variability between sites. 3. Conduct surveys for potential locations in which to establish new populations. The surveys should also confirm that there is only a single population stretching across both the Triangle and Edgewood Park properties, rather than two or more populations separated by a quarter mile or more. 4. Work with partners and landowners to establish new populations. 5. Work with partners to produce and implement management plans specific to white-rayed pentachaeta conservation at each population site. (USFWS, 2021)

# SPECIES ACCOUNT: *Potentilla hickmanii* (Hickman's potentilla)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A perennial herb from a woody taproot. Leaves are basal, with 4-7 pairs of deeply cleft leaflets. Stems are prostrate or decumbent, mostly 8-15 cm long. Slender flowering stems, 4-25 mm long, bearing yellow flowers arise from each stem. Blooms April-August. (NatureServe, 2015)

**Taxonomy**

Astragalus tener var. titi (Figure 4) was first collected by Mrs. Joseph Clemens in 1904. It was first described by Alice Eastwood as Astragalus titi based on those specimens collected by Clemens near Moss Beach, Monterey (Eastwood 1905). Eastwood named the plant A. titi in honor of Dr. F. H. Titus, who also collected specimens of this plant. Jepson (1936) considered these two taxa synonymous. Howell (1938) compared type specimens of A. tener and A. tener var. titi and confirmed two different plants, based on the low decumbent habit and smaller flowers of A. tener var. titi. Barneby (1950) published the name A. tener var. titi, noting differences from A. tener var. tener (alkali milk-vetch) in size of various flower parts, habitat, and geographic range. Astragalus tener var. tener is native to alkaline grass flats in the Central Valley, San Francisco Bay region, and the lower Salinas Valley (Barneby 1950). Additionally, crossing studies and enzyme electrophoresis concluded that A. tener var. titi is a valid taxon(Liston 1992) (USFWS, 2004).

**Historical Range**

Potentilla hickmanii was historically known from two general areas along the central coast of California: on the Monterey Peninsula in Monterey County, and in the Half Moon Bay area in San Mateo County. The type specimen was collected from the Monterey Peninsula “near the reservoir which supplies Pacific Grove” and described by Alice Eastwood in 1902. Several other collections were made from the Monterey Peninsula during the 1930s, but detail on specific locations is lacking. (USFWS, 2009)

**Current Range**

California endemic. One extant population in Monterey County. One large population exists in San Mateo County. The total range extent consists of 3 areas and about 9 sq. mi. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollinated (USFWS, 2004)

**Breeding Season**

Adult: Seeds are produced late in the season (USFWS, 2004).

**Reproduction Narrative**

Adult: Potentilla hickmanii has protogynous flowers with a stigma that is receptive to pollen before the pollen-bearing anthers open within the same flower (Jones and Stokes Associates 1996). This mechanism can reduce self-pollination and increase the possibility of outcrossing. It is also likely that some level of interpopulational genetic diversity exists (B. Ertter in litt. 1997). Seeds are produced late in the season. Plants may produce little to no seeds in drier years, especially among early-blooming flowers (Jones and Stokes Associates 1996, B. Ertter in litt. 1997). This lack of seed set might be due to the observed absence of pollinators during blooming time of dry years. Natural population increases appear during wet years, although these population increases may not occur during dry years (Doak et al. 2000). Additionally, recent greenhouse research indicates that some plants previously counted as up to five individuals may have been one single plant with a branched caudex (V. Yadon in litt. 2002). Research was conducted during 1998 and 1999 to explore environmental factors that limit seed production and establishment, and how a limitation might vary through the plants' flowering season (Doak et al. 2000). Evidence for pollen limitation of seed set was apparent and pollen augmentation also significantly reduced the probability of reproductive failure (Doak et al. 2000). Reproductive failure may exist if both pollinator visitation and pollen dispersal is low. Doak et al. (2000) observed only one pollinator in the 2-year study (i.e., a small beetle). Additionally, this research discovered that developed, mature seed was found significantly more frequently in plants that were within at least 50 centimeters (20 inches) of each other than in isolated plants (Doak et al. 2000). Potentilla hickmanii will grow and bloom year-round under cultivated conditions. However, cultivated flowers that bloom later in the year tend not to set seed (V. Yadon in litt. 2002). Plants with early flowers that were grown in a hot house set seed apparently without benefit of pollinators (V. Yadon in litt. 2002) (USFWS, 2004).

**Habitat Type**

Adult: coastal scrub/forest (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits coastal bluff scrub and closed-cone pine forest (Smith & Berg 1988). Freshwater marshes, seeps and streamlets in open forested areas near the coast, 0-75 m. (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species and the low number of known populations.

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Decreasing (NatureServe, 2015)

**Population Growth Rate:**

Decline of 70-90%   (NatureServe, 2015)

**Number of Populations:**

2 (USFWS, 2025)

**Population Size:**

~7,500 total (USFWS, 2025)

**Population Narrative:**

Hickman's potentilla occurs in very small numbers (<80) at Indian Village in Monterey County and a larger population (~5,000) occurs on land managed by the Golden Gate National Recreation Area near Montara in San Mateo County.  (USFWS, 2020).  We consider there to be two extant populations of Hickman's potentilla: the Indian Village population in Monterey County, and the Montara population in San Mateo County. The Indian Village population occurs within approximately 0.33 acres (ac) of grassland habitat managed by the Del Monte Forest Conservancy (DMFC) bordered by Monterey pines, a golf course, and residential development. The Montara population consists of a series of subpopulations covering approximately 50 ac within coastal prairie, grassland, and coastal scrub habitat managed by the National Park Service (NPS) as part of the Golden Gate National Recreation Area (GGNRA). Since listing in 1998, the Indian Village population has been very small, with as few as eight individuals and as many as 79 following outplanting efforts (Table 1) (Service 2009, pp. 5-6; DMFC 2016, p. 5; Vaughan 2020, pers. com.; McCorkle 2020, pers. com.). Intermittent outplanting, weed management, and herbivore control since the early 1990s (Service 2009, p. 5) and as recently as 2015–2020 (DMFC 2016, entire; Vaughan 2020, pers. com.; Service 2020) likely aided in preventing the loss of the population. However, the population has recently declined to about 20 individuals from the high of 79 in 2020 (Table 1). Herbivory, mold, competition, and possibly drought have driven the recent mortality (Vaugh 2025, pers. com.). The Montara population occurs on land that was formerly owned by the Peninsula Open Space Trust and transferred to NPS in 2011 (NPS 2020). Monitoring and weed control have increased since NPS began management of the population. Monitoring by NPS since 2013 suggests that the average population size is closer to 6,500 individuals (Chasse et al 2024, pp. 45-48), in comparison to historical averages between 2,000 and 3,000 (Service 2009, p. 5). NPS is currently engaged in restoration activities to support and expand the existing patches of the Montara population through shrub removal (mostly Cotoneaster spp.) in conjunction with grassland restoration and Hickman's potentilla outplanting (E. Wrubel 2025, pers. com.). Seed propagated in park nurseries was used to outplant a total of 272 plants between 2022 and 2023 in or near known occupied habitat in this population (USFWS, 2025)

***Threats and Stressors***

**Stressor:** Development (USFWS, 2009)

**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** current threats to the population at Pebble Beach, Monterey County, are relatively the same as at the time of listing. Because a second population has been discovered since the time of listing (Montara population in San Mateo County) and threats to the population are less than they are for the Pebble Beach, Monterey County, population, the threats to the species overall are less than they were at the time of listing. In addition, the Montara population has been transferred from private ownership to state and local agency ownership (CalTrans and Peninsula Open Space Trust ), and long-term plans are to transfer these lands to California State Parks and Golden Gate National Recreation Area, respectively. However, threats to the habitat remain at both locations, and include conversion of coastal terrace prairie habitat by native and nonnative species, alteration in hydrology, and recreation. The Pebble Beach population is threatened with extirpation from alteration and destruction of habitat because the size of coastal prairie where Potentilla hickmanii occurs is less than 0.25 ac (0.1 ha) and the number of individuals is so few; therefore, the remaining individuals may not be able to persist if the condition of the habitat continues to decline (USFWS, 2009).

**Stressor:** Predation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Predation on Potentilla hickmanii by mule deer (Odocoileus hemonius) on the Pebble Beach population in Monterey County has been observed by Yadon (in litt. 1997) and others (Jones and Stokes Associates 1996). Since the time of listing, herbivory by voles (Microtus spp.), snails (various species), and slugs (various species) has also been observed on both vegetative and reproductive structures (Doak et al. 2000). As recently as 2008, Staub (in litt. 2008) noted that gophers (Thomomys sp.) and mice (various species) are likely affecting the population. With so few individuals comprising this population (11 individuals as of 2008), predation exacerbates the threat of stochastic extinction (see Factor E). We have also become aware that the Montara population in San Mateo County is within an area being grazed by cattle (CNDDB 2008). Cattle grazing may be either beneficial or deleterious to the species, depending on the intensity and duration. Cattle grazing may benefit the species by reducing competition from nonnative species. Too little grazing may allow nonnative species to outcompete Potentilla hickmanii, while too much grazing may result in predation or trampling of Potentilla hickmanii. We do not have specific information concerning the intensity or the overall impact of grazing that is occurring within this area (USFWS, 2009).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** This species occurs within a portion of the Monterey Peninsula included in the California Coastal Zone. The Del Monte Forest Land Use Plan of 1984 was developed to comply with the Coastal Act's requirement that all counties prepare a plan for those portions of the Coastal Zone within their jurisdiction. Once the Del Monte Forest Land Use Plan was certified by the Coastal Commission, development permits within the Del Monte Forest coastal zone became the responsibility of the County of Monterey. The County of Monterey also has designated

certain areas, including where Potentilla hickmanii grows, as Environmentally Sensitive Habitat Areas. Protection of listed species through the California Coastal Act and local land use designations is dependent upon the discretion of the lead agency involved. Although no projects have been proposed for the site where Potentilla hickmanii grows, these state and local regulations may not protect the species from secondary impacts that occur from such threats as changes in hydrology in adjacent areas and the spread of nonnative species (USFWS, 2009).

**Stressor:** Competition with nonnative species (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** At the Monterey Peninsula site, at least five nonnative plant species occur within Potentilla hickmanii habitat. These include: hairgrass, various bromes, tall fescue, and ryegrass (Ferreira 1995, Yadon pers. comm. 2008). Nonnative grasses including Harding grass (Phalaris aquaticus) also occur at the Montara site. Several of these nonnative taxa are known to outcompete and displace native species in general (Bossard et al. 2000). To determine the effects of competition on Potentilla hickmanii, Doak compared the number of inflorescences and the number of flowers on Potentilla hickmanii seedlings within plots where surrounding vegetation was either clipped or unclipped; Potentilla hickmanii seedlings in the clipped plots produced more flowers and inflorescences than those in the unclipped plots (Doak et al. 2000). At the Montara site, pampasgrass was noted as being a potential threat to one colony of Potentilla hickmanii (Kramer 2008) (USFWS, 2009).

**Stressor:** Reproductive failure (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Reduced number of new plants
**Narrative:** At the time of listing, we discussed that reproductive failure was a concern, primarily because the Monterey Peninsula population had a very low number of new seedlings established over a 2- year period (Morosco 1997). In addition, low seed set had been observed by several biologists (Ertter in litt. 1997, Yadon in litt. 1997). Since the time of listing, Doak et al. (2000) compared seed set in flowers that were cross-pollinated by hand with those in a control group. Based on number of ovules, each flower has the potential to produce approximately 10 seeds; the researchers found that hand-pollinated flowers achieved a higher seed set than the control group (4.8 per flower compared to 3.2) (Doak et al. 2000). The lack of pollinators observed in the field has been put forth as a potential cause for low seed set by several observers (Yadon in litt. 1997, Ertter in litt. 1997, Doak et al. 2000) (USFWS, 2009).

**Stressor:** Small numbers of individuals and populations (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of genetic variability/extinction
**Narrative:** Conservation biology literature discusses that small populations are threatened by inbreeding depression (Ellstrand and Elam 1993). Small populations can have significantly lower germination rates than larger populations of the same species due to high levels of homozygosity (Menges 1991). Based on historical records, we believe that urban development and secondary impacts associated with such development has already reduced the distribution of this species in the two areas where it occurs. Indirect effects from urbanization in the watersheds include

changes in hydrology, changes in vegetation, and an increase in nonnative species. The effects of competition with nonnative species is most problematic immediately adjacent to urban areas and in habitat that has been isolated or fragmented by development (Alberts et al. 1993). While any one of these factors may not be enough to threaten the survival of Potentilla hickmanii independently, its limited range, the cumulative and synergistic effects of all of these factors combined could be a threat to the survival and recovery of Potentilla hickmanii (USFWS, 2009).

**Stressor:** Alteration of fire frequency (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** At the time of listing, we discussed that alteration of fire frequency was a potential threat to all five taxa in the listing rule, due to fire suppression activities that increased on the Monterey Peninsula as development increased over time; we did not discuss specifically how reducing the frequency of fires in the area would affect Potentilla hickmanii. Although Potentilla hickmanii itself is associated with grassland habitats, the small meadow where it occurs is within an opening of Monterey pine forest. Without periodic fire, the pine forest would tend to expand in range over time and eventually shade out the habitat where Potentilla hickmanii occurs. Shading by Monterey pine was also noted as a threat to several colonies of Potentilla hickmanii at the Montara population (Kramer 2008). Based on current information, alteration of fire frequency may continue to be a threat to Potentilla hickmanii at both sites (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). Recently, the potential impacts of climate change on the flora of California were discussed by Loarie et al. (2008). Based on modeling, they predicted that species' distributions will shift in response to climate change, specifically that the species will "move" or disperse to higher elevations and northward, depending on the ability of each species to do so. Species diversity will also shift in response to these changes with a general trend of diversity increases shifting towards the coast and northwards with these areas becoming de facto future refugia. However, predictions of climatic conditions for smaller sub-regions such as California remain uncertain. It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects. While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to Potentilla hickmanii at this time (USFWS, 2009).

***Recovery***

**Reclassification Criteria:**
At least five viable populations (i.e., populations that are stable or increasing based on a minimum of 10 years monitoring) occur in suitable habitat (addresses Listing Factors A and E). This criterion is relevant and up-to-date. This criterion has not been met. In addition to the two

populations known at the time of listing, one outplanting effort is underway at Point Lobos State Park (USFWS, 2009).

All five of the sites are on land that is protected from human-induced disturbance. Funds must be available for appropriate long-term management. As determined by research, protected habitat must be of adequate size (large enough to support a functioning ecosystem; e.g., species present to support seed dispersal and pollination, areas that support fluctuating distributions, areas that harbor suitable unoccupied habitat for population expansion) and configuration to ensure that ecosystem and community processes and associated species (e.g., hydrologic regime, food webs, pollinator fauna, forest meadow communities) are maintained, and that an adequate diversity of sites exist for population expansion and for colonization of new areas as microhabitat conditions change. One of these protected sites should be the Indian Village (Pebble Beach) population; another should be the Montara population in San Mateo County (addresses Listing Factors A and E). This criterion is relevant and up-to-date. This criterion has not been met (USFWS, 2009).

Surrounding vegetation has been managed for a reduction of nonnative plant species and nonnative snails and slugs. The populations should be adequately maintained, such that encroachments by nonnative plants and herbivorous predators (including deer) are not negatively affecting Potentilla hickmanii directly or indirectly (addresses Listing Factor C). Individuals have been caged at the Pebble Beach population, and this has reduced deer browse. However, additional management is needed to control nonnative species. This criterion is relevant and upto-date. This criterion has been partially met for one population (USFWS, 2009).

The populations have been appropriately managed to such a degree that monitoring has determined the populations are of adequate size, density, and number that the trend for each of the populations is projected to be stable or increasing in the future (addresses Listing Factors A and E). Population censusing and demographic studies have been conducted for the Pebble Beach population, but not in a manner that is able to detect long-term trends. This criterion is relevant and up-to-date. This criterion has not been met (USFWS, 2009).

A seed bank has been established at a recognized institution certified by the Center for Plant Conservation (addresses Listing Factor E). This criterion is relevant and up-to-date. This criterion has been partially met in the following way: a portion of seed from the Pebble Beach population that was previously collected for research is being stored at the University of California, Santa Cruz (UCSC); UCSC is not a Center for Plant Conservation affiliate. A small amount of seed was collected from the Montara population in 1995 by staff from the University of California, Berkeley (Jones and Stokes 1996); its current disposition is unknown (USFWS, 2009).

Recovery Priority Number: 5C

**Delisting Criteria:**
Delisting Criterion 1) threats are reduced or eliminated so that protected populations are capable of persisting without significant human intervention or perpetual endowments are secured for management necessary to maintain the continued existence of the species. The most outstanding management needs currently are: a) maintaining and restoring habitat through control of nonnative grass species , and b) control of herbivory by deer and small mammals.  (USFWS, 2019).

Delisting Criterion 2) unoccupied habitat in the area has been assessed for its suitability for reintroduction efforts; the Monterey Peninsula area should be further assessed for potential sites. Two additional, new populations are established and protected where appropriate. (USFWS, 2019).

Delisting Criterion 3) all protected populations remain viable for at least 10 years to demonstrate long-term viability under a range of environmental conditions. We expect above-ground population size to fluctuate annually, based on response to amount and timing of rainfall (e.g. see Fox et al. 2006). Even though this is a perennial species, the aboveground portion is herbaceous and dies back each year, and thus responds to some extent like an annual species. Therefore, a period of 10 years should be long enough to include most of the variability in rainfall that occurs in this region (Zedler & Black 1989; NOAA 2018). (USFWS, 2019).

**Recovery Actions:**

- Work with Pebble Beach Company to evaluate current conditions and improve habitat conditions at the Pebble Beach site. Determine if additional measures can be taken to reduce threats from overwatering, invasive nonnative species, and herbivores (a portion of recovery tasks 1.4.3 and 2.3) (USFWS, 2009).
- Continue pollination ecology research initiated by Doak to determine if lack of pollinators is limiting seed set at the Pebble Beach site. Conduct research to identify pollinators at the Montara site and compare with those at Pebble Beach (a portion of recovery task 3.2.3) (USFWS, 2009).
- Seek additional sites for outplanting additional populations in Monterey and San Mateo Counties. State Park lands (aside from Point Lobos) may offer opportunities for outplanting (a portion of recovery task 4.2.3) (USFWS, 2009).
- Coordinate with Peninsula Open Space Trust to determine if management actions need to be taken to protect or enhance habitat for the species on lands they manage prior to transfer to Golden Gate National Recreation Area (GGNRA). Seek assurance from GGNRA that necessary management actions be continued (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: The following actions are recommended based on the current 5-Year Review: 1. Continue management of herbivory and competing species at the Indian Village population. 2. Continue outplanting efforts at Indian Village to increase population size so that adequate natural recruitment is possible. 3. Restore associated native species to the Indian Village site to promote natural ecosystem processes. 4. Finalize and implement the National Park Service plan to manage and restore habitat and outplant Hickman’s potentilla at the Montara population. 5. Resurvey and monitor the Point Lobos introduction sites. 6. Evaluate additional introduction sites in San Mateo and Monterey Counties. 7. Continue seed banking efforts until adequate seed from both populations have been stored. (USFWS, 2020)
- RECOMMENDATIONS FOR FUTURE ACTIONS: We recommend the following actions: 1. Establish outplanting and management program at Indian Village. Management should include grassland restoration, competitive vegetation control, and herbivory control. 2. Expand Montara populations to new areas of suitable habitat and increase abundance of existing but small patches. 3. Reintroduce Hickman’s potentilla to Point Lobos with adequate funding for a sustained management program. 4. Develop a common garden experiment and genetic study to assess whether seed from

each population should be kept separate or mixed. 5. Identify additional introduction sites in San Mateo and Monterey Counties. 6. Continue seed banking efforts until adequate seed from both populations have been stored (USFWS, 2025)

# SPECIES ACCOUNT: *Prunus geniculata* (Scrub plum)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 2/20/1987; Southeast Region (R4)

**Physical Description**

The scrub plum is a heavily branched, broad-crowned shrub that can reach 2 m in height, although 0.5 m may be more typical at sites with frequent fires. It grows from gnarled, half-buried trunks and spreads by sucker shoots. Its young twigs are strongly geniculate (zig-zag shaped), while its lateral branches are either short, stubby, spur shoots bearing leaves and flowers, or are strongly tapering and spine-like. The bark of old stems is thin, gray, usually lichen-encrusted, and forms small rectangular or square plates. The bark of new shoots is lustrous reddish-brown or purplish and smooth. The scrub plum's leaves are crowded on the spur shoots (an arrangement typical of the Rosaceae family) and are widely spaced on the normal shoots. The stipules are linear-subulate, roughly 5 mm long, green, and pectinately fringed at the margins with reddish glands. The leaf blades are ovate to obovate or elliptic, 1 to 3 cm long, short-acuminate, and serrulate with gland-tipped teeth. The leaf base is rounded or broadly cuneate. The leaf stalk is a third to half as long as the blade. The scrub plum has small, fragrant flowers that are 11 to 13 mm across when open. Like the leaves, flowers found on the spur shoots are rather crowded, while those found on the regular shoots or the spine bases are spaced further apart. The pedicels extend only slightly beyond the bud scales, so the flowers give the appearance of being sessile. The flowers are radially symmetrical with a 3 mm long hypanthium (the cup-shaped structure formed by the united portions of the bases of the sepals, petals, and stamens). The 5 calyx lobes are radially symmetrical, spreading to ascending triangular with acute apices, sparsely ciliate on the margins, reddish or green, with the bottom surfaces smooth and the upper surfaces white-tomentose. The 5 petals are white, spreading, and about 5 mm long. The petal blades are ovate to obovate with rounded tips and attenuated bases ending in short, ciliate-margined claws. The stamens are numerous, roughly 0.5 mm long, and borne on the rim of the hypanthium. The fruit of the scrub plum is an ovoid or ellipsoidal drupe, 12 to 25 mm long, and dull reddish in color. It has a thin, bitter flesh and a slightly flattened seed. (USFWS, 1999)

**Taxonomy**

Prunus geniculata was first described by Roland M. Harper in 1911 (Harper 1911). There has been no additional treatment of this species. The common name "scrub plum" was first used by Small (Small 1933). (USFWS, 1999)

**Historical Range**

See current range/distribution.

**Current Range**

In Florida, the range includes Lake County, west and southwest of Lake Apopka; the southwest and northwest corners of Orange and Osceola counties, respectively; and Polk and Highlands counties, from the City of Lake Wales south to the Highlands County/Glades County border. (USFWS, 2009)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

Adult: Scrub plum is a rare plant with a very narrow range and small, widely scattered populations. It frequently forms small colonies of several plants but may grow as solitary individuals (unpublished FNAI data). It prefers fairly open areas without a dense canopy, but older plants are able to survive in dense shade (Schultz, pers. obs.). Scrub plum's life history has not been reported in the literature. Many birds, rodents and other mammals are known to be fond of plum fruit and are probably responsible for the dissemination of the species (Van Dersal, 1938). Gopher tortoise (Gopherus polyphemus) could also be a vector. Kral (1983) states that P. geniculata respond vigorously to fire disturbance and historically was probably fire maintained due to its presence in frequently burned sandhills.; ASEXUAL; Perfect; Predominantly outcrossing; SEXUAL; BIOTIC; Birds; Mammals; BIOTIC; Hymenoptera; Insects, other; (NatureServe, 2015). From the various research efforts, we now know that scrub plum: (1) has a rare breeding system characterized by the presence of male and bisexual flowers on the same plant, (2) is partially self-incompatible and that inbreeding depression is high in self-compatible individuals, and (3) experiences high rates of fruit loss due to abortion and pre-dispersal predation. Recent research has also confirmed that scrub plum is long-lived and experiences low mortality, and populations persist for long periods in the absence of fire (Pace-Aldana et al. 2006; Menges et al. 2008; C. Weekley, Archbold Biological Station, personal communication, 2009). Current information also supports previous reports that this species is a strong postburn resprouter (Weekley et al. 2007, Weekley and Menges 2003, Menges et al. 2007) and that recruitment is low (Service 1999; Weekley and Menges 2003, 2007). Weekley and Menges (2008) are currently evaluating the effects of various land management treatments on a number scrubendemic plants, including scrub plum (USFWS, 2009).

**Habitat Type**

Adult: Turkey oak sandhill and evergeen oak-sand pine (USFWS, 2009)

**Spatial Arrangements of the Population**

Adult: Clumped (USFWS, 2009)

**Environmental Specificity**

Adult: Narrow/specialist (USFWS, 2009)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from USFWS, 2009)

**Site Fidelity**

Adult: High (inferred from USFWS, 2009)

**Habitat Narrative**

Adult: Species inhabits deep, yellow sands of longleaf pine-turkey oak sandhill and white, excessively leached, wind-deposited soils of evergreen scrub oak-sand pine scrub (NatureServe, 2015). High site fidelity and ecological integrity of the population as well as low tolerance range are inferred based on the specific habitat requirements of this species.

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Scrub plum's life history has not been reported in the literature. Many birds, rodents and other mammals are known to be fond of plum fruit and are probably responsible for the dissemination of the species (Van Dersal, 1938). Gopher tortoise (Gopherus polyphemus) could also be a vector (USFWS, 2009).

***Population Information and Trends***

**Number of Populations:**

64 (USFWS, 2023)

**Population Size:**

2500 - 10,000 individuals (USFWS, 2009)

**Population Narrative:**

Responds vigorously to fire disturbance; cannot withstand soil disturbance of shade. Sometimes common, but usually only a few individuals at a site (NatureServe, 2015). FNAI updated its records for scrub plum in the 6 summer of 2008 and confirmed 83 extant populations. These 83 populations contained from 1 to 10,200 plants (A. Johnson, Florida Natural Areas Inventory, personal communication, 2009). Forty-five populations contained 10 or more plants (USFWS, 2009). Prunus geniculata is a long-lived, heavily branched shrub, that thrives in fire-maintained scrub habitat native to ancient ridges in central Florida. There are estimated to be 64 extant populations in 5 counties. Of these populations, 40 are found on conservation lands and 13 of those had their conditions ranked as excellent or good on when last observed. There were 51 populations that are either found on private lands or have lower ranked conditions. Additionally, only six populations on the conservation lands have an estimated size over 100 individuals (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Fire Suppression (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The most pervasive threat to scrub plum on public land is habitat degradation due to fire suppression. Most land managing agencies in Florida are not able to use prescribed fire at the rates, frequency, and/or intensity needed to restore and maintain most of Florida’s fire-adapted ecosystems (R. Mulholland, Florida Department of Environmental Protection, personal communication, 2007; Service 2006). Consequently, the difficulties land managing agencies currently face in implementing prescribed fires probably have resulted in the degradation of scrub plum habitat in some areas (USFWS, 2009).

**Stressor:** Urban development (USFWS, 2009)

**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Scrub plum that occur on non-conservation private lands also are vulnerable to destruction due to urban development, such as construction of roads; installation of utilities and other infrastructure; and residential, commercial, and industrial construction. Scrub plum on each private parcel is vulnerable to this threat at any time. Several populations are located in areas previously platted for residential development and these populations are at greatest risk, especially when economic conditions improve and residential construction resumes at is historic pace. One small population is imminently threatened by land clearing for commercial development. In 2006, the Service issued an incidental take permit for two fossorial skinks on about 45 acres in west-central Lake County. Several hundred scrub plum plants were also found on this parcel along with six other federally listed plants (Service 2005). The entire parcel has not yet been developed but as land clearing proceeds individual plants will be destroyed (USFWS, 2009).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** On private properties, Federal or State laws provide little protection for scrub plum. Since the majority of extant scrub plum populations occur on unprotected private lands, we conclude that existing regulatory mechanisms are inadequate to protect this species (USFWS, 2009).

**Stressor:** Low seed viability (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of genetic diversity
**Narrative:** Scrub plum produce few viable seeds and recruitment is extremely low (Weekley et al. 2007; B. Pace-Aldana, TNC, personal communication, 2008). Loss of seeds due to inbreeding depression reduces the number of germinable seeds. These effects may be exacerbated by habitat fragmentation and fire exclusion (C. Weekley, Archbold Biological Station, personal communication, 2009) (USFWS, 2009).

***Recovery***

**Reclassification Criteria:**
Applicable to the South Florida populations: 1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations required to ensure 20 to 90 percent probability of persistence for 100 years. (USFWS, 1999)

Applicable to the South Florida populations: 2. When these populations, within the historic range of P. geniculata are adequately protected from further habitat loss, degradation, and fire suppression. (USFWS, 1999)

Applicable to the South Florida populations: 3. When these sites are managed to maintain the high pine and xeric oak scrub communities to support P. geniculata; (USFWS, 1999)

Applicable to the South Florida populations: 4. When monitoring programs demonstrate that these sites support sufficient population sizes, are distributed throughout the historic range, and are sexually or vegetatively reproducing at sufficient rates to maintain the population. (USFWS, 1999)

Applicable to the entire species range: The 1996 recovery plan lists four criteria necessary to reclassify the scrub plum from endangered to threatened status: (1) there are eight populations at four sites; (2) at least 10 years of demographic monitoring is conducted at one of these locations; (3) scrub plum is monitored at all locations; and (4) there must be protected locations in Highlands, Polk, and Lake counties. (USFWS, 1996)

Recovery Priority Number: 2

**Delisting Criteria:**
Applicable to the entire species range: To delist the scrub plum, 20 populations must be present at 5 sites and there must be 10 additional years of monitoring. (USFWS, 1996).

**Recovery Actions:**

- S1. Determine current distribution of P. geniculata. Conduct surveys for P. geniculata. Conduct surveys for P. geniculata. Maintain distribution of known populations and suitable habitat in GIS database. (USFWS, 1999)
- S2. Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties has been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- S3. Conduct research on life history characteristics of P. geniculata. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species more specific biological information is needed. (USFWS, 1999)
- S4. Monitor existing populations of P. geniculata. Develop monitoring protocol to assess population trends for P. geniculata. Develop a quantitative description of the population structure of P. geniculata. (USFWS, 1999)
- S5. Provide public information about P. geniculata. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of P. geniculata and other rare species requires a self sustaining, secure number of natural populations. (USFWS, 1999)
- H1. Prevent degradation of existing habitat. Extensive habitat loss, degradation, and fragmentation have already occurred throughout the range of this species. Both urbanization and fire suppression have decreased the available habitat. To date, there are six protected sites for P. geniculata in Polk and Highlands counties. (USFWS, 1999)

- H2. Restore areas to suitable habitat. Native habitats that have been disturbed or that have experienced a long history of fire suppression may be good candidates for future reserves. (USFWS, 1999)
- H3. Conduct habitat-level research projects. Study the response of P. geniculata to various land management practices, such as prescribed fire regimes, vegetative thinning, and control of exotic/invasive vegetation. (USFWS, 1999)
- H4. Monitor habitat/ecological processes. Monitor the effects of land management actions, such as prescribed fire, exotic plant control, etc., on the habitats where P. geniculata occurs. (USFWS, 1999)
- H5. Provide public information about scrub and its unique biota. Educational efforts, especially those conducted by Archbold Biological Station, have been successful. Without these successful efforts, the Lake Wales Ridge NWR would not have been created. Florida's system of biological preserves depends on a broad base of public understanding and support for its funding and future success. In addition to past and ongoing educational efforts by The Nature Conservancy, Bok Tower Gardens, and Archbold Biological Station, future efforts by these organizations, and the Florida Park Service, the Florida Division of Forestry, the South Florida Water Management District, the Florida Native Plant Society, and local garden clubs are crucial in increasing public appreciation of scrub and high pine communities, and their associated plant species. The Arbuckle Appreciation Day sponsored by the Florida Division of Forestry has been especially successful. (USFWS, 1999)
- Recommendation for Future Action from 2009 5-Year Review: Revise the recovery criteria to establish measurable goals for demographic monitoring, including but not limited to: the number of populations that should be monitored, the demographic parameters that should be measured, the demographic performance levels/rates that should be met, and the timeframe within which these levels/rates should be attained/maintained (USFWS, 2009).
- Recommendation for Future Action from 2009 5-Year Review: Continue demographic monitoring on the Carter Creek tract of the LWRNWR and reinitiate demographic monitoring on TNC's Tiger Creek and Longleaf Pine Preserves. Conduct Level 2 (see Menges and Gordon 1996) monitoring on multiple sites using populations in different habitats and with different management regimes (USFWS, 2009).
- Recommendation for Future Action from 2009 5-Year Review: Conduct a rangewide survey of genetic diversity in scrub plum. Such a survey could help in identifying populations that might be targeted for acquisition or included as a propagule source for creation of new populations on sites undergoing restoration (USFWS, 2009).
- Recommendation for Future Action from 2009 5-Year Review: Evaluate breeding system to identify S-locus and assay S-allele diversity within populations to assess the degree of self-incompatibility and role of inbreeding depression in seed viability (USFWS, 2009).
- Recommendation for Future Action from 2009 5-Year Review: Implement management activities on public lands that contain scrub plum, including prescribed fire at return intervals and intensities necessary to restore and/or maintain the various xeric vegetative communities that support this species (USFWS, 2009).
- Recommendation for Future Action from 2009 5-Year Review: Purchase or otherwise protect large scrub plum populations on unprotected lands. Protection should target scrub plum populations that are sufficiently large, or could be large if adequately managed, as to be self-sustaining and viable long-term (USFWS, 2009).
- Recommendation for Future Action from 2009 5-Year Review: Explore opportunities to encourage landowners to conserve and manage property known to contain this species

(USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES • Collaboration with conservation land managers to increase habitat suitability of occupied habitat by promoting beneficial management options to increase population persistence wherever additional opportunities exist when engaging with agency management personnel. • Encourage landowners whose populations occur on conservation lands to monitor occupied habitat for increased data of long-term species trends. • Initiate long-term monitoring programs for populations with highest viability potential on conservation lands to discern long-term species trends (USFWS, 2023).

# SPECIES ACCOUNT: *Pseudobahia bahiifolia* (Hartweg's golden sunburst)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

An annual herb, about 6-15 cm tall, covered throughout with white, wooly hairs. Flower heads (March or April) are bright yellow, and are borne singly at the ends of the branches. (NatureServe, 2015)

**Historical Range**

The historical distribution of Pseudobahia bahiifolia is not known specifically but is thought to have spread approximately 200 miles along the eastern San Joaquin valley and foothills from Stanislaus County in the south to Yuba County in the Sacramento Valley to the north (Stebbins 1991). The distribution once extended north to Yuba County in the Sacramento Valley, based on the 1847 type collections of Karl Hartweg; however, these occurrences are now extirpated (Stebbins 1991). (USFWS 2007)

**Current Range**

The current distribution of the majority of P. bahiifolia occurs in two isolated clusters, including six extant occurrences near Friant along both sides of the San Joaquin River in high pumice content soils (Fresno and Madera Counties) and six occurrences near Cooperstown in Stanislaus County. Pseudobahia bahiifolia grows in loam or sandy loam soil associated with Amador and Pentz series (Stanislaus County), Rocklin series (Fresno and Madera County), Amador and Hornitos soils (Merced County) (Stebbins 1991). (USFWS, 2007)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Flowerind and fruiting occur in March-April (NatureServe, 2015).

**Reproduction Narrative**

Adult: Grazing levels must be reduced during flowering and fruiting (March-April). Overgrazing during this period has been documented to be detrimental. The greatest threat to this species is destruction of habitat by ag, development and heavy grazing (NatureServe, 2015).

**Habitat Type**

Adult: Grasslands/woodlands (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits non-native grasslands and occasionally grassland-blue oak woodland community ecotones in the Central Valley of California. The composition of the prehistoric grassland communities in this area is unknown; the communities have long-since become dominated by exotic grasses. P. bahiifolia generally occurs in areas with Mima mound topography: small mounds (30 cm to 2 m in height) interspersed with shallow basins that may form vernal pools. The plants nearly always occur on north-northeast facing mound slopes, preferentially on the upper slopes where grass cover is minimal. Plant can also occur along shady creeks or the margins of vernal pools. Plant distribution is closely correlated with certain soil types; prefers highly acidic, shallow soils derived from rhyolitic tuff. (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species and the low number of known populations.

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

23 presumed extant (USFWS, 2023)

**Population Size:**

10,000 to >1,000,000 individuals (USFWS, 2023)

**Population Narrative:**

About 32,000 total plants in 1990 (Stebbins 1991 Status Survey, cited in USFWS 1997). 16 Populations (USFWS 1997). (NatureServe, 2015). The current species distribution and abundance of Hartweg's golden sunburst is similar to what we described in our final listing rule and 2007 status review (Service 1997, p. 5543; Service 2007, p. 2). The known occurrences of Hartweg's golden sunburst are concentrated in the eastern San Joaquin Valley in Stanislaus, Madera, Merced, and Fresno Counties (Table 1; Service 2007, p. 6). At the time of the last 5-year review, the distribution of the majority of Hartweg's golden sunburst occurred in two isolated clusters, including six extant occurrences near the community of Friant along both sides of the San Joaquin River in high pumice content soils (Fresno and Madera Counties) and six extant occurrences near Cooperstown in Stanislaus County (Service 2007, p. 6). The three occurrences (Diversity Database occurrence numbers 6, 7, and 17) near Cooperstown house the largest known populations of Hartweg's golden sunburst and have measured at over 10,000 individual plants (Diversity Database 2023). Currently, there are six known Diversity Database occurrences of Hartweg's golden sunburst that have had over 1,000 individuals estimated or counted during a survey (Vollmar Consulting 2010, pp. 64, 119). In addition, five Diversity Database occurrences of Hartweg's golden sunburst were discovered since the 2007 status review. Two of the new occurrences (Diversity Database occurrences 37 and 38) contained over 1,000 individuals when they were discovered; (Vollmar Consulting 2010, pp. 1, 18; Diversity Database 2023). Abundance of Hartweg's golden sunburst fluctuates greatly from year to year due to weather conditions such as rainfall. The surveys completed since the previous 5-year review do not alter our understanding of the species' current distribution or abundance and population estimates or trends have not been determined (USFWS, 2023).

***Recovery***

**Recovery Actions:**

- The draft recovery plan is currently under development
- Protect lands with known occurrences of either species of Pseudobahia, particularly those occurrences with the largest and most dense populations, through conservation easements, acquisition in title, or other methods. Manage these properties to protect and enhance growth of P. bahiafolia and P. peirsonii (USFWS, 2007).
- Work with landowners to gain access to their property for surveying and monitoring populations of both Pseudobahia species (USFWS, 2007).
- Conduct coordinated surveys of all recorded occurrences of both species of Pseudobahia. Establish systematic periodic surveys where possible of known occurrences. Begin surveys in potentially suitable habitat of both species of Pseudobahia based on soil type and habitat characteristics (USFWS, 2007).

- Complete and publish the draft recovery plan and ultimately finalize the recovery plan. Much of the information contained in Stebbins' two studies (1989, 1991) is still valid and is directly applicable to a recovery plan (USFWS, 2007).
- Maintain a viable, protected seed collection for both species of Pseudobahia. Ensure sufficient seeds (approximately 5,000 per site, USFWS 2006a) are taken from as many sites as possible to maintain genetic heterogeneity (USFWS, 2007).
- Recovery Priority Number: 5C

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of the Hartweg's golden sunburst and San Joaquin adobe sunburst. Some of these recommendations have already been discussed in the previous 5- year review (Service 2007, pp. 17–18) and remain valid. 1. Habitat Acquisition, Management, and Restoration. Known occupied sites with Hartweg's golden sunburst and San Joaquin adobe sunburst present should be protected. Resource agencies and private partner groups should work to ensure land protection through acquisition or easement, and large unprotected areas currently occupied by the species should be given the highest priority. Large, formerly occupied sites that are unoccupied but have a high restoration potential and the sites with recent occurrences should also be considered. Protected lands must also be adequately managed or restored based on the best available science to enhance the growth of the species. 2. Work with Landowners to Gain Access and Conduct Coordinated Surveys. Gaining access to private lands where no surveying and monitoring has occurred will provide more information on the species. Coordinate surveys in these previously known occurrences and continue surveys in potentially suitable habitat based on soil type and habitat characteristics, similar to the work Vollmar Consulting conducted in 2010. 3. Develop a Recovery Plan. Hartweg's golden sunburst and San Joaquin adobe sunburst were initially included in a "Draft Recovery Plan for Fifteen Plants from the Southern Sierra Foothills, California". This plan was in development in 2007, however, the plan was never finalized. Much information contained in Stebbins' two studies (1989, 1991) is still valid and is directly applicable to a recovery plan. Additionally, the methods of establishing a new population of Hartweg's golden sunburst at Friant Ranch can be incorporated (Live Oak Associates 2015, entire). 4. Maintain a Viable, Protected Seed Collection. For both Hartweg's golden sunburst and San Joaquin adobe sunburst ensure sufficient seeds, approximately 5,000 per site (Cypher 2006, pp. 2–3), are taken from as many sites as possible to maintain genetic heterogeneity. Currently, there are 4,057 seeds of Hartweg's golden sunburst and 37,069 seeds of San Joaquin adobe sunburst stored (California Plant Rescue 2023, unpaginated) (USFWS, 2023).

# SPECIES ACCOUNT: *Pseudobahia peirsonii* (San Joaquin adobe sunburst)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

An annual herb, about 1-6 dm tall, and loosely covered with white, wooly hairs. Flower heads (March or April) have bright yellow rays and are borne singly at the ends of the branches. (NatureServe, 2015)

**Taxonomy**

Pseudobahia peirsonii has had no changes in its scientific name or to its taxonomic classification since it was first described in 1949 by the California botanist Phillip A. Munz. Common names used for P. peirsonii include San Joaquin adobe sunburst, Tulare pseudobahia, and San Jaoquin adobe sunflower (Stebbins 1991). The San Jaoquin adobe sunburst is the preferred common name since it was used in the original listing notice (62 FR 5542)

**Historical Range**

The historical distribution of Pseudobahia peirsonii is not known because when the species was first described in 1949, extensive areas with suitable habitat for this species in the lower San Joaquin Valley were already converted to agriculture. This extensive land conversion precluded establishing a meaningful baseline survey of P. peirsonii (Stebbins 1991). (USFWS, 2007)

**Current Range**

Three major population concentrations of P. peirsonii now include: east of Fresno in Fresno County, west of Lake Success in Tulare County, and northeast of Bakersfield in Kern County (CNDDB 2007). (USFWS, 2007)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Habitat Type**

Adult: Grasslands/woodlands (NatureServe, 2015)

**Environmental Specificity**

Adult: Moderate (Inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (NatureServe, 2015)

**Site Fidelity**

Adult: High (NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits non-native grasslands and occasionally grassland-blue oak woodland community ecotones in the Central Valley of California. The composition of the prehistoric grassland communities in this area is unknown; the communities have long-since become dominated by exotic grasses. P. peirsonii occurs only on heavy adobe clay soils which retain moisture into the summer dry season (NatureServe, 2015).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

32 (USFWS, 2007)

**Population Narrative:**

The plant is found at 32 extant occurrences distributed in Fresno, Tulare and Kern Counties. Population numbers can fluctuate widely from one year to another. This fluctuation is believed to depend on annual climatic conditions, specifically the amount of seasonal rainfall, and also on competition from non-native plants (Stebbins 1989, 1991; E. Cypher, CDFG, pers. comm. 2007). Because of these annual fluctuations, population trends for these species are difficult to deduce and can not be reliably completed in a few years of surveys (Stebbins 1989). Actual plant numbers are not as useful an index of population health as is the condition of occupied habitat and general population condition (62 FR 5542) (USFWS, 2007). The current species distribution of San Joaquin adobe sunburst is similar to what we described in our final listing rule and 2007 status review, with occurrences found in Fresno, Tulare, and Kern counties (Table 2; Service 1997, p. 5543; Service 2007, p. 3). Since the 2007 status review, an additional ten new occurrences were added to the Diversity Database, although one is a historical occurrence that is possibly extirpated (Diversity Database occurrence 54; Diversity Database 2023). The known occurrences of San Joaquin adobe sunburst are in three major population concentrations east of Fresno in Fresno County, west of Lake Success in Tulare County, and northeast of Bakersfield in Kern County (Diversity Database 2023). Two new occurrences (52 and 51) expand the known range of San Joaquin adobe sunburst approximately 15 miles south (Diversity Database 2023). Typically, all occurrences report fewer than 5,000 plants and more often only a few hundred plants (Diversity Database 2023). However, occurrence 53, located at Tollhouse Ranch owned by The Nature Conservancy, observed approximately 3,000 plants in 2015 and then over 11,090 plants in 2016 (Diversity Database 2023). Abundance of San Joaquin adobe sunburst fluctuates greatly from year to year due to weather conditions such as rainfall. The surveys that have been completed since the previous 5-year review do not significantly alter our understanding of the species' current distribution or abundance and population estimates or trends have not been determined (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Residential development (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** At the time of listing, the threat to P. peirsonii was primarily due to the planned 462-acre combined Quail Lakes housing development and recreational lake in Fresno County that would affect the large occurrence (CNDDB occurrence number 31) of 5,000 plants surveyed in 1990. Completion of this project included compensation for environmental impacts which involved off-site wetland construction, transplantation of P. peirsonii and top soil translocation to a protected area within the development site, and preservation of two high density sub-populations of P. peirsonii within the protected site (EIP Associates 1994). During post-construction monitoring of these sub-populations, P. peirsonii at this location were not seen for four years; however, large numbers were observed in a single season during the fifth year of monitoring (Halstead in litt. 2007). In the 2003 season John Stebbins did not observe any plants at this location (J. Stebbins in litt. 2007). Residential development still remains a threat to P. peirsonii at the following locations (two occurrences): 1. A proposed parcel split of a privately owned 65-acre parcel in Fresno County near the city of Clovis, and the proposed residential development of these sub-parcels, is located within the area described to contain Pseudobahia peirsonii occurrence number 36 (Halstead and Associates 2006, CNDDB 2007). Surveys for P. peirsonii were performed on this property in 2004 and 2005 and no plants were found (Halstead in litt. 2007). We lack adequate information on the reproductive ecology and seed bank dynamics of this species to determine whether or not it may reappear at this site in the future. 2. The proposed Round Mountain Estates project would develop a 600-acre parcel at Round Mountain in Fresno County, an area occupied by about 40 acres of Pseudobahia peirsonii. Surveys in 1993 and 1996 revealed the 40 acres support an apparently stable P. peirsonii population and that current land use continues to be moderate cattle grazing (J. Gurule, Live Oak Associates, pers. comm. 2007). Compensation recommended for this project by the consultant is to protect in perpetuity the 40 acres that contain the P. peirsonii occurrence (Hartesveldt Ecological Consulting Services [now Live Oak Associates] 1996) (USFWS, 2007).

**Stressor:** Agricultural conversion (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** When federally listed in 1997, conversion of habitat to agricultural use was considered a significant but secondary threat to Pseudobahia peirsonii. Eight of the original recorded occurrences of P. peirsonii had already been extirpated from their locale due to various agricultural conversions by the time Stebbins (1991) surveyed the sites. We do not believe that agricultural conversion presents a serious threat to P. peirsonii at this time since occurrences are now on either public land or private land used for cattle ranching (E. Cypher pers. comm. 2007). However, P. bahiifolia is still threatened by agricultural development, as it was at the time of listing, because of the pressure to convert ranch lands with occurrences of P. bahiifolia to orchards and vineyards (E. Cypher pers. comm. 2007) (USFWS, 2007).

**Stressor:** Flooding (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat

**Narrative:** Inundation of Pseudobahia peirsonii plants caused by the creation of Lake Success in Tulare County extirpated two of the originally recorded occurrences of P. peirsonii before the species was listed (Stebbins 1989, CNDDB 2007). Three occurrences of P. peirsonii are now found at the Lake Success Recreation Area which is managed by the U.S. Army Corps of Engineers. Two of these occurrences are historically recorded and one occurrence is believed to be a relict of one of the original occurrences that were documented as extirpated when Lake Success was first filled (EDAW 2006a). Flooding at Lake Success continues to be a threat to the three local occurrences of P. peirsonii (E. Cypher in litt. 2007). Excessive rainfall during an exceptionally wet year could raise the level of Lake Success and cause inundation of at least one of the occurrences (E. Cypher in litt. 2007). In addition, two proposals for the improvement of the Lake Success dam could affect at least one other occurrence of P. peirsonii. The U.S. Army Corps of Engineers plans to move the dam 300 feet downstream of its current location and then increase the size of the new spillway (E. Cypher in litt. 2007). Compensation by transplanting was addressed, but is not considered a reliable option for saving the affected populations of P. peirsonii owing to the limited success of previous transplanting efforts (E. Cypher in litt. 2007). As a result of the creation of Lake Success, one population was subjected to the additional threat of adverse recreational activity, since that population was located on the highly impacted shoreline (Stebbins 1989, 62 FR 5542, CNDDB 2007 The Fancher Creek flood control project, completed in the mid-1990s, impacted about 40 percent of the second largest population of Pseudobahia peirsonii (CNDDB occurrence number 30, 62 FR 5542). However, P. peirsonii are still found at the Fancher Creek site and surveys are conducted on a regular basis (P. Bryan in litt. 2007). The possible inundation of at least part of the existing local occurrence during an exceptionally heavy rainfall season remains a threat to this occurrence because no flood control system can protect against all conceivable flood events (Stebbins 1991, Fresno Metropolitan Flood Control District 2007) (USFWS, 2007).

**Stressor:** Protected occurrences (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Two occurrences of Pseudobahia peirsonii are located on public, nonFederal land in Fresno County owned and managed by the Fresno Metropolitan Flood Control District (CNDDB occurrence numbers 16 and 30). Although these occurrences are monitored by surveys and protected by fencing, flooding remains a possible threat to these occurrences. Lake Success was created when the Tule River was dammed by the earthen Success Dam, which was constructed by the U.S. Army Corps of Engineers in 1961. The property around Lake Success, owned and managed by the U.S. Army Corps of Engineers, located just east of Porterville in Tulare County, contains three occurrences of Pseudobahia peirsonii. Two of these occurrences were previously recorded in the CNDDB as occurrence numbers 10 and 19; however, a new occurrence was also discovered and may be the continuation of a population that was covered by the lake when the Success Dam was first built (EDAW 2006a). The sizes of these populations were recorded as 120 individuals for occurrence 10, 30 individuals for occurrence 19, and 45 individuals for the new occurrence (EDAW 2006a). The population numbers from this recent survey appear to indicate these occurrences are somewhat stable when compared with population numbers recorded in previous surveys (1985, 1986, 1988, 2003) (EDAW 2006a; T. Beyerl, EDAW, pers.comm. 2007). These occurrences receive a certain amount of protection because they are on federally operated public land; however, flooding from this dam remains a viable threat to the local occurrences. Lewis Hill Preserve consists of 110 acres of grass-covered hills with rock outcrops

located north of Porterville in Tulare County. This preserve, owned and managed by the Sequoia Riverlands Trust, contains Pseudobahia peirsonii occurrence number 28, as well as the rare wildflower, Fritillaria striata (striped adobe lily) (Sequoia Riverlands Trust 2007). This preserve is not open to the public. Although formal surveys for the listed plant species have not been conducted since 1990, the presence of P. peirsonii was confirmed by preserve personnel during the 2006 flowering season (H. Destin, Sequoia Riverlands Trust, pers. comm. 2007). Currently the Lewis Hill preserve is not actively managed, but future management activities such as prescribed burns and grazing are being planned to control invasive weedy plants (H. Destin pers. comm. 2007). Before Pseudobahia peirsonii was listed in 1997, as compensation for impacts to the four subpopulations of occurrence number 31 by construction of the Quail Lake residential development in Fresno County (see above), two of the highest-density sub-populations were protected and a new sub-population was created by trans-locating soil from the two impacted sub-populations and seeding the soil with seeds collected earlier (completed in 1993) (62 FR 5542, EIP Associates1994). This compensation was done in compliance with the California Endangered Species Act and California Environmental Quality Act. The area, south of Clovis in Fresno County, containing these sub-populations is protected as natural habitat in perpetuity (EIP Associates 1994). Subsequent monitoring revealed that individuals originating from seeds sewn into the trans-located soil, as well as the individual plants in the original two dense populations, were numerous, healthy, and reproducing in 1998 (J. Halstead in litt. 2007). However, P. peirsonii is not clearly present at Quail Lakes every year and the habitat in the area of the translocated soil appeared to be significantly degraded in 2006 (J. Halstead in litt. 2007, J. Stebbins in litt. 2007) (USFWS, 2007).

**Stressor:** Overgrazing and trampling (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of individual plants
**Narrative:** Cattle ranching was recognized as a threat to the Pseudobahia species in the original listing rule (62 FR 5542) because of the possibility of excessive grazing and trampling by cattle, which could destroy many individuals of the two species (Stebbins 1989). In 1997, when first listed, about 50 percent of known occurrences of P. peirsonii were found on private property that was used primarily for cattle grazing. Moderate grazing regimes are not believed to seriously affect either of the plant species, and may actually enhance their growth due to the removal of nonnative, aggressive, invasive grasses and forbs (Stebbins 1989, Marty 2005). Cattle do not preferentially target either of the Pseudobahia species while grazing (E. Cypher pers. comm. 2007). In addition, profitable cattle ranching may indirectly benefit the two Pseudobahia species by discouraging residential development of ranch land (E. Cypher pers. comm. 2007). Cattle grazing and trampling are no longer considered a serious threat to either species unless the grazing times are extended, leading to excessive trampling and consumption (USFWS, 2007).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** When listed in 1997, we noted that most of the occurrences of both the Pseudobahia species were located on private land and, thus, State and Federal laws were limited in their ability to regulate potentially detrimental human activity at these locations (62 FR 5542). No significant changes to the Federal or State laws have provided increased protection for these

species (USFWS, 2007).

**Stressor:** Non-native plants (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The final listing rule noted that the intrusive and aggressive characteristics of herbaceous weedy species appear to be detrimental to habitat quality of the two Pseudobahia species. Plants mentioned as being common non-native associates of P. bahiifolia include Erodium circutarium (red-stem filaree), E. botrys (longbeak stork's bill), Bromus mollis (soft brome or soft chess), and Bromus madritensis ssp rubens (foxtail chess). Plants mentioned as being common non-native associates of P. peirsonii include Avena fatua (wild oats), Brassica kaber (wild mustard), Bromus mollis (soft brome or soft chess), Bromus madritensis ssp rubens (foxtail chess), and Erodium circutarium (red-stem filaree) (62 FR 5542). Non-native grasses and forbs continue to proliferate throughout the range of the two Pseudobahia species and these non-native species continue to invade locations that the two species occupy. Thus, non-native plants remain a significant threat to the two Pseudobahia species (E. Cypher pers. comm. 2007) (USFWS, 2007).

**Stressor:** Road maintenance and widening (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Stebbins (1991) lists several road maintenance projects that would affect populations of Pseudobahia peirsonii. The most extensive project was the proposed widening of State Route 180 in Fresno County that may destroy plants on both sides of the road. Six other occurrences were also determined to be threatened by road maintenance activities conducted by the California Department of Transportation (CALTRANS) which include spraying herbicides, grading, scraping, slope stabilization, road widening, and road alignment. The listing rule noted that road maintenance activities were a threat to P. peirsonii (62 FR 5542). However, subsequent CALTRANS maintenance activities and road alignment did not appear to directly affect the occurrences of P. peirsonii; rather, the disturbance created from the maintenance appears to indirectly and moderately threaten both species of Pseudobahia by encouraging the growth of non-native weedy vegetation which competes with the two listed species of Pseudobahia (J. Stebbins in litt. 2007) (USFWS, 2007).

**Stressor:** Transmission line maintenance (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Two occurrences of Pseudobahia peirsonii (CNDDB occurrence numbers 23 and 24) inhabit areas beneath two transmission lines supported by Southern California Edison (SCE). The properties where the transmission lines are located are considered "rights of way", and are mostly within privately owned lands. Stebbins (1991) recognized that these populations would need to be protected from the machinery and traffic (human and vehicular) that would impact the area when maintenance actions were performed on the transmission lines, and this was considered a threat when the species was listed (62 FR 5542). Routine maintenance activities include patrol road maintenance, line maintenance, and overhead canopy maintenance. Routine

maintenance actions are scheduled by SCE annually, avoid the active time periods for local listed plants, and require a minimum of off-road activities (Entrix, Inc. 1997). A more substantial threat to P. peirsonii is from emergency repairs to the power lines due to catastrophic failure, natural disasters, or vandalism where the need to conduct repairs expeditiously would increase the chances of incidental damage to the plants during the repair effort. Entrix, Inc. (1997) conducted a survey for P. peirsonii and found only one occurrence along one of the two transmission lines where the species was thought to occur. SCE maintenance personnel are provided with environmental and endangered species training to ensure they avoid impacting listed species (Entrix, Inc. 1997) (USFWS, 2007).

**Stressor:** Drought (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** At the time of listing drought was considered a threat to small and marginal populations of either Pseudobahia species (62 FR 5542). Natural cycles of drought are not likely to threaten the larger occurrences of either of the Pseudobahia species owing to the drought-adaptive nature of the plants (E. Cypher pers. comm. 2007). However, where populations persist on only marginal habitat, the addition of prolonged drought conditions is likely to result in higher rates of mortality in the short term, with the effects of low reproductive output and survivorship persisting after the drought has ceased (E. Cypher pers. comm. 2007). It is unknown how quickly the Psuedobahia populations may rebound after severe climatic conditions (USFWS, 2007).

**Stressor:** Small population size (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:** Loss of genetic variability
**Narrative:** The two species of Pseudobahia each require separate and specific soil conditions for successful germination and growth, so that the distribution of these plants is limited to the occurrences of these soil types (Stebbins 1991). The conversion to agricultural use of the geographic areas where these soil types are found began before a baseline survey of either plant could be performed, so the historic distribution can only be assumed based on a variety of factors, including soil type. The conversion to agriculture and to other land uses (discussed above) which are adverse to the proliferation of the two species have resulted in fragmented populations, many of which are of extremely limited population size (E. Cypher pers. comm. 2007). For example, about 67 percent of the P. bahiifolia and 62 percent of the P. peirsonii populations with known counts have less than 100 plants from the last surveys that were recorded (CNDDB 2007). In addition, some of the sites are questionable as to whether they are still producing any plants at all; for example, two of the presumed extant occurrences of P. bahiifolia are single sightings of unknown numbers of plants that have not been verified since 1937 and 1939, respectively (CNDDB 2007). At the time of listing it was recognized that such small populations may be highly susceptible to extirpation due to chance events, inbreeding depression, or additional environmental disturbance (Gilpin and Soule 1988; Goodman 1987, 62 FR 5542). The conservation biology literature commonly notes the vulnerability of species known from one or very few locations and/or from small populations (e.g., Shaffer 1981 and 1987, Primack 1998, Dunning et al. 2006). In particular, small population size makes it difficult for such species to persist while sustaining the impacts of habitat loss, competition with non-native plants, and other impacts such as prolonged drought. If an extirpation event occurs in a

population that has been fragmented, the opportunities for re-colonization will be greatly reduced due to physical isolation from other source populations. The small size of populations, along with the geographic isolation of the separate populations of both Pseudobahia species remains a threat (E. Cypher pers. comm. 2007) (USFWS, 2007).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 2

**Recovery Actions:**
- The draft recovery plan is currently under development (USFWS, 2007).
- Protect lands with known occurrences of either species of Pseudobahia, particularly those occurrences with the largest and most dense populations, through conservation easements, acquisition in title, or other methods. Manage these properties to protect and enhance growth of P. bahiafolia and P. peirsonii (USFWS, 2007).
- Work with landowners to gain access to their property for surveying and monitoring populations of both Pseudobahia species (USFWS, 2007).
- Conduct coordinated surveys of all recorded occurrences of both species of Pseudobahia. Establish systematic periodic surveys where possible of known occurrences. Begin surveys in potentially suitable habitat of both species of Pseudobahia based on soil type and habitat characteristics (USFWS, 2007).
- Complete and publish the draft recovery plan and ultimately finalize the recovery plan. Much of the information contained in Stebbins' two studies (1989, 1991) is still valid and is directly applicable to a recovery plan (USFWS, 2007).
- Maintain a viable, protected seed collection for both species of Pseudobahia. Ensure sufficient seeds (approximately 5,000 per site, USFWS 2006a) are taken from as many sites as possible to maintain genetic heterogeneity (USFWS, 2007).

***Conservation Measures and Best Management Practices:***
- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of the Hartweg's golden sunburst and San Joaquin adobe sunburst. Some of these recommendations have already been discussed in the previous 5- year review (Service 2007, pp. 17–18) and remain valid. 1. Habitat Acquisition, Management, and Restoration. Known occupied sites with Hartweg's golden sunburst and San Joaquin adobe sunburst present should be protected. Resource agencies and private partner groups should work to ensure land protection through acquisition or easement, and large unprotected areas currently occupied by the species should be given the highest priority. Large, formerly occupied sites that are unoccupied but have a high restoration potential and the sites with recent occurrences should also be considered. Protected lands must also be adequately managed or restored based on the best available science to enhance the growth of the species. 2. Work with Landowners to Gain Access and Conduct Coordinated Surveys. Gaining access to private lands where no surveying and monitoring has occurred will provide more information on the species. Coordinate surveys in these previously known occurrences and continue surveys in potentially suitable habitat based on soil type and habitat characteristics, similar to the work Vollmar Consulting conducted in 2010. 3. Develop a Recovery Plan. Hartweg's golden sunburst and San Joaquin adobe sunburst were initially included in a "Draft Recovery Plan for Fifteen Plants from

the Southern Sierra Foothills, California". This plan was in development in 2007, however, the plan was never finalized. Much information contained in Stebbins' two studies (1989, 1991) is still valid and is directly applicable to a recovery plan. Additionally, the methods of establishing a new population of Hartweg's golden sunburst at Friant Ranch can be incorporated (Live Oak Associates 2015, entire). 4. Maintain a Viable, Protected Seed Collection. For both Hartweg's golden sunburst and San Joaquin adobe sunburst ensure sufficient seeds, approximately 5,000 per site (Cypher 2006, pp. 2–3), are taken from as many sites as possible to maintain genetic heterogeneity. Currently, there are 4,057 seeds of Hartweg's golden sunburst and 37,069 seeds of San Joaquin adobe sunburst stored (California Plant Rescue 2023, unpaginated) (USFWS, 2023).

# SPECIES ACCOUNT: *Ptilimnium nodosum* (Harperella)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/28/1988; Northeast Region (Region 5) (USFWS, 2015)

**Physical Description**

An annual herb with slender, erect stems, up to 12 dm high. The roots are shallow, diffuse-fibrous, and the plants have a faint scent of dill. Unlike those of the more common members of this genus, the leaves of P. nodosum are reduced to hollow, quill-like structures. Broad clusters of small white flowers bloom mostly in July and August. (NatureServe, 2015)

**Taxonomy**

As of 2008, the U.S. FWS treatment includes P. fluviatile (AR, AL; river form, does not produce asexual buds), P. viviparum (MD, WV, VA, NC; river form, produces asexual buds), and P. nodosum sensu stricto (GA, SC; pond form) in P. nodosum, as does Kartesz (1994 and 1999); this is the treatment followed here. However, recent information suggests they may be tentatively treated as distinct entities, although not necessarily as distinct species (David Maddox pers. comm. to Alan Weakley and to Larry Morse). Specifically, a 1994 isozyme study found that there was substantial genetic differentiation among rather than within these three groups, supporting designation as distinct entities (Kress et al. 1994 cited in Douglas 2008). A 2008 DNA study (nuclear rDNA ITS sequences) found that "viviparum" accessions formed a monophyletic group, but "nodosum sensu stricto" accessions did not, with South Carolina populations forming a monophyletic group, but Georgia populations falling at the base of the clade alongside "fluviatile" accessions (Feist and Downie 2008). In summary, although there is clearly more than one distinct entity within the current broad-sense circumscription of P. nodosum, there is not yet a clear consensus on how to divide the material and at what taxonomic level entities should be distinguished. (NatureServe, 2015)

**Current Range**

Currently known from scattered sites in western Maryland, eastern West Virginia, northeastern Virginia, north-central North Carolina, central South Carolina, central Georgia, northeastern Alabama, and west-central Arkansas. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Asexual (vegetatively) and sexual (NatureServe, 2015)

**Lifespan**

Adult: 1 year (USFWS, 2015)

**Breeding Season**

Adult: July to August (USFWS, 1990)

**Reproduction Narrative**

Adult: Ptilimnium nodosum is an annual that reproduces both vegetatively and via seed; it is thought that established patches may persist over the long-term primarily by vegetative reproduction, while novel habitat colonization may occur primarily via seed. These multiple reproduction modes also appear to provide a survival mechanism for variable water levels; since sexual reproduction becomes more difficult within increasing water depth, the plants produce seeds and reproduce sexually in dry years, while in wet years they produce plantlets and reproduce vegetatively. It appears that both forms of reproduction contribute to overall population size in most years, with the contribution of each dependent upon hydrological patterns (Douglas 2008). Marcinko and Randall (2008) studied the mating system of P. nodosum, with the following findings. Flowers were self-compatible, but strong intrafloral protandry essentially prevented autonomous selfing. (NatureServe, 2015)

**Habitat Type**

Adult: Riverine, and palustrine (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Spring/spring brook, herbaceous wetland, riparian, temporary pool (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Saturated sites; flooding; water fluctuations (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Prefers saturated habitat, periodic flooding, sunny areas. Restricted to intermediate water depths (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Patches (USFWS, 1990)

**Environmental Specificity**

Adult: Moderate (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Moderate (USFWS, 1990)

**Site Fidelity**

Adult: High (USFWS, 1990)

**Habitat Narrative**

Adult: Ptilimnium nodosum occurs in three habitat types: rocky/gravelly shoals or cracks in bedrock outcrops beneath the water surface in clear, swift-flowing streams (usually in microsites that are sheltered from rapidly moving water); edges of intermittent pineland ponds or low, wet savannah meadows on the Coastal Plain; and granite outcrop seeps. In all habitat-types, the species occurs in a narrow range of water depths; it is intolerant of deep water and of conditions that are too dry. However, the plants readily tolerate periodic, moderate flooding - something to which few potential competitors are adapted. P. nodosum seeds generally germinate during short-duration spring floods and the plants have completed their life cycle by late summer or fall, just as water levels are lowest and competing species are moving in. The dominant species at P. nodosum sites is often Panicum hemitimon. Other species may include many sedges in the genera Rhynchospora (e.g., B. perplexa, R. microcarpa), Carex (e.g., C. walteri, C. lupulina), Eleocharis (e.g., E. tricostata, E. melanocarpa), Psilocarva, Dichromena colorata, and Fimbristylis. Dicot associates include Hypericum fasciculatum, ii. denticulatum, H. myrtifolium, Rhexia vircrmnica, R. mariana, B. aristosa, Proserpinaca pectinata, several Ludwicria species, and Sclerolepis uniflora (Kral 1983). (USFWS, 1990; NatureServe, 2015)

***Dispersal/Migration***

**Dispersal**

Adult: Low (USFWS, 1990)

**Dispersal/Migration Narrative**

Adult: Seeds readily float, so dispersal probably is mediated by water flow; however, safe sites downstream are infrequently and haphazardly found. Further, seeds have no structures to facilitate aerial dispersal and drop quickly to the ground, with many seeds germinating directly under the parent plant. The natural founding of new pond populations is probably very rare because of the plant’s (apparently) poor capacity for long distance dispersal and the fragmented dispersion of appropriate habitat. Thus, seed dispersal to new sites is probably a rare event. (USFWS, 1990)

***Population Information and Trends***

**Population Trends:**

Long-term trends suggest a decline of 30 to 70%, whereas short-term trends indicate a decline of >50% (NatureServe, 2015)

**Species Trends:**

Declining (NatureServe, 2015)

**Number of Populations:**

28 (USFWS, 2024)

**Population Size:**

>1,000,000 (USFWS, 2024)

**Additional Population-level Information:**

28 Total extant populations, 16 of which are protected (USFWS, 2024)

**Population Narrative:**

This species may be somewhat resistant, but is sensitive to dry conditions and dependent on narrowly defined hydrologic conditions. Vulnerable to upstream development. Many sites have been lost. Approximately 25% of mapped occurrences are ranked historical or extirpated. Long-term population trends suggest a decline of 30 to 70%, whereas short-term trends indicate a decline of greater than 50%. The total number of known individuals appears to be approximately 500,000. One population (drainage/watershed) in West Virginia is estimated to contain 400,000 plants, and all populations in Arkansas are estimated to total 50,000-100,000 plants in a good year (Douglas 2008). Many of the other extant populations are small; nine of the populations (drainages/watersheds) are estimated to contain less than 400 plants (Douglas 2008). Approximately 45 occurrences are believed extant, about half of which are in Arkansas with the other states in the range having 1-5 each. Thirteen occurrences are considered historical (predominantly in Alabama and South Carolina) and 1 (in Georgia) has been extirpated. The U.S. Fish and Wildlife Service (Douglas 2008) regards 24 "populations" as extant, with "population" defined as "sites located within one drainage or watershed... each may have a number of discrete sites (element occurrences)." Under this view, there are 9 extant populations in Arkansas and 1-3 in each of the other states. (NatureServe, 2015)

***Threats and Stressors***

**Stressor:** Water fluctuations (USFWS, 1990)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fluviatile tends to occupy a narrow range of water depths, manipulations of water flow upstream from populations can easily destroy suitable habitat by inundation or persistent desiccation. Dams, reservoirs, or other water impoundments or diversions would almost certainly threaten any P. nodosum downstream. Natural fluctuation in water flow causes significant yearly variation in subpopulation persistence. Small subpopulations are particularly susceptible to loss during normal high water events. Thus, small populations such as those in North Carolina or Maryland’s Fifteen Mile Creek are at significant yearly risk. Hydrological manipulations on rivers with small populations should be strictly avoided or controlled. Nodosum, like Fluviatile, depends on intermediate water levels and is threatened by either dry conditions or total inundation. Thus, the primary threats to Nodosum populations are hydrological manipulation and physical destruction of their pond habitats. (USFWS, 1990)

**Stressor:** Water quality (USFWS, 1990)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fluviatile is apparently also sensitive to reductions in water quality. Siltation caused by heavy construction, residential development, and agriculture has been cited as detrimental to the plant. The negative effect of sediment on Fluviatile was substantiated in a greenhouse experiment: turbidity equal to that near a bridge construction site reduced Fluviatile growth rate by 40% (Maddox and Bartgis 1990b). (USFWS, 1990)

**Stressor:** Stream acidification (USFWS, 1990)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Another greenhouse experiment indicates that stream acidification (especially pH ~ 5.0) may cause significant plant mortality (Maddox and Bartgis 1990b). Plants growing in water with pH approximately equal to 3.4 had a 70% mortality rate; in water with pH = 4.6 plants grew at a significantly lower rate than controls. This is potentially important in Alabama, where the extant population has historically experienced low pH due to mining. At Maryland and West

Virginia sites, the pH is typically 7.0. However, the acid neutralizing capacity is very low, suggesting that minor acid inputs could significantly lower pH. Other water quality variables, such as increased sewage or nitrate concentration, may also be detrimental. (USFWS, 1990)

**Stressor:** Alterations in hydrology (USFWS, 1990)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Coastal plain ponds everywhere are threatened by active drainage for conversion to pine plantations or row crops (Godfrey and Wooten 1979). Lowered water tables are probably detrimental to Nodosum through increased competitive and physiological stress. While hydrological manipulations directly to the pond are clearly detrimental, ditching and other manipulations of the water table from some distance away may affect coastal plain ponds, although the exact area of effect is not known (Pat Phillips, U.S. Geological Survey, pers. comm. 1989). The effective distance of such manipulations clearly is important in determining the zone around a population needed to ensure protection of the hydrological resource. (USFWS, 1990)

**Stressor:** Dredging (USFWS, 1990)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Occasionally ponds are dredged to create deep ponds for livestock; these deeper water levels probably disrupt the life cycle of Nodosum, a small plant. (USFWS, 1990)

***Recovery***

**Reclassification Criteria:**
1. Thirteen populations (the number of currently extant populations) have been relatively stable in population size for five years. (USFWS, 1990)

2. All thirteen populations are permanently protected. (USFWS, 1990)

Recovery Priority Number: 8

**Delisting Criteria:**
1. Thirteen populations (the number of currently extant populations) have been relatively stable in population size for five years. (USFWS, 1990)

2. All thirteen populations are permanently protected. (USFWS, 1990)

3. There are at least 26 self-sustaining populations in existence. To reach this level, at least thirteen new populations will have to be discovered or established. This is the total number of current and historically known populations. (USFWS, 1990)

4. The populations are distributed throughout the historical range from Arkansas to Maryland. (USFWS, 1990)

5. All 26 populations are permanently protected. (USFWS, 1990)

**Recovery Actions:**

- Protect plants and their habitat through landowner cooperation, land protection, and regulatory authorities. (USFWS, 1990)
- Where needed, seek conservation of watersheds to protect populations. (USFWS, 1990)
- Search for additional populations. (USFWS, 1990)
- Study species and habitat characteristics. (USFWS, 1990)
- Develop a cultivated sources of plants and provide for seed storage. (USFWS, 1990)
- Implement appropriate management techniques, particularly for pond populations. (USFWS, 1990)
- Re-establish populations within the species' historical range. (USFWS, 1990)
- Inform the public about the plant's status and recovery needs. (USFWS, 1990)
- Population surveys and inventories have been performed at all current sites by State Heritage Programs or botanists from various universities. Active population monitoring occurs only in Maryland and West Virginia. (USFWS, 1990)
- Surveys for new populations have been undertaken in all states containing extant populations, except Arkansas. New populations were verified in Maryland in 1988 and Arkansas in 1990. Significant potential habitat or recent unconfirmed records remain to be investigated in Alabama, Georgia, North and South Carolina, Arkansas, southern Missouri, and eastern Oklahoma. (USFWS, 1990)
- The Nature Conservancy, Western Pennsylvania Conservancy, and Maryland Department of Natural Resources have begun a comprehensive program to protect Sideling Hill Creek, including upstream areas as buffer. To date, a number of tracts have been registered in Maryland and Pennsylvania, a tract has been acquired on the border of Maryland and Pennsylvania, and the potential purchase of the most significant tract supporting p. nodosum is being negotiated by the State of Maryland and The Nature Conservancy. (USFWS, 1990)
- The Nature Conservancy has acquired an easement on one Cacapon River subpopulation. Additional subpopulations in West Virginia have been added to the Conservancy's registry program. The U.S. Fish and Wildlife Service contracted with The Nature Conservancy in 1990 to expand landowner contact efforts on the Cacapon River. (USFWS, 1990)
- The Maryland Natural Heritage Program has conducted an extensive two—year investigation of the ecology and life history of Fluviatile (Maddox and Bartgis 1989, 1990a, 1990b). (USFWS, 1990)
- The Maryland Natural Heritage Program has collaborated with the Smithsonian Institution on a study of electrophoretically detectable genetic variation throughout the range of P. nodosum. This study is expected to be completed in spring of 1991. (USFWS, 1990)
- The Maryland Natural Heritage Program has produced and distributed several information brochures on the biology of P. nodosum and its habitat. (USFWS, 1990)
- In a 1988 survey conducted by the Center for Plant Conservation to determine the plant taxa in most imminent danger of extinction, P. nodosum was identified by botanists as a "B" priority taxon, i.e., one which could go extinct in the wild within the next ten years. The Center has assisted in the recovery of the plant: 7,500 seeds have been collected as part of the National Collection of Endangered Plants and are housed at the North Carolina Botanical Garden (NCBG), one of the Center's participating institutions in the region. All seeds were collected from the Tar River area in Granville County, North Carolina. Although not currently being propagated at NCBG, these seeds provide a valuable conservation resource. (USFWS,

1990)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The following is a list of priority future actions based on this review. If the proposed action was also identified in the recovery plan, the action number from the plan is listed. Monitoring & Population Viability Research (Recovery Plan Actions 5.1 & 5.2): More consistent monitoring both for individual populations and between populations is needed throughout the species' range. Monitoring of some populations has not occurred or has been infrequent, and it is difficult to assess the overall status of the species as a result. The proposed monitoring protocol from the recovery plan should be reviewed and updated, and then used consistently throughout the range of the species so that data between populations are more comparable. Monitoring should record changes to the watershed from effects such as: changes in or modifications to the hydrologic regime, siltation, pollutants, and invasive competitors. Additional monitoring and research to help understand the significance and extent of population fluctuations is also required to help biologists and managers determine what the minimum viable population size is and/or when a population can be considered self-sustaining. Establishing these types of measures will allow managers to more effectively evaluate population trends in relation to the recovery status of the species. More consistent monitoring of individual populations would allow threats to be identified and potentially averted and would provide more comprehensive information on the rangewide population status. Revisions to the monitoring protocols may be necessary over time to take into account the results of any population viability research that may be conducted and/or assist in gathering data that would support the needed research. Seed collection, storage, and cultivation (Recovery Plan Action 7.0): To preserve germ plasm and genetic diversity of the species, efforts to gather and store seeds from throughout the range should be increased. The North Carolina Botanical Garden has established a program to provide for long-term seed storage, and some efforts in this regard have been made. Some seeds have also been stored at the National Center for Genetic Resources Preservation in Fort Collins, Colorado. However, a more coordinated and concentrated effort is needed. This is particularly important for populations that may be extremely small, threatened, or isolated such as those in Virginia and pond-form populations in South Carolina and Georgia. Samples from the southern and western portion of the range (Alabama and Arkansas) are also lacking. Efforts to cultivate plants from various populations to maintain a source of plants for reintroduction projects should also be increased. The importance of this is illustrated by the fact that the potentially unique genotype from the Siloam Outcrop site in Georgia could have been permanently lost if not for the fortuitous collection and cultivation of plant material prior to the unexpected destruction of the site. A coordinated database of the source and location of stored seeds and cultivated materials is also needed, so that biologists and researchers can access this material and minimize additional disturbances to natural populations. Conduct further genetic and morphological studies (Recovery Plan Action 6.0): Additional research to evaluate genetic diversity in populations throughout the range is needed to help inform management efforts, including potential propagation, augmentation, and reintroduction efforts. Common garden tests should also be conducted that would take individuals from various locations encompassing the range of morphological characteristics expressed by the species and then grow them under uniform conditions in the greenhouse. This would provide an economical way to allow researchers to determine whether the variations in form are genetically or environmentally induced. Results from these studies would help guide management decisions such as selecting source populations for reintroduction/augmentation efforts and prioritizing populations for protection. They would also help further clarify whether recovery units should be established, or recovery criteria should be revised to ensure that genetic and morphological diversity is maintained. Long-term protection and management (Recovery Plan Actions 1.5 & 2.0): A combination of both protection of occupied habitats and development of watershed-level management plans is needed to accomplish this task. Focused management strategies should be developed for distinct portions of the range. For example, long-term protection is particularly important for pond-form populations. Only five are known to exist. Three of these populations are tenuous, another one is a reintroduction site, and only one of the five is permanently protected. Efforts should be increased to place the remaining pond form populations under protection, through either direct purchase or conservation easement. Because the habitats that support the pond form tend to be more discrete than riverine systems, it is much easier to permanently protect these populations and manage threats. For riverine populations, efforts should be increased to purchase or manage additional lands in watersheds that already have some protection, thereby reducing the potential for threats. For larger-scale watersheds, or those that are primarily private lands, managers should also focus on working with watershed groups, local governments, or other entities to develop management guidelines, zoning criteria, improved water quality standards, and other similar measures (USFWS, 2024).

# SPECIES ACCOUNT: *Purshia (=Cowania) subintegra* (Arizona Cliff-rose)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 5/29/1984; Southwest Region

**Physical Description**

Arizona cliffrose is a member of the Rose Family (Rosaceae). It is a low, straggling woody perennial usually 1 - 2 meters (in) (3 - 6 feet) high and generally wider than tall. In the Cottonwood population, plants can reach a maximum of 2.4 in (8 feet) tall and 3.7 m (12 feet) in diameter. The horizontal lower branches are spreading, and the central branches are irregularly ascending (Denhain and Fobes 1992b). New shoots tend to be red-brown and pubescent with a red dot below the fascicle. The older branches have light gray bark that becomes shreddy. The herbage is not viscid (sticky), although some resin glands may be present, causing slight stickiness. The shape of Purshia subintegra leaves is variable. The leaves are very narrow and short: averaging about 8 millimeters (mm) (0.3 inch) long (Denham and Fobes 1992b) and 3 mm (0.1 inch) wide. Leaves usually have no lobes, but occasionally have 1 or 2 rounded, shallow lobes or teeth just below the leaf tip. The margins (edges) of the leaves are curled towards the underside (revolute). The upper leaf surface is bright or dark green and usually has no punctate glands. The upper leaf surface is usually loosely arachnoidpubescent (having a few long hairs) on the upper surface, but sometimes it is hairless. The lower surface is densely white-lanate (wooly) and usually has no punctate glands. Each flower is born on a single stalk (peduncle). The end of the peduncle gradually merges with the beginning of the narrowly funnelform hypanthium, the flower part bearing the sepals, petals, and stamens. The average length of the hypanthium plus peduncle is 5.1 mm (< 0.3 inch) (Reichenbacher 1993). The hypanthium has no stipitate (stalked) glands or has few glands. The typical flower has 3 - 7 pistils and 5 white or pale yellow petals that are about 10 mm (0.4 inch) long, slightly smaller than P. stansburiana flowers. Occasionally, flowers have 8 - 12 petals per flower (Denham and Fobes 1992a). As the achenes (fruits) develop, the style remains attached and forms a short, white, feathery plume. (USFWS, 1995)

**Taxonomy**

Purshia subintegra genetic variability, phenotypic plasticity, and past and recent hybridization with P. stansburiana have complicated taxonomic identification. Phenotypic and genetic variability among populations has been studied using morphometrics and molecular (DNA) analysis. Schaack (1987) described the San Carlos Basin (i.e., Bylas) population of P. subintegra as P. pinkavae, and designated P. subintegra to be of hybrid origin involving a cross between P. stansburiana and P. pinkavae. Kartesz (1994) treats P. subintegra as a hybrid. Reichenbacher (1994) states that although there is some character variation between the four populations of P. subintegra, multivariate analysis clearly indicates they exhibit a coherent syndrome of characters, and the taxonomy developed by Schaack is not supported by the analysis. The Recovery Plan concludes that P. subintegra is distinct from the more common P. stansburiana, despite sometimes overlapping plant characteristics (USFWS 1995). Travis et al. (2008) re-examined the genetic variation within P. subintegra and state that molecular evidence indicates a distinct classification for the Bylas population in support of the hypothesis that this population represents a separate species per Schaack (1987). However, the authors conclude that a broader taxonomic analysis of the genus is necessary to confirm such a distinction. Henrickson's unpublished description of P. subintegra notes considerable variation in key characteristics within the species. Characteristics used for identification, such as occasionally lobed (or toothed) leaves, exhibit a continuum of variability between and within individuals, change seasonally (e.g., as leaves are shed during drier periods sometimes leaving only unlobed leaves), and sort out independently from other key characteristics. The demarcation between Schaack's pinkavae and P. subintegra is not discrete (Henrickson, pers. comm., 2013). Pending further studies, the USFWS continues to recognize that the four described populations of P. subintegra comprise one distinct species. Regarding nomenclature, Travis et al. (2008) present strong evidence for a hybrid origin of P. subintegra. Based on their molecular data and hypothesized pre-historic biogeography of the region (Anderson 1993), hybridization occurred during the late Pleistocene (11,000 to 13, 000 years before the present). There has been a growing consensus for this explanation and increased use of the following nomenclature indicating a hybrid origin: Purshia ×subintegra (Kartesz 2013; Integrated Taxonomic Information System, 2013). However, such a designation for a species believed to be of hybrid origin is discretionary (International Code of Botanical Nomenclature (Article H:3.3) 2012). (USFWS, 1995))

**Historical Range**

See Current Range.

**Current Range**

In Arizona, in Graham, Maricopa, Mohave, and Yavapai counties. All known occurrences of P. subintegra are located in four disjunct populations, which occur along the sub-Mogollon region of central Arizona over a distance of 320 kilometers (200 miles) (Rutman 1992). (USFWS, 2013)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Food Source**

Adult: sunlgiht

**Competition**

Adult: yes, especially creasote

**Food/Nutrient Narrative**

Adult: This species aquires its energy from sunlight via photosynthesis.

**Reproductive Strategy**

Adult: Flowering plant that attracts pollinators

**Lifespan**

Adult: many years

**Dependency on Other Individuals or Species**

Adult: lepidopterans, dipterans, and bees

**Breeding Season**

Adult: late March through early May

**Reproduction Narrative**

Adult: Purshia subintegra generally flowers from late March through early May and is visited by a wide variety of insects, including lepidopterans, dipterans, and bees. Typically, hundreds of flowers are produced on each mature plant, which can reproduce for many years (USFWS 1995). Flower and seed production varies between years based on climatic conditions, plant vigor, browsing, and other factors. Native wild bees and introduced honeybees (Apis mellifera) are the most important pollinators, the latter becoming the predominant pollinator later in the flowering season (Fitts et al. 1993). Fruit dispersal occurs when summer rains dislodge seeds from plants (USFWS 1995). Experiments have shown that this species is partially self-compatible, but sets significantly more seeds and produces fruit more often when outcrossed (Fitts et al. 1993).

**Habitat Type**

Adult: desert

**Habitat Vegetation or Surface Water Classification**

Adult: limestone soils

**Geographic or Habitat Restraints or Barriers**

Adult: Restricted by competition with other plants

**Spatial Arrangements of the Population**

Adult: Clumped according to suitable resources

**Environmental Specificity**

Adult: specialist; narrow habitat requirements

**Tolerance Ranges/Thresholds**

Adult: unknown

**Site Fidelity**

Adult: high

**Habitat Narrative**

Adult: This species has narrow habitat requirements and occurs at four widely separated areas across central Arizona. These sites differ slightly in elevation and associated vegetation, but all sites have limestone soils (generally white but also reddish in color) derived from Tertiary lacustrine (lakebed) deposits. At each site P. subintegra is part of a locally unique vegetative community (Anderson 1993). The geographic and local distribution of P. subintegra appears to be limited by competition from other plant species rather than a requirement for a specific soil type. These soils are relatively infertile and have significantly lower amounts of phosphorus and organic matter compared with surrounding areas where P. subintegra is absent (Anderson 1986, 1993). These surrounding areas are typically dominated by creosotebush (Larrea tridentata), which is thought to have a competitive advantage over P. subintegra due to its aggressive seedling establishment (Anderson 1993). Creosotebush is unable to grow on the relatively infertile lacustrine soils. However, it has been found growing together with P. subintegra in the Verde Valley, in areas with higher amounts or organic matter and phosphorus. This suggests that the distribution of P. subintegra within these limestone soil conditions is limited primarily by competition from creosotebush, rather than a requirement for specific soil properties (Anderson 1986, 1993, 1996).

***Dispersal/Migration***

**Motility/Mobility**

Adult: not mobile

**Dispersal**

Adult: only the seeds

**Dispersal/Migration Narrative**

Adult: Fruit dispersal occurs when summer rains dislodge seeds from plants (USFWS 1995).

***Population Information and Trends***

**Population Trends:**

Declining

**Species Trends:**

Declining

**Population Growth Rate:**

unknown

**Number of Populations:**

4 (USFWS, 2022)

**Population Size:**

Unknown, estimated to exceed 40,000

**Minimum Viable Population Size:**

unknown

**Resistance to Disease:**

unknown

**Population Narrative:**

The total number of plants in the four P. subintegra populations is not known, but has been estimated. Not all areas of potential habitat have been surveyed, and in some areas, such as Cottonwood, the presence of hybrids between P. subintegra and P. stansburiana, or introgressed forms, has complicated population estimates (USFWS 2001). Despite the potential conservation significance of hybrids, the USFWS considers these plants to be outside the definition of the species (USFWS 1995) and are not included in population estimates. In 1988, a total number for all four populations (i.e., recovery units) was estimated to exceed 40,000 plants, although a large percentage may have included hybrids (USFWS 1988). About 10,000 plants are thought to currently occur in the predominant subpopulation at Burro Creek (USFWS 2004). At the time of listing, the USFWS estimated 243 ha (600 ac) of habitat at Burro Creek, and 40 ha (100 ac) at Bylas with an estimated 700 plants (USDI 1984). The Horseshoe Lake population is estimated to include 750 plants (USFWS 1987) over an unspecified area. The Cottonwood population covers the largest area, estimated at over 405 ha (1,000 ac) (USFWS 1995), with the amount of occupied habitat recently calculated to be 78 ha (194 ac) (Goodwin 2012). Total Cottonwood population numbers were previously not known, but were conservatively estimated to include tens of thousands of plants (USFWS 2007). The most recent, intensive survey places this number considerably lower, at a total of 8,272 P. subintegra plants within the Cottonwood population (Goodwin 2012). Acceptance of this figure would result in a downward adjustment of the estimated total numbers of known plants in the four populations by one-half, or to about 20,000. This adjustment may be the result of a more intensive survey as opposed to a large scale decline in numbers. We have no demographic trend information from monitoring the four populations, but population viability modeling suggests that P. subintegra will slowly decline in the Cottonwood population under more arid scenarios (Maschinski et al. 2006). Purshia subintegra populations are genetically variable, exhibit phenotypic plasticity in response to environmental conditions, and hybridize with P. stansburiana. Gene exchange through backcrossing hybrids (introgression) of P. subintegra and the more common P. stansburiana has resulted in hybrid swarms in the Cottonwood and Horseshoe Lake populations (USFWS 1995). A hybrid swarm is a “hybrid population,” maintained by backcrossing and/or crossing with other hybrids, which may be stable or spread. The proliferation of hybrids has the potential to negatively affect long-term population dynamics of P. subintegra through interference competition and loss of genetic integrity (Fitts et al. 1993; Baggs and Maschinski 2001b). At the same time, hybridization may act as a mechanism to increase genetic diversity in a population, enhancing adaptation and survival, therefore potentially benefiting conservation of P. subintegra (Baggs and Maschinski, 2001b). Hybrid swarms illustrate the migratory and dynamic nature of evolving plant populations, and may provide the key to the future of the genus and species. For this reason, conservation of these hybrid swarms is important (USFWS 1995). A recent study by Travis et al. (2008) confirmed the presence of a hybrid swarm in the Verde Valley and emphasized its conservation significance. Because introgressed forms appear to possess potential fitness advantages under hotter, drier conditions, they may provide a viable refuge for P. subintegra genome in the face of climate change (Travis et al. 2008). The paper also identified three distinct genetic lineages of P. subintegra: the Cottonwood (Verde Valley) population, which is currently undergoing introgression; the Burro Creek and Horseshoe Lake populations, which exhibit an ancient natural hybrid origin; and the Bylas population, which is genetically distinct from the others. These findings underscore the complex genetics of this species and the importance of conserving all four populations. (USFWS, 2013). For Arizona cliffrose, the four recovery units are analogous to the four known populations of the species, which we will refer to as populations from this point forward. The four populations are Burro Creek, Cottonwood, Horseshoe Lake, and Bylas (USFWS, 2022)

***Threats and Stressors***

**Stressor:** Urbanization (USFWS, 1995)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Habitat loss due to urbanization is a serious threat for the Cottonwood Arizona cliffrose population. Urbanization does not appear to be a threat to the other three populations, which are either on Federal land, which precludes urbanization, or they occur where development is unlikely. A significant amount of Arizona cliffrose habitat has already been lost due to development in the Cottonwood area, but the amount of habitat loss has not been estimated. The threat of urbanization continues, because some occupied habitat remains on private lands that could be developed and a substantial amount of habitat is on State Trust land. The transfers of land from Federal ownership into private or State ownership is an indirect threat to Arizona cliffrose. These land exchanges significantly reduce the protections offered by the Endangered Species Act and may contribute to urbanization or other actions causing habitat loss or degradation. These types of transfers would be subject to section 7 consultation procedures. (USFWS, 1995)

**Stressor:** Mineral Exploration and Development (USFWS, 1995)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Mining and mining-related activities are a serious threat to the long-term survival of this species, particularly in the Burro Creek area. The soils supporting Arizona cliffrose populations are known to contain high quality bentonite (BLM 1993), a type of clay used for cosmetics and pharmaceuticals. Drilling and bulk sample procurement have reduced the number of plants and amount of available or undisturbed habitat in the Burro Creek area. (USFWS, 1995)

**Stressor:** Cattle and Feral Burro Browsing Effects (USFWS, 1995)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In 1987, the BLM- Kingman Resource Area began monitoring the effects of livestock browsing on Arizona cliffrose near Burro Creek with the objective of determining the amount of utilization. Internode distances on five branches were measured on each of 50 Arizona cliffrose plants. Cages were constructed around 25 Arizona cliffrose plants to prevent browsing by livestock, wild burros, and mule deer. Twenty-five plants were left uncaged to serve as a control. Their results showed that browsing activity resulted in 65% utilization of Arizona cliffrose (BLM 1993). This high level of utilization can reduce plant vigor and fecundity, cause lack of seedling establishment, and change the form class of Arizona cliffrose plants, causing them to look hedged. Under this level of utilization, more palatable, associated plant species may be overutilized, resulting in disturbed ecosystem functions and degraded ecological values. The BLM continued monitoring Arizona cliffrose utilization after a fence was constructed in 1989 to exclude cattle and burros from an approximately one square mile area. This large exclosure included the caged and uncaged plants that had been monitored since 1987. After the fence was built, utilization of the Arizona cliffrose plants dropped to 16% in 1989 and 18% in 1990 (BLM 1993). Utilization of caged plants was similar to uncaged plants. These results indicate that livestock and burros were responsible for most of the browsing activity on Arizona cliffrose. Some browsing continues within the exclosure, probably from mule deer and other wildlife. Livestock and burros may occasionally enter the exclosure if the fence is not maintained. Most plants appear to be responding favorably to the lower levels of browsing. However, it appears that some plants that were very heavily browsed over a long period of time may never recover. Only observational data are available regarding the effects of livestock grazing on the Bylas

Arizona cliffrose population. At the Graham County population, Bingham (1977) noted that no young plants were observed during a one hour search in the grazed open area, whereas juvenile plants were present along an adjacent fenced ungrazed highway right-of-way. In 1986, the BIA (/n litt. 1986) noted that the absence of quantities of dried manure and lack of hoofprints to the north of Highway 70 indicated low grazing pressure. They also noted that Arizona cliff rose plants south of Highway 70 were browsed, probably because nearby Poison Spring offers a source of water for livestock and wildlife. (USFWS, 1995)

**Stressor:** Roads and Utilities (USFWS, 1995)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** All of the Arizona cliffrose populations have roads and/or utility right-of-ways within or near them. The Burro Creek population is divided by a graded dirt road paralleled by the Southern Union Gas Company pipeline and Arizona Electric Power Cooperative Incorporated high voltage power line. The gas pipeline has been in existence since at least 1969 (Butterwick 1979). No estimate of the amount of habitat lost to these developments in the Burro Creek area has been made. The Kinginan Resource Management Plan (Kinginan RMP) (BLM 1993 proposed a one-mile wide utilities corridor that overlies Arizona cliffrose habitat. The BLM may grant right-of-ways through this utility corridor (BLM 1993). A graded dirt road (Forest Road 205) and a gated road (Forest Road 530) passes near one of the three Horseshoe Lake subpopulations. Forest Road 479 passes near a second subpopulation. U.S. Highway 70, a two-lane paved road, bisects the population near Bylas. Numerous paved and dirt roads pass through the Cottonwood population. Highway 89A nearly forms the eastern border and Rocking Chair Road passes through the Arizona cliffrose habitat. Its expansion is being planned. Other roads to access housing or for recreational purposes create a network through the habitat. Roads and trails have direct and indirect effects. Road surfaces constitute lost habitat. The amount of habitat and number of plants lost to roads have not been estimated. Roads can change the local hydrology, affecting the amount of precipitation received and absorbed in a local area, changing the direction and speed of runoff, and perhaps changing erosion rates and patterns. These changes can adversely or beneficially affect survivorship and fecundity of individuals. Soil compaction occurs in areas of moderate to heavy vehicle use. Roads can provide access to ORV and other users that may adversely affect Arizona cliffrose and its habitat. ORVs can destroy young plants, harm mature plants, prevent seedling establishment or seed germination, cause soil compaction, and otherwise disrupt the soil surface. Arizona cliffrose plants have colonized a lightly used vehicle trail on the Coconino National Forest. These plants indicate that Arizona cliffrose in the actively reproducing Verde Valley population can recover after light soil surface disturbance. Unknowingly, local residents of the Verde Valley have been using Arizona cliffrose habitat as a parking lot. The parking area is located at the intersection of Rocking Chair Road and U.S. Highway 89A. The area of impact has been expanding during recent years, increasing the number of plants and amount of habitat already lost. The Coconino Forest Plan (U.S. Forest Service 1987) states that the Forest will manage roads adjacent to the Verde Valley Botanical Area to prevent vehicular intrusion." In the same document, the Forest committed to blocking and obliterating existing roads entering the area within the first ten years of plan implementation. To date, road blocking and obliteration has not yet occurred. (USFWS, 1995)

**Stressor:** Recreation (USFWS, 1995)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** The Cottonwood population is adversely affected by recreation of several types. An unofficial shooting range near the eastern portion of this population on the Coconino National Forest has caused the loss of an unknown number of plants and acres of habitat. Shooters park within an Arizona cliffrose population at the base of a small hill and shoot into the population on the hill. The soil at the well-used parking area and roads leading to the shooting range is compacted and eroding, devoid of vegetation, and probably incapable of supporting cliffrose plants unless restored. The area is used not only by shooters, but also by nighttime recreationists. In addition to the shooting range, other spots in the Arizona cliffrose Cottonwood population are frequented by night-time recreationists. These “party spots” are generally severely impacted by vehicles, devoid of vegetation, and littered with trash. ORV recreationists drive through the Cottonwood population, in some cases ignoring signs or cutting fences to gain access to prohibited areas. A fence completely surrounds a section of Arizona State Trust land, which was used by ORV users despite trespass notices. The primary damage to Arizona cliff rose habitat in the Cottonwood area has occurred in Township 16 North, Range 3 East, section 36 by vehicles entering the section from the west. The State Land Department has been successful at notifying the offenders and eliminating this use (Denham /n I/U. 1994). Denham and Fobes (1 992d) also noted ORV damage in the southeast corner of Township 16 North, Range 3 East, section 22 and the northeast corner of section 27. The ORV users entered a parcel of private land via the Coconino National Forest and rode across the property. ORVs are not currently a problem at Horseshoe Lake. The Tonto National Forest Plan (U.S. Forest Service 1985) closed the area to ORV use except where posted as open but has minimally enforced the closure. Despite the presence of a nearby lake and campground, ORV use has not yet been reported within the subpopulations. The amount of recreational activity occurring within the core Burro Creek subpopulation is poorly known. Increased recreational activity may occur within the Clay Hills Area of Critical Environmental Concern (ACEC) when the Burro Creek campground is developed (BLM 1993). The Burro Creek site is a wellknown destination for rock collecting enthusiasts. These visitors may affect Arizona cliffrose by turning over rocks and disturbing seedling establishment microsites. They also may occasionally drive short distances across country to reach collecting sites and crush plants. Whether or not these visitors adversely affect Arizona cliffrose is unknown. (USFWS, 1995)

**Stressor:** Control of Insect Pests (USFWS, 1995)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** General pesticides are often used to control cropland insect pests and sometimes used to control rangeland insect pests. Two Arizona cliffrose populations (Horseshoe Lake and Cottonwood) occur very close to lands under cultivation. A private parcel of land near Horseshoe Dam is being cultivated to provide food for livestock. We do not know if pesticides are currently being applied on the cultivated lands near Arizona cliffrose populations. Four Arizona cliffrose populations occur in areas that are grazed. High densities of rangeland pests have never been reported within Arizona cliffrose populations. If problem densities develop, however, they may be accompanied by proposals from Federal and State agencies to apply chemical controls, including general pesticides. General pesticides such as malathion, a commonly used rangeland and cropland pesticide, can drastically decrease target and non-target insect populations. Insect population sizes are regulated by a number of variables, including weather, inter-and intra-

specific competition, vertebrate predators,and insect predators and parasitoids (Belovsky 1989, Wang and Walgenbach 1989, Hostetter et a!. 1989, Dysart and Onsager 1989, Lockwood 1993). General pesticides will kill target herbivorous insects as well as the insect predators and parasitoids that regulate the herbivores. Herbivorous insects and their predators and parasitoids are usually in a dynamic balance, rarely reaching high, damaging densities except in unnatural circumstances such as the introduction of nonnative pests or in association with various agricultural practices including livestock grazing (Auerbach 1991, Brusven and Fielding 1989, Belovsky 1989). For a review of the field experiments and models of arthropod predator-prey systems that demonstrate this dynamic ecosystem balance, see Hassell (1978). Herbivorous insects recover more quickly after pesticide applications than do their predators and parasitoids because herbivores tend to have a higher fecundity and shorter generation time. Consequently, herbivorous species will more quickly become resistant to chemicals, and their populations will rebound faster and typically at higher densities because predator/parasitoid controls are lost or reduced. Thus, general pesticide applications tend to exacerbate insect population imbalances rather than resolve them. Concern about applying chemical pesticides within or near endangered plant populations has tended to focus on the adverse effects of pesticides on pollinators. For plants that depend on insects for pollination, seed set may be drastically reduced when pollinator populations are reduced by pesticides (Tepedino and Griswold 1989). Avoiding the blooming period of endangered plants may not remove these adverse effects. Fitts et a!. (1993) provide the following explanation: It is obvious that, for the plant, the most dangerous time to spray is during the blooming period. It is less obvious that it may also be risky to spray when bloom is past; many important pollinators are either eusocial, or multivoltine species, i.e., adults are present throughout the growing season, foraging on other plants. These adults are the progenitors of the next years' pollinator crop; removing them will eliminate progeny and, thus the number of pollinators flying in the following year. Information needed to effectively manage insects as part of the ecosystem containing Arizona cliffrose includes the Identification of all insects beneficial to Arizona cliffrose, including pollinators, and an understanding of their life histories and habitat needs. Until such information is obtained, the U.S. Department of Agriculture, Animal and Plant Health Inspection Service has agreed to restrict certain pesticides within a 4.8 km (three-mile) radius of Arizona cliffrose populations. (USFWS, 1995)

**Stressor:** Herbicides (USFWS, 1995)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbicides are sometimes used to control plant growth along paved roads. Although paved roads pass through the Verde Valley and Bylas Arizona cliffrose populations, we do not know if herbicides are used there. Herbicides should not be used along roadsides within Arizona cliffrose populations because treated plants are destroyed. (USFWS, 1995)

**Stressor:** Inundation (USFWS, 1995)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Arizona cliff rose plants and habitat were probably inundated when Horseshoe Dam and its spillway were built on the Verde River in 1944-1946 (FraserDesign 1991). Additional plants and habitat were probably lost when the conservation pool level of Horseshoe Lake was raised in the 1950's to the current elevation of 618 in (2,026 feet). Habitat inundation most likely

occurred in the Chalk Mountain area. If the height of the conservation elevation is increased further, the action would probably inundate additional plants and habitat. The Salt River Project, a utility company, operates the reservoir on a daily basis without specific approvals from Reclamation (Project Manager, Arizona Projects Office, Bureau of Reclamation, in !itt. 1994). (USFWS, 1995)

**Stressor:** Habitat Loss (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In our 2013 5-year review, we reported that the proposed Bella Montaña Residential Community Development, a 283-hectare (700-acre) parcel, would remove 47 cliffrose plants in the eastern-most known extent of the Cottonwood Recovery Unit (USFWS 2007). We also reported conservation measures proposed as a part of the development to protect and enhance cliffrose habitat (USFWS 2007). At the time of this review, the development has not occurred yet, but the consultant for the project has notified us that the project proponent plans to move forward on this project in the near future (N. Sanders, pers. comm., 2021). The original Coconino National Forest Land and Resource Management Plan (Forest Plan) stated that the Forest Service would withdraw the Verde Valley Botanical Area, which contains approximately 50 to 60 percent of the plants in the Cottonwood Recovery Unit, from locatable mineral entry within 10 years of the implementation of the Forest Plan (USFS 1987). To date, the Forest Service has not completed this withdrawal. However, the current Forest Plan indicates that the Cottonwood Recovery Unit has low potential for mining activity and includes a guideline that botanical areas and areas with federally threatened or endangered species be considered for no surface occupancy or mining leases (USFS 2018) (USFWS, 2022).

**Stressor:** Herbivory (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In our 2013 5-year review, we stated that the grazing allotments that contain the Horseshoe Recovery Unit were not active, and these allotments remain inactive. In their revised Land Management Plan, the Tonto National Forest included 3,590 acres, encompassing all the known occurrences of cliffrose in the Horseshoe Recovery Unit within the Horseshoe Recommended Botanical Area (USFS 2022). The Forest Service manages Botanical Areas to maintain or enhance their unique characteristics. Management standards for Recommended Botanical Areas prohibit livestock grazing, mineral extraction, and camping. Additional management guidelines restrict other activities unless necessary to restore or maintain natural conditions or protect natural resources. The finalization of the Horseshoe Botanical Area would address Recovery Actions 1b and 3b. In our 2013 5-year review, we reported that the BLM constructed a fence around the Clay Hills Research Natural Area of Critical Environmental Concern in 1989 to protect the Burro Creek Recovery Unit from the threat of herbivory by livestock and feral burros. After fence construction, browsing utilization of cliffrose decreased from about 65 percent to about 16 to 18 percent (Reichenbacher and Anderson 2022). The BLM continues to monitor the condition of the fence (USFWS 2013) and repaired damaged sections in late 2021 through early 2022 (J. Acton, pers. comm., 2022). Heavy browsing on cliffrose by native ungulates (e.g., mule deer [Odocoileus hemionus]) is evident in the Burro Creek and Horseshoe recovery units. This might be especially prevalent during drought conditions when ungulates

browse on a wider variety of available plants because of limited forage (Reichenbacher and Anderson 2022) (USFWS, 2022).

**Stressor:** Climate Change (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In our 2013 5-year review, we identified climate change as a threat to the cliffrose, specifically through decreased seedling recruitment in response to increased aridity and decreased precipitation (USFWS 2013). Climate modeling for 2050 through 2074 projects that increased temperatures will lead to increased monthly mean vapor pressure deficit in Arizona (Alder 2014); thus, cliffrose will continue to experience drought conditions. While we have little quantitative data showing past effects of drought on vegetation in cliffrose habitat, photographs from 2022 repeated at photo points from the 1980s and 1990s in the Burro Creek, Cottonwood, and Horseshoe recovery units show increased dead shrubs and increased dead branches on shrubs, including cliffrose individuals (Reichenbacher and Anderson 2022). Most cliffrose plants in the three recovery units recently observed (Burro Creek, Cottonwood, and Horseshoe) have not flowered in two years and exhibit signs of stress (Reichenbacher and Anderson 2022) (USFWS, 2022).

***Recovery***

**Reclassification Criteria:**
We will consider Arizona cliffrose for downlisting when: (USFWS, 2019)

1. A single, long-term monitoring plan for all Arizona cliffrose populations and habitat is developed and implemented. (USFWS, 2019)

2. Land managers conserve existing habitat, in each recovery unit, in perpetuity to prevent further habitat loss and/or degradation. (USFWS, 2019)

3. Each of the four recovery units contains a population of Arizona cliffrose that is stable or increasing over a period of at least 10 years. (USFWS, 2019)

Recovery Priority Number: 8

**Delisting Criteria:**
In addition to meeting downlisting criteria 1 and 2, we will consider Arizona cliffrose for delisting when: (USFWS, 2019)

1. Each of the four recovery units contains a population of Arizona cliffrose that is stable or increasing over a period of at least 20 years. (USFWS, 2019)

**Recovery Actions:**
- Produce and implement management plans for each of the four recovery units. This recovery task must be completed before recovery criterion 3 can be met. Commitment of the appropriate Federal and State land management agencies and the San Carlos Indian Community towards managing this sensitive habitat is critical to the recovery and survival of

Arizona cliffrose. If new populations are found, management plans covering those populations should be produced and implemented. (USFWS, 1995)

- Initiate research and other actions needed to monitor the species' status and guide recovery efforts. Best management efforts are guided by good biological and ecological information. Currently, too little is known about Arizona cliffrose to determine the most appropriate management actions to effect recovery and determine population stability. Research, studies, and other actions are needed to provide a sound basis for management. (USFWS, 1995)
- Eliminate or minimize threats to the species. Threats which prevent the recovery of Arizona cliffrose should be eliminated. The most important current threats to Arizona cliffrose are habitat loss due to mineral exploration and development, urbanization, recreation, roads, and utilities, and habitat degradation due to livestock grazing and recreation. Reducing or eliminating these and all other threats will lead to the recovery of Arizona cliffrose. (USFWS, 1995)
- Enforce and apply existing laws and regulations. Full use of all Endangered Species Act regulatory control should be used to manage and protect Arizona cliffrose populations. Arizona State law should also be applied and enforced. (USFWS, 1995)
- Information and education. Exchange of information and ideas among private landowners, the scientific community, the public, and Federal, State and local agencies is essential to a successful recovery program. Scientific information, including results of field and greenhouse research, monitoring data, trip reports, agency reports, and scientific literature should be readily available to all parties interested in the management and survival of Arizona cliffrose. Ideas should be freely exchanged so that optimal recovery strategies can be outlined and implemented. Meetings of interested parties to discuss new information or management issues or strategies should be encouraged. Preliminary or refined research or monitoring data should be presented at local, regional, and national gatherings of professional scientists so that a broad professional audience may have opportunities to comment on, and potentially enhance, recovery of Arizona cliffrose. (USFWS, 1995)
- Recommendations for Future Actions from 2013 5-Year Review: 1) We recommend the development or completion of management plans for the Cottonwood population (including the VVBA), the Horseshoe Lake population, and the Bylas population. The plans for each of these populations would be developed by the respective land managing agency (CNF, TNF, and the San Carlos Apache Tribe) with the offered assistance of the USFWS. These management plans should address newly understood or emerging threats such as climate change and invasive weeds. (USFWS, 2013)
- Recommendations for Future Actions from 2013 5-Year Review: 2) We recommend the appropriate agencies analyze the monitoring data they have collected to date to determine demographic trends in their respective P. subintegra populations. This will allow the USFWS to determine whether a given population is viable or on a trend toward viability, in support of downlisting criteria one. The USFWS can assist in coordinating this effort to facilitate consistency and comparability between the various monitoring methods employed by each agency. (USFWS, 2013)
- Recommendations for Future Actions from 2013 5-Year Review: 3) We recommend the modification or addition of standardized long-term demography monitoring techniques to existing monitoring schemes, or the establishment of standardized long-term monitoring protocols within all four populations. The USFWS can facilitate this process and assist in monitoring design and coordinating standardization between agencies. (USFWS, 2013)

- Recommendations for Future Actions from 2013 5-Year Review: 5) We recommend that the terms “viability” and “significant upward trend towards viability,” as used in the first downlisting criterion, be defined or described for P. subintegra for the purpose of developing an objective and measurable criterion. The USFWS will lead this effort in coordination with land managing agencies and subject matter experts. (USFWS, 2013)
- Since 1989, when a fence was set around the main Burro Creek subpopulation, the BLM has continued to monitor grazing on P. subintegra in the main population as well as the two subpopulations. Herbivory of P. subintegra has been low within the ACEC, recorded at 3 to 9.4 percent utilization for the past six years (Peck 2009b; Peck 2012). Grazing use in the two outlier populations has also been low, ranging from 2.5 to 8 percent. The BLM had predicted livestock grazing at these sites would be light because cattle would be less likely to travel in the area due to the rugged terrain and distance from water. Evidence of herbivory at all sites has been attributed to wildlife, and is well below the trigger of 20 percent for determining if reinitiation of formal consultation is necessary (Hall 1993). The ACEC fence is inspected annually and repaired as needed. The VVBA is within the Windmill Allotment. Section 7 consultations with the CNF were conducted in 1992 and 1997 for the Windmill Allotment Management Plan. Grazing has been excluded from the Rocking Chair and Cornville pastures since 1992, while seasonal grazing has continued in the Gyberg pasture under a deferred rest rotation system (USFWS 1995). Range inspection memoranda, from 2001 to 2006, state that there was light to no use of P. subintegra within the North Gyberg Pasture. The Horseshoe Lake P. subintegra population on the TNF is contained within three grazing allotments. Current management in the Sears Club/Chalk and the St. Clair allotments is non-use due to the allotments being vacant (Willard, pers. comm., 2012). The Sears Club/Chalk Allotment, which contains most of the population, is scheduled for evaluation, under the National Environmental Policy Act, in 2013. The three pastures in the Cartwright Allotment (Lime Creek, Professor, and Long Canyon) have been removed from grazing (USFS 2008). Currently, the threat from grazing appears to be at a low level at three of the populations; the level of grazing effects at the Bylas population is not quantified to our knowledge.

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • We recommend the development or completion of management plans for the Cottonwood population (including the Verde Valley Botanical Area), the Horseshoe Lake population, and the Bylas population. The respective land managing agency (Coconino and Tonto National Forests, and the San Carlos Apache Tribe) would develop these plans with the offered assistance of the Service. These management plans should address newly understood or emerging threats such as climate change and invasive weeds. This action would address Recovery Action 1. • We recommend the land management agencies (i.e., BLM, Coconino and Tonto National Forests, and the San Carlos Apache Tribe) implement long-term demographic monitoring within all four populations. This will allow the Service to determine whether a given population is viable or on a trend toward viability. The Service can assist in coordinating this effort. This action would address Recovery Action 2c. • We recommend continued research on pollination, seed germination and seedling establishment, propagation, comparison of recruitment rates among populations, life history characteristics, and growth rates to better understand the threats of and potential measures to address climate change. This action would address Recovery Action 2. • We recommend land managers consider caging seedlings during years of high seed production (i.e., years of moderate or high precipitation) to increase recruitment of seedlings into the juvenile stage (Maschinski et al. 2004; Haskins et al. 2018). This action would address Recovery Action 3. • We recommend collecting seed representing each of the four recovery units, with regular supplemental collections, and maintaining the collection in at least one Center for Plant Conservation partner botanical or seed storage institution. We did not include biobanking as a recovery action in the Recovery Plan. However, after we completed the Recovery Plan in 1995, researchers improved techniques and knowledge that increase the potential contribution of biobanking to cliffrose conservation. We therefore include this recommendation to preserve some of the species' genetic diversity for potential future population augmentations or reintroductions (USFWS, 2022).

# SPECIES ACCOUNT: *Rhodiola integrifolia ssp. leedyi* (Leedy's roseroot)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 04/22/1992; Great Lakes-Big Rivers Region (R3) (USFWS, 1992)

**Physical Description**

Leedy's Roseroot is a perennial herb with multiple leafy stems from a scaly root crown that is usually visible in the rock crevices where the plants are growing. Leaves are glaucous, oblong, blue-green, and thick-succulent, with irregularly toothed to entire margins. The dark red and yellow flowers (May-August) are arranged in rounded clusters at the ends of the stems. (NatureServe, 2015)

**Taxonomy**

Listed as a subspecies of Sedum integrifolium, a revised scientific name of Rhodiola integrifolia ssp. leedyi, as treated by Kartesz (1999) was accepted by the USFWS in 2010 (USFWS, 2010).

**Historical Range**

Apparently the Leedy's roseroot is not known to have occurred in historical times in other locations than present. (USFWS, 2015)

**Current Range**

Leedy's roseroot is found today in only six locations in two widely separated states. Four populations of several thousand plants each are found in Fillmore and Olmsted Counties, Minnesota. The other two are in upstate New York, a large population on the shores of Seneca Lake and a single plant at Watkins Glen. (USFWS, 2015). Also occurs at Harney Peak, Black Hills National Forest, South Dakota (Olfelt and Freyman 2014, p. 908). (USFWS, 2015b).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Usually sexual reproduction; some vegetative (USFWS, 1998)

**Dependency on Other Individuals or Species**

Adult: Bees and syrphus flies as pollinators (USFWS, 1998)

**Breeding Season**

Adult: Flowers in June (USFWS, 1998)

**Other Reproductive Information**

Adult: Olfelt (1998, p. 16) found a seed germination rate for Leedy’s roseroot of 77% and described this as high for a rare plant, but lower than that of related subspecies. (USFWS, 2015b).

**Reproduction Narrative**

Adult: Flowering occurs in early June. Clausen (1975) reports bees and syrphus flies as pollinators; Sather (1993a) observed bees on New York plants. Seeds are winged and adapted for wind dispersal. Seeds produced by plants at Glenora Cliff, New York, sometimes germinate in their follicles and produce seedlings on the parent plant (Clausen 1975). Plants grown in a Minnesota greenhouse from seed flowered their first season after germination (Joel P. Olfelt, University of Minnesota, pers. comm. 1996). Although, newer growth on the long-lived rootstocks breaks off to form clones, which have lived at least 36 years in cultivation (Clausen 1975), Olfelt and Luby (in press) report finding little clonal reproduction. Of 81 stems they assayed, 75 had unique markers, indicating those 75 stems had not been produced by cloning. (USFWS, 1998)

**Habitat Type**

Adult: Cliff ledges and talus slopes (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Ground water or cool air (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from USFWS, 1998)

**Environmental Specificity**

Adult: Very narrow specialist (USFWS, 1998)

**Habitat Narrative**

Adult: The habitat is limited to north or east-facing talus slopes or cliff ledges where ground water (primarily in New York) or cool air (primarily in Minnesota) constantly seep through the strata or between the rocks, maintaining a cool, wet environment throughout the summer. (NatureServe, 2015; USFWS, 1998)

***Dispersal/Migration***

**Motility/Mobility**

Adult: Low (inferred from USFWS, 1998)

**Dispersal**

Adult: Wind dispersal of seeds (USFWS, 1998)

**Dispersal/Migration Narrative**

Adult: Plants are specific to a particular habitat which limits dispersal. The preferred cold air cliff faces with seepages are rare. (USFWS, 1998)

***Population Information and Trends***

**Population Trends:**

Unknown. Inferred from information (USFWS, 2021)

**Number of Populations:**
6 (USFWS, 2015)

**Population Size:**
>4,000 individuals (USFWS, 2021)

**Adaptability:**
Low (inferred from NatureServe, 2015)

**Population Narrative:**
Populations may be increasing or decreasing (NatureServe, 2015). USFWS (2015) indicates that the four Minnesota populations have several thousand plants each, but NatureServe (2015) indicates only 1500-2000 plants in all Minnesota populations. The New York population at Seneca Falls consists of "a large population" (USFWS, 2015) or "several thousand plants" (NatureServe, 2015). There is one plant at Watkins Glen, NY; it is likely introduced. (USFWS, 2015; NatureServe, 2015). The South Dakota population of Leedy's roseroot occurs on Black Hills National Forest on a cliff at approximately 7,000 feet above sea level. White spruce (Picea glauca) is the dominant overstory species on the north-northeast facing slope directly below the cliff; and ponderosa pine (Pinus ponderosa) is the dominant tree species in the general vicinity (U.S. Forest Service, in litt.). About seven patches of Leedy's roseroot may inhabit only a total of 10-50 square meters of the cliff face (Fig. 4; U.S. Forest Service, in litt. 2001; 2011). (USFWS, 2015b). The most recent census data indicate that the population at the Glenora Cliffs site in New York has increased since the most recent census and remains above 4,000 plants. At the Glenora Falls site, the population of 45-50 plants did not change between 2017 and 2020. The single individual that makes up the Watkins Glen State Park population in New York was inadvertently destroyed during construction of a new trail. Partners at the State University of New York College of Environmental Science and Forestry have applied for Section 6 funding to collect seeds from plants at New York sites, propagate Leedy's roseroot in a greenhouse environment, and outplant individuals at Watkins Glen State Park (Wiley (NYFO) pers. comm. January 27, 2021). All Minnesota populations have increased since the most recent census in 2020, although overall trends since 1997 are mixed with the Whitewater WMA population declining and populations at Simpson Cliffs, Deer Creek, and Bear Creek being relatively stable (Olfelt 2020a; Appendix B). No changes were noted for the South Dakota population of Leedy's roseroot in 2016 and 2017 (USFWS, 2021).

***Threats and Stressors***

**Stressor:** Ground water contamination (USFWS, 1992)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Contamination of ground water is likely though filling or dumping in sink holes adjacent to the cliffs. Sink holes are highly vulnerable because they provide direct access to the ground water and are the main source of seepage on the cliffs. (USFWS, 1992)

**Stressor:** Agricultural pesticides (USFWS, 1992)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** The use of agricultural pesticides in adjacent upland farmland (cropland in Minnesota and vineyards in New York) may directly affect the quality of the ground water. (USFWS, 1992)

**Stressor:** Residential development (USFWS, 1992)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In New York, homes are being built above the cliffs. Many homeowners have built stairs down the cliffs to Seneca Lake and some have cleared vegetation from the cliff or cut trees at the top of the cliff to enhance the view. Some trees have been simply dumped over the cliffs. (USFWS, 1992)

**Stressor:** Road building and quarrying (USFWS, 1992)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Road building and quarrying in the karst region of Minnesota would affect the subsurface water flow in an area and change the required groundwater seepage at a cliff face. (USFWS, 1992)

**Stressor:** Erosion and rock slides (USFWS, 1992)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The slopes where the roseroot occurs are unstable. Natural erosion of the cliffs occurs and may denude the vegetation. Heavy runoff may directly dislodge plants from cliffs or may result in gullies being cut into a population site. Logging above some of the Minnesota sites may also cause erosion affecting the cliffs. (USFWS, 1992)

**Stressor:** Grazing (USFWS, 1992)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Grazing may damage plants on the lower, gentler slopes of the cliffs where dislodged plants have again taken root.

**Stressor:** Climate change and catastrophic wildfire (USFWS, 2015b).
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Leedy's roseroot already inhabits the highest elevation habitat available in the ecoregion and would not be able to move to higher – and presumably cooler and moister – habitats if climate change rendered its current habitat unsuitable. In addition, as ponderosa pines succumb to mountain pine beetle, drop needles, and fall the risk of a wildfire in forest around the Leedy's roseroot population is likely to increase (C. Monks, pers. comm. 2014). (USFWS, 2015b).

***Recovery***

**Delisting Criteria:**
All three privately owned Minnesota populations must be protected by conservation easements or fee acquisition by a public agency or private conservation organization. (USFWS, 1998)

The Whitewater Wildlife Management Area, Minnesota, population must be protected from or removed from any confirmed contamination threat and has been demonstrated to be self-maintaining for five years. (USFWS, 1998 and USFWS 2021)

The Glenora Falls, New York, population must be protected. (USFWS, 1998)

Habitat for 4,000 plants in multiple sites, evenly distributed along a 2-mile stretch of Glenora Cliff, New York, must be protected. The two most-distant subpopulations protected at Glenora Cliff must be at least 1.5 miles apart. (USFWS, 1998)

Protected populations must be geographically distinct, self-sustaining, and have been protected for five consecutive years by measures that will remain effective following delisting. (USFWS, 1998)

**Recovery Actions:**
- Map all populations, and identify all affected landowners. (USFWS, 1998)
- Determine hydrologic relationships between upland areas and S. integrifolium ssp. leedyi populations. (USFWS, 1998)
- Establish and administer a permanent infrastructure for Leedy's roseroot site protection and secure funding for that protection. (USFWS, 1998)
- Contact landowners, landowner associations, and land trusts; secure their involvement in conservation strategies; compensate them for costs of fee acquisition, enrollment in conservation easements or other programs; prepare management plans for public and private protected areas. (USFWS, 1998)
- Establish, implement, and review a monitoring program. (USFWS, 1998)
- Provide public education, including advance landowner contact. (USFWS, 1998)
- Develop and maintain a genetic bank. (USFWS, 1998)
- 2015 recommended actions - 1. Review threats to the species, beginning with the information in this review, to ensure that recovery criteria are revised appropriately to address all significant threats to the species. Prepare a list of threats based on this assessment and have it reviewed by species' experts to ensure that it is complete and accurate. Finally, revise the recovery criteria, as appropriate. (USFWS, 2015b).
- 2015 - 1.1: Determine whether and to what degree any Leedy's roseroot populations are threatened by the instability of their cliff side habitats and whether heavy rains are likely to pose a threat any population. Use this information to determine whether the recovery criteria should be revised to address specific related threats and revise the criteria, if appropriate. (USFWS, 2015b).
- 2015 - 1.2: Determine whether and to what degree any Leedy's roseroot populations are threatened by gully formation or by poor soil conservation practices. Revise the recovery criteria to address this factor if it poses a threat. This potential threat may currently be most relevant to the population at Whitewater Wildlife Management Area in Minnesota. (USFWS, 2015b).

- 2015 - 1.3: Determine whether grazing or logging poses a direct or indirect threat to any Leedy's roseroot population. If they do, revise the recovery criteria to ensure that no site is considered to be protected unless the threats are adequately minimized. (USFWS, 2015b).
- 2015 - 1.4. Consider revising the recovery criteria to clarify that the protections required for each Leedy's roseroot population must preclude the following: 1.4.1. Filling or dumping material into any sink holes where that activity could result in exposure of Leedy's roseroot to harmful contaminants or alteration of groundwater flows to cliffs where Leedy's roseroot occurs; 1.4.2. The use of any pesticides or herbicides where it would result in the exposure of Leedy's roseroot to harmful compounds; and, 1.4.3. Road building or quarrying that would affect groundwater flows in any Leedy's roseroot cliff side habitats. (USFWS, 2015b).
- 2015 - 1.5: Consider revising the recovery criteria to require that protection of Leedy's roseroot habitat at the Glenora Cliff site in New York would preclude the construction of stairs, vegetation clearing (except for invasive species), laying of pipes, and dropping felled trees where these activities would likely cause adverse effects to Leedy's roseroot. (USFWS, 2015b).
- 2015 - 1.6. Consider revising the recovery criteria to further clarify that the populations around Seneca Lake must be protected from residential development, cliff-face alteration, and hydraulic fracturing (fracking) that could affect ground water quality and flow. (USFWS, 2015b).
- 2015 - 1.7. Review the preliminary hydrogeological assessment prepared for Leedy's roseroot in Minnesota (Spetzman and Cremers 1999) and develop a plan to assess the risk of groundwater contamination for each of the four Minnesota populations and measures that would protect the taxon from this threat. Consider engaging the appropriate regional hydrologist with the Minnesota Department of Natural Resources, Division of Ecological and Water Resources to help develop this plan. Ensure that the plan is sufficient to determine the following: 1.7.1. The extent to which transport of agricultural chemicals into sinkholes poses a risk of exposing Leedy's roseroot to contaminated groundwater. 1.7.2. The locations of sinkholes – or the areas in which they may occur – that should be protected to ensure that each Leedy's roseroot population is safe from effects to groundwater flows or groundwater contamination. 1.7.3. The area in which road building or quarrying may expose Leedy's roseroot to the effects of any changes in groundwater discharge. 1.7.4. The specific practices that would need to be implemented to mitigate any specific threats of exposing Leedy's roseroot to changes in groundwater discharge or to contaminated groundwater and to alleviate any ongoing exposure. It may also be prudent to carry out similar actions in New York. (USFWS, 2015b).
- 2015 - 2. Revise the recovery plan to address the Leedy's roseroot population that is now confirmed in South Dakota. (USFWS, 2015b).
- 2015 - 3. It may still be unclear whether the taxon may be conserved by relying only on the protection of the seven known extant populations. The seven populations include four in Minnesota; two in New York; and, one in South Dakota. Consider developing a range wide viability assessment that assesses the species' recovery criteria and determines whether extant populations would ensure sufficient redundancy and representation for the subspecies; and to develop criteria that may be used to determine whether or not the populations that are essential to recovery are sufficiently resilient. (USFWS, 2015b).
- 2015 - 4. Define "self-sustaining" per the recovery criteria or eliminate it from revised criteria. (USFWS, 2015b).

- 2015 - 5. Ensure that an adequate seed banking program is established for Leedy’s roseroot. (USFWS, 2015b).
- Enrollment in permanent conservation easements, private land trusts, or landowner associations with effective land management plans to minimize impacts on S. integrifolium ssp. leedyi populations. (USFWS, 1998)
- Acquisition of fees to provide tax relief or other compensation to landowners. (USFWS, 1998)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: • Manage each population as a unique management unit o Prioritize conservation of large population centers at the Glenora Cliffs and WWMA sites o Prioritize conservation of genetic diversity at the Deer Creek site by collecting seeds • Evaluate abiotic and biotic factors associated with Leedy’s roseroot in New York, Minnesota, and South Dakota sites o Use information to develop management recommendations • Revise recovery criteria to address threats related to cliff instability and heavy rains • Conduct DNA microsatellite analysis on South Dakota population and additional populations in New York (USFWS, 2021).

# SPECIES ACCOUNT: *Rhododendron chapmanii* (Chapman rhododendron)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 5/23/1979; Southeast Region (R4)

**Physical Description**

Chapman's rhododendron is a small (0.5 - 2m in height), evergreen shrub with stiffly ascending branches. Leaves are alternate, 3 to 6cm long, obovate with tapered bases, obtuse or rounded apices, somewhat wrinkled, and with entire but curled undermargins. Shade leaves are less wrinkled and curled. Petioles are from 2 to 6mm long. New stems, petioles and under surface of leaves are usually scurfy, dotted reddish brown. Flowers, borne in terminal clusters, have light pink, funnel-shaped corollas about 3cm long with 5 fused petals. Fruit capsules, about lcm long, are borne in clusters which persist several years and are present on almost all plants. It blooms prolifically with large clusters in late March to early April. (USFWS, 1983)

**Taxonomy**

Asa Gray (1877) described R. chapmanii and credited Chapman (1860) with recognizing the taxon as a variety growing in the sandy pine barrens of west Florida (Duncan and Pullen, 1962). Recent authors treat as R. minus var. chapmanii (Godfrey, 1988; Duncan & Pullen, 1962; Luteyn et al., 1996). Kartesz (1994) treats as full species. R. minus var. minus occurs in Georgia and southern Appalachians (Duncan & Pullen, 1962) (NatureServe, 2015).

**Historical Range**

Endemic to Florida, in Gulf, Liberty, Gadsden, and Clay counties. (USFWS, 2019a)

**Current Range**

Endemic to Florida and restricted to Gulf, Liberty/Gadsden and Clay counties. (USFWS, 2019a)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Blooms in mid-March to early April (USFWS, 2019a)

**Reproduction Narrative**

Adult: Although R. chapmanii flowers and fruits abundantly, no seedlings were observed in the 1996 monitoring event (author, pers. obs.), and only one was found in the 1985 monitoring event (Hardin, et al., 1985). Plants are grown from seed for the nursery trade (Hardin, et al., 1985), so presumably they are reasonably easy to germinate and grow in captivity.; Ann Redmond made notes and diagrams of five plants that she excavated to a depth of ca 20 cm near the permanent monitoring plots in Gulf and Liberty/Gadsden counties (Redmond, 1985).

She observed that clumps of stems, which would have been considered several "plants" for monitoring purposes from an above-ground point of view, often were found to arise from the same underground rootstock when excavated. Thus there were actually fewer genetic individuals present than there were stem clumps tagged. She also noted evidence of areas in the rootstock where former stems had died and rotted away and evidence of grafting between stems from different sources. From her rough diagrams it appears that the underground biomass of rootstock plus roots would exceed the biomass of the aboveground stems. All of the excavations showed rhizomes heading out from the central rootstock to beyond the area of the excavation which generally covered an area of less than 1 square meter. PHENOLOGY: Rhododendron chapmanii has a fairly narrow two to three week flowering period which may begin from mid- March to early April (Duncan and Pullen, 1962; Hardin et al., 1985; Schultz and Johnson, 1996). A hard freeze in January and March 1985 may have delayed and reduced flowering in that year by killing the buds (Hardin, et al., 1985) (NatureServe, 2015).

**Habitat Type**

Adult: Bbetween upland mesic or scrubby flatwoods and floodplain swamps or baygalls; mesic pine flatwoods (USFWS, 2019a)

**Habitat Vegetation or Surface Water Classification**

Adult: Terrestrial

**Dependencies on Specific Environmental Elements**

Adult: Acidic sandy soil (USFWS, 2019a)

**Spatial Arrangements of the Population**

Adult: Clumped (USFWS, 2019a)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Rhododendron m. chapmanii usually occurs in a transitional area between upland mesic or scrubby flatwoods and floodplain swamps or baygalls. This species is also found within mesic pine flatwoods or on the lower elevations of the sandhills. Consequently, it appears to require acidic sandy soil, good to moderately welldrained to somewhat poorly drained sandy soils of 0-5% slope, and no flooding. The Camp Blanding population grows on the edge of xeric hammock next to a stream bank. The plants tolerate full sun to moderate shade (Negron-Ortiz, 2010, pers. observ.), and heavy shade once they are mature as at Camp Blanding (Hall 2005). (USFWS, 2019a)

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2019)

**Number of Populations:**

4 (USFWS, 2024)

**Population Size:**

approximately 3,000 clumps (USFWS, 2019a)

**Population Narrative:**

Rhododendron m. chapmanii is restricted to the Florida panhandle with only three known opulations occurring in coastal Gulf County, Liberty and Gadsden counties in the vicinity of Hosford, and Clay County on the Camp Blanding Military Reservation. The population near Hosford is the largest and is privately owned by AgReserve Inc., which may maintain timber production and agricultural uses of the lands. The smallest and most geographically isolated of these populations is within the Florida National Guard post at Camp Blanding, about 165 miles east of the Hosford population. Throughout Florida, surveys and censuses collectively recorded about 55 occurrences or sites. Although we have limited information regarding trends, current data assessment suggest the presence of only 35 sites (about 36 % decline). In May 2019 FNAI performed a comprehensive review of all R.m. chapmanii element occurrences (EO2). The 55 areas where the species was observed are currently mapped as 23 EOs. This is based on NatureServe 2004 guidance (EO separation distance of 1 km) with the addition of separation based on differences in management practices, threats, and habitat conditions. If considering only the parameter of 1 km separation distance, the 23 EOs technically represent 15 EOs (J. Annis, FNAI, 07/02/2019, pers. comm.). (USFWS, 2019a). Rhododendron chapmanii is a small evergreen shrub presently comprised of four populations located in five Florida counties four of which are in the panhandle. A new occurrence was recorded in 2022, increasing the total occurrences to 16 and extending the geographic range 80km northwest from the nearest known population (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Urbanization (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In addition to being one of the largest private landowners in northwest Florida, the St Joe Company is also one of the largest real estate operating companies in the Southeast. This Company develops both residential and commercial properties along roadways and near or within business districts in the region. Urbanized land in Florida, statewide, is projected to double by 2070 along with a growth of about 33.7 million residents–almost 15 million more people than in 2010 (University of Florida GeoPlan Center 2017). Since the species occurs on Company-owned property in Gulf, Liberty, and Gadsden counties, Florida, there is no guarantee that these properties will not be utilized for residential or commercial development in the near future. Therefore, residential or commercial development is a threat. (USFWS, 2019)

**Stressor:** Forestry practices (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The timber industry in North Florida became well established in the 1850s. Privately owned companies grow trees for their byproducts by mechanically preparing the site for

planting, planting seedlings, and mechanically harvesting the trees. Harvesting typically involves thinning, and later clear cutting the site; the process is then repeated. The St. Joe Company had close to a million acres in timber in the eastern region of the panhandle and they plan to continue to harvest and replant indefinitely. Tree farming, i.e., privately owned forest managed (clearcutting, mechanical site preparation, and pine plantations) for timber production, is a primary threat since there are many thousands of acres of tree farms. In 2013, the St Joe Company sold more than 380,000 acres of its land to AgReserves, Inc., a for-profit company that has primarily focused on cattle grazing. The land sold included timberlands in Bay, Calhoun, Franklin, Gadsden, Gulf, Jefferson, Leon, Liberty and Wakulla counties. The safety of the Hosford population, sold to AgReserves, Inc., is undetermined because it is not protected. Also, the Gulf County population is primarily on tree farm land; therefore, tree farming is a threat to this species. (USFWS, 2019)

**Stressor:** Fire suppression (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Suppression of fire continues to threaten pineland and savanna flora as fire is an important element in the maintenance of flatwoods (Abrahamson and Hartnett 1990). Fire influences community structure and composition (Abrahamson and Hartnett 1990), and with insufficient frequency in longleaf pine communities, a woody midstory quickly develops (Glitzenstein et al. 1995), negatively affecting the understory diversity. Several studies have shown that frequent prescribed fire regimes are important for maintenance of flatwoods diversity (Hiers et al. 2007). Prescribed burnings are needed to maintain optimal habitat for R.m. chapmanii populations; specifically to avoid the encroachment of Cyrilla racemiflora L. (swamp titi). (USFWS, 2019)

**Stressor:** Drainage (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Drainage of adjacent bogs to increase areas of pine plantings affects seasonal hydrology. Drained sites become more desiccated, and this affect processes such as seed germination and seedling establishment. Therefore, drainage of adjacent bogs is still a threat due to tree farming activities. (USFWS, 2019)

**Stressor:** Overutilization (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** The Recovery Plan identified this as a threat to R.m. chapmanii. Specifically, the Plan suggested that this species was taken from the wild for ornamental purposes (Tatum and Lake 1979). According to Simmons (1983), numerous plants were removed in the late 1940's from the Camp Blanding for the nursery trade. Similarly, 100-200 plants were removed from the Hosford population (USFWS 1983). Therefore, this species was a 'commercially exploited plant'3 and is still sold by several nurseries (e.g., https://shop.shadygardensnursery.com/). This activity does not currently seem to be a major problem because most cuttings and seeds come from plants collected in the past. However, we cannot discount the possibility of sporadic plant removal.

(USFWS, 2019)

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Endangered Species Act (Act) of 1973, as amended prohibits the removal of federally listed threatened and endangered plants or the malicious damage of such plants on areas under federal jurisdiction, or the destruction of endangered plants on non-federal areas in knowing violation of state law or regulations or in the course of any violation of a state criminal trespass law. However, the Act does not provide protection for plants on private lands or unless it's in violation of state law. Several populations of R.m. chapmanii occur on private timberland. While the Act requires federal agencies to carry out programs for the conservation of endangered and threatened species, no such programs are stipulated for private landowners. Neither section of the Act provides protection for plants on private lands as long as the activity is permissible under state/local laws. Seeds of both threatened and endangered species found on federal lands are regulated under the Act. In addition, the seeds of an endangered species are regulated if they are going to be purchased/traded/bartered in interstate commerce. Since R.m. chapmanii is an endangered species, the seeds are regulated under the specified conditions. However, the seeds are not regulated if they are provided freely (no exchange of money, goods, or services; 7 CFR 319.37.2, USDA 2008). The State requires permission of private landowners for collecting of state-listed plants from their property. Rhododendron m. chapmanii is protected under Florida State Law, chapter 581.185: Preservation of native flora of Florida, which includes preventions of take, transport, and the sale of the plants listed under the State Law. The rule Chap. 5B-40, Florida Administrative Code, contains the "Regulated Plant Index" (5B-40.0055) and lists endangered, threatened, and commercially exploited plant species for Florida; defines the categories; lists instances where permits may be issued; and describes penalties for violations (Coile and Garland 2003). This law does not protect habitat. Based on the information summarized above, the existing regulatory mechanisms are deemed inadequate for plants. (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**
1. The dense 10-acre population near Hosford is maintaining a stable or increasing population of healthy plants. (USFWS, 1983).

2. The remaining part of the Hosford population continues to occupy at least 200 acres with at least 500 plants. (USFWS, 1983)

3. The Gulf County population continues to occupy at least 200 acres with at least 500 plants. (USFWS, 1983)

4. The Camp Blanding population continues to have at least 20 plants. (USFWS, 1983)

5. There is a permanent increase of about 1,000 plants at any combination of sites 2, 3, and 4 to increase to a total of at least 2,000 plants at these sites. (USFWS, 1983)

Recovery Priority Number: 8C

**Delisting Criteria:**
1. The three (3) existing populations (Hosford, Gulf, and Clay) and their occupied habitat are conserved, restored, and properly managed, and monitoring demonstrates that the populations are stable or increasing over multiple prescribed burn cycles, evidenced by a type of natural recruitment and/or multiple size-classes (addresses Factors A and D). (USFWS, 2019b)

2. At least five (5) new populations are discovered or established within the historic range of the species on lands protected by a conservation mechanism, and exhibit stable or increasing trends over multiple prescribed burn cycles, evidenced by a type of recruitment and/or multiple size-classes (addresses Factors A and E). (USFWS, 2019b)

3. Threats (e.g. urban development, timbering, agriculture, inadequate fire management, invasive species) have been reduced and/or managed to a degree that R. m. chapmanii will remain viable into the foreseeable future (addresses Factors A and D). (USFWS, 2019b)

**Recovery Actions:**
- 1. Highest priority for the recovery of Chapman's rhododendron should be to reverse the habitat and population declines that are occurring in the wild population. This can be accomplished through a combination of protection, management and monitoring. Most important in accomplishing this goal is to establish and maintain a strong, friendly and longlasting working relationship with the St. Joe Paper Company, which owns over 99 percent of the wild population and its habitat. The Company has expressed a willingness to help (pers. comm.), and, indeed, has already taken some steps to protect the species and its habitat. Camp Blanding guards the small population there rather closely, and has expressed willingness to help manage the site. (USFWS, 1983)
- 2. Strengthening existing populations by planting nursery-grown plants is clearly less important than habitat protection and management. Tt may nevertheless prove to be essential for long-term survival of the species. Tt provides a tested (plantings have been done by Simons in the wild in Suwannee, Levy and Putnam Counties with 100 percent success rates) and easy method to quickly strengthen a population. (USFWS, 1983)
- 3. Establish new populations. Determine historical range. Locate suitable habitat. Obtain permission and cooperation for establishing planting. Collect seed. Grow plants and plant out in December - January at a 20 by 20 foot spacing (about 100 per acre). (USFWS, 1983)
- 4. Research is the lowest priority, because it seems least important from the standpoint of the immediate and near-term needs of the species. However, the farther one looks into the future, the more important research is. The amount of research recommended here is the minimum necessary to provide for implementation of this recovery plan. (USFWS, 1983)
- The level of occupancy of the three existing populations persists as at least: 5,000 acres for Hosford, 6,000 acres for Gulf County with a minimum of 2,000 clumps, and 30 clumps for Clay County (addresses Factors A and D) and management with prescribed fire is implemented on a 3 to 5 year return interval. (USFWS, 2019b)
- Foster a partnership with the current landowner of the AgReserves, Inc. to promote the protection of the Hosford population (found in Liberty and Gadsden counties) and help implement best management practices (e.g., prescribed fire, mowing/fuel reduction, invasive species removal) (addresses Factors A and D). (USFWS, 2019b)

- A long-term ex-situ conservation program is ongoing to help avert the risk of extinction from stochastic events, environmental catastrophes, or development. The living collection should emphasize the privately owned Hosford population and coastal areas (see Justification of criteria 1 and 3). The collection should be maintained at botanical gardens and other Service approved facilities for research, recovery, and public outreach (addresses Factors A and E, and representation). The full genetic diversity represented in the Hosford population needs to be protected through ex-situ management efforts. (USFWS, 2019b)
- The contribution of sexual reproduction to population maintenance is assessed via research related to in-situ soil seed bank, seed viability, and seedling recruitment (in-situ seed germination, seedling survival and growth) (addresses Factors A, D, E, and resiliency). (USFWS, 2019b)
- The genetic composition within and among populations is assessed to clarify species boundaries, define evolutionarily significant units, detect inbreeding, identify clonal reproduction, and determine effective management (addresses Factors A, D, E; informs the ecological principle of representation). (USFWS, 2019)
- Assess the R. m. chapmanii demographic responses (e.g., recruitment, reproduction, and mortality) to hurricane and fire disturbances (addresses Factor E and resiliency). (USFWS, 2019b)
- A comprehensive census is conducted throughout the present distribution and on new locations where appropriate habitat exists (addresses Factor A and redundancy). (USFWS, 2019b)
- Acquisition of the following private lands will benefit the status of this species: - Several land parcels adjacent to the SJSBP, Gulf County that has Chapman's Rhododendron and a suite of other rare species. - The Hosford population located in Liberty and Gadsden counties. (USFWS, 2019a)
- Complete a comprehensive census (e.g., the total number of individuals, number of flowering vs. non-flowering plants, and whether seedling recruitment is occurring) throughout the present distribution. Follow a standardized method for accurate population counts to ensure consistency in collected data. (USFWS, 2019a)
- Conduct surveys for new populations where similar habitat exists. This action can include the use of aerial photographs and species distribution modeling methods to initially determine potential sites, with subsequent validation or inspection of the sites for plants. Follow a standardized method for accurate population counts to ensure consistency in collected data. (USFWS, 2019a)
- Garden propagation and reintroduction. An ex-situ seed collection should be actively pursued and implemented to help avert the risk of extinction from stochastic events, environmental catastrophes, or development. The living collection should emphasize the privately owned Hosford population and coastal areas, and maintained at botanical gardens and other Service approved facilities for research, recovery, and public outreach. (USFWS, 2019a)
- Complete a population genetic study to determine the levels and distribution of genetic diversity within and among populations of R. m. chapmanii. The study should test whether the Camp Blanding population is an artificial (planted) population. The Recovery Plan deemed it "unlikely" that this population was planted, but this would provide a further test. (USFWS, 2019a)
- The contribution of sexual reproduction to population maintenance is assessed via research related to in-situ soil seed bank, seed viability, and seedling recruitment (in-situ seed

germination, seedling survival and growth). (USFWS, 2019a)
- Assess the R. m. chapmanii demographic responses (e.g., recruitment, reproduction, and mortality) to hurricane disturbance. (USFWS, 2019a)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIVITIES • Foster a working relationship to establish protection and management agreements with private landowner AgReserve, Inc. • Hosford population: A comprehensive survey is needed to assess the status of the plants and corresponded habitat. This recommendation is a priority. • Conduct surveys/inventories/demographic studies on each known population every five years. Note: Atlanta Botanical Garden initiated a detailed demographic study of Chapman's rhododendron in 2021 at St. Joseph State Buffer Preserve (CP #F20AC10631). • Reintroduce plants within the historic range, specifically in the sites where the plants have been extirpated, or in potential suitable habitat suggested by the species distribution modeling developed by FNAI (2022). • Acquisition of land parcels adjacent to the St. Joseph State Buffer Preserve, Gulf County that has Chapman's rhododendron and a suite of other rare species (USFWS, 2024).

# SPECIES ACCOUNT: *Rhus michauxii* (Michaux's sumac)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015) 9/28/1989

**Physical Description**

A low-growing, densely hairy, dioecious shrub, mostly 0.3 to 0.6 m tall. Leaves are pinnately compound with 7-13 leaflets that are coarsely toothed. Female plants produce erect clusters of greenish-yellow to white 4-5 parted flowers and conspicuous red drupes. Flowers from April to June. Fruits persist from August through September or October (NatureServe, 2015).

**Taxonomy**

Andre Michaux discovered this species on July 20, 1794 in Mecklenburg County, NC (the area is now part of Union County). He named the species Rhus pumila in 1803; however, since the specific epithet pumila had already been used for another species, Sargent assigned the name R. michauxii in 1895 (Barden and Matthews 2004). There have been no changes to the taxonomic classification or nomenclature since Rhus michauxii was listed as endangered in 1989 (USFWS, 2014).

**Historical Range**

Historically endemic to the Inner Coastal Plain and lower Piedmont of North Carolina, South Carolina, and Georgia (USFWS 1989). HISTORIC RANGE: From the time of its discovery in 1895 until 1989, half of the known occurrences of Rhus michauxii have been extirpated (USFWS 1989). Thirty-two occurrences were historically reported from 23 counties in NC, SC, and GA (USFWS 1989). Four occurrences historically known from Cobb, Columbia, Newton, and Rabun counties, GA, are believed extirpated (Murdock and Moore 1991, Patrick 1993). Historical collections are known from Florence, Kershaw, and Oconee counties, SC. Following extensive, unsuccessful searches of their last known locations, as well as other areas of suitable habitat, Michaux's sumac is believed extirpated from the state (USFWS 1989, Murdock and Moore 1991). Historical and/or extirpated NC records exist (year last seen in parentheses) for Durham (1949), Franklin (1914), Hoke (1981), Johnston (1833), Lincoln (prior to 1917), Mecklenburg (pre-1800s), Moore (1901), Orange (1964), Robeson (1982), Wake (1942), and Wilson (1958) counties (Murdock and Moore 1991, NCNHP 1993). Considered extirpated from Florida, where the original collection was made in 1961 in Alachua County (Murdock and Moore 1991). Apparently by 1989 the collection site had been developed and was occupied by at least one residential home. Kathy Burkes of FNAI notes: "Whether the plants seen in 1961 were waifs carried far afield from the Piedmont by humans or other animals in "recent" times, or were true relicts of a former wide distribution reaching south into Florida is another question. We may never know for sure about that." (NatureServe, 2015).

**Current Range**

When the recovery plan was completed in 1993, R. michauxii was believed extant at 21 sites in NC and GA. No populations were known from VA at that time. R. michauxii was believed to be extinct at 20 sites in the coastal plain and piedmont of NC, South Carolina (SC), GA and Florida (FL). Since listing, additional occurrences have been found in GA, NC and VA. As of 2014, there are 43 parent populations, rangewide. The GANHP database currently lists four extant occurrences of R. michauxii and two additional subpopulations are considered historical or extirpated. NCNHP records currently indicate a total of 33 extant populations. An additional 13 sites in NC are now considered historical, extirpated or failed to find. The VANHP database indicates that there are six occurrences extant within the state with no known historical or extirpated populations. This information is summarized in Table 1 and additional information about each element occurrence (EO) is included in Appendix C. Following current NatureServe methodology, some of these sites are now considered sub-populations or sub-sets of larger populations or principal EOs. See Table 1 for an additional explanation of this methodology. Several populations of R. michauxii are now considered historical or extinct, including all previously known sites in FL and SC. Rhus michauxii was collected in Alachua County, FL in 1961. Attempts to relocate this population in 2006 (and prior to 2006) were unsuccessful (Herring 2006). Three sites known from SC (one site each in Florence, Kershaw and Oconee counties) were considered extirpated before the species was federally listed as endangered in 1989. (USFWS, 2021)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Asexual: vegetative (USFWS, 2014)

**Reproduction Narrative**

Adult: Most of the surviving populations appear to contain plants of only one sex and therefore reproduce only vegetatively, if at all. Due to the rhizomatous nature of the species, this may mean that the single-sex populations are clones of one or a few individuals; two populations sampled for genetic diversity by Sherman-Broyles et al. (1992) appeared to each consist of a single clone (USFWS, 1993). Single sex populations that are clonal in nature prohibit sexual reproduction and seed production in this species. In populations where seeds are produced, it appears that seed germination is very low (USFWS, 2014). Although specific pollinators are unknown, Michaux's sumac, like other species in the genus, is probably pollinated by insects. Sherman-Broyles et al. (1992) observed that bees visited the flowers of other sumac species and that birds dispersed the fruits (USFWS, 1993).

**Habitat Type**

Adult: Open Woodland (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Michaux's sumac occurs in sandy or rocky open woods, sometimes in association with circumneutral soils (USFWS 1990). In the fall line sandhills region it occurs in submesic loamy swales. In the eastern Piedmont, it occurs on sand soils derived from granite. In the central Piedmont, it occurs on clayey soils derived from mafic rocks (Weakley 2004). In all of its habitats, Rhus michauxii is dependent upon some form of disturbance to maintain the open quality of its habitat (USFWS 1989). Periodic, naturally occurring fires provided such disturbance historically. Today, however, many of the Michaux's sumac occurrences are in areas that are artificially disturbed, such as highway and railroad rights-of-way, pine plantations, edges of cultivated fields, and other cleared lands (USFWS 1989, TNC 1991-93, NCNHP 1993, Center for Plant Conservation 2002). Although roadside occurrences appear to be thriving in the presence of some level of disturbance (i.e., mowing), they are always under the constant threat of catastrophic disturbance. Roadbed widening or heavy equipment activity on cleared lands, for example, may dramatically reduce the number of individuals. These reductions, if they come at a crucial stage in the species' reproductive cycle (i.e., during flower or fruit production), could have severe long-term effects on the population. Although it appears that Michaux's sumac can rebound from large disturbances, it is not clear how much genetic diversity is lost with each disturbance. In the North Carolina Sandhills region, naturally occurring Rhus michauxii appears to be restricted to slightly loamy, but still well- drained, sites which are scattered through longleaf pine/scrub oak/wiregrass woodlands. Loamy soil sites are usually found in slight depressions, swales, or along lower slopes and are quickly recognized by their high diversity of herbs, especially with regard to their high number of legume, composite and grass species (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance range are inferred based on specific habitat needs and low number of populations.

***Dispersal/Migration***

**Motility/Mobility**

Adult: Birds? (USFWS, 1993)

**Dispersal/Migration Narrative**

Adult: Sherman-Broyles et al. (1992) observed that bees visited the flowers of other sumac species and that birds dispersed the fruits (USFWS, 1993).

***Population Information and Trends***

**Population Trends:**

Short-term Trend: Decline of <30% to relatively stable. Long-term Trend: Decline of 30-50% (NatureServe, 2015)

**Number of Populations:**

38 (USFWS, 2021)

**Population Narrative:**

Currently, state natural heritage programs recognize 38 extant natural populations (31 in North Carolina, one in Georgia and six in Virginia), plus four additional introduced populations in Georgia and one in North Carolina. Of these populations, 18 are ranked A or B by their respective natural heritage programs. According to natural heritage program records, the ranks of eight populations (13 occurrences) have improved and 34 populations (51 occurrences) have remained stable. The ranks of 11 populations (20 occurrences) have declined since the 2014 5-Year Review indicating that those occurrences have fewer stems than previously observed, or possibly even disappeared. (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Fire suppression (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** This species is threatened by fire suppression and the ecological succession (competition and/or shading by woody species) that occurs in areas that are not burned on a regular basis (USFWS, 2014).

**Stressor:** Low reproductive capacity (NatureServe, 2015)
**Exposure:**
**Response:**
**Consequence:** Population degradation
**Narrative:** Low reproductive capacity resulting from the geographic isolation of small single-sex populations is a threat to this species (USFWS 1990) (NatureServe, 2015).

**Stressor:** Logging (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat/Loss of plants
**Narrative:** Forested populations are threatened by timber operations. Logging activities can crush plants and 9 or compact the soil where they grow (USFWS, 2014).

**Stressor:** Herbicides (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:** Loss of plants
**Narrative:** Sites located within utility rights-of way are threatened by herbicide use, mowing during critical growth periods, and ground disturbing activities (USFWS, 2014).

**Stressor:** Development (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Habitat destruction, the result of development or land conversion, also threatens this species (Boyer 1996) (USFWS, 2014).

**Stressor:** Climate change (USFWS, 2014)

**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The effects of climate change on this species are unknown at this time. However, since this species occurs on dry soils in fire maintained habitat, it seems reasonable to believe that it will not be negatively affected by the predicted increase in droughts and wildfires (USFWS, 2014).

***Recovery***

**Delisting Criteria:**
1. It has been documented that at least 19 self-sustaining populations exist and that necessary management actions have been undertaken by the landowners or cooperating agencies to ensure their continued survival (USFWS, 1993).

2. All of the above populations and their habitat are protected from present and foreseeable human-related and natural threats that may interfere with the survival of any of the populations (USFWS, 1993).

**Recovery Actions:**
- Revisit known populations that have not been visited in the past three years; monitor the habitat condition of each site including threats and fire regime; monitor population size and evidence of reproduction (sexual, asexual and seed viability); discuss conservation options with landowners where appropriate; update Natural Heritage Program files with this information (USFWS, 2014).
- Search for additional populations throughout the range of the species (USFWS, 2014).
- Prioritize known sites for protection (USFWS, 2014).
- Protect additional populations through fee simple acquisition, conservation easements, etc. (USFWS, 2014).
- Develop management plans including the use of prescribed fire for all protected populations (USFWS, 2014).
- Develop standardized monitoring protocols, initiate long-term population monitoring and determine the criteria for sustaining populations (USFWS, 2014).
- Reinstate monitoring that was initiated in the early 1990s by Boyer (1996) (USFWS, 2014).
- Conduct research on general biology of the species including life history and reproductive biology (breeding systems, seed production and seedling survivorship) (USFWS, 2014).
- Compare, genetically, the populations of questionable taxonomy in VA with those known from NC and GA (especially populations suspected of hybridizing with other species of Rhus) (USFWS, 2014).
- Work with NC Botanical Garden to conserve seeds and germplasm, and develop propagation protocols (USFWS, 2014).
- Consider augmenting populations to increase genetic variation (USFWS, 2014).

***Conservation Measures and Best Management Practices:***
- RECOMMENDATIONS FOR FUTURE ACTIONS The recommended actions listed in the 2014 5-Year Review remain important to the conservation and recovery of Rhus michauxii and efforts to accomplish those actions should continue. Since the 2014 5-Year Review, progress has been made on several recommendations for future actions. • Surveys have resulted in the discovery of four new

populations and one new subpopulation of Rhus michauxii. • The Georgia Plant Conservation Alliance has augmented Rhus michauxii populations with plants of the opposite sex and created three new safeguarding populations with male and female plants from different locations. Rhus michauxii has been reintroduced to a previously known site in North Carolina. • Research has been conducted on the pollination ecology of Rhus michauxii. • A genetics study looking at purported hybrids of Rhus michauxii is ongoing at Virginia Tech Conservation Management Institute. • The NCBG, SBG and ABG conserve seeds and maintain live Rhus michauxii plants in their collections for research, reintroductions and education. • The Service has encouraged land managers to develop and implement management plans by providing a template management plan to managers. The Service recommends initiating or continuing the following efforts that will contribute to the recovery of the species: • Consider updating/amending the recovery plan to include quantifiable downlisting criteria. • Revisit known populations that have not been visited in recent years. • Monitor the habitat condition of each site including threats and fire regime. • Monitor population size and evidence of reproduction (sexual, asexual and seed viability). • Discuss conservation options with landowners, where appropriate. • Provide updates about each population visited to natural heritage programs. • Search for additional populations throughout the range of the species. • Prioritize unprotected sites for protection. • Protect additional populations through fee simple acquisition, conservation easements, etc. • Encourage the development of updated management plans, including the use of prescribed fire, for all protected populations. • Develop standardized monitoring protocols, initiate long-term population monitoring and determine the criteria for self-sustaining populations. • Conduct research on general biology of the species including life history and reproductive biology (breeding systems, seed production and seedling survivorship). • Identify which populations contain hybrids and determine if they pose harm to the species and/or need special management considerations. • Work with the North Carolina Botanical Garden to conserve seeds and germplasm, and develop propagation and out-planting protocols. • Develop a plan to augment single-sex populations in order to increase genetic variation. (USFWS, 2021)

# SPECIES ACCOUNT: *Rorippa gambellii* (Gambel's watercress)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A perennial rhizomatous (with creeping underground stems) branched herb that can grow up to 2 meters (6 feet) tall (this height is confirmed by John Chesnut [in litt. 1998] at Oso Flaco Lake). It roots at lower stem nodes, while the upper stem generally remains erect (Figure 2, Photo 2). It blooms from April to July, producing dense inflorescences (flower clusters) with white flowers; the lateral inflorescences may bloom through August. The inflorescences produce 15 to 30 fruits with about 10 to 30 seeds each (Price 1989). The plant has pinnate (feather-shaped) leaves with 7 to 13 uniform leaflets, which are angular and dentate (toothed) in the upper leaves. Small lobes are present at the base of the leaf stalk. Lower flower stalks often have bracts (specialized leaves), and pedicel (flower stalk) junctions with the main stem are flat. These characters separate this taxon from a look-alike, watercress (Rorippa nasturtium-aquaticum), whose three to seven lateral leaflets are entire or wavy-margined and smaller than the terminal leaflet; the leaflets are more lobed than angular in the upper leaves. The smaller flowers of Rorippa nasturtium aquaticum are supported by pedicels without bracts or flat stem junctions. Moreover, the linear and narrower fruits of Rorippa gambelii have more finely reticulate (net-patterned) seeds, which are arranged in one row per chamber, versus two rows per chamber in Rorippa nasturtium-aquaticum. (USFWS, 1998)

**Taxonomy**

Nasturtium gambelii was originally described as Cardamine gambellii in 1876 based on a specimen collected by William Gambel in 1844 in the vicinity of Santa Barbara (Watson 1876). Nasturtium gambelii, the currently recognized name, was originally listed by the Service as endangered under the name Rorippa gambellii (Service 1993). While the circumscription of the species (the limits of the species characters and range) has remained constant since its original description, it has been recognized under several different names (some of the names have similar spelling, but because they were recorded with slightly different names they are listed separately), including Cardamine gambellii (Watson 1876, Abrams 1944), Cardamine gambelii (Jepson 1923; Munz 1959, 1968, 1970, 1974; Hoover 1970; Roberts 1989), Rorippa gambelii (Smith 1976, 1998; Roberts 1998; Service 1998, CNPS 2001), Rorippa gambellii (Al-Shehbaz and Rollins 1988, Rollins 1993, Service 1993, Skinner and Pavlik 1994), Nasturtium gambellii (Al-Shehbaz and Price 1998), and Nasturtium gambelii (Index of California Plant Names 2009). (USFWS, 2011)

**Historical Range**

Historically, Nasturtium gambelii occurred in cismontane regions (on the coastward side of the mountains) of central and southern California, in Orange, San Bernardino, Los Angeles, Santa Barbara, and San Luis Obispo Counties, California. (USFWS, 2011)

**Current Range**

Pure Nasturtium gambelii plants are currently known from one remaining wild population on Vandenberg Air Force Base in Santa Barbara County, California (Keil 1997, CNDDB 2010), and one additional site where plants were introduced in October 2008 on the Refuge in San Luis

Obispo County, California. (USFWS, 2011)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Self-pollinating (NatureServe, 2015)

**Reproduction Narrative**

Adult: Pollinator exclusion experiments have been conducted on this species in the field (Mazer et al. 1994) and demonstrated seed set in bagged specimens. No pollinators were ever seen in 2 seasons of fieldwork. Soil cores taken from the sites where Rorippa are still extant show a viable seed bank in the soil throughout the spring and summer growing season. These seeds germinated under greenhouse conditions. Detailed mortality and longevity data are not yet available for these dormant seeds. The average lifetime fruit and seed production for the Black Lake Canyon population of Rorippa has been estimated at 85.8 fruits and 882 seeds.; Rorippa gambelii requires permanent fresh or brackish wetland areas. It is intolerant of competition and seems to require clearings to survive. Encroaching eucalyptus trees are competing for water and light, and alleopathic effects from the trees may also be harming the Rorippa population. No known diseases or pests attack Rorippa. The very limited distribution of this species and changes in local hydrology are threatening it with extinction.; Predominantly selfing (NatureServe, 2015).

**Habitat Type**

Adult: Wetlands (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits permanent wetlands, fresh or brackish, in marshes or along the borders of lakes and slow-flowing streams or ditches. Soils are acidic sandy peats. Sea level to 450 m elevation. (NatureServe, 2015). High eclogical integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the limited number of populations and the specific haibtat requirements of this species.

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seed dispersal needs further research (USFWS, 1998)

***Population Information and Trends***

**Population Trends:**

Decreasing (NatureServe, 2015)

**Number of Populations:**

1 (USFWS, 2022)

**Population Narrative:**

There is currently only one extant, non-hybridized Gambel's watercress population at VSFB, consisting of two separate colonies that occupy a total of 0.024 hectare/0.06 acre (Lum 2021, pers comm). Abundance is unknown due to difficulty of discerning genetically unique individuals above-ground. Currently, we do not have any proposed outplanting projects for the species. (USFWS, 2022) . In 2020, the Service funded a project designed to evaluate the hybridization potential of Gambel's watercress and learn more about its reproductive biology and breeding strategy in an ex situ, greenhouse setting. Santa Barbara Botanic Garden (SBBG) staff made three bulk Gambel's watercress seed collections from the two extant patches at VSFB to start this work in August of 2021. They collected a total of 3,371 seeds from the eastern patch and 1,888 seeds from the western patch. SBBG will bank any seeds not used in direct support of the project (Schneider 2021, pers comm). These banked seeds are of use for additional seed bulking efforts, outplanting recovery projects, and can serve as backup in the event of catastrophic loss of the species. (USFWS, 2022)

***Threats and Stressors***

**Stressor:** Development/Urbanization (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Since the time of listing, there has been a loss and degradation of habitat due to development and urbanization and a conversion of marsh habitat due to the collateral, but indirect, effects from development and urbanization. Some of this habitat loss has occurred in watersheds that are classified as impaired by the Regional Water Quality Control Board due to excessive amounts of nitrogen and other nutrients (California State Water Resources Control Board 2006a). The vegetation in these watersheds exhibits excessive growth that is consistent with biostimulation and eutrophication (California State Water Resources Control Board 2006a, California State Water Resources Control Board 2006b, Central Coast Ambient Monitoring Program 2002, Dodds et. al. 1998). The excessive growth of some vegetation (e.g., willows, bulrush, Typha (cattails)) causes type conversion of habitat (such as at Black Lake Canyon and Oso Flaco Lake) and a decline in the quantity and quality of habitat suitable for Nasturtium gambelii. Most of the historical populations and their surrounding areas are urbanized and/or indirectly impacted by urbanization, which has further limited this species' ability to colonize adjacent suitable habitat. These conditions also limit sites and opportunities for successful

introductions and reintroductions. (USFWS, 2011).

**Stressor:** Predation (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Herbivory has been noted on plants at the introduced site on the Refuge (M.A. Elvin, pers. obs. 2009) and on plants under propagation at University of California, Irvine (UCI) Arboretum (Barry Nerhus, U.C. Irvine, pers. comm. 2006). While this plant may be able to withstand some herbivory, the herbivory may cause a reduction in its reproductive success due to the loss of flowers and the corresponding reduction in the production of seeds. The extent of this threat is not known, but the loss of even a few flowers due to herbivory, if it led to an even slight decrease in reproductive success, may have a significant effect on the long-term survival of N. gambelii because there are so few individuals remaining in the wild. Therefore, the relative threat from predation is greater now than was thought to be the case at the time of listing, because there are fewer populations and fewer individuals per population than at the time of listing (USFWS, 2011).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** From the time of listing until recently, existing regulatory mechanisms appear to have done little to ameliorate threats to Nasturtium gambelii, and substantial threats remain; however, recent efforts to improve protections may provide additional benefit to the species in the future. Other Federal and State regulatory mechanisms (e.g., CEQA, California Coastal Act) provide discretionary protections for the species based on current project review and permitting practices (USFWS, 2011).

**Stressor:** Small population size (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Extinction/lack of genetic diversity
**Narrative:** The conservation biology literature commonly notes the vulnerability of taxa known from very few locations or from small and highly variable populations (e.g., Shaffer 1981, 1987; Primack 2006; Groom et al. 2006). The small size of the gene pool of the species (Mazer et al. 2000) may depress reproductive vigor, or increase the likelihood that a single human-caused or natural environmental disturbance (e.g., flood, drought, disease) could cause the extinction of Nasturtium gambelii. Small populations are threatened by inbreeding depression (Ellstrand and Elam 1993). Small plant populations can have significantly lower germination rates than larger populations of the same species due to high levels of homozygosity (having identical pairs of alleles for any given gene), which could result in the expression of disadvantageous traits (Menges 1991). Genetic stochasticity results from changes in gene frequencies due to founder effect, random fixation, or inbreeding (Shaffer 1981). The low levels of genetic variation among and within populations could impair the species' ability to adapt to changes in the environment or contribute to inbreeding depression (i.e., loss of reproductive fitness or vigor). The existence of less than five populations and the small number of individuals in these populations places Nasturtium gambelii at extreme risk of extinction due to low levels of genetic diversity (USFWS,

2011).

**Stressor:** Other natural or manmade factors (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat/extinction
**Narrative:** Natural catastrophes such as fire, landslide, or prolonged drought could result in the loss of populations (Shaffer 1981), particularly for species with fewer than five populations. An increase in urban development has reduced the range of Nasturtium gambelii considerably. Indirect effects from urbanization in the watershed include changes in hydrology, changes in vegetation, and an increase in nonnative species. Increasing development in the area will likely increase threats from stochastic events. We believe that the existence of one known wild population and the small number of individuals in the population exacerbate the risk of extinction to Nasturtium gambelii from stochastic events.

**Stressor:** Competition with nonnative species (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The effects of competition with nonnative species are most problematic immediately adjacent to urban areas and in habitat that has been isolated or fragmented by development (Alberts et al. 1993). These factors may not be enough to threaten the survival of Nasturtium gambelii independently, but taking into account its limited range, the cumulative and synergistic effects of all of these factors combined could be a threat to the survival and recovery of N. gambelii (USFWS, 2011).

**Stressor:** Nutrient loading in watersheds (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Threats identified since the time of listing include excessive amounts of nitrogen and other nutrients in watersheds that either currently support or historically supported Nasturtium gambelii. These nutrient levels can cause excessive growth of vegetation (biostimulation) in some species that may out-compete N. gambelii plants. The excessive growth of other vegetation (both native and nonnative) can have direct effects on N. gambelii individuals. The other plants can outcompete N. gambelii individuals for essential physical and biological elements (i.e., space for growth, food, water, light, minerals). This stress likely effects the survival of some individual plants or occurrences and increases the impact of threats to the species from stochastic events (USFWS, 2011).

**Stressor:** Climate change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Park et al. (1989) projected that of the saltmarshes along the coast of the contiguous United States, 30 percent would be lost with a 1.6-foot (0.5-m) SLR, 46 percent with a 3.3-foot (1-m) SLR, 52 percent with a 6.6-foot (2-m) SLR, and 65 percent with a 9.8-foot (3-m) SLR. While we cannot project directly to California from the estimates of Park et al. (1989) who focused on the

east coast and Gulf coast of the United States, we can anticipate that with a projected SLR of up to almost 6.6 feet (2 m) that much of the coastal saltmarshes in California would be lost by 2100. Beaches, dunes, and coastal areas would be subject to greater and more frequent wave attack, with a general rule of thumb that 50 to 100 feet (15 to 30 m) of beach width will be lost from use for every foot of sea level rise by the year 2100 (CCC 2001, Heberger et al. 2009). This is estimated to result in erosion and shoreline retreat between 459 and 1 ,083 feet (140 and 330 m), corresponding to an estimated loss of approximately 1.4 square miles (896 acres) of dunes in San Luis Obispo County by the year 2100 (CCC 2001, Heberger et al. 2009). Because Nasturtium gambelii historically occurred in coastal dune habitats throughout its range, erosion of these areas caused by an estimated rise in sea level could cause a loss of individual plants and seed banks for this species (USFWS, 2011).

**Stressor:** Genetic swamping (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:** Lack of genetic variability
**Narrative:** The N. gambelii plants at Oso Flaco Lake appear to be genetically compromised and introgressed with the locally abundant nonnative species N. officinale based on morphological and molecular evidence of hybridization (Mazer et al. 2000; Prince 2008a, 2008b; CNDDB 2009, 2010; CNPS 2009). The N. gambelii population (at VAFB) has at least two individuals that may be of hybrid origin with N. officinale (Prince 2008a, 2008b). The introgression of N. gambelii plants at Oso Flaco Lake and the potential introgression of two N. gambelii plants at VAFB (Mazer et al. 2000; Prince 2008a, 2008b; CNDDB 2009, 2010; CNPS 2009) suggest the species is in danger of extinction.

***Recovery***

**Reclassification Criteria:**
1. When new plants are established so that there are at least 5 populations of at least 500 individuals each (USFWS, 1998)

2. When some of the populations occur in permanently protected habitats within the Black Lake Canyon and the dune lakes area  (USFWS, 1998)

3. When some of the populations are in other areas of suitable habitat with the species' historical range in the United States (USFWS, 1998)

4. When the populations remain viable for at least 5 years. Viable populations are defined as those that are showing natural reproduction and either stable or increasing in size over time, without artificial augmentation(USFWS, 1998)

**Delisting Criteria:**
1. If threats are reduced or eliminated so that protected populations are capable of persisting without significant human intervention or perpetual endowments are secured for management necessary to maintain the continued existence of the species. The most outstanding management needs currently are: a) controlling competition with nonnative species and hybridization with common watercress, and b) managing water conditions, particularly flow and nutrient loads, that the species depends on. (USFWS, 2019)

2. If populations are established across the species ecological settings (in addition to Black Lake Canyon and the Dune Lakes area in San Luis Obispo County), including suitable site(s) in the Santa Barbara County and Ventura County region (e.g.; the San Antonio Creek drainage on Vandenberg Air Force Base or comparable sites); and coastal wetlands in Los Angeles, Orange, or San Bernardino Counties (USFWS, 2019)

3. If the populations remain viable for at least 10 years. Because this species has narrow microhabitat conditions that it will tolerate, particularly with respect to water flow and nutrient loads, and in light of fluctuations that can occur with climatic conditions and local water availability and nutrient loading, the persistence of populations with these varying conditions over time needs to be confirmed. (USFWS, 2019)

**Recovery Actions:**

- 1. Protect, maintain, and enhance species habitats. The most important immediate objective in the recovery plan for and Rorippa gambelii is the protection of its habitat. - Coordinate among agencies involved in recovery activities. - Define and maintain the sensitive Resource Area boundary and restrictions at Black Lake Canyon. - . Establish protection agreements. - Acquire key land parcels and conservation easements. Enhance existing habitat at Black Lake Canyon. - Continue to protect, maintain, and enhance habitat in the Dune Lakes area. - . Communicate species and habitat protection information to all concerned parties. (USFWS, 1998)
- 2. Document and monitor population and habitat characteristics. - Conduct plant surveys. - Protect newly discovered populations. - Monitor all populations and habitats. (USFWS, 1998)
- 3. Conduct research on the ecology and biology of the species. - Identify potential impacts of conducting research. - Determine population characteristics and life history of the species. - valuate species' tolerances. - Investigate the effects of genetic diversity. (USFWS, 1998)
- 4. Augment existing populations. In addition to protecting existing and newly discovered habitats of Rorippa gambelii, monitoring these populations and their habitats, and conducting research on the biology and ecology of the species, attempts should be made to augment existing populations. (USFWS, 1998)
- 5. Establish new populations. Because Rorippa gambelii currently has very restricted distribution in California, establishment of new populations within the historic range of the species at potentially suitable sites other than at historic sites should be attempted. If new populations are successfully established, it will reduce the likelihood that a catastrophic event could result in the extinction of the species with its current restricted distribution. (USFWS, 1998)
- 6. Evaluate Progress and Update Management and Recovery Guidelines. Results of all recovery activities should be evaluated and incorporated into updated management and recovery guidelines for the species. All relevant information should be distributed. (USFWS, 1998)
- Work with the U.S. Air Force at Vandenberg Air Force Base to implement site-specific management activities in the immediate future to avoid and alleviate threats (such as from stochastic events) to prevent the loss of the last, known remaining wild population (USFWS, 2011).

- Work with others to establish new populations in the near future to reduce the risk of extinction to Nasturtium gambelii in each of the two ecological regions of its historical range in California (coastal central California and coastal southern California) (USFWS, 2011).
- Work with others to establish and maintain ex situ stock populations with at least one institution in each of the three ecological regions of its historical ranges (USFWS, 2011).
- Work with the Central Coast Regional Water Quality Control Board to determine nutrient levels in the watersheds which historically supported Nasturtium gambelii in the recent past (particularly Black Lake Canyon and Oso Flaco Lake) to determine what may have led to the loss of N. gambelii form these sites, and work with local landowners and stakeholders to alleviate (and remove) any threats to N. gambelii that are associated with water quality (USFWS, 2011).
- Continue genetic analyses to determine the extent of variation within and between Nasturtium gambelii populations and the magnitude of the threat of gene swamping from N. officinale to help determine an appropriate recovery and reintroduction strategy (USFWS, 2011).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Conduct annual monitoring of both the VSFB and Oso Flaco Lake Gambel's watercress populations. Include counting and reporting the number of above ground vertical stems and global positioning system (GPS) mapping of occupied spatial area, co-occurring and co-dominant vegetation, presence of natives versus nonnative species, percent canopy cover, hydrological conditions, timing of phenology, and presence of potential insect pollinators. Consistent data collection and reporting will allow for meaningful comparisons and analyses of trends. 2. Implement threats management activities at each population, including vegetation management such as trimming and removal, invasive weed abatement, and sediment removal and erosion controls. 3. Document the presence and extent of common watercress within the San Antonio Creek and Osos Flaco Lake watersheds. Improve assessment of morphological traits of pure versus hybrid Gambel's watercress to better facilitate rapid visual assessments of introgression in the field. Conduct control and eradication of common watercress where appropriate. 4. Develop an effective rapid method for sequencing and genotyping to characterize Gambel's watercress genetic population structure and accurately evaluate abundance. 5. Determine if the seed bank harbors additional Gambel's watercress genetic diversity. If so, introduction/reintroduction projects may utilize such grown out plants and potentially restore lost genetic integrity to the species. 6. Determine how vegetative succession and other hydrological changes associated with eutrophication and biostimulation are affecting the species and employ remedial measures to restore occupied habitats to optimal conditions for recovery. 7. Research the species reproductive biology to evaluate and quantify hybridization with common watercress, including self-compatibility, breeding system, seed viability, and morphology of pure and hybrid lineages. Work to better understand the species pollinators, fruiting and seed production, and optimal ecological factors that favor Gambel's watercress growth and population expansion. 8. Conduct genetic studies and other controlled experiments to evaluate the hypothesis that hybrid individuals have reduced viability and that when we remove common watercress, selective forces may act over successive generations to return genotypes back to pure Gambel's watercress forms. (USFWS, 2022)

# SPECIES ACCOUNT: *Sarracenia rubra ssp. alabamensis* (Alabama canebrake pitcher-plant)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015) 3/10/1989

**Physical Description**

An insectivorous perennial herb with light green, red-veined leaves that form erect, vase-like structures, 1-5 dm tall (in late summer, these are enlarged and turn yellow-green). Flowers are 5-merous, with maroon petals that are constricted medially, to 2.5 cm in width and 3.6 cm in length; pendent, borne singly on an erect, leafless scape to 60 cm in height. Flowering season: late April to early June (NatureServe, 2015).

**Taxonomy**

There is taxonomic uncertainty within the genus Sarracenia as a whole but the Services and others recognize the taxon as a subspecies within the "rubra complex" (i.e., Sarracenia rubra ssp. alabamensis) (USFWS, 2018).

**Historical Range**

The Alabama canebrake pitcher plant is a carnivorous plant that is endemic to central Alabama, with all known populations, extant and extirpated, found in the Fall Line Hills ecoregion (USFWS, 2019). Species historically occurred in Autauga, Chilton, and Elmore Counties, Alabama. In Autauga County one population has since been extirpated (Byrd 2016) and the remaining five now represent three populations, with two populations continuing as distinct populations and three of the former populations now representing three sub-populations comprising one population. No extant populations are known to occur in Elmore County (USFWS, 2018).

**Current Range**

There are currently seven natural, extant populations of Alabama canebrake pitcher plant known (Autauga County – 3; Chilton County – 4) (USFWS, 2018). All are found in the Fall Line Hills ecoregion (see Griffith et al. 2001 for ecoregion description). Furthermore, within this ecoregion, most of the species' populations are known from the Upper Alabama subbasin (8-digit hydrologic unit code: 03150201) while the remaining populations are known from the Lower Coosa subbasin (03150107) (USFWS, 2019).

**Critical Habitat Designated**

Yes;

***Life History***

**Food/Nutrient Resources**

**Food/Nutrient Narrative**

Adult: This is a carnivorous plant, although it is unclear what benefit it receives from its carnivory (USFWS, 1992). Studies found that Alabama canebrake pitcher plants captured comparatively more flying insects than crawling insects, likely due to the species' relatively tall stature (USFWS, 2018).

**Reproductive Strategy**

Adult: Vegetatively

**Lifespan**

Adult: Perennial herb, 60+ years (USFWS, 2012)

**Dependency on Other Individuals or Species**

Adult: Likely pollinators for this species are small bumblees (USFWS, 2018).

**Reproduction Narrative**

Adult: Seedling recruitment was reported to be absent from the majority of populations (Brewer and Chesser 2009), further inhibiting recovery efforts, as well as long-term viability and evolutionary potential. Because the species can reproduce vegetatively, seedling recruitment may not be paramount at sites experiencing light to moderate levels of fire exclusion; however, vegetative reproduction may not compensate for mortality or the lack of sexual reproduction at some sites (Brewer and Chesser 2009) (USFWS, 2012). Likely pollinators are small bumblebees (Bombus spp.) which have a flight distance of 1 mile; at distances greater than 1 mile, pollen flow (and consequent gene flow) is restricted by the inability of pollinators to traverse this distance (USFWS, 2018).

**Habitat Type**

Adult: Hillside seepage bogs and in bottomland or streamside vegetation(USFWS, 2012)

**Environmental Specificity**

Adult: Narrow. Specialist or community with key requirements common. (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Sarracenia rubra ssp. alabamensis inhabits two distinct habitat types that share similar floristic composition. The majority of sites are characterized as hillside seepage bogs, permanently saturated areas that attain their greatest development where an impervious layer of clay lies in close proximity to the ground surface. Precipitation, once reaching this clay zone, becomes restricted and is gradually propelled along a sloping gradient until surfacing further downslope. The other habitat type occurs in association with bottomland or streamside vegetation. Unlike the foregoing habitat, moisture conditions are generally maintained with greater connection to topography and precipitation amounts (USFWS, 2012). All extant populations of S. rubra ssp. alabamensis occur in close association with the following combination of arborescent and herbaceous species (which therefore serve as the best indicators of suitable habitat): Osmunda cinnamomea (cinnamon fern), Rhynchospora chalarocephala (loosehead beak sedge), Dichanthelium scoparium (velvet panicgrass), Xyris torta (twisted yellow-eyed grass), Eriocaulon decangulare (tenangle pipewort), Arundinaria gigantea (giant cane), Cleistes bifaria (small spreading pogonia), Calopogon tuberosus (tuberous grass pink), Platanthera ciliaris (yellow-fringed orchid), Viola primulifolia (white violet), Rhexia nashii (maid Marian), Eryngium integrifolium (blue coyotethistle), Asclepias rubra (red milkweed), Magnolia virginiana (sweetbay magnolia), Solidago rugosa (wrinkle-leaf goldenrod), Eupatorium fistulosum (joe pye weed), Fuirena squarrosa (hairy umbrella-sedge), and Sphagnum spp. Bottomland and streamside populations generally contain a greater proportion of woody species and A. gigantea (U.S. Fish and Wildlife Service 1992, Garrett 2004, Schotz 2006) (USFWS, 2012). It is most vigorous in open bogs and declines when the habitat becomes overgrown with woody vegetation (NatureServe, 2015).

***Dispersal/Migration***

**Dispersal**

Adult: Seed dispersal is poorly understood but studies with similar pitcher plants indicate seed dispersal distances from parent plants at typically a few inches and water or birds may facilitate dispersal over longer distances, but this remains unstudied for Alabama canebrake pitcher plant (USFWS, 2018).

**Dispersal/Migration Narrative**

Adult: Brewer and Chesser (2009) at the University of Mississippi recently completed a study correlating seedling recruitment and population dynamics in relation to site differences. They found that seedling recruitment was greater on sites with higher soil moisture content as opposed to drier sites. This correlation held true even when comparing unmanaged wet sites to managed dry sites (USFWS, 2012).

***Population Information and Trends***

**Population Trends:**

Stable (USFWS, 2018)

**Species Trends:**

Stable (USFWS, 2018)

**Number of Populations:**

8 (USFWS, 2023)

**Population Narrative:**

Given proper habitat conditions, this species has demonstrated high fecundity - able to grow quickly and reproduce. According to anecdotal information furnished by wildflower enthusiasts, some sites historically contained thousands of plants. Was likely stable when fires were allowed to burn freely and naturally across the landscape, covering thousands of acres. Only recently, within the past 60 years, has public sentiment changed in opposition to free-ranging fires, due to the impact such fires have on timber production, agriculture, and development. Consequently, a broad range of fire maintained species, including Sarracenia rubra ssp. alabamensis, have become critically imperiled (NatureServe, 2015). Short-term trends indicate that species has remained stable, despite the recent loss of one small population and apparent local population declines at some sites which are likely offset by population increases at the largest sites. Currently, there are seven natural, extant populations of this species (3 in Autauga

County and 4 in Chilton County) where a population is considered distinct if separated by at least 1 mile from nearest known neighbors; no new populations have been discovered since 2012. Currently, individual subpopulations range in size from 3 or 4 plants to well over 200 and all populations are privately owned. Only 3 populations are comprised of 100 or more individuals, while 2 populations have fewer than 10 individuals (Byrd 2016, 2017, Yawn 2018). Several attempts to augment and establish populations are known but information on sites is limited and their contribution to recovery is uncertain. Conservation efforts in cooperation with various entities has occurred and 3 populations are permanently protected and managed by TNC but three populations have been extirpated since the species was listed (USFWS, 2018). The species is currently only found in Autauga and Chilton Counties and is considered extirpated in Elmore County, Alabama. Of Alabama canebrake pitcher-plant's 12 known populations, 8 are extant (including one small population consisting entirely of transplanted individuals and their progeny), and 4 are extirpated. While one population was discovered since the 2018 5-year review, another population has since been extirpated. In addition to few extant populations, small population size remains a threat with most (5 of 8) populations having less than 100 plants. Only 3 populations have 100 or more plants and only 1 population has over 1,000 plants. Two populations occur on conservation lands; however, one of these protected populations is also the largest known population (encompassing nearly threequarters of the species' entire known population in the wild). While overall population size has increased since the mid-1990s by over 48%, active recruitment of the species is generally low, with recent observations noting seedlings at only 3 populations, which represent only a small fraction of individuals within each of these populations. Discovery of additional populations and population augmentation have also contributed to recent population increases (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Woody succession (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The inability to regularly burn some sites has reduced habitat suitability by allowing continued encroachment of woody species that increase shade for this shade-intolerant species (USFWS, 2012).

**Stressor:** Fire suppression (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** All populations occur in fire-maintained habitat, requiring an active prescribed burning regimen to sustain species viability and site integrity. As with all pitcher-plants, S. rubra ssp. alabamensis is intolerant of shade, quickly becoming depauperate and unable to reproduce with the encroachment of woody vegetation. Therefore, site integrity and viability of all populations are inherently linked to regular prescribed burning. Efforts by U.S. Fish and Wildlife Service, ALNHP, TNC, and Atlanta Botanical Gardens to adequately maintain specific populations have been hampered by difficulties in obtaining permission to apply prescribed fires at some of the known populations and unfavorable burning condition (USFWS, 2012).

**Stressor:** Gravel mining (USFWS, 2012)

**Exposure:**
**Response:**
**Consequence:** loss of habitat
**Narrative:** Gravel mining in close proximity to another population has adversely altered the hydrology of the site, further hampering recovery efforts (Byrd 2011, Tassin in litt. 2011b) (USFWS, 2012). However, the cooperation and interest in conserving this site by the landowner has allowed land management activities to reduce the impacts of gravel mining induced hydrologic alterations (Byrd 2016, 2017, ANHP 2018, Yawn 2018) (USFWS, 2018).

**Stressor:** Drainage of wetlands/bogs (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** loss of habitat
**Narrative:** Alabama canebrake pitcher plant populations continue to be threatened by development and incompatible land use, such as drainage for agriculture and livestock grazing (USFWS, 2012).

**Stressor:** Habitat modification (USFWS, 2018).
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The species continues to be threatened by development, agricultural activities, gravel mining, and livestock management (Schotz 2006, Byrd 2016, 2017, ANHP 2018, Yawn 2018), which can exacerbate threats posed by inadequate habitat management (e.g., fire exclusion) and encroachment of competing vegetation (including non-native invasive species)(USFWS, 2018).

**Stressor:** Hydrologic alterations (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Two populations have historically been subjected to hydrological alterations as a result of beaver (Castor canadensis) activities, one of which was nearly extirpated by flooding. Beaver trapping has occurred at one of these populations to reduce their impact (USFWS, 2018).

**Stressor:** Inadequate habitat management (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Inadequate habitat management threatens the long-term viability of some populations. All populations occur in habitat requiring periodic fire to maintain site ecological integrity and population viability. The lack of prescribed fire or periodic mowing and hand clearing of competing vegetation at some sites allows for unchecked growth of woody species and other fast-growing herbaceous species that can increase shade and competition for resources. Alabama canebrake pitcher plant is intolerant of shade, with individual plants and, ultimately, populations, quickly becoming depauperate and unable to reproduce following woody species encroachment and consequent increased shade. Prescribed fires and other vegetation clearing activities help to maintain Alabama canebrake pitcher plant’s necessary open, sunny habitat. In addition, over the years, ANHP, TNC, and ABG have occasionally had difficulties

obtaining landowner permission to apply prescribed fires at some sites, thus hampering necessary efforts to adequately maintain these sites (Byrd 2016, ANHP 2018). One small population was recently lost, possibly due to incompatible road right-of-way maintenance, such as herbicide application (Byrd 2016). Habitat management is need to promote seedling recruitment. Alabama canebrake pitcher plant continues to be extremely vulnerable due to the small number of populations and small population size at many of these sites (USFWS, 2018).

***Recovery***

**Reclassification Criteria:**

1. At least 10 geographically distinct populations of sufficient size within the Fall Line Hills ecoregion in Alabama exhibit stable or increasing population trends, as evidenced by natural recruitment and multiple generations over an appropriate time span. Populations are considered to be geographically distinct when they are separated by at least 1 mile (1.6 kilometer) from their nearest neighbors. (Addresses Factors A, B, E) (USFWS, 2019).

2. These 10 populations are protected by a conservation mechanism that addresses the conservation needs of the Alabama canebrake pitcher plant. (Addresses Factors A, D) (USFWS, 2019).

3. Protected populations are managed to promote open canopies, integrity of native plant communities, and Alabama canebrake pitcher plant growth. (Addresses Factors A, E) (USFWS, 2019).

Recovery Priority Number: 6

**Delisting Criteria:**

In addition to meeting downlisting criteria, the Alabama canebrake pitcher plant will be considered for delisting when the following criteria are met:

4. At least 10 additional geographically distinct populations of sufficient size (as described in Criterion 1) within the Fall Line Hills ecoregion in Alabama exhibit stable or increasing population trends, as evidenced by natural recruitment and multiple generations over an appropriate time span. (Addresses Factors A, B, D, E) (USFWS, 2019).

5. The Upper Alabama and Lower Coosa sub-basins within Fall Line Hills ecoregion each support at least three (3) viable populations protected by a conservation mechanism. (Addresses Factors A, E) (USFWS, 2019).

**Recovery Actions:**

- A. Continue use of prescribed fires at protected sites and encourage owners of unprotected sites to conduct prescribed fires as frequently as possible (USFWS, 2012).
- B. Continue to track population trends and evaluate management needs as a means to gather baseline data and implement long-term monitoring efforts (USFWS, 2012).
- C. Continue surveys in vicinity of known populations and revisit all known historical sites regularly (USFWS, 2012).
- D. Work to secure protection, either through conservation easements or acquisition, of privately-owned populations (USFWS, 2012).

- E. Renew contact with state and county highway departments to ensure proper protective measures are implemented for those areas where plants occur on roadside rights-of-way (USFWS, 2012).
- F. Continue to preserve genetic material from all populations to the extent possible through long-term seed storage and propagation efforts at the Atlanta Botanical Gardens, Georgia (USFWS, 2012). Efforts have expanded to include Auburn University's Donald E. David Arboretum (USFWS, 2018).
- G. Implement all other tasks identified in the recovery plan, as appropriate (USFWS, 2012).
- H. Update the recovery plan, as appropriate (USFWS, 2012).
- Continue use of prescribed fires at protected sites and encourage owners of unprotected sites to conduct prescribed fires as frequently as possible (USFWS, 2012).
- Continue to track population trends and evaluate management needs as a means to gather baseline data and implement long-term monitoring efforts (USFWS, 2012).
- Continue surveys in vicinity of known populations and revisit all known historical sites regularly (USFWS, 2012).
- Work to secure protection, either through conservation easements or acquisition, of privately-owned populations (USFWS, 2012).
- Renew contact with state and county highway departments to ensure proper protective measures are implemented for those areas where plants occur on roadside rights-of-way. 10 (USFWS, 2012).
- Continue to preserve genetic material from all populations to the extent possible through long-term seed storage and propagation efforts at the Atlanta Botanical Gardens, Georgia (USFWS, 2012).
- Implement all other tasks identified in the recovery plan, as appropriate (USFWS, 2012).
- Update the recovery plan, as appropriate (USFWS, 2012).

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES Current recovery criteria are presented in the Recovery Plan Amendment (Service 2019) while the Recovery Plan (Service 1992) provides a detailed discussion of necessary recovery actions. During this status review, new and/or targeted potential recovery activities were identified and are included below. These actions are recommended to support and promote recovery of the Alabama canebrake pitcher-plant. Use of a numbered list for these recommendations is for convenient reference only and does not necessarily imply prioritization of any activity over others. Recovery Activities 1. Continue the use of prescribed fire at protected sites and encourage and cooperate with landowners of unprotected sites to conduct prescribed fire as frequently as possible to maintain favorable habitat conditions. 2. Where use of prescribed fire is not feasible, use fire surrogates such as hand clearing and mowing of competing vegetation to maintain favorable habitat conditions. 3. Work with landowners and cooperators to secure adequate protection of privately-owned populations. 4. Work with state, county, and local transportation departments to ensure proper protective measures are implemented for those areas where Alabama canebrake pitcher-plants occur within roadside rights-of-way. 5. Continue to preserve genetic material from all populations through long-term seed storage and live plant collections ex situ (off-site). Monitoring and Research Activities 1. Continue to track population trends and evaluate management needs and efficacy. 2. Expand surveys in the vicinity of known populations and revisit known historical sites regularly to locate and/or relocate populations. 3. Determine the extent that current ex situ collections represent the genetic diversity of in situ populations and expand ex situ collections if necessary (USFWS, 2023).

# SPECIES ACCOUNT: *Sarracenia rubra ssp. jonesii* (Mountain sweet pitcher-plant)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015) 9/30/1988

**Physical Description**

An insectivorous perennial herb with waxy-green, maroon-veined leaves that form erect, vase-like "pitchers" with ascending "lids." The pitchers are usually about 4.5 dm tall and are often partially filled with a broth of decaying insects. The sweet-smelling flowers are borne singly, each nodding on erect flowering stems that are usually taller than the pitcher. Flower petals are pendulous, maroon on the outside and yellowish, tinged with red on the inner surface. Blooms in spring. (NatureServe, 2015)

**Taxonomy**

Treated as a subspecies of Sarracenia rubra by Kartesz (1994 checklist), but considered a distinct species (S. jonesii) by North Carolina Heritage Program (1993), CITES (2001), and FNA (vol. 8, 2009). (NatureServe, 2015)

**Historical Range**

See current range/distribution.

**Current Range**

Endemic to a few mountain bogs and waterslides in southwest North Carolina and northwest South Carolina on both sides of the Blue Ridge divide (U.S. Fish and Wildlife Service 1990). Four populations are in the French Broad River drainage in Henderson and Transylvania Counties, North Carolina, five are in the Saluda River drainage in Greenville County, South Carolina, and one population is in the Enoree River drainage also in Greenville County, South Carolina (U.S. Fish and Wildlife Service 1990). (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Food/Nutrient Narrative**

Adult: Carnivory is the most striking interaction between members of the genus Sarracenia and other species, though the precise benefit to pitcher plants from this highly specialized adaption is not understood. Christensen (1976) found that when insects were fed to Sarracenia flava, there was no consequent increase in calcium, magnesium, or potassium in the plants' leaf tissue. However, nitrogen and phosphorus did increase, indicating that carnivory may be useful in soils low in these elements. Folkerts (1982) suggests that carnivory may be used to obtain micronutrients, such as molybdenum, which are present at very low levels in a low ph environment. Folkerts (1982) also proposes that carnivory may be important at times of nutrient stress since nutrient levels in bogs decrease over the course of the growing season. Another possibility is that the breakdown of prey detritus from decaying pitchers may help fertilize the soil around the plants (Christensen 1976). In addition to carnivory, pitcher plants have intricate relationships with several different animal taxa. Members of the genus Sarracenia are the exclusive food of at least five species of moth (Damman and French 1987), and other insects are known to live inside pitchers (U.S. Fish and Wildlife Service 1990). Some insects may be restricted to S. jonesii (T. Gibson, pers. comm., in U. S. Fish and Wildlife Service 1990).

**Reproductive Strategy**

Adult: Asexual and sexual (NatureServe, 2015)

**Lifespan**

Adult: Perennial herb (USFWS, 1990)

**Breeding Season**

Adult: Flowering occurs from April to June, with fruits ripening in August (U.S. Fish and Wildlife Service 1990) (NatureServe, 2015).

**Reproduction Narrative**

Adult: REPRODUCTION: Reproduction in S. jonesii occurs by seed and by fragmentation of the rhizomes, but the relative importance of sexual versus vegetative reproduction is not known (U.S. Fish and Wildlife Service 1990). Flowering occurs from April to June, with fruits ripening in August (U.S. Fish and Wildlife Service 1990). Pollinators of S. jonesii are not know, but bumblebees are important pollinators of other species of Sarracenia (U.S. Fish and Wildlife Service 1990). Water is the only known means of seed dispersal (U.S. Fish and Wildlife Service 1990). GENETICS: Many populations of S. jonesii are small and have likely been isolated for a long time. Consequently, inbreeding depression may be occurring (U.S. Fish and Wildlife Service 1990).; ASEXUAL; Perfect; Predominantly outcrossing; SEXUAL; Vegetative spread; ABIOTIC; Water; BIOTIC; Insects, other (NatureServe, 2015).

**Habitat Type**

Adult: Bogs (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/Specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: The mountain sweet pitcher plant occurs in two types of habitat, depression bogs and cataract bogs. Most commonly, this species is found in depression bogs with flat to gently sloping topography in valley bottoms not subjected to flooding (Schafale and Weakley 1990; U.S. Fish and Wildlife Service 1990). The soils of these bogs are deep, poorly drained loam/sand/silt, with high organic matter and acidic pH. The soil series is usually Toxaway silt loam or Hatboro loam (U.S. Fish and Wildlife Service 1990). These bogs are palustrine and usually fed by seepages. The moisture level within the bogs ranges from permanently saturated to intermittently dry (Schafale and Weakley 1990). In the cataract bog habitat, the pitcher plants grow in thin strips along the edges of the waterfall, or on soil islands actually on the granite rock face where moisture conditions are appropriate (U.S. Fish and Wildlife Service 1990; S. Benjamin, pers. observ.). Shrub species associated with Sarracenia jonesii populations include Rhus vernix (poison sumac), Aronia arbutifolia (chokeberry), Alnus serrulata (alder), Rhododendron maximum (rhododendron), Rhododendron viscosum (azalea), Viburnum cassinoides (viburnum), Kalmia angustifolia (sheep laurel) and Kalmia latifolia (mountain laurel) (U.S. Fish and Wildlife Service 1990). Associated herb species include several sedges (Carex leptalea, C. muricata, C. folliculata, and C. collinsii), twigrush (Cladium mariscoides), beak rush (Rhynchospora alba), bulrush (Scirpus expansus), and several Sphagnum species (U.S. Fish and Wildlife Service 1990) (NatureServe, 2015). Clumped spatial arrangement of the population, high ecological integrity of the community and site fidelity and low tolerance ranges are inferred based on the specific habitat requirements of this species and the relatively low number of known populations.

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: At least some seed dispersal is by water; however, little else is known, including how far seeds can be dispersed by this vector and others and what conditions are optimal for dispersal (USFWS, 1990).

***Population Information and Trends***

**Population Trends:**

Short term trend: Decline of 10-30% (NatureServe, 2015)

**Number of Populations:**

15 (USFWS, 2021)

**Population Narrative:**

The species persists in 12 extant populations across North and South Carolina, in remnant bog habitats that are subject to repeated threats from the continued alteration of the surrounding landscape, particularly the ecological processes (namely hydrologic regimes) which render these wetlands suitable for species such as S. jonesii (USFWS, 2013). NatureServe (2015) notes that there is a short-term population decline of 10-30%. Low resiliency, representation and redundancy are inferred based on the low number of populations and the specific habitat requirements of this species.

***Threats and Stressors***

**Stressor:** Stream channelization (USFWS, 2013)
**Exposure:**

**Response:**
**Consequence:** Loss of habitat
**Narrative:** This, in conjunction with stream channelization efforts throughout the surrounding watershed, continues to work against the processes which create new wetland acreage, which in turn forces those species that are dependent upon these habitats to be confined to whatever remnant acreage that remains (USFWS, 2013).

**Stressor:** Lack of beaver dams (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Beavers were largely eliminated from much of the southern Appalachian landscape by the turn of the last century. Although still active, their effectiveness at creating new wetland habitat is severely hindered by humans who regard beavers as a nuisance species, and repeatedly breach beaver impoundments (USFWS, 2013).

**Stressor:** Wetland draining (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Because many bogs are located in low-lying flat areas favored for agriculture, they often have been the focus of wetland ditching and draining efforts which have left the hydrology of these sites inherently altered. Further compounded by a nearly complete absence of natural disturbance regimes (such as grazing and/or fire) that may have played a role in keeping woody vegetation at low densities, the structure and composition of southern Appalachian wetlands faces a nearly constant and synergistic set of threats (USFWS, 2013).

**Stressor:** Lack of fire (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Periodic fire may have also played an historical role in keeping some mountain bog habitats structurally open, with the higher light levels favored by species such as S. jonesii. Most Sarracenia species occur in fire-prone habitats, and many Sarracenia species decline during periods of prolonged fire suppression. The historical role of fire in mountain bogs is less clear than in coastal plain habitats, but the presence of fire-adapted species such as pitch pine (Pinus rigida) certainly suggests a role for fire in the formation and maintenance of these habitats. However, the extent to which fire suppression may be causing or exacerbating woody vegetation encroachment in bog habitats is presently speculative, at best (USFWS, 2013).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 5C

**Delisting Criteria:**
Criterion 1: It has been documented that at least four populations within each drainage (Enoree, French Broad, and Saluda Rivers) are self-sustaining and that necessary management actions

have been undertaken by the landowners or cooperating agencies to ensure their continued survival (USFWS, 2013).

Criterion 2: …All 12 of the above populations and their habitat are protected from present and foreseeable human-related and natural threats that may interfere with the survival of any of the populations (USFWS, 2013).

**Recovery Actions:**

- Protect existing populations and essential habitat. Develop interim research and management plans in conjunction with landowners. Search for additional populations. Determine habitat protection priorities. Evaluate habitat protection alternatives (USFWS, 1990).
- Determine and implement management necessary for long-term reproduction. establishment. maintenance, and vigor. Determine population size and stage-class distribution for all populations. Study abiotic and biotic features of the species' habitat. Conduct long-term demographic studies. Determine the effects of past and ongoing habitat disturbance. Define criteria for self-sustaining populations and develop appropriate habitat management guidelines based upon the data obtained from Tasks 2.2 through 2.4. Implement appropriate management techniques as they are developed from previous tasks. Develop techniques and reestablish populations in a suitable habitat within the species' historic range (USFWS, 1990).
- Develop a cultivated source of plants and provide for long-term seed storage (USFWS, 1990).
- Enforce laws protecting the species and/or its habitat (USFWS, 1990).
- Develop materials to inform the public about the status of the species and the recovery plan objectives. Prepare and distribute news releases and informational brochures. Prepare articles for popular and scientific publications (USFWS, 1990).
- Annually assess success of recovery efforts for the species (USFWS, 1990).
- Recovery Task 2.1: Determine population size and stage class distribution for all populations • Map the spatial extent of each population, assess flower abundance and (of lower priority, only if time permits) the abundance of pitchers/clumps. Perform these assessments in a manner that ensures comparability to the baseline maps and other data obtained for these sites in 1991 and 1992 (Rudd and Sutter 1998 and references therein). Assess whether the spatial extent and/or abundance of populations has remained stable, increased or decreased since that time, accounting for any increases due to population augmentation efforts. Record information on environmental parameters that can impact the plant (e.g., light availability and depth to water table) to examine possible correlations with these parameters and the population size and stage class distribution for all populations (USFWS, 2013).
- Recovery Task 2.7: Develop techniques and re-establish populations in suitable habitat within the species' historic range. • Work with the Atlanta Botanical Garden (ABG) to summarize prior reintroduction, augmentation and introduction activities across all populations. Using this information, conduct site visits as needed to obtain current estimates of transplant survivorship for prior augmentation efforts. • Use this information, supplemented by updated data on overall spatial extent (obtained from mapping) and estimates of flower/pitcher abundance, to assess each population for its current potential to be self-sustaining without augmentation. For populations where augmentation is deemed

necessary (this may currently be most populations), establish preliminary population objectives clarifying the minimum desired number of plants at each location, and a strategy and timeline for meeting this objective through augmentation. Work with ABG and landowners to implement actions required to meet this objective at as many sites as possible, and then discontinue additional augmentation while monitoring is undertaken to determine transplant survivorship and population trends at the new (augmented) baseline (USFWS, 2013).

- Recovery Task 3: Develop a cultivated source of plants and provide for long-term seed storage • Review the provenance of material currently held as seeds or otherwise represented in exsitu holdings at botanical gardens (esp. ABG but also the North Carolina Botanical Garden) to ensure that all known extant populations are represented. • Work with ABG to assess the viability of seed collections, and the longevity of seeds held in long-term storage (USFWS, 2013).
- Recovery Task 6: Annually assess success of recovery efforts • The two existing recovery criteria (for de-listing) are largely redundant; revise criteria that are more specific, objective, and measurable. • Establish down-listing criteria (for reclassification from endangered to threatened). • Finalize technical revision to the federal list of threatened and endangered plant species, changing taxonomy from Sarracenia rubra ssp. jonesii to Sarracenia jonesii.

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTION The 2013 5-year review included a list of recommendations to improve recovery of the species. These actions, listed below, remain applicable to species recovery. x Map the spatial extent of each population, assess flower abundance and (of lower priority, only if time permits) the abundance of pitchers/clumps. Perform these assessments in a manner that ensures comparability to the baseline maps and other data obtained for these sites in 1991 and 1992 (Rudd and Sutter 1998 and references therein). Assess whether the spatial extent and/or abundance of populations has remained stable, increased or decreased since that time, accounting for any increases due to population augmentation efforts. x Work with the Atlanta Botanical Garden (ABG) to summarize prior reintroduction, augmentation, and introduction activities across all populations. Using this information, conduct site visits as needed to obtain current estimates of transplant survivorship for prior augmentation efforts. x Use this information, supplemented by updated data on overall spatial extent (obtained from mapping) and estimates of flower/pitcher abundance, to assess each population for its current potential for self-sustainability without augmentation. For populations where augmentation is deemed necessary (this may currently be most populations), establish preliminary population objectives clarifying the minimum desired number of plants at each location, and a strategy and timeline for meeting this objective through augmentation. Work with ABG and landowners to implement actions required to meet this objective at as many sites as possible, and then discontinue additional augmentation while monitoring is undertaken to determine transplant survivorship and population trends at the new (augmented) baseline. x Review the provenance of material currently held as seeds or otherwise represented in exsitu holdings at botanical gardens (especially ABG but also the North Carolina Botanical Garden) to ensure that all known extant populations are represented. x Work with ABG to assess the viability of seed collections, and the longevity of seeds held in long-term storage. x The two existing recovery criteria (for de-listing) are largely redundant; devise revised criteria that are more specific, objective, and measurable (in accordance with Service Recovery Planning Guidance). x Devise downlisting criteria (for reclassification from endangered to threatened) similarly in accordance with Service Recovery Planning Guidance. x Finalize technical revision to the federal list of threatened and endangered plant species (previously submitted to the Service Atlanta Regional

Office), changing taxonomy from Sarracenia rubra ssp. jonesii to Sarracenia jonesii. In light of new information, additional future actions are recommended below: x Work with partners and species experts to develop a standardized monitoring protocol that could be used on many different types of mountain sweet pitcher plant sites. x Work with partners and land managers to conduct range-wide monitoring. x Provide support and, if feasible, pool resources for management and monitoring. x Continue to support research efforts investigating species biology, hybridization, and management techniques. x Determine what constitutes a “self-sustaining” population and determine the appropriateness of the criterion for a species dependent on active management. (USFWS, 2021)

# SPECIES ACCOUNT: *Schoenocrambe barnebyi* (Barneby reed-mustard)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 01/14/1992; Mountain-Prairie Region (Region 6) (USFWS, 2016)

**Physical Description**

Schoenocrambe barnebyi is a perennial herbaceous plant with sparsely leafed stems 22 to 35 cm (9 to 15 inches) tall arising from a woody root crown. The leaves are entire with a smooth margin, 1.5 to 5 cm (0.6 to 3 inches) long and 0.5 to 2.5 cm (0.2 to 1 inch) wide. The leaf blades are alternately arranged on the stem and are attached to the stem by a petiole. The flowers of S. barnebyi have petals that are light purple with prominent darker purple veins and measure about 12 mm (0.4 inch) long and 2.5 mm (0.1 inch) wide. The entire flowers are about 1 cm (0.4 inch) across in full anthesis and are displayed in a raceme of, commonly, two to eight flowers at the end of the plant’s leafy stems (Welsh and Atwood 1980, Rollins 1982, Welsh et al. 1987). Flowers (May-June) have pale purple petals, prominently veined with darker purple. (USFWS, 1994; NatureServe, 2015)

**Taxonomy**

Rollins (1982), in reevaluating the cruciferous genera of Schoenocrambe and Thelypodiopsis, moved T. argillacea and T. barnebyi from Thelypodiopsis to Schoenocranibe as S. argillacea and S. barnebyi. Welsh and Chatterley (1985) moved Glaucocarpuni suffrutescens to the genus Schoenocranibe to complete what morphologically appears to be a discrete phylogenetic unit among the Brassicaceae. The genus Schoenocrambe currently includes five known species, two (S. linearifolia and S. linifolia) are abundant wide—ranging species from the dry lower elevations of the interior western Cordilleras. S. Iinearifolia occurs from southern Colorado and northern Arizona southward to western Texas and Durango and Sonora, Mexico. S. linifolia occurs from southeastern British Columbia, Canada, and western Montana southward to eastern Nevada and northern New Mexico. The remaining three, S. argillacea, S. barnebyl, and S. suffrutescens, are rare endemic species from low elevations of the northern and western portions of the Colorado Plateau in the State of Utah (Rollins 1982, Welsh et al. 1987). (USFWS, 1994)

**Current Range**

Endemic to the Canyonlands of south-central Utah, where known from two distinct clusters of occurrences: one in the southern portion of the San Rafael Swell near Muddy Creek in southern Emery County and the other in Capitol Reef National Park in the Fremont River drainage west of Fruita in central Wayne County. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 1994)

**Breeding Season**

Adult: April to May (USFWS, 1994)

**Reproduction Narrative**

Adult: We have little information on the biology and life history of Barneby reed-mustard. Plants reproduce sexually and flower from late April to mid or late May (Welsh and Neese 1984). (USFWS, 1994)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Bare rock/talus/scree, desert (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs at elevations between 1460 and 1985 meters on sparsely vegetated sites (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Mixed desert shrub communities (shadscale, Eriogonum, Ephedra), in sparsely vegetated sites on steep, eroding north to northeast facing slopes (elevations between 1460 and 1985 meters). Grows in xeric, fine-textured red clay soils rich in selenium and gypsum of the Moenkopi Formation, and, rarely, on soils eroded from it that now overlie the Chinle Formation and on the Carmel Formation. Associated species include Abronia fragrans, Amelanchier utahensis, Artemisia dracunculus, Astragalus brandegeei, Atriplex confertifolia, Chrysothamnus nauseosus, Ephedra torreyana, Ephedra viridis, Eriogonum corymbosum, Erioneuron pulchellum, Erioneuron pilosum, Hilaria jamesii, Monolepis nuttalliana, Opuntia polyacantha, Phacelia rafaelensis, Sporobolus sp., Stanleya pinnata, and Townsendia incana. (NatureServe, 2015)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Gravity, wind and rain are thought to be the primary dispersal agent of seeds (Welsh and Neese 1984). (USFWS, 1994)

***Population Information and Trends***

**Population Trends:**

Unknown (NatureServe, 2015)

**Number of Populations:**

4 (USFWS, 2021)

**Population Size:**

<3,000 (USFWS, 2021)

**Population Narrative:**

The species has the same number of populations (four) and estimated total population size (less than 3,000 plants) that we reported in our last status review (Table 1; USFWS 2011). (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Mining (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The primary threat to Schoenocrambe barnebyi identified at the time of listing and in the Recovery Plan was habitat loss and degradation associated with future uranium mining on BLM lands (57 FR 1398, January 14, 1992; USFWS 1994). Mining related activities may result in increased surface disturbances, increased foot and vehicle traffic, reduced air quality, vegetation disturbance, and removal of top soil and overburden. Surface disturbances may impact the species by crushing or trampling plants, causing soil erosion and compaction, degrading suitable habitat, losing pollinator populations and habitat, reducing plant vigor and reproductive potential, reducing seed bank quantity and quality, and increasing invasive plant occurrences thereby increasing fire risk (Brock and Green 2003; BLM 2008a). All of the known individuals on BLM land occur in areas that are open to mineral exploration or development (BLM 2008a). Six mining claims occur near the Sy's Butte/Hidden Splendor Mine and mining activities may have extirpated a portion of this population during the 1950s and 1960s (Anderson 1985; USFWS 1994). Mining shafts from this time period are currently being closed (Conrad pers. comm. 2009; Ivory pers. comm. 2009). With the exception of the Lucky Strike Mine, there has been no mining since the 1960s (Conrad pers. comm. 2009; Ivory pers. comm. 2009). Because BLM lands remain open to mineral exploration and development and there are existing mining claims near the Sy's Butte/Hidden Splendor Mine population that may recommence at any time (Conrad pers. comm. 2009), future uranium mining continues to be a threat on BLM lands. The Service considers this threat to be currently low because it has been over 40 years since active mining occurred, and we are not aware of any current mining proposals in this area. (USFWS, 2011)

**Stressor:** Grazing (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Livestock grazing may result in the direct loss or damage to plants and their habitat through trampling, soil compaction, increased soil erosion, invasion of noxious weeds, and disturbance to pollinators (Kauffman et al. 1983; Fleischner 1994; Kearns et al. 1998; DiTomaso 2000). Sheep and cattle grazing were identified as possible historic threats to populations of Schoenocrambe barnebyi (57 FR 1398, January 14, 1992; USFWS 1994). At the time of listing, the intensity of grazing at known S. barnebyi populations was not expected to significantly impact the species. Grazing intensity has not increased since we finalized the Recovery Plan (BLM 2009). However, the Service does not have any monitoring data that evaluates the effects of grazing on S. barnebyi populations. (USFWS, 2011)

**Stressor:** Off-highway vehicle use (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Services did not identify off-highway vehicle (OHV) activities as threats to Schoenocrambe barnebyi when we listed the species in 1992, nor in the Recovery Plan (57 FR 1398, January 14, 1992; USFWS 1994). The OHV use may result in the direct loss or damage to plants and their habitat through soil compaction, increased soil erosion, reduced air quality, invasion of noxious weeds, and disturbance to pollinators and their habitat (Eckert et al. 1979; Lovich and Bainbridge 1999; Ouren et al. 2007; Wilson et al. 2009). The use of OHVs in Utah has exploded in popularity over the past several decades (Burr et al. 2008). From 1998-2006, the number of registered OHVs in Utah has increased by 233% (Burr et al. 2008). The known Schoenocrambe barnebyi population on BLM lands (Sy's Butte/Hidden Splendor Mine) occurs in an area that is open to OHV traffic along designated routes only (BLM 2008a). Although illegal OHV use occurs within the vicinity (BLM 2011), to date, no direct or indirect impacts to the population or individual plants have been documented (Ivory 2009). Due to the remoteness of the population and the steepness of the terrain, the Service expects the overall scope of the threat to be low. (USFWS, 2011)

**Stressor:** Erosion (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Erosion was not considered a threat at the time of listing or in the recovery plan (57 FR 1398, January 14, 1992; USFWS 1994). However, natural erosion of Schoenocrambe barnebyi habitat was listed as a potential threat in a 1992 survey report for the BLM (Ecosphere 1992). Schoenocrambe barnebyi grows in very steep habitats with sparse vegetation. Plants may be uprooted, damaged or destroyed by gullying, slumping or rockslides. Under natural circumstances, the Service presumes the species has adapted to living on a highly erodible substrate. However, erosion may increase as climate changes. Climate change will likely increase heavy precipitation events which can increase soil erosion (Nearing et al. 2004; IPCC 2007; see section 2.3.2.5 below).In addition, erosion may be accelerated through surface disturbing activities. As previously described, OHV use and grazing occur in the habitat of Schoenocrambe barnebyi on BLM lands. Although the Service believes the overall threat level of these activities to be currently low, the Service does not have monitoring data to adequately evaluate the effects, including erosion, of these uses to the plants. (USFWS, 2011)

**Stressor:** Trampling (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing and in our Recovery Plan, we identified trampling by Capitol Reef visitors as the primary impact on the Schoenocrambe barnebyi population at Sulphur Creek (57 FR 1398, January 14, 1992; USFWS 1994). However, trampling from hiking activities was later evaluated and determined to be unlikely (Clark 1997). Visitors tend to remain along the trail in the creek bottom, away from the plants and the habitat due to the steepness of the terrain. An historic livestock trail through the population is no longer in use but is occasionally used by deer (Clark pers. comm. 2009a). All other sites within Capitol Reef were evaluated for potential

impacts caused by hiking trails but none were documented (Clark 2005b). For these reasons, we no longer consider trampling a threat. (USFWS, 2011)

**Stressor:** Invasive species and fire (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasive species and fire were not considered threats at the time of listing or in the species' Recovery Plan (57 FR 1398, January 14, 1992; USFWS 1994). However, the spread of nonnative invasive species is considered the second largest threat to imperiled plants in the United States (Wilcove et al. 1998). Invasive plants—specifically exotic annuals—negatively affect native vegetation, including rare plants. One of the most substantial effects is the change in vegetation fuel properties that, in turn, alter fire frequency, intensity, extent, type, and seasonality (Menakis et al. 2003; Brooks et al. 2004; McKenzie et al. 2004). Shortened fire return intervals make it difficult for native plants to reestablish or compete with invasive plants (D'Antonio and Vitousek 1992). Mining, grazing, and unauthorized OHV use are activities that disturb soil surfaces within Schoenocrambe barnebyi habitat on BLM lands. In general, B. tectorum is known to invade areas in response to these types of surface disturbing activities (Hobbs 1989; Rejmanek 1989; Hobbs and Huenneke 1992; Evans et al. 2001). These types of surface disturbing activities do not occur on the populations in Capitol Reef. Currently wildland fires are considered unlikely to occur in S. barnebyi's habitat due to the sparseness of vegetation associated with the species (Borthwick pers. comm. 2009c; Ivory pers. comm. 2009). (USFWS, 2011)

**Stressor:** Herbivory (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Schoenocrambe barnebyi appears to be highly palatable to deer (Clark 2005b). The Service expects browsing to be localized and only affect a small portion of the populations. However, we do not have any information that browsing is occurring at a level that negatively impacts the species as a whole (Clark 2005b; Ivory 2009). For these reasons, this factor has the potential to affect the species. (USFWS, 2011)

**Stressor:** Small populations (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The original listing decision cited the limited distribution and low population numbers as a factor affecting the species (57 FR 1398, January 14, 1992). The species' rarity and limited distribution make it highly vulnerable to localized stochastic extinction events. While more sites have been found since the species was listed, it remains narrowly distributed in few populations and may be in decline (Clark 1997; Anderton 2002). Half of the sites have fewer than 100 plants (Clark 2005b; see Table 2). Although small population size is an intrinsic vulnerability of the species, some sites may hold so few plants that they are not demographically stable in the medium to long term and some may be lost as a result of natural variation in population numbers in the short term. Population genetics studies have not been undertaken for Schoenocrambe barnebyi, but despite the overall lack of information on the population ecology of the species,

the Service does know that small populations are at an increased risk of extinction due to the potential for inbreeding depression, loss of genetic diversity, and lower sexual reproduction rates (Ellstrand and Elam 1993; Wilcock and Neiland 2002). Only the larger sites of S. barnebyi may have sufficient genetic variability to provide for long-term adaptation to natural or manmade changes in their environment. Small population size in and of itself is not considered a threat; however, it may increase the species' vulnerability if other threats discussed in this analysis are impacting the species. Even a small localized disturbance such as mining, OHV-related activities, or fire could result in the extirpation of a site. The Service determined the threat of climate change (see discussion below) has an overall threat level of moderate. Therefore, the Service considers the overall threat level for small population size to be moderate. (USFWS, 2011)

**Stressor:** Climate change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Species with limited ranges and restricted habitat requirements also are more vulnerable to the effects of global climate change (IPCC 2002; Jump and Penuelas 2005; Machinski et al. 2006; Krause 2010). Climate change was not discussed in the original rule to list the species or in the Recovery Plan. Over the past 50 years, the frequency of cold days, cold nights, and frosts have become less frequent over most land areas, and hot days and hot nights have become more frequent (IPCC 2007). Changes in the global climate system during the 21st century are hypothesized to be larger than those observed during the 20th century (IPCC 2007). For the next two decades, a warming of about 0.2°C (0.4°F) per decade is projected (IPCC 2007). Afterward, temperature projections increasingly depend on specific emission scenarios (IPCC 2007). Various emissions scenarios suggest that by the end of the 21st century, average global temperatures are expected to increase of 0.6 to 4.0°C (1.1 to 7.2°F) with the greatest warming expected over land (IPCC 2007). Localized projections suggest the southwest may experience the greatest temperature increase of any area in the lower 48 States (IPCC 2007). Effects related to climate change, such as persistent or prolonged drought conditions, increased invasions of exotic species and pests, and increased heavy rainfall events, may affect the long-term persistence of S. barnebyi. Climate change could potentially reduce the overall abundance of Schoenocrambe barnebyi. However, a large degree of uncertainty exists regarding the extent of such effects. For these reasons, this factor has the potential to affect the species. Further studies should be conducted to monitor and minimize the effects of this potential threat. (USFWS, 2011)

**Stressor:** Lack of scientific knowledge/monitoring (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The lack of scientific knowledge of Schoenocrambe barnebyi may cause the species to be managed below optimal levels. While not a threat in and of itself, this factor affects our ability to manage and recover the species. We lack scientific knowledge and monitoring data throughout the range of the species. We know little about S. barnebyi--its pollinators, range, habitat, and population trends. For example, we do not know why the original population estimate for BLM population was 2,000 individuals but surveys since have counted less than 200 plants. We do not know whether this represents a reduction in plant numbers or is an artifact of survey effort, making it difficult to analyze overall threat levels for the species. Because of this lack of scientific knowledge, opportunities for better management of the species could

potentially be missed. Based on our current limited understanding of the species, we consider the overall threat levels for threats discussed in sections 2.3.2.1, 2.3.2.4, and 2.3.2.5 are all low. We could potentially move the species toward downlisting, recovery, and eventual delisting if we could better quantify the degree of threat the species faces and work toward alleviating those threats. However, the only site that has longer, albeit irregular, monitoring data shows the plant may be in decline, potentially negatively impacted by drought (Clark 1997; Anderton 2002), and potentially able to recover (Clark pers. comm. 2009b). The lack of trend data following the drought makes it difficult to determine to what degree drought may be a threat to the species. (USFWS, 2011)

***Recovery***

**Reclassification Criteria:**
1. Discover or establish a minimum of five separate populations with 2,000 or more individuals per population for each species. These populations must be demonstrated to be at or above minimum viable population levels. (USFWS, 2011)

2. Document the presence of or, if necessary, establish formal land management designations which would provide for long—term protection on undisturbed habitat for the above five populations of each species. (USFWS, 2011)

Recovery Priority Number: 17

**Delisting Criteria:**
1. Discovery or establishment of a minimum of 10 separate populations with 2,000 or more individuals per population for each species. These populations must be demonstrated to be at or above minimum viable population levels. (USFWS, 2011)

2. Document the presence of or, if necessary, establish formal land management designations which would provide for long—term protection on undisturbed habitat for the above 10 populations of each species. (USFWS, 2011)

**Recovery Actions:**
- Inventory suitable habitat for S. argillacea, S. barnebyl, and S. suffrutescens and determine with a reasonable degree of accuracy the population and distribution of each species. (USFWS, 2011)
- Establish and conduct at least three minimum viable population studies on each of at least three different populations of each species. (USFWS, 2011)
- Document the presence of or, if necessary, establish formal land management designations which would provide for long—term protection on undisturbed habitat for each species. (USFWS, 2011)
- Control activities which affect the habitat of S. argillacea, S. barnebyi, and S. suffrutescens through sections 7 and 9 of the Endangered Species Act and other relevant laws and regulations. (USFWS, 2011)
- The BLM and Capitol Reef should establish long-term trend monitoring to provide base line demographic data for the species. In addition to collecting baseline demographic data, BLM and Capitol Reef should collect data on the species’ response to habitat conditions including how the factors considered in this 5-year review are affecting the species. (USFWS, 2011)

- Determine pollinators or pollination mechanisms including the identification of pollinators, pollinator availability, and their habitat requirements. (USFWS, 2011)
- Asses seedbank viability, including seed viability and dispersal mechanisms and determining germination requirements. (USFWS, 2011)
- Analyze population genetics to assess potential impacts from inbreeding depression. (USFWS, 2011)
- Determine the species' vulnerability to prolonged drought and the potential impacts of climate change. (USFWS, 2011)
- Determine the species response to invading nonnative species and its response to increased fire frequencies. (USFWS, 2011)
- Determine habitat requirements, including soils, aspects, and climatic variables. (USFWS, 2011)
- Determine the effects livestock grazing has on the species and its habitat. (USFWS, 2011)
- Determine the effects OHV use has on the species and its habitat. (USFWS, 2011)
- Determine the effects mining has on the species and its habitat. (USFWS, 2011)

***Conservation Measures and Best Management Practices:***

- Recommended future actions: Based on recent discussions with other Federal agencies and partners, we recommend the following future actions: (1) avoid and minimize impacts from mineral exploration and development and other activities in occupied habitat; (2) develop a habitat suitability model for the species; (3) survey potential suitable habitat for occupancy; (3) establish demographic and population trend monitoring within all populations; (4) provide habitat protections through regulatory mechanisms or conservation plans; (5) evaluate reproductive success and pollinator limitations; (6) collect seeds and implement propagation efforts in horticulture facilities; (7) establish new populations; and (8) develop public awareness and appreciation for the species' conservation (USFWS 2020). (USFWS, 2021)

# SPECIES ACCOUNT: *Schoenocrambe suffrutescens* (Shrubby reed-mustard)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/06/1987; Mountain-Prairie Region (Region 6) (USFWS, 2016)

**Physical Description**

Shrubby reed-mustard is a perennial herb in the mustard family, with clumped stems 10 to 25 cm (4 to 12 inches) tall arising from a branching woody root crown. The leaves are entire with a smooth margin, 1.0 to 2.5 cm (0.4 to 1 inch) long and 0.3 to 1.0 cm (0.12 to 0.4 inch) wide. The leaf blades are alternately arranged on the stem and are subsessile or attached to the stem by a short petiole. The flowers of Shrubby reed-mustard have petals that are light yellow or greenish yellow and spatulately shaped measuring about 10 mm (0.4 inch) long and 3 mm (0.12 inch) wide. The entire flowers are about 1 cm (0.4 inch) across in full anthesis and are displayed in a raceme of, commonly, 5 to 20 flowers at the end of the plant's leafy stems. This herb produces yellow flowers May through June. (USFWS, 1994; NatureServe, 2015)

**Taxonomy**

The species was first discovered in 1935 by Edward Graham, described by Reed Rollins as Thelypodium suffrutescens (Graham 1937), and, in 1938, renamed Glaucocarpum suffrutescens (Rollins 1938; 52 FR 37416; October 6, 1987). The species was listed under the latter name (52 FR 37416; October 6, 1987). Since then, its genus was changed to Schoenocrambe (57 FR 1398; January 14, 1992), Glaucocarpum (Al-Shehbaz 2005), and most recently Hesperidanthus (AlShehbaz 2010). This last taxonomic change is currently accepted in the Flora of North America and the integrated taxonomic information system (ITIS) (Al-Shehbaz 2010; ITIS 2017). However, The Service will still use Schoenocrambe suffrutescens until a formal change in the Federal Register is completed. (USFWS, 2019)

**Current Range**

The species is endemic to the Uinta Basin region in northeastern Utah, and found exclusively within the Lower Green-Desolation Canyon and Willow Creek watersheds. (USFWS, 2019)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 1994)

**Dependency on Other Individuals or Species**

Adult: The following native bee species may be Schoenocrambe suffrutescens pollinators: Dialictus perdifficilis, D. sedi, Evylaeus pulveris, Andrena walleye, A. prunorum and Halictus rubicundus (USFWS 1994; Tepedino 2000; Lewis 2010). (USFWS, 2010)

**Breeding Season**

Adult: April to May (USFWS, 2010)

**Other Reproductive Information**

Adult: Shrubby reed-mustard could be pollinator limited if adequate and appropriate insect pollinators are not available (Lewis and Schupp 2014). Seed set is significantly lower in individuals that self-pollinate compared to individuals that are fertilized by cross-pollination (pollen from another plant; Lewis and Schupp 2014). These results also indicate that cross-pollination is critical for maximizing reproduction of the species. A related study of road dust impacts to shrubby reed-mustard found that increases in dust deposition reduced reproduction in the species by significantly decreasing the numbers of mature seeds produced, and showed trends of decreased seed numbers and weight (Lewis 2017). Mean stomatal conductance also significantly decreased with increasing dust presence on leaves, which may impact the overall health and reproductive capacity of the species (Lewis 2017). (USFWS 2019)

**Reproduction Narrative**

Adult: Reproduction is sexual (USFWS 1994), and the species is capable of self-pollination (Tepedino 2000). Flowering for this species occurs in April to May and fruiting occurs May to June. The following native bee species may be Schoenocrambe suffrutescens pollinators: Dialictus perdifficilis, D. sedi, Evylaeus pulveris, Andrena walleye, A. prunorum and Halictus rubicundus (USFWS 1994; Tepedino 2000; Lewis 2010). (USFWS, 2010)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Desert, forest/woodland, woodland - conifer (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs at elevations between 1555 and 1981 meters. (NatureServe, 2015)

**Environmental Specificity**

Adult: Broad (inferred from NatureServe, 2015)

**Dependency on Other Individuals or Species for Habitat**

Adult: Commonly on level to moderately sloping ground surfaces. Soils are dry, shallow, and fine-textured, and are usually overlain by shale fragments. (NatureServe, 2015)

**Habitat Narrative**

Adult: Mixed desert shrub communities and, at some locations, in pinyon -juniper and desert shrub, on semi-barren, white-shale layers of the Evacuation Creek Member of the Green River Formation. Commonly on level to moderately sloping ground surfaces. Soils are dry, shallow, and fine-textured, and are usually overlain by shale fragments. 1555-1981 m elevation. (NatureServe, 2015)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available.

***Population Information and Trends***

**Population Trends:**

Decline (NatureServe, 2015)

**Species Trends:**

Decline (NatureServe, 2015)

**Number of Populations:**

7 (USFWS, 2019)

**Population Size:**

3,161 (USFWS, 2019)

**Additional Population-level Information:**

Range-wide population trend monitoring plots were established by the BLM in 2017. Preliminary findings suggest that open interspaces are important habitat components for the species (BLM 2017). Species monitoring provided a laseline density of 1.9 shrubby reedmustard plants per one-meter squared for monitoring plots; however, subsequent consecutive surveys are needed to refine our understanding of species density (BLM 2017). It is too early to determine demographic and population trends from this monitoring effort. (USFWS, 2019)

**Population Narrative:**

In 2019, the Service estimated shrubby reed-mustard was limited to 3,161 individuals within three geographic areas and seven populations. The range of the Bad Land Cliffs population has been extended from the 2010 estimate after the discovery of 232 new individuals in an area that was previously unsurveyed (BLM 2017). (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Oil and gas development (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Oil and gas resource development operations pose a significant threat to Schoenocrambe suffrutescens populations and habitat (USFWS 1990; 1994). All known populations of S. suffrutescens that occur on Federal lands are leased for oil and gas development (USFWS 1994). In addition, an ongoing natural gas project (currently in the first phase of development) overlaps the entire range of three of the known seven S. suffrutescens populations. These populations account for over 40 percent of the species' known suitable habitat and over 80 percent of all known individuals (USFWS 2008a). Development continues in unoccupied suitable habitat, thereby limiting potential expansion and recovery of the species. Furthermore, development continues to occur in habitats immediately adjacent to occupied habitats. While steps have been taken to minimize these indirect effects, it is unknown if this adjacent development is adversely impacting the viability of S. suffrutescens populations. These

indirect effects, and the protections currently provided, are discussed below. (USFWS, 2010)

**Stressor:** Habitat fragmentation (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Schoenocrambe suffrutescens exists in small, low-density populations that might be prone to negative effects from habitat fragmentation. For example, small plant populations fluctuate more widely over time and the smaller the remnant, the more susceptible the population is to extinction (Soulé et al. 1992; Forman and Alexander 1998; Menges 2002; Lienert 2004). Small plant populations can lose genetic variation and their population viability decreases (Ellstrand and Elam 1993; Lienert 2004; Kolb 2008). Fruit set, germination rate, offspring survival, and total numbers of flowers per plant are higher in larger populations than in small populations (Paschke et al. 2002). Similarly, the number of capsules per plant and the number of seedlings per plant are positively correlated with population size (Schmidt and Jensen 2000). Roads associated with energy exploration and development cause a high level of habitat fragmentation. Increased oil and gas developments result in more roads developed in and near S. suffrutescens habitat. Ecological effects of roads to plants can extend more than 328 feet (100 meters) from the road (Angold 1997; Forman 2000; Forman and Deblinger 2000). Disturbance can occur directly from construction or indirectly from road dust, discussed further below (Farmer 1993; Angold 1997; Trombulak and Frissel 2000). There is a strong correlation between vegetation composition and health with distance from a road, although it may take decades for the full effects of road development to be realized (Auerbach et al. 1997; Myers-Smith et al. 2006). (USFWS, 2010)

**Stressor:** Road dust (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Schoenocrambe suffrutescens may be impacted by the indirect effects of road dust associated with oil and gas development. Road traffic mobilizes and spreads dust (Farmer 1993; Trombulak and Frissell 2000), and for every vehicle traveling 1 mile (1.6 kilometers) of unpaved roadway once a day, every day for a year, approximately 2.5 tons of dust are deposited along a 1,000-foot (~300-meter) corridor centered on the road (Sanders pers. comm. 2008). Dust deposition tends to be highest near the road and decreases with increasing distance from the road (Spatt and Miller 1981; Everett 1980; Walker and Everett 1987; Santelmann and Gorham 1988; Myers-Smith et al. 2006). For example, in one study 97 percent of dust was deposited within 410 feet (125 meters) of the road (Walker and Everett 1987). The distance from a road at which dust can affect vegetation varies (see McCrea 1984; Myers-Smith et al. 2006), but negative impacts can occur up to 984 feet (300 meters) away from the road (Everett 1980). Dust negatively affects photosynthesis, respiration, transpiration, water use efficiency, leaf conductance, growth rate, plant vigor, gas exchange, and allows the penetration of phytotoxic gaseous pollutants (Eller 1977; Spatt and Miller 1981; Thompson et al. 1984; Farmer 1993; Sharifi 1997; Trombulak and Frissell 2000; Hobbs 2001). Dust comprised of finer particulates was shown to cause more improper functioning of the stomata than larger particles (Ricks and Williams 1974; Eller and Brunner 1975; Eveling and Bataille 1984; Rawson and Clarke 1988; Hirano et al. 1995). Clogged stomata result in increased water loss in two ways: due to an increased transpiration rate because of increased temperatures and due to clogged stomata that are

unable to close at night (Hirano et al. 1995). Other dust effects include inhibiting sunlight from reaching the surfaces of dusted plants (Sharifi et al. 1997). Additionally, a decrease in infra-red light reflectance can result in dusted leaves with a 4 to 5°F (2 to 3°C) higher temperature (Sharifi et al. 1997) compared to undusted leaves (Hirano et al. 1995). Soils near roads can have significantly lower nutrient levels, altered organic horizon depth, higher bulk density, and lower moisture (Auerbach et al. 1997). Furthermore, soil characteristics and plant community composition can remain significantly different up to 28 years after road development (Myers-Smith et al. 2006). We do not know if dust negatively affects plant pollinators. (USFWS, 2010)

**Stressor:** Plant-pollinator interactions (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Many of the negative effects of habitat fragmentation to plants are due to effects on plant-pollinator interactions (Debinski and Holt 2000; Moody-Weis and Heywood 2001; Aizen et al. 2002; Gathmann and Tscharntke 2002; Lennartsson 2002; Kolb 2008). Fragmented plant populations appear to be less attractive to insect pollinators, which spend more time in larger, unfragmented plant habitats (Aizen et al. 2002; Lennartsson 2002; Kolb 2008; Goverde et al. 2002). Furthermore, insect pollinator diversity increases in larger populations (Mustajarvi et al. 2001) and decreases in isolated habitats with smaller plant population sizes (Steffan-Dewenter and Tscharntke 1999). Lower pollinator visitation rates are associated with lower seed sets and reproductive success in fragmented sites compared to intact sites (Jennersten 1988).Bumblebees were observed visiting more flowers on fewer flower stalks in sparser plant populations (Mustajarvi et al. 2001; Goverde et al. 2002). This led to increased self-pollination or near-neighbor pollination contributing to inbreeding (Goverde et al. 2002; Lennartsson 2002). Inbred plants produce fewer flowers and seeds, have smaller plant height and smaller leaf-size, and reduced reproductive success (Steffan-Dewenter and Tscharntke 1999; Lienert 2004; Kolb 2008). Overall, we believe energy related development can cause serious impacts to Schoenocrambe suffrutescens through habitat fragmentation, increased road dust, and disruption of plant-pollinator interactions. Current 300 feet (91 meters) buffers are likely adequate to minimize impacts to the species. Nevertheless, in 2009, the Service initiated studies to quantify the effects of continued energy development related to these factors. (USFWS, 2010)

**Stressor:** Building stone mining (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Schoenocrambe suffrutescens habitat is associated with commercially valuable building stone. Building stone mining can directly disturb individual plants and their habitat, with other effects similar to oil and gas development, including habitat fragmentation, increased dust, and pollinator disturbance. Building stone mining was a significant historical threat to the species. Previous commercial stone excavation caused the extirpation of a portion of the species' population in the vicinity of Big and Little Pack Mountains (USFWS 1994). Today, this factor is only a substantive issue on private land. Although approximately 57 percent of mapped Schoenocrambe suffrutescens populations on BLM lands are open to leasing (BLM GIS data, September 2009), building stone mining does not currently occur in occupied habitat on BLM land (Hansen pers. comm. 2009). On private lands, building stone is currently mined in Schoenocrambe suffrutescens occupied habitat. At one site, seven individual plants and

occupied habitat were destroyed (Brunson 2010). We do not know how widespread this impact is across S. suffrutescens habitat on private lands. With so few individuals of this species, we believe that the loss of any individuals could significantly impact the species. Therefore, based on recently documented disturbance on private lands, the Service believes that building stone mining remains a threat to this species. (USFWS, 2010)

**Stressor:** Small populations (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** When Schoenocrambe suffrutescens was listed, it was known to occur in only nine populations with fewer than 3,000 individuals total, including three populations of fewer than 30 plants each. Recent estimates do not indicate significant changes. Small populations and species with limited distributions are vulnerable to relatively minor environmental disturbances (Given 1994). Small populations are also at an increased risk of extinction due to the potential for inbreeding depression, loss of genetic diversity, and lower sexual reproduction rates (Ellstrand and Elam 1993; Wilcock and Neiland 2002). Lower genetic diversity may, in turn, lead to even smaller populations by decreasing the species' ability to adapt, thereby increasing the probability of population extinction (Barrett and Kohn 1991; Newman and Pilson 1997). Species with limited climatic ranges and restricted habitat requirements are typically the most vulnerable to extinction (Intergovernmental Panel on Climate Change [IPCC] 2002; Machinski et al. 2006). The risk of extinction is expected to increase for species with low population numbers (IPCC 2002; Jump and Penuelas 2005). The Service lacks information on the population genetics of Schoenocrambe suffrutescens. Recent observations indicate this species produces more seed when it is outcrossed (Lewis 2010). Therefore, the fewer plants are located at a site, the less chance for cross-fertilization. Because population numbers are very low for this species, we consider small population size a threat to S. suffrutescens, but without further research or information, the Service cannot predict the magnitude of this threat. (USFWS, 2010)

**Stressor:** Invasive species (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Exotic species are common along highways because seeds are carried and deposited along roads by vehicles, and spread via vehicle-caused air turbulence (Forman and Alexander 1998). Roads promote the spread of invasive species by altering soil characteristics, stressing native vegetation, and providing easier movement by wild or human vectors (Trombulak and Frissell 2000). Spread of invasive species via roads coupled with increased road dust can exacerbate the impact on native species: an increase in fine dust particles can increase nonnative, exotic plant species (Reynolds et al. 2001). Invasive, exotic plant species can contribute to the extinction of native plants (Soulé et al. 1992). Cheatgrass (Bromus tectorum) was documented in Schoenocrambe argillacea habitat (Glisson 2005), in the vicinity of the Big Pack Mountain S. suffrutescens population. Cheatgrass can out-compete native species for soil nutrients and water (Melgoza et al. 1990; Aguirre and Johnson 1991; Pyke and Novak 1994). If it establishes in sufficient density in native plant communities, cheatgrass increases flammability, leading to shortened fire return intervals that make it difficult for native plants to re-establish (D'antonio and Vitousek 1992). Halogeton (Halogeton glomeratus) has been documented growing in S. suffrutescens occupied habitat (Brunson 2009; Buys and Associates 2009, Lewis

2010). Halogeton quickly infests areas that are either left barren from fire or disturbed from mechanical or land management means (Pavek 1992). Halogeton tends to be a poor competitor, but it can accumulate sodium in the soil and alter soil microbiota to the disadvantage of native plants (Kitchen and Jorgensen 2001; Kitchen and Carlson 2008). Although invasive species are present in Schoenocrambe suffrutescens habitat, they have not been noted at high levels. Their distribution is likely to increase over time as invasive annuals increase biomass and seed production at elevated levels of carbon dioxide (Mayeux et al. 1994; Smith et al. 2000; Ziska et al. 2005). Regardless, we do not consider invasive species a threat to S. suffrutescens now or for the foreseeable future. (USFWS, 2010)

**Stressor:** Climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change is likely to affect long-term survival or distribution of native species. In the southwestern United States, including Utah and Schoenocrambe suffrutescens habitat, average temperatures have increased ~1.5°F (0.8°C) compared to a 1960-1979 baseline (Karl et al. 2009). By the end of this century, temperatures are expected to warm a total of 4 to 10°F (2 to 5°C) in the Southwest (Karl et al. 2009). Hot extremes, heat waves, and heavy precipitation will increase in frequency, with the Southwest experiencing the greatest temperature increase in the continental United States (IPCC 2007). We do not know how changes in precipitation will affect Schoenocrambe suffrutescens. However, we do know that increased drought can be detrimental to many drought-tolerant species. Drought conditions led to a noticeable decline in survival, vigor and reproductive output of rare plants in the southwest during the drought years of 2001-2004 (Roth 2008a, 2008b; Clark and Clark 2007; Hughes 2005; Anderton 2002; Van Buren and Harper 2002, 2003). On the other hand, there is some indication that high-stress areas may contain plants that are adapted to that stressor, and drought-adapted species may experience lower mortality during severe droughts (Gitlin et al. 2006). Effects related to climate change, such as persistent or prolonged drought conditions, may affect the long-term persistence of Schoenocrambe suffrutescens, but without further research or information, it is difficult to predict how. (USFWS, 2010)

***Recovery***

**Reclassification Criteria:**
1. Discover or establish a minimum of five separate populations with 2,000 or more individuals per population for each species. These populations must be demonstrated to be at or above minimum viable population levels. (USFWS, 1994)

2. Document the presence of or, if necessary, establish formal land management designations which would provide for long—term protection on undisturbed habitat for the above five populations of each species. (USFWS, 1994)

Recovery Priority Number: 5C

**Delisting Criteria:**
1. Discovery or establishment of a minimum of 10 separate populations with 2,000 or more individuals per population for each species. These populations must be demonstrated to be at

or above minimum viable population levels. (USFWS, 1994)

2. Document the presence of or, if necessary, establish formal land management designations which would provide for long—term protection on undisturbed habitat for the above 10 populations of each species. (USFWS, 1994)

**Recovery Actions:**

- Inventory suitable habitat for S. argillacea, S. barnebyl, and S. suffrutescens and determine with a reasonable degree of accuracy the population and distribution of each species. (USFWS, 2011)
- Establish and conduct at least three minimum viable population studies on each of at least three different populations of each species. (USFWS, 2011)
- Document the presence of or, if necessary, establish formal land management designations which would provide for long—term protection on undisturbed habitat for each species. (USFWS, 2011)
- Control activities which affect the habitat of S. argillacea, S. barnebyi, and S. suffrutescens through sections 7 and 9 of the Endangered Species Act and other relevant laws and regulations. (USFWS, 2011)
- We recommend conducting range-wide, comprehensive surveys for Schoenocrambe suffrutescens within the next year, especially in the Gray Knolls area on tribal land. These data should be used to define and delineate populations, and to help revise the Recovery Plan. (USFWS, 2010)
- Monitoring plots were established for testing plant response to disturbance, and basic demographic data are being collected. We recommend continuing to collect data from at least a portion of these plots indefinitely, even past the need for the disturbance study, to be able to answer basic demographic questions and to monitor reproduction. (USFWS, 2010)
- The previous geological nomenclature that was commonly used to identify potential Schoenocrambe suffrutescens habitat was discarded (Weiss 1990), thus complicating an already difficult search for this species. The Service needs to accurately characterize parent material, soil, and landscape characteristics for S. suffrutescens. This research would allow us to more accurately identify unoccupied but potentially important habitat, areas for focused surveys and reintroduction, and areas where oil and gas development are unlikely to harm the species. (USFWS, 2010)
- Schoenocrambe suffrutescens should be reintroduced to new areas of suitable but unoccupied habitat near existing populations. (USFWS, 2010)
- Basic biological and ecological information should be obtained for this species, including pollination mechanisms and pollinators. This research began in 2010. (USFWS, 2010)
- Studies to quantify the effects of dust, invasive species, and disturbance from continued energy development were initiated in 2009. These studies should be continued until the Service has enough data to draw conclusions. (USFWS, 2010)
- The Service should consider collecting seeds to include this species in the Center for Plant Conservation collection. Seeds should also be tested for viability and longevity. (USFWS, 2010)
- Nearly 40 percent of the mapped Schoenocrambe suffrutescens populations occur on non-Federal lands. We should continue to work with the Uintah and Ouray Indian Reservation, SITLA, and private landowners to survey and conserve S. suffrutescens habitat and increase

outreach efforts. (USFWS, 2010)
- On Federal lands, the Service should continue to avoid development in Schoenocrambe suffrutescens populations and suitable, unoccupied habitat as much as possible, unless research becomes available to indicate that S. suffrutescens is unaffected by development. The Service should ensure that developers follow established conservation measures when disturbance occurs and that habitat fragmentation is reduced as much as possible. (USFWS, 2010)
- Using research collected on soil characteristics and response to disturbance, the Service should identify and establish core conservation areas in minimally-disturbed habitat (both occupied and unoccupied) for long-term protection of S. suffrutescens. (USFWS, 2010)
- Once the Service has new survey data and research data available, the Service recommends revising the Recovery Plan to explicitly address the relevant listing factors. Time and cost required to meet the criteria and recover the species should be included in the Recovery Plan. (USFWS, 2010)
- The Service will continue to monitor the acceptance of Hesperidanthus as the correct genus for this species and will officially change this species' name through an FR notice as needed. (USFWS, 2010)

***Conservation Measures and Best Management Practices:***
- Recommended future actions: We recommend increased surveys of potential suitable habitat on all landowner types to better estimate total number of individuals, delineate populations, identify important connectivity corridors, and allow planning for landscape level protections. Additional research that provides a better understanding of current population demographics, population trends, and impact of threats is also necessary to evaluate the effectiveness of current protections and identify when recovery criteria are met. The designation and management of protected areas that reduce impacts from identified threats remains necessary to facilitate this species' recovery. Additionally, we recommend revising the recovery plan and specifically reevaluating the recovery goals and criteria based on new population numbers, habitat requirements, connectivity analysis, and potential changes in threat type and intensity. (USFWS, 2019a)
- RECOMMENDATIONS FOR FUTURE ACTIONS: 1) Reestablish and continue the long-term demographic monitoring across the range of H. suffrutescens. Incorporate plant community data collection. 2) Continue to survey potential habitat across the range focusing on the gaps between, and the edges of, known populations. This would help address downlisting criteria one. 3) Development of a management plan or a formal land designation by the Bureau of Land Management and partner agencies with assistance from the Service. These plans should address current effects from building stone removal and livestock grazing, as well as new or emerging threats such as climate change (USFWS, 2024).

# SPECIES ACCOUNT: *Schwalbea americana* (American chaffseed)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/29/1992; Southeast Region (Region 4)

**Physical Description**

Schwalbea is an erect herb with unbranched stems or stems branched only at the base, growing to a height of3.0 to 6.0 dm (12 to 24 in). The plant is densely albeit minutely hairy throughout, including the flowers. The leaves are alternate, lance-shaped to elliptic, stalkless, 2.5 to 5.0 cm (0.8 to 2 in) long, and entire; the upper leaves are reduced to narrow bracts. The large, purplish-yellow, tubular flowers, 3.0 to 3.5 cm long (1.2 to 1.4 in) are borne singly on short stalks in the axils of the uppermost, reduced leaves (bracts) and form a many flowered, spike-like raceme. The showy flowers have a high degree of bilateral symmetry elaborated for pollination by bees (Pennell 1935). The fruit is a narrow capsule approximately 10 to 12 mm (0.4 to 0.5 in) long, with a septicidal dehiscence. The numerous seeds are pale greenish brown or yellowish-tan, narrowly linear, somewhat flattened or compressed, slightly curved, and enclosed in a loose-fitting, sac-like structure that provides the basis for the common name, chaffseed (Musselman and Mann 1978). Flowering occurs from April to June in the southern part of the species' range, and from June to mid-July in the northern part of its range. Fruits mature from early summer in the South to October in the North (Johnson 1988). (USFWS, 1995)

**Taxonomy**

Pennell (1935) recognized a northern and southern species of Schwalbea, Schwalbea americana L. and Schwalbea australis Pennell, respectively. He distinguished Schwalbea americana by mostly recurved hairs and leaves up to 1.0 cm (0.4 in) wide or less, and Schwalbea australis by a pubescence of mostly upcurved hairs and leaves up to 1.5 cm (0.6 in) wide. Schwalbea americana was known from Massachusetts southward to Virginia, and Schwalbea australis was known from North Carolina to Kentucky and southward to Florida and Louisiana. Fernald (1937) found characters of the leaves and calyx lobes to vary over the total range so that recognition of two species was unwarranted. Following an examination of herbarium material, Musselman and Mann (1977) concurred that there was little taxonomic merit in recognizing more than a single species. Therefore, the U.S. Fish and Wildlife Service accepts the more recent treatments of Fernald (1937) and Musselman and Mann (1977), which recognize Schwalbea americana and Schwalbea australis as one species, Schwalbea americana. In this plan, SchwaIbea americana will be henceforth referred to as the monotypic genus Schwalbea. (USFWS, 1995)

**Historical Range**

Historically known from Massachusetts and New York south along the East Coast to Florida and west along the Gulf Coast states to Texas. (NatureServe, 2015)

**Current Range**

Currently found in the following states: Massachusetts, New Jersey, North Carolina, South Carolina, Georgia, Alabama, Florida, and Louisiana. (USFWS, 2019a)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Asexual and sexual (outcrossing) (NatureServe, 2015)

**Dependency on Other Individuals or Species**

Adult: Schwalbea produces showy, insect-pollinated flowers with a high degree of zygomorphy elaborated for pollination by bees (Pennell 1935). (USFWS, 1995)

**Breeding Season**

Adult: April to June (USFWS, 1995)

**Other Reproductive Information**

Adult: The germination rates of collected Schwulbea seeds are high. Kirkman (1993) reported that the germination rate of seeds placed in petri dishes, with and without cold stratification, was approximately 90 percent. (USFWS, 1995)

**Reproduction Narrative**

Adult: This species produces showy, insect-pollinated flowers; the high degree of zygomorphy elaborated for pollination by bees (Pennell 1935). Reproduction primarily occurs via outcrossing (sexual) but can also reproduce asexually. Flowers bloom between April and June. (USFWS, 1995; NatureServe, 2015)

**Habitat Type**

Adult: Palustrine and terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Bog/fen, forest/woodland, savanna, woodland - mixed (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Sunny open areas (NatureServe, 2015)

**Environmental Specificity**

Adult: Sunny areas (NatureServe, 2015)

**Dependency on Other Individuals or Species for Habitat**

Adult: The root parasitic behavior of Schwalbea has been known since 1856 (Musselman and Mann 1977). Schwalbea is considered the rarest root parasitic plant in the South, and, like most parasitic Scrophulariacese, it is not host-specific. (USFWS, 1995)

**Habitat Narrative**

Adult: Characteristically, Schwalbea occurs in sandy (sandy peat, sandy loam), acidic, seasonally moist to dry soils. The species is generally found in habitats described as pine flatwoods, fire-maintained savannas, ecotonal areas between peaty wetlands and xeric sandy soils, and other open grass-sedge systems (Kral 1983). Schwalbea appears to be shade intolerant and, therefore, occurs in areas maintained in an open to partially open condition. In Georgia, Scwalbea occurs in ecotonal areas between freshwater wetlands and upland pine forests. In North Carolina, the species occurs in moist to dryish pine flatwoods, longleaf pine/wiregrass savannas, and on longleaf pine/oak sandhills composed of Upper Cretaceous deep, white sands, at the western edge of the coastal plain. In South Carolina, the predominant habitat is described as fire-maintained (or mowed, as under power lines), dry, well-drained, longleaf pine flatwoods. The soil is generally a sandy loam. In New Jersey, Schwalbea occurs in open areas that have been maintained by mowing within a pitch pine community. The site is next to a roadcut through a cedar swamp. (USFWS, 1995)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: The structure of the Schwalbea seed, somewhat flattened or compressed, slightly curved, and enclosed in a loose-fitting sac-like structure, suggests wind dispersal; however, no information is available to support this hypothesis. Information is lacking on both the mechanism and distance of seed dispersal. (USFWS, 1995)

***Population Information and Trends***

**Population Trends:**

Long-term trends indicate population declines from 50 to 90%, whereas short-term trends suggest declines of 10 to 30% (NatureServe, 2015)

**Species Trends:**

Declining (NatureServe, 2015)

**Number of Populations:**

43 (USFWS, 2019a)

**Population Size:**

2500 - 10,000 individuals (NatureServe, 2015)

**Adaptability:**

Moderate (NatureServe, 2015)

**Population Narrative:**

When Schwalbea was listed as an endangered species in 1992, 19 extant occurrences were known from the following States: New Jersey (1), North Carolina (1), South Carolina (11), Georgia (4), Florida (1), and Mississippi (1). At the completion of the recovery plan in 1995, extensive searches for this species that occurred in the Southeast, namely North and South Carolina, increased the number of extant occurrences to 72: New Jersey Pleasantville, New Jersey(1), North Carolina (18), South Carolina (42), Georgia (10), and Florida (1). The last comprehensive review of this species status occurred in 2008. At that time, 53 occurrences were extant (30% of sites extant) in 2008: New Jersey (2), North Carolina (11), South Carolina (33), Georgia (4), Alabama (1), Florida (1), and Louisiana (1). It is important to note that in the 1995 recovery plan and 2008 5-year review, the terms population and occurrence were used interchangeably. Since some Schwalbea populations have multiple element occurrences or sites per population, the number of populations across the species range was over-reported in some cases. In order to standardize population numbers across state boundaries, NatureServe's (2018) population delimitation guidelines were used for all extant populations across Schwalbeas' range in this five-year review. Historic and unknown occurrences were not delimited. Currently, there are 43 extant populations across the species range: Massachusetts (1), New Jersey (2), North Carolina (6), South Carolina (18), Georgia (9), Alabama (2), Florida (3), and Louisiana (2). (USFWS, 2019a)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2019a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat destruction and adverse modification of suitable habitat for Schwalbea continue to be major threats for this species. Development along the coast continues to threaten Schwalbea by (1) direct loss of habitat and (2) indirect threats due to urbanization resulting in fire suppression from either local air pollution regulations or safety concerns. Fire suppression continues to threaten this species on both private and public lands. Conversion of longleaf flatwoods and savannas to commercial pine plantations and agriculture fields continue to threaten this species. Although new Schwalbea populations are being discovered, the number of extant populations declined by approximately 25% since the last 2008-five year review. (USFWS, 2019a)

**Stressor:** Herbivory (USFWS, 2019a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbivory continues to serve as a minor threat to the species, herbivores include the striped leaf beetle (Kuschelina sp.), Chrysomelid leaf beetle sp., and Buckeye caterpillar (Junonia coenia) larvae (M. Jenkins, Florida Department of Agriculture and Consumer Resources, pers. comm. 2017; Bob Dellinger, U.S. Forest Service, pers. comm. 2017). The Lethcoe, FMNF population suffered from herbivory when fresh new growth sprouted following a prescribed fire. (USFWS, 2019a)

**Stressor:** Small population size (USFWS, 2019a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Small population size was noted as a threat in the last 2008 five-year review and remains a threat today. Populations that appear stable throughout time contain at least 100 individuals. Currently, 20 populations contain 100 or more individuals. Small populations are highly vulnerable to extirpation, especially in the absence of prescribed fire. Small populations may be less resilient to environmental changes related to climate change. (USFWS, 2019a)

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2019a)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Because the Act only grants protection to plants when a Federal nexus is involved (e.g., federal permit required, federally funded projects), existing regulatory mechanisms are inadequate to protect Schwalbea. Schwalbea receives protection from state rare plant protection laws in Massachusetts, New Jersey, North Carolina, South Carolina, Georgia, and Florida. (USFWS, 2019a)

**Stressor:** Drought (USFWS, 2019a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since Schwalbea is mostly (can occur outside of ecotone areas in longleaf flatwoods) an ecotone species occurring in transitional areas between uplands and freshwater wetlands, an increase in drought frequency and decrease in precipitation events could threaten smaller, less resilient populations. (USFWS, 2019a)

***Recovery***

**Reclassification Criteria:**
1. Long-term protection is achieved for 50 geographically distinct, self-sustaining populations. The population sites must be protected from development and other anthropogenic threats that may interfere with the species' survival. Protection of populations on private lands will be evidenced through landowner agreements or conservation easements. Protection of Schwalbea on public lands will be secured through agreements that ensure the long-range protection, management, and monitoring ofSchi4.ulbea. Protected sites will be distributed to include, at a minimum, all of the States currently supporting Schwalbea, with at least four populations in the northern portion of the species' range. Site protection agreements will cover the immediate occurrence site and, where possible, enough contiguous unoccupied habitat to allow for dispersal and natural colonization and expansion of the species. (USFWS, 1995)

2. Management agreements or plans are developed for the 5O protected occurrence sites with the primary objective of ensuring that an ecosystem capable of supporting viable populations of Schwalbea will be permanently maintained. In the case ofprivate ownership, these management agreements could be part of the conservation easement or landowner agreement. (USFWS, 1995)

3. Viable populations of Schwalbea are established at four sites in the northern portion of the species' range (Massachusetts to Virginia), preferably with genetic material from the only remaining northern population in New Jersey. (USFWS, 1995)

4. Biennial monitoring shows that the 50 protected populations are viable as well as stable or increasing over a 10-year period. Demographic population data will be required to meet this condition. (USFWS, 1995)

5. Life history and ecological requirements are understood sufficiently to reliably predict the effectiveness of protection, management, and monitoring. (USFWS, 1995)

**Delisting Criteria:**

1. Protection via a conservation mechanism is achieved for 50 geographically distinct, self-sustaining populations (Addresses listing factors A, D, and E). (USFWS, 2019b)

2. Protected populations will be distributed to include all of the states currently supporting Schwalbea, and at least four populations in the northern portion of the species range (Massachusetts to Virginia) (Addresses listing factors A, D, and E). (USFWS, 2019b)

3. The land management plans or agreements for the 50 protected Schwalbea populations must include management objectives that abate threats to Schwalbea such as fire suppression, hog damage, and/or silviculture practices (Addresses listing factors A, D, and E). (USFWS, 2019b)

**Recovery Actions:**

- Protect extant populations and manage habitat. Identify ownership of all known populations. Establish contact with landowners and negotiate landowner agreements or conservation easements. Ensure that activities and management on public lands are consistent with the protection and management of Schwalbea. Use existing regulatory mechanisms to protect Schwalbea. Conduct additional surveys. (USFWS, 1995)
- Expand the extent of Schwalbea In the northern portion of the current range. The New Jersey occurrence of Schwalbea, which is critical to maintaining the northern range of the species, will receive continued protection. In addition, populations should be established in New Jersey, Delaware, Maryland, New York, Connecticut, and Massachusetts to guard against the extirpation of the species from the northern portion of its range. Data are not currently available that indicate the genetic significance of the remaining northern population; however, Pennell (1935) considered the northern and southern populations of Schwalbea trlbea to be distinct species, with the southern species occurring as far north as Virginia (Reveal and Broome 1981). Genetic analyses (Recovery Task 6 below) may further support the significance of maintaining viable populations from the northern gene pool. (USFWS, 1995)
- Investigate best management techniques. ContInue experiments to determine the effects of fire. Conduct experiments to determine the effects of other disturbances. (USFWS, 1995)
- Investigate the species' biology. Conduct research to obtain more comprehensive information on life history and population demography. Determine minimum viable population size. (USFWS, 1995)
- Investigate genetic variability. Genetic analyses should be conducted to determine inter and intra-genetic variability of populations. Differences in the genetic composition of populations may influence site protection and reintroduction priorities. Ongoing genetic analyses may be sufficient to determine if significant variability exists. (USFWS, 1995)
- Monitor populations. Meeting the recovery objectives is contingent upon the stabilization of viable populations over time. Consistent monitoring will provide population data necessary to determine if the recovery objectives are being met. (USFWS, 1995)
- Review recovery progress and revise recovery plan as necessary. The overall success of the recovery program should be periodically assessed, and recommendations regarding appropriate changes in recovery objectives or tasks as suggested by research, studies, or monitoring should be implemented. (USFWS, 1995)
- Research and determine if in situ recruitment and reintroduction can occur under different levels of soil disturbance and watering regimes. (USFWS, 2019a)

- Continually search for new populations in areas managed for quail and/or red-cockaded woodpeckers or any areas with a 1-2 year fire return interval within the species' historic range. (USFWS, 2019a)
- Survey unknown and historic populations and if present negotiate landowner agreements or conservation easements. (USFWS, 2019a)
- Develop an easy and repeatable Schwalbea survey form and methodology for range-wide use in order to tract/monitor recovery populations annually. (USFWS, 2019a)
- Research the germination ecology of Schwalbea in regards to moisture and light requirements and seedling recruitment / host attachment to understand Schwalbea's regeneration strategy. (USFWS, 2019a)
- Research fire seasonality effects, especially early April and late July/August fires, in conjunction with rainfall patterns/climatic fluctuations. (USFWS, 2019a)
- Continue population reintroductions within the historic range and introductions into protected areas with 1-3 year fire return intervals. (USFWS, 2019a)
- Expand the extent of Schwalbea in the northern portion of the current range. (USFWS, 2019a)

# SPECIES ACCOUNT: *Sclerocactus brevihamatus ssp. tobuschii* (Tobusch fishhook cactus)

***Species Taxonomic and Listing Information***

**Commonly-used Acronym:** SCLTOB

**Listing Status:** Endangered; 12/08/1979; Southwest Region (Region 2)

### Physical Description

A cactus armed with fishhook-shaped spines. The hemispheric or short-columnar stems of mature plants are 3 to 10 centimeters (cm) (1.2 to 3.9 inches (in)) tall and 1 to 10 cm (0.4 to 3.9 in) in diameter; however, although the largest recorded individuals are as much as 10 cm ( 3.9 in) in diameter, few wild plants are greater than 5 cm (2.0 in) in diameter (Poole and Janssen 2002, p. 7). The stems are supported on short, conical taproots from which emerge numerous fibrous roots that typically grow horizontally along the surfaces and fissures of rock strata. The stems bear tubercles (podaria) up to 12 millimeters (mm) (0.5 in) long that have a groove (sulca) along their upper surfaces. The tubercles are arranged in 5 to 8 ribs (Marshall 1952, p. 79), or from 8 to 12 ribs (Poole et al. 2007, p.442). However, we note that the tubercles within each rib are nearly distinct from each other; the ribs, which may spiral, are difficult to discern, especially in smaller individuals, and the tubercles appear to alternate. Spines arise from areoles at the apex of each tubercle. The spines are of two types: Radial spines are fine, straight, from 1 to 2 cm (0.4 to 0.8 in) long, spreading at right angles to the tubercle from the edges of the areoles. From 3 to 5 thicker, flattened central spines, 2 to 4 cm (0.8 to 1.6 in) in length, arise from nearer the center of the areoles and project more or less outward from the stem; one of the central spines is abruptly recurved, and may reach 180° of curvature in older individuals. Spines are yellowish at first, and may have reddish tips, turning gray with age. Flowers emerge from the bases of young tubercles near the stem apex, and have numerous yellow tepals. Fruits are spineless, elongate, from 2.5 to 3 cm (1 to 1.2 in) long, turning reddish-green and usually splitting open along 1 or more lines when mature. (USFWS, 2017)

### Taxonomy

The genus Ancistrocactus, which means "fishhook", contains four species, three occurring in the region of the Rio Grande River in southern Texas and adjacent Mexico, and one occurring farther south (Benson, 1982). According to Benson (1982) this genus is mostly closely related to Coryphantha and Neolloydia, all three genera being in the vast complex group of plants intermediate between Mammillaria and Echinocactus. Systematics of the Cactaceae has always been controversial. No single treatment is universally accepted, and the steady accumulation of phylogenetic analyses has forced continual revisions. In particular, there is no consensus among cactus authorities regarding the taxa pertaining to the related genera of Ancistrocactus, Sclerocactus, and Ferocactus. The following sources provide a brief review of the prevailing classifications. A number of synonyms have been applied to this taxon, including Ancistrocactus tobuschii (W.T. Marshall) W.T. Marshall ex Backeb, Echinocactus tobuschii (W.T. Marshall) Weniger and Ferocactus tobuschii (W.T. Marshall) N.P. Taylor. (USFWS, 1987; USFWS, 2010). An extensive discussion of the taxonomy is provided in the Species Status Assessment of 2017 (USFWS, 2017).

**Historical Range**

Endemic to the Edwards Plateau of Texas. (USFWS, 2017)

**Current Range**

In the following central counties in Texas: Bandera, Edwards, Kerr, Kimble, kinney, Real, Uvalde, and Val Verde. (USFWS, 2017)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 2017)

**Lifespan**

Adult: >10 years (USFWS, 2017)

**Dependency on Other Individuals or Species**

Adult: Pollinators; most common were several species of halictid bees (USFWS, 2017)

**Breeding Season**

Adult: Late January to mid-March (USFWS, 2017)

**Other Reproductive Information**

Adult: Tobusch fishhook cactus plants begin reproducing when they have grown to a diameter of about 2 cm (occasionally less); this is estimated to require 9 years of growth in the wild. Flowering occurs between late January and mid-March, depending on locality, and lasts a few weeks in each population. Honey bees and halictid bees are effective pollinators, although the latter group may be more active later in the flowering season. The breeding system is primarily by outcrossing, although self-fertilization occurs rarely. Fruits ripen around mid-May. (USFWS, 2017)

**Reproduction Narrative**

Adult: Tobusch fishhook cactus grows slowly, reaching a reproductive size of about 2 centimeters (0.8 inches) in diameter after 9 years. It flowers between late January and mid-March, and its major pollinators are honey bees and halictid bees. The breeding system is primarily out-crossing, but the species is capable of self-fertilization. Reproductive individuals produce an average of 112 seeds per year. Ants may be seed predators, dispersers, or both. Mammals or birds may also accomplish longer-distance seed dispersal. We have little evidence of a persistent soil seed bank. (USFWS, 2017)

**Habitat Type**

Adult: Terrestrial (USFWS, 2017)

**Habitat Vegetation or Surface Water Classification**

Adult: Shortgrass grasslands, oak-juniper woodlands, semi-desert shrublands (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Full sunlight (USFWS, 2017)

**Spatial Arrangements of the Population**

Adult: Discontinuous patches (USFWS, 2018)

**Environmental Specificity**

Adult: Moderate, with some key requirements (USFWS, 2017)

**Habitat Narrative**

Adult: The riparian habitats described in the original status report are atypical. The great majority of documented populations occur in upland sites dominated by Ashe juniper-live oak woodlands and savannas on outcrops of early Cretaceous limestone. Soils are classified in the Tarrant, Ector, Eckrant, and similar series. Within a matrix of woodland and savanna, the species occurs in discontinuous patches of very shallow, gravelly soils where bare limestone rock and rock fragments comprise a large proportion of the surface cover. Associated vegetation includes small bunch grasses and forbs. The species' distribution within habitat patches is clumped and tends to be further from woody plant cover. The presence of spikemosses (Selaginella spp.), and perhaps other cryptogams, may be useful indicators of fine-scale habitat suitability. Wildfire (including prescribed burning) causes negligible damage to Tobusch fishhook cactus populations. The species probably does not require fire for germination, establishment, or reproduction, but periodic burning may be necessary to prevent the encroachment of woody plants into its habitats. (USFWS, 2017)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Ants remove a large proportion of seeds, pulp, and funiculi, but whether the ants consume the seeds, or effectively disperse them, is not known. Mammals or birds also consume fruits and may accomplish longer-distance seed dispersal. Moderate numbers of viable seeds have been found in the soil near live plants, but the extent and longevity of soil seed banks is unknown. (USFWS, 2017)

***Population Information and Trends***

**Population Trends:**

Increasing (USFWS, 2017)

**Resiliency:**

It is likely that Tobusch fishhook cactus has multiple, resilient populations (USFWS, 2017). 'Resilience and Redundancy. Resilience refers to the population size necessary to endure stochastic environmental variation (Shaffer and Stein 2000, pp. 308-310). Redundancy refers to the number and geographic distribution of populations or sites necessary to endure catastrophic events (Shaffer and Stein 2000, pp. 308-310). The recovery plan (USFWS 1987, p. 14) established a recovery criterion of 4 protected populations with at least 3,000 individuals, but did not show

how this level was determined. However, we now understand that insect parasites are able to devastate large, dense populations. We conclude that few large populations are much more vulnerable than many small populations, and that this recovery criterion should be amended. Poole and Birnbaum (2003, p. 1), using the surrogate species method of Pavlik (1996, pp. 136-137), estimated a MVP for Tobusch fishhook cactus of 1,200 individuals (Section II.7.5). Since few individual colonies reach this size, and since large colonies are more vulnerable to insect parasites, we recommend that the MVP of 1,200 individuals be applied to metapopulations that consist of multiple colonies distributed at a landscape scale. The resilience of Tobusch fishhook cactus derives not merely from the size of metapopulations, but also their density. Colonies that are too small or too isolated may incur loss of genetic diversity and inbreeding; Rayamajhi (2015, pp. 63-64) found relatively high inbreeding coefficients in 3 of 8 populations, which he attributed to mating of close relatives within small, isolated populations. Conversely, vulnerability to insect parasitism increases when metapopulations become too dense, or when colonies become too large. Therefore, we believe that there must be some optimal range of metapopulation density and colony size, although we do not currently know what those optima are. These concepts of metapopulation size and density depend on how metapopulation boundaries are delimited. The EO concept is a good starting point, but may have to be revised for Tobusch fishhook cactus considering its specific population dynamics. The determination of Tobusch fishhook cactus viability is more challenging, since few surveys have been conducted on the roughly 95 percent of the potential habitat that is privately owned. Furthermore, since the populations are small and widely distributed, there is a low probability of detecting populations on any fixed area, such as a state park. It is likely that metapopulations are distributed over areas that are larger than individual parks and natural areas. We can speculate that the population densities found on the small number of areas that have been quantitatively surveyed are representative of the entire global distribution of this subspecies. Since 2009, several new quantitative surveys were conducted for highway, pipeline, and power line developments. These surveys provided data from transects that cross the subspecies' range and provide more evidence for its range of densities. Based on all available evidence, we provisionally estimate that the global population size is about 480,000 individuals (Appendix 2). Regardless of how this number is divided into metapopulations, we believe that it is likely that Tobusch fishhook cactus has multiple, resilient populations' (USFWS, 2017).

**Representation:**

Tobusch fishhook cactus currently possesses sufficient genetic diversity to conserve long-term adaptive capability. However, habitat fragmentation and disruption of gene flow among populations may have occurred too recently to be detected through genetic analyses. Considering the naturally low densities of Tobusch fishhook cactus populations, gene flow among them may be easily disrupted. (USFWS, 2017). Representation. Representation refers to the genetic diversity, both within and among populations, necessary to conserve long-term adaptive capability (Shaffer and Stein 2000, pp. 307-308). Rayamajhi (2015, (pp. 53, 54, 65, 66, 79, 80) found relatively low levels of genetic differentiation among 9 populations of Tobusch fishhook cactus (low pairwise FST and GST levels, discussed in II.2), regardless of the distance between populations. He found evidence of substantial gene flow among populations, suggesting that the documented populations may interact with additional (undocumented) populations (at least in the recent past) (p. 67). However, recently isolated populations may not yet show genetic differentiation, in part because individuals can live and contribute to the local gene pool at least for several decades. Most of the populations studied had healthy levels of outbreeding, but 3 populations were at relatively higher risk of inbreeding effects and may have suffered recent genetic bottlenecks through population declines (P. 97). Based on controlled pollination experiments, Emmett (1995) found effective fertilization (fruit set, seed production, and seed viability) within isolated colonies in his study area (p. 87). This affirms empirically that at least some isolated colonies still possess a sufficient level of genetic diversity. The low level of genetic differentiation among populations is not unusual for endemic taxa, and may also indicate a fairly recent divergence of subspecies tobuschii from subspecies brevihamatus. There is evidence of gene flow throughout the subspecies' range and possible interaction of the monitored populations with undocumented populations on surrounding private lands. Genetic differentiation within most, but not all populations, is sufficiently high for effective fertilization and out-crossing. We conclude that Tobusch fishhook cactus currently possesses sufficient genetic diversity to conserve long-term adaptive capability. However, habitat fragmentation and disruption of gene flow among populations may have occurred too recently to be detected through genetic analyses. Considering the naturally low densities of Tobusch fishhook cactus populations, gene flow among them may be easily disrupted. Therefore, maintaining the continuity of potential habitats throughout the subspecies range should have a high conservation priority. We recommend that viability monitoring should be continued long enough to determine population dynamics and demographic trends at the metapopulation and subspecies levels (USFWS, 2017).

**Redundancy:**

It is likely that Tobusch fishhook cactus has multiple, resilient populations (USFWS, 2017). 'Resilience and Redundancy. Resilience refers to the population size necessary to endure stochastic environmental variation (Shaffer and Stein 2000, pp. 308-310). Redundancy refers to the number and geographic distribution of populations or sites necessary to endure catastrophic events (Shaffer and Stein 2000, pp. 308-310). The recovery plan (USFWS 1987, p. 14) established a recovery criterion of 4 protected populations with at least 3,000 individuals, but did not show how this level was determined. However, we now understand that insect parasites are able to devastate large, dense populations. We conclude that few large populations are much more vulnerable than many small populations, and that this recovery criterion should be amended. Poole and Birnbaum (2003, p. 1), using the surrogate species method of Pavlik (1996, pp. 136-137), estimated a MVP for Tobusch fishhook cactus of 1,200 individuals (Section II.7.5). Since few individual colonies reach this size, and since large colonies are more vulnerable to insect parasites, we recommend that the MVP of 1,200 individuals be applied to metapopulations that consist of multiple colonies distributed at a landscape scale. The resilience of Tobusch fishhook cactus derives not merely from the size of metapopulations, but also their density. Colonies that are too small or too isolated may incur loss of genetic diversity and inbreeding; Rayamajhi (2015, pp. 63-64) found relatively high inbreeding coefficients in 3 of 8 populations, which he attributed to mating of close relatives within small, isolated populations. Conversely, vulnerability to insect parasitism increases when metapopulations become too dense, or when colonies become too large. Therefore, we believe that there must be some optimal range of metapopulation density and colony size, although we do not currently know what those optima are. These concepts of metapopulation size and density depend on how metapopulation boundaries are delimited. The EO concept is a good starting point, but may have to be revised for Tobusch fishhook cactus considering its specific population dynamics. The determination of Tobusch fishhook cactus viability is more challenging, since few surveys have been conducted on the roughly 95 percent of the potential habitat that is privately owned. Furthermore, since the populations are small and widely distributed, there is a low probability of detecting populations on any fixed area, such as a state park. It is likely that metapopulations are distributed over areas that are larger than individual parks and natural areas. We can speculate that the population densities found on the small number of areas that have been quantitatively surveyed are representative of the entire global distribution of this subspecies. Since 2009, several new quantitative surveys were conducted for highway, pipeline, and power line developments. These surveys provided data from transects that cross the subspecies' range and provide more evidence for its range of densities. Based on all available evidence, we provisionally estimate that the global population size is about 480,000 individuals (Appendix 2). Regardless of how this number is divided into metapopulations, we believe that it is likely that Tobusch fishhook cactus has multiple, resilient populations' (USFWS, 2017).

**Number of Populations:**

511 sites (USFWS, 2017)

**Population Size:**

Globally about 480,000 individuals (USFWS, 2017)

**Population Narrative:**

The TXNDD (2016) lists 97 EOs, totaling 3,336 individuals in 8 counties of the Edwards Plateau of Texas. • From 2009 to 2016 we received additional sources of population data, primarily from surveys conducted for development projects. • A total of 118 permanent plots at 12 protected natural areas have been monitored from 1991 through 2013. Plot data reveals that mortality is often very high, and consistently exceeds recruitment; however, the known population sizes have steadily increased, due to the discovery of previously undetected individuals and colonies. • The probability of detecting live Tobusch fishhook cactus individuals during a single survey is highly variable; Reemts (2014) calculated an overall detection rate of 50 percent. The inability to detect all living members of a population confounds determinations of population size and demographic trends. • Demographic population viability analyses of monitored populations, using integral projection models, predicted stable or increasing trends for 2 or 3 populations, moderate declines for 2 populations, and large to precipitous declines in 5 populations over the next 50 years. When expected climate changes were included in the analyses, 4 populations responded negatively to climate changes and 6 populations responded positively (compared to PVA without climate changes). We estimate that the global population size for Tobusch fishhook cactus is about 473,000 individuals distributed over an area of over 2 million ha (5 million ac). (USFWS, 2017)

***Threats and Stressors***

**Stressor:** Land Use Changes (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Relatively little urban and industrial development is occurring within the semi-arid, sparsely populated eight-county known range of Tobusch fishhook cactus. However, a significant ongoing trend throughout the species' range is the subdivision of large ranches into many small "ranchettes," leading to a proliferation of roads, fences, power lines, and residential development, all of which contribute incrementally to habitat loss and fragmentation. Land subdivision also engenders changes in land use and management which may be both beneficial and detrimental to Tobusch fishhook cactus. For example, the predominant, historic land use

throughout the Edwards Plateau has been grazing of livestock, including goats, cattle, sheep, and horses. In many cases, poor rangeland management during the last century has caused the depletion of herbaceous vegetation, cessation of the natural wildfire cycle, proliferation of dense juniper stands, soil erosion, and reduced infiltration and storage of rainwater in the soil profile; all of these changes are likely to have harmed Tobusch fishhook cactus populations. The change to a primarily recreational land use often entails continued grazing, in order to obtain agricultural tax exemptions, but at a sustainable stocking density (landowners may subsequently convert an agricultural exemption to a wildlife exemption). Currently, both large and small landowners are more aware of and concerned with conservation issues than during the last century. Prescribed burning may be one of the most important vegetation management tools for sustaining Tobusch fishhook cactus populations; the proliferation of residential development within the species' habitat makes this tool more challenging for natural resource managers to use. The subdivision of privately-owned land and associated threats are likely to continue. (USFWS, 2017)

**Stressor:** Changes in vegetation and wildfire frequency. (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Bray (1904, pp. 14–15, 23–24) documented the rapid transition of grasslands to woodlands in the Edwards Plateau occurring more than a century ago; he attributed this change to over-grazing, the depletion of grasses, and the cessation of wildfires. Fonteyn et al. (1988, p. 79) state that savannas covered portions of the pre-settlement Edwards Plateau, and since 1850 were transformed to shrubland or woodland "primarily by suppression of recurring natural and anthropogenic fires and the introduction of livestock." They list the fire-sensitive Ashe Juniper as the most successful of many woody plants that have invaded grasslands. Reemts (2014 p. 1). lists the encroachment of woody plants into the rocky, open habitat as one of several habitatrelated threats to Tobusch fishhook cactus. However, the historic extent of grasslands in the Edwards Plateau is an area of active scientific debate. It is likely that woodlands were most abundant on slopes in the Balcones Escarpment (which includes the southern and eastern portion of the Tobusch fishhook cactus range) and that grasslands were more abundant on flatter, deeper soils in the western Edwards Plateau (Diamond et al. 1995, pp. 191-193; Diamond and True 2008, pp. 53-54; Murray et al. 2013, pp. 298, 302). (USFWS, 2017)

**Stressor:** Livestock grazing. (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The recovery plan stated "Ancistrocactus tobuschii plants have been observed that were either uprooted or had apical meristem injuries from livestock trampling." Nevertheless, livestock trampling and herbivory have not subsequently been identified as significant causes of mortality or damage to Tobusch fishhook cactus plants. The recurved spines and small size probably discourage herbivory of Tobusch fishhook cactus plants. Livestock are not attracted to the sparsely vegetated outcrops where Tobusch fishhook cactus plants typically occur, and the plants are protected to some degree by surrounding rocks. While livestock trampling probably occurs in grazed habitats, particular where animals are concentrated, we have no evidence that it represents a significant threat to the species. A number of healthy Tobusch fishhook cactus populations occur on well-managed rangeland. We conclude that livestock grazing, especially where juniper thinning and prescribed burning are used to manage rangeland, is generally

compatible with conservation of this cactus. (USFWS, 2017)

**Stressor:** Illicit collection. (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Many rare cactus populations have been depleted by overzealous collectors. The recovery plan lists collection by unscrupulous cactus and succulent fanciers as a threat to the species. Westlund (1991, pp. 2, 35, 39) found six specimens of Tobusch fishhook cactus, grown legally from seed, for sale in commercial nurseries. Poole and Janssen (2002, p.9) noted that one population of Tobusch fishhook cactus was heavily depleted by collection, but concluded that "collection is not currently perceived to be a grave threat." Although illicit collection has not significantly impacted the species, the wild populations openly accessed by the public remain vulnerable. The potential threat of illicit collection might be diminished if seeds and plants of legally-propagated Tobusch fishhook cactus are easier and less expensive to obtain than wilddug specimens. (USFWS, 2017)

**Stressor:** Parasites. (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Tobusch fishhook cactus weevil (Gerstaeckeria sp. nov.) and cactus longhorn beetle (Moneilema spp.) parasitize and kill Tobusch fishhook cactus plants and have contributed significantly to drastic declines in many of the known populations (Calvert 2003, all). Considering that the weevil (Gerstaeckeria sp. nov.) is a new species, and that it may be an obligate parasite of Tobusch fishhook cactus (Calvert 2003, p. 12), the weevil itself may be no less endangered than its host. Periodic outbreaks of insect parasitism appear to be an unavoidable natural cycle. For this reason, the recovery criterion of 3,000 individuals per population may be unattainable or unsustainable, as such large cactus populations would eventually host very large parasite populations, leading to their collapse. The most appropriate conservation strategy may be to protect larger numbers of small, widely-spaced populations, rather than fewer large populations that are more vulnerable to parasites; however, we do not currently know what the optimal parameters of size and spacing should be..(USFWS, 2017)

**Stressor:** Other herbivory. (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Poole and Birnbaum (2003, pp. 11-12) report that jackrabbits browse the cactus, but in most sites cause less than 2 percent mortality. If the root systems are not too badly damaged, they may regenerate one or more new stems. Feral hogs have uprooted plants in many sites (also observed by Reemts (2015, p. 1)). An unidentified ant species has also caused 1 percent mortality at some sites by creating mounds on top of the stems. Federally-listed plants occurring on private lands have limited protection under the ESA, unless also protected by State laws; the State of Texas also provides very little protection to listed plant species on private lands. Approximately 95 percent of Texas land area is privately-owned. It is reasonable to assume that the vast majority of existing Tobusch fishhook cactus habitat, including sites that have not been documented, occurs on private land. Therefore, most of the species' populations and habitats

are not subject to Federal or State protection unless there is a Federal nexus, such as provisions of the Clean Water Act or a federally-funded project. The ESA does provide some protection for listed plants on land under Federal jurisdiction. However, Tobusch fishhook cactus populations have not been documented on Federal land. International trade of Tobusch fishhook cactus (as Sclerocactus brevihamatus ssp. tobuschii) is regulated under CITES Appendix I (Convention on International Trade in Endangered Species of Wild Fauna and Flora 2009). (USFWS, 2017)

**Stressor:** Demographic consequences of small population size and density. (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Poole and Birnbaum (2003, p. 1) estimated an MVP of 1,200 individuals (Section II.7.5). Small populations are less able to recover from losses caused by random environmental changes (Shaffer and Stein 2000, pp. 308-310), such as fluctuations in recruitment (demographic stochasticity), variations in rainfall (environmental stochasticity), or changes in the frequency of wildfires. Tobusch fishhook cactus has a predominantly out-crossing breeding system. The probability of successful fertilization between unrelated individuals is reduced in small, isolated populations. The remaining plants would produce fewer viable seeds, further reducing population recruitment and engendering a downward spiral toward extirpation. The demographic consequences of small population size are compounded by genetic consequences (discussed below), since reduced out-crossing corresponds to increased inbreeding. In addition to population size, it is likely that population density also influences population viability; density must be high enough for gene flow within metapopulations, but low enough to minimize parasite infestations. (USFWS, 2017)

**Stressor:** Genetic consequences of small population sizes. (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Small, reproductively isolated populations are susceptible to the loss of genetic diversity, to genetic drift, and to inbreeding. The loss of genetic diversity may reduce the ability of a species or population to resist pathogens and parasites, to adapt to changing environmental conditions, or to colonize new habitats. Conversely, populations that pass through a “genetic bottleneck” may subsequently benefit through the elimination of harmful alleles. Nevertheless, the net result of loss of the genetic diversity is likely to be a loss of fitness and lower chance of survival of populations and of the subspecies. Genetic drift is a change in the frequencies of alleles in a population over time. Genetic drift can arise from random differences in founder populations and the random loss of rare alleles in small isolated populations. Genetic drift may have a neutral effect on fitness, but is also a cause of the loss of genetic diversity in small populations. Genetic drift may also result in the adaptation of an isolated population to the climates and soils of specific sites, leading to the development of distinct ecotypes and to speciation. For example, the genetic divergence of Sclerocactus brevihamatus subspecies brevihamatus and tobuschii (Section II.2; Rayamajhi 2015, pp. 67, 98) may have resulted when populations of the species brevihamatus migrated into separate geographic regions, and once separated, each population adapted to different soils, climate, and pollinator species. Inbreeding depression is the loss of fitness among offspring of closely related individuals. While most animal species are susceptible to inbreeding depression, plant species vary greatly in response to inbreeding. Rayamajhi (2015, pp. 63-64) found relatively high inbreeding coefficients in 3 of 8

populations, which he attributed to mating of close relatives within small, isolated populations. Nevertheless, we do not know to what extent inbreeding has reduced fitness of these populations. (USFWS, 2017)

**Stressor:** Private land ownership. (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A large portion of the known individuals and populations of Tobusch fishhook cactus occurs on privately owned land. This does not constitute a threat to the subspecies, and in fact many landowners have demonstrated interest and enthusiasm for its conservation. However, private ownership makes conservation more challenging for several reasons. Access to populations and habitats is subject to the interests of hundreds of individual landowners. Consequently, our knowledge of the subspecies' actual status is far from complete. Establishing and maintaining cooperative relationships with large numbers of private landowners is time-consuming, and these important relationships may lapse when personnel of conservation organizations retire or pursue other career choices. The ownership of private lands changes hands over time, and future owners may choose not to continue conservation efforts that were supported by previous owners. Hence, it is difficult to assure permanent conservation on private lands. These challenges underscore the importance of effective landowner outreach in the conservation of Tobusch fishhook cactus. (USFWS, 2017)

**Stressor:** Climate change. (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Fifth Assessment Report of the Intergovernmental Panel on Climate Change (IPCC) (IPCC 2013, p. 23) projects the following changes by the end of the 21st century, relative to the 1986 to 2005 averages: It is virtually certain that most land areas will experience warmer and/or fewer cold days and nights; it is virtually certain that most land areas will experience warmer and/or more frequent hot days and nights; it is very likely that the frequency and/or duration of warm spells and heat waves will increase in most land areas; it is very likely that the frequency, intensity, and/or amount of heavy precipitation will increase in mid-latitude land masses; it is likely that the intensity and/or duration of droughts will increase on a regional to global scale. We do not know how Tobusch fishhook cactus responded to prior climate changes, nor can we determine how these projected climate changes, forecast by the range of models and emissions scenarios, will affect the synecology of Tobusch fishhook cactus and its habitat. Warmer winters could extend the growing season and improve reproduction and survival of Tobusch fishhook cactus, but might also increase survival of parasite larvae. Heavier, less frequent rainfall could reduce establishment of Tobusch fishhook cactus seedlings, but perhaps less so than the bunch grasses that it competes with. Zaya et al. (2014, pp. 37-38) projected that expected climate changes will be detrimental to 4 populations and beneficial to 6 others. Thus, although it is likely that the projected climate changes will affect the survival of Tobusch fishhook cactus in infinitely complex ways, we do not currently know what the net result of beneficial and detrimental effects will be. (USFWS, 2017)

***Recovery***

**Reclassification Criteria:**
No longer applicable due to revision to Threatened status. (USFWS, 2018)

Recovery Priority Number: 9C

**Delisting Criteria:**
1. Populations or portions of metapopulations occur within 10 or more protected natural areas. Protected natural areas include lands owned by federal, state, or local government agencies, or by private landowners, that are legally protected for the purpose of conserving native plants and animals and their habitats. Examples include, but are not limited to, state parks, state natural areas, and state wildlife management areas, conservation easements on private lands, lands owned and managed for conservation by non-profit organizations, and legally-binding long-term management agreements with other public agencies or private landowners. To be considered under this criterion, the potential habitats of Tobusch fishhook cactus must be managed in a manner that promotes the continued survival of the subspecies. (USFWS, 2019)

2. The 10 or more protected natural areas described in the previous criterion must conserve the full geographic and ecological range of the subspecies. To meet this criterion, one or more protected natural areas must occur within each of four equal-area quadrants (northeast, northwest, southeast, and southwest) of the subspecies' natural range. (USFWS, 2019)

3. Populations or portions of metapopulations within each protected natural area have 1,200 or more mature individuals. This criterion may be met by combining multiple protected areas that occur within the same metapopulation, as defined above. (USFWS, 2019)

4. Periodic monitoring indicates that the minimum viable population level of 1,200 mature individuals within each protected natural area has remained stable or has increased over a period of 45 years. Monitoring (censuses) of each protected natural area must be conducted at least once every 5 years. The size of large populations may be estimated through statistically valid sampling methods. (USFWS, 2019)

**Recovery Actions:**
- 1. Remove immediate human threats to Ancistrocactus tobuschii by protecting known populations from collecting and habitat destruction. (USFWS, 1987)
- 2. Establish a permanent living collection at a botanical garden or university. Even though plants in a living collection can not substitute for healthy populations in natural habitats, a living collection would still contribute significantly to the overall recovery effort. Much information on ecological requirements and reproductive potential could be obtained most easily from a living collection. In addition, a permanent well documented and accessible living collection, together with appropriate seed banking, could provide an important source of material for non-destructive research, maintenance of wild popula- tions, and public awareness. An adequate living collection would remove the necessity of repeatedly returning to wild populations to collect plants for various recovery projects. (USFWS, 1987)
- 3. Minimize long-range threats to Ancistrocactus tobuschii by development of biological information relevant to recovery. A better understanding of the demography of populations and the life history and ecological requirements of the species would provide information useful to management. (USFWS, 1987)

- 4. Establish a long-term (five year) survey program to more precisely determine the true distribution of the species. Surveys for this cactus will be difficult because it is easily overlooked, particularly in the summer and fall when it is hidden by perennial grasses. (USFWS, 1987)
- 5. Develop a comprehensive trade management plan for all cacti. Studies are needed to determine what species are in trade, the overall trend of trade in listed cacti, and the feasibility of reducing collecting pressure on wild populations by promoting a commercial artificial propagation program. These studies should be national in scope and address all cacti. The results will be used to develop policy and a comprehensive trade management plan for all cacti. Strategies for effective implementation of law enforcement responsibilities under ESA, CITES, Lacey Act, and State laws need to be developed. (USFWS, 1987)
- 6. Develop a program to provide propagated plants and seeds to the commercial market. If information from task 5 indicates that artificial propagation will reduce collecting from the wild, an effort should be made to see that adequate sources of propagated plants are commercially available. This may be particularly helpful for Ancistrocactus tobuschii because several of the historic sites are easily accessible and already well known from the literature. (USFWS, 1987)
- 7. Develop public awareness, appreciation, and support for preservation of the species. Public education is extremely important to this species' successful recovery. Landowners usually do not realize that this species exists and most will support protection and con-servation efforts if they learn that a unique plant grows on their land. (USFWS, 1987)
- Recommended Future Actions from 2010 5-Year Review: 1. Continue monitoring and surveying the established protected reserves. 2. Conduct surveys of high-potential habitat within the known range of the species, focusing on sites that have not previously been surveyed. 3. Establish new reserves, using the LBJWC conservation fund and other resources. 4. Conduct public outreach efforts to encourage conservation of the species and its habitat on private lands; establish a private landowner support group, similar to the group now actively working to conserve Texas snowbells (Styrax platanifolius ssp. texanus). 5. Continue to investigate ecology and management, with special emphasis on woody plant control and prescribed burning; compare effects of prescribed burning conducted at different times of the year. 6. Investigate the factors influencing reproduction and dispersal in the wild, with emphasis on the fate of seeds collected by ants. 7. Apply sound management, as needed, to protected sites. 8. Investigate the phylogenetic and taxonomic relationship between Sclerocactus brevihamatus ssp. brevihamatus, S. brevihamatus ssp. tobuschii, S. scheeri, and other closely related taxa of Sclerocactus and/or Ancistrocactus. 9. Collect seeds of representative populations for propagation and seed banking, establish germ-plasm (live plant) refugia, and develop techniques for successful propagation and reintroduction. 10. Revise the 1987 recovery plan. (USFWS, 2010)

# SPECIES ACCOUNT: *Sclerocactus brevispinus* (Pariette cactus)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 09/15/2009; Mountain-Prairie Region (R6) (USFWS, 2016)

**Physical Description**

Small cactus with very short (2 mm) central hooked or straight spines. (NatureServe, 2015)

**Taxonomy**

The original listing rule for S. glaucus (44 FR 58868, October 11, 1979) included all hookless (straight central spines) Sclerocactus populations in western Colorado and northeastern Utah, and referred to them as S. glaucus per Benson (1966, pp. 50-57; 1982, pp. 728-729). This taxonomic classification is not supported by the results of more recent research. Genetic studies (Porter et al. 2000), common garden experiments (Hochstätter 1993; Welsh et al. 2003), and a reevaluation of the morphological characteristics of S. glaucus, led to separating this species into three distinct species: S. brevispinus, S. glaucus, and S. wetlandicus (Hochstätter 1993; Heil and Porter 2004). We recognized these three distinct species as threatened on September 15, 2009 (74 FR 47112). The Flora of North America recognizes 15 species in the genus Sclerocactus, including these 3 species (Heil and Porter 2004). Comparative DNA sequences (Porter et al. 2000) infer common ancestry between S. brevispinus and S. wetlandicus, but infer S. glaucus is more closely related to S. parviflorus (Devil's claw cactus) and S. whipplei (Whipple's fishhook cactus). The common name for S. glaucus was changed to Colorado hookless cactus as the species is endemic to western Colorado. S. wetlandicus is now known as the Uinta Basin hookless cactus as this species occurs across Utah's Uinta Basin. S. brevispinus is now known as the Pariette cactus as it is limited to the Pariette Draw of the central Uinta Basin. The Uinta Basin hookless cactus complex will be used to refer to the combination of all three species previously listed as a single entity (USFWS, 2010)

**Current Range**

Known only from a single area a few miles across in the Pariette Draw region of Duchesne County, Utah, U.S.A.

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Predominately insect pollinated (surrogate S. glaucus information) (USFWS, 2007)

**Breeding Season**

Adult: Flowering occurs in April-May, and fruits mature in May-June (surrogate S. glaucus information) (NatureServe, 2015).

**Reproduction Narrative**

Adult: Reproduction is predominantly sexual, although individuals may sprout multiple stems. Flowering occurs in April-May, and fruits mature in May-June. The species appears to be predominantely outcrossing but is marginally self-compatible. Ants and gravity appear to be the primary dispersal mechanisms (Peggy Lyon pers comm. 1998). Seed dispersal may be a limiting factor in the distribution of Sclerocactus glaucus (NatureServe, 2015). Information from S. glaucus is being used a surrogate information for S. wetlandicus due to the species similiarities and based on the following quote 'Because we lack life history data specific to S. wetlandicus, we have included life history data for S. glaucus, which should correlate to characteristics for S. wetlandicus' USFWS, 2010. Believed to be dispersed by heavy down-pours (Tepedino et al. 2010).; ABIOTIC; Water;  (NatureServe, 2015). The species' life history is poorly known, but it is thought to be a longlived perennial usually flowering after 3 or 4 years. A broad assemblage of native bees, and possibly other insects including ants and beetles, pollinates S. brevispinus (USFWS 1990, p. 7) (USFWS, 2007).

**Habitat Type**

Adult: Clay badlands (NautreServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species is endemic to highly saline and alkaline soils, restricted to clay badlands within a single geologic formation in Utah. Occurs on exposed clay hills and in saltbush and sagebrush flats, 1400-1500 m. (NatureServe, 2015). High ecological integrity of the population and site fidelity as well as low tolerance ranges are inferred based on the species habitat requirements of the species and the relatively small geographic area this species inhabits.

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Unknown

**Population Size:**

between 30,500 and 42,281 individuals (USFWS, 2020)

**Population Narrative:**

Cumulative survey data represents the best scientific information available regarding the number of individuals for Sclerocactus. The known range-wide population size for Uinta Basin hookless cactus is between 83,408 and 110,815 individuals, and the known range-wide population size for Pariette cactus is between 30,500 and 42,281 individuals (USFWS 2019).

(USFWS, 2020)

***Threats and Stressors***

**Stressor:** Oil and Gas Development and Associated Impacts (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The BLM is monitoring S. brevispinus populations and neighboring Sclerocactus species, including impacts associated with oil and gas development. Initial results show potential effects of oil and gas development (i.e., roads and well pads) on the survival and reproductive success of S. brevispinus (72 FR 53215, September 18, 2007) (USFWS, 2010.

**Stressor:** Collection (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Illegal collection is a significant threat to S. brevispinus. The original listing of S. glaucus concluded that the cactus is prized among collectors and threatened by unregulated commercial trade (44 FR 58869, October 11, 1979). Collectors prefer larger, reproductive age individuals, leaving behind a younger, less reproductive population. As of 2006, approximately 96 percent of the known range of S. brevispinus (at the time, 5,733 ha or 14,166 ac) was within 400 m (1,312 ft) of a well (Service 2006). Such development facilitates human access and discovery by illegal collectors (72 FR 53216, September 18, 2007) (USFWS, 2010).

**Stressor:** Livestock Grazing and Trampling (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Nearly all S. brevispinus potential habitat on BLM land is leased for grazing. The species range overlaps four BLM grazing allotments. Most of the area is grazed by sheep, either continuously or on a deferred rotation, with some cattle grazing on the western and eastern edges of S. brevispinus potential habitat. Livestock grazing results in S. brevispinus mortality when livestock trample individual cacti (Service 1990; Utah Natural Heritage Program 2006; BLM 2008; 72 FR 53215, September 18, 2007). Overgrazing—the continued heavy grazing beyond the recovery capacity of forage plants (Vallentine 1990)—by domestic livestock degrades western ecosystem functions and structures (Fleischner 1994). Overgrazing can facilitate the establishment of invasive species like cheatgrass (Masters and Sheley 2001), which are difficult to eradicate and tend to outcompete native vegetation, including cacti. Invasive weeds (including Bromus tectorum and Halogeton glomeratus) are prevalent on BLM lands in the range of S. brevispinus cactus and less so on tribal lands where grazing has been concentrated in areas outside of suitable cactus habitat (72 FR 53214, September 18, 2007) (USFWS, 2010).

**Stressor:** Predation (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals

**Narrative:** Parasitism by the cactus-borer beetle (Moneilema semipunctatum) is a significant but localized source of mortality to all Sclerocactus species on the Colorado Plateau, especially in larger, mature, reproducing individuals (Service 1990; 72 FR 53216, September 18, 2007). Parasitism is identified as a threat to Sclerocactus plants, however additional studies are needed to determine the long-term, population-level effects of the cactus-borer beetle to S. brevispinus. Another source of mortality is lagomorph and rodent browsing. While there have been numerous observations of Sclerocactus being removed by desert cottontail rabbits (Sylvilagus audubonii) and unknown rodents (CNHP 2010b; BioLogic 2008; Clayton 2006), in subsequent years some of these plants have re-sprouted (Clayton 2010). Browsing likely goes unnoticed unless a marked individual is revisited within a 1- to 2-year period. We know very little about the magnitude of this threat (USFWS, 2010)

**Stressor:** Climate Change, Drought, and Impacts to the Vegetative Community (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Climate change is likely to affect long-term survival of native species, including S. brevispinus, especially if longer or more frequent droughts occur. For the southwestern region of the United States, warming is occurring more rapidly than elsewhere in the country with an increase of 1.5°F (0.8°C) since 1979 (Karl et al. 2009). Under lower emission scenarios temperature is expected to increase 5°F (2.8°C) and under higher emission scenarios temperature is expected to increase 10°F (5.6°C) by the end of the century, from the 1979 baseline (Karl et al. 2009). Other future projections for the southwest include more intense and longer-lasting heat waves, an increased probability of droughts that are worsened by higher temperatures, heavier downpours, increased flooding, and increased erosion (Karl et al. 2009, pp. 129-134). The levels of aridity of recent drought conditions and perhaps those of the 1950s drought years may become the new climatology for the southwestern United States (Seager et al. 2007). Effects related to climate change (e.g., such as persistent or prolonged drought conditions, changes in community assemblages and the ability of nonnative species to succeed) may affect long-term persistence of S. brevispinus. While the potential impacts of climate change could be serious, improved projections are needed to better understand this potential threat. S. brevispinus mortality due to drought is well documented (Service 1990; 72 FR 53217, September 18, 2007). Many dead S. brevispinus individuals were observed in the Uinta Basin after the severe drought of 1976 to 1977 (Service 1990). In addition, noxious weeds are often able to out-compete native species under drought conditions (Everard et al. 2010). Drought conditions could further hinder BLM’s efforts to control noxious weeds and restore native vegetation, which is already difficult due to the extreme environment of the Uinta Basin (Service 1990; BLM 2005, 2008) (USFWS, 2010).

**Stressor:** Pesticides (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of indivduals
**Narrative:** S. brevispinus lives in or near areas that receive herbicide and pesticide treatments to remove undesirable species, such as noxious weeds and insect pests (Service 1990). Individual cacti are likely to be directly affected by these chemicals, and indirectly by effects on pollinators or by movement of contaminated soils (Service 1990). However, specifics of the species' pollination biology are currently unquantified (USFWS, 2010)

**Stressor:** Vulnerability Related to Population Size and Distribution (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Extinction
**Narrative:** S. brevispinus' small population size and restricted distribution means the species is vulnerable to extinction by natural processes or human disturbance (Ellestrand and Elam 1993; Levin et al. 1996). For example, random events causing population fluctuations or population extirpations become a serious concern when the number of individuals or the geographic distribution of the species is very limited. Similarly, a single human-caused or natural environmental disturbance could destroy the entire population. The species' slow reproductive rate also increases the risk of effects of stochastic events as it is unlikely that the species will be able to rebound quickly (e.g., exhibit a high rate of population growth), even if environmental conditions improved after such an event. Other issues related to this factor include loss of genetic variability, which may reduce a species ability to respond to changing environmental conditions, (Godt et al. 1996) and inbreeding depression, which can decrease fertility and survival rates (Levin et al. 1996). No information exists to indicate that the species' range and population numbers have been significantly larger than they are currently, except for recent documented losses due to oil and gas development and illegal collection (USFWS, 2010).

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** We are not aware of any city, county or state laws, ordinances or zoning that provide for protection or conservation of the S. brevispinus or its habitat. Removal, damage, or destruction of plants on private lands is  can be allowed through consultation with the Service. Conservation needs of S. brevispinus are addressed through interagency consultation (section 7 requirements) typically between the Service, BLM, and Bureau of Indian Affairs (BIA). Through this process, conservation measures are implemented on a project-by-project basis to minimize the loss of individual cacti from oil and gas activities. These measures include preconstruction cactus surveys and a required buffer around individual cacti. For example, the Castle Peak/Eightmile Flat Oil and Gas Expansion Project Final Environmental Impact Statement included conservation measures to specifically protect S. brevispinus and its habitat (BLM 2005). The BLM also has attempted to establish protected areas for S. brevispinus. The Pariette Wetlands Area of Critical Environmental Concern (ACEC) was established in 1994. The ACEC, intended to provide protection for this species, contains approximately 1,250 ha (3,086 ac) or 8 percent of the potential habitat of S. brevispinus. Management prescriptions for the ACEC state that the BLM will authorize no action in suitable habitat for threatened and endangered species if it would jeopardize the continued existence of the species or result in severe modification of the habitat (BLM 2008). Although the BLM Vernal Field Office Resource Management Plan designated the Pariette Wetlands ACEC as "no surface occupancy" for oil and gas development (BLM 2008), pre-existing lease rights still allow surface disturbance from oil and gas development within the ACEC (BLM 2005). As of November 2009, the ACEC contains one well for approximately every 30 ha (74 ac), with more development planned. The BLM is currently deferring approval of new wells and ancillary facilities located within the Pariette Wetlands ACEC until a master development plan is completed. In addition to the ACEC and project-specific protections such as cactus surveys, we need to establish consistent guidance and Resource

Management Plan designations that provide adequate regulatory mechanisms over the longer term to protect large portions of the range of the S. brevispinus (USFWS, 2010).

**Stressor:** Invasive and Noxious Weeds (USFWS, 2020)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasive species were not considered a threat to Sclerocactus at the time of the listing (44 FR 58868, October 11, 1979), but were identified as a threat in 2010 (USFWS 2010a, b). Increased disturbance from land use activities (oil and gas development, grazing, ORV use) and climate change are likely to facilitate the invasion and spread of invasive species such as cheatgrass (Bromus tectorum), halogeton (Halogeton glomeratus) and Russian thistle (Salsola tragus; Brooks 2003, Masters and Sheley 2001, Brooks and Pyke 2001). Invasive species compete with native plants for resources such as sunlight, soil nutrients, water, pollinators, and space. Invasive species alter plant composition and density in a variety of habitats from forested to desert ecosystems (Di Tomaso 1998, Young et al. 1998, Wilcove et al. 1998, Mack et al. 2000, Levine et al. 2003, Trombulak and Frissell 2000). This competition for resources may indirectly impact Sclerocactus by reducing individual fitness and reproduction, as well as the population by reducing seedling recruitment and population size (Di Tomaso 1998, Young et al. 1998, Wilcove et al. 1998, Mack et al. 2000, Levine et al. 2003, Trombulak and Frissell 2000). The most frequently observed invasive species occurring in Sclerocactus habitat are cheatgrass and flatspine stickseed (Lappula occidentalis; Hornbeck 2018). Monitoring plots recorded cheatgrass in 25 and 57 percent of plots for Pariette cactus and Uinta Basin hookless cactus, respectively (Hornbeck 2018). Flatspine stickseed was recorded in 35 and 22 percent of plots for Pariette cactus and Uinta Basin hookless cactus, respectively (Hornbeck 2018). (USFWS, 2020)

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 5C

**Delisting Criteria:**
For Pariette cactus – All four core 2 areas have a stable or increasing growth trend (average lambda (λ) ≥ 0.095) over a minimum period of 10 consecutive years and predictive modeling (using data from a minimum of a 10-year monitoring period) indicates that the likelihood for long-term survival of the metapopulation is at least 95 percent over a 100-year period (USFWS, 2023).

For Pariette cactus – The metapopulation maintains a size distribution that contains individuals in all size classes over a 5-year minimum period and where the largest size class maintains a stasis rate no less than 0.85. Size classes for Pariette cactus are defined as: class 1:<19.7 mm; class 2: 19.7–40 mm; class 3: 40.1–75 mm; and class 4: >75 mm (Hornbeck 2020) (USFWS, 2023).

For Pariette cactus – Genetic diversity across the metapopulation is maintained at levels such that there is a high probability (95 percent) of two core 1 populations persisting over the long term (100 years) within each core 2 area (USFWS, 2023).

For Pariette cactus – Disturbance that contributes to the degradation and loss of habitat (e.g., roads, recreation, livestock) does not exceed established tolerance thresholds for each core 2 area (percent of habitat) (USFWS, 2023).

For Pariette cactus – Protected areas will be formally established by land managers for at least one genetically important population and at least one connectivity corridor (as identified using connectivity analysis) to provide long-term protection from anthropogenic threats. Methods may include but are not limited to ACECs, Resource Management Plan special designations, Tribal resolutions, conservation agreements, and conservation easements (USFWS, 2023).

**Recovery Actions:**

- Priority 1 Actions 1. Monitor two core 1 areas within each core 2 area for Pariette cactus and eight core 2 areas for Uinta Basin hookless cactus to evaluate short- and long-term population trends across the metapopulation and support predictive modeling. Monitoring should be conducted for a minimum of 10 years (Recovery Criteria 1 and 2). 2. Reduce impacts from livestock, feral horses, and herbivores on a landscape scale (in all subpopulations) through herd management, grazing rotations and rest, and habitat improvements (Recovery Criterion 1). 3. Develop disturbance tolerance thresholds for each core 2 area (Recovery Criterion 4). 4. Formalize conservation measures with partners to be implemented with, and prior to, all surface disturbing projects. Conservation measures may be documented in a memorandum of understanding, resource management plan, conservation agreement, recreation management plan, travel management plan, or similar document (Recovery Criteria 1, 2, 3, 4, and 5). 5. Restore disturbed areas within core habitat so that new surface disturbance is less than the tolerated threshold identified in Recovery Action 3 (Recovery Criteria 1, 2, and 3). 6. Resurvey subsampled areas (targeted and repeat) to update abundance and population estimates (Recovery Criteria 1, 2, 3, 4, and 5) (USFWS, 2023).
- Priority 2 Actions 7. Evaluate current genetic diversity across the species range to identify subpopulations at risk, those needing protections, and those of high importance (Recovery Criterion 2). 8. Conduct a connectivity analysis to identify important gene flow corridors (Recovery Criterion 2). 9. Restore or improve connectivity corridors between core 1 and core 2 areas that are important for maintaining gene flow across the species range and limit new surface disturbance in important existing connectivity corridors (Recovery Criteria 2 and 3) (USFWS, 2023).
- Priority 3 Actions 10. Update disturbance calculations on an annual basis for each core area (Recovery Criterion 3). 11. Develop a predictive model to evaluate the long-term trend and projected survival probability of each species under likely future scenarios, including climate change (Recovery Criteria 1, 2, 3, 4, and 5). 12. Reestablish Sclerocactus individuals on restored sites and monitor effectiveness (Recovery Criteria 1, 2, and 4). 13. Establish areas for permanent protections that provide the greatest benefit towards maintaining the redundancy, representation, and resiliency of the species (Recovery Criteria 1, 2, 3, and 5). 14. Develop and implement management plans for each protected area (Criterion 5) (USFWS, 2023).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS We recommend that objective and quantifiable recovery criteria be established for each species, so that concrete goals can be established and progress towards recovery can be quantified. The recovery plans for these species should be completed in FY2021 as budgets allow. Based on ongoing actions and preliminary results, we recommend the continuation of the range-wide Sclerocactus monitoring program in order to track population trend over a long period of time. Management actions which result in preserving or improving intact habitat, population size class diversity, seedling recruitment, gene flow, and pollinator movement should be a high priority for both species. (USFWS, 2020)

# SPECIES ACCOUNT: *Sclerocactus glaucus* (Colorado hookless Cactus)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 10/11/1979; Mountain-Prairie Region (Region 6) (USFWS, 2016)

**Physical Description**

A squat, globular, spiny succulent. Each mature stem is 3-12 cm tall, 4-9 cm wide, although during the driest part of the year the stem may shrink to below ground-level. Central spines are straight (hookless). The plants are inconspicuous except when in flower (April-May), when showy, fragrant, pink to magenta flowers appear at the top of the stem. (NatureServe, 2015)

**Taxonomy**

The original listing rule for S. glaucus (44 FR 58868, October 11, 1979) included all hookless (straight central spines) Sclerocactus populations in western Colorado and northeastern Utah, and referred to them as S. glaucus per Benson (1966, pp. 50-57; 1982, pp. 728-729). Genetic studies (Porter et al. 2000), common garden experiments (Hochstätter 1993; Welsh et al. 2003), and a reevaluation of the morphological characteristics of S. glaucus have led to separating this species into three distinct species: S. brevispinus, S. glaucus, and S. wetlandicus (Hochstätter 1993; Heil and Porter 2004). The Flora of North America recognizes 15 species in the genus Sclerocactus, including these 3 species (Heil and Porter 2004). Comparative DNA sequences (Porter et al. 2000) infer common ancestry between S. brevispinus and S. wetlandicus, but infer S. glaucus is more closely related to S. parviflorus (Devil's claw cactus) and S. whipplei (Whipple's fishhook cactus). The common name for S. glaucus was changed to Colorado hookless cactus as the species is endemic to western Colorado. S. wetlandicus is now known as the Uinta Basin hookless cactus as this species occurs across Utah's Uinta Basin. S. brevispinus is now known as the Pariette cactus as it is limited to the Pariette Draw of the Central Uinta Basin. (USFWS, 2010)

**Current Range**

Colorado hookless cactus is an endemic plant found in Delta, Montrose, Mesa, and Garfield Counties, Colorado. There are two population centers of Colorado hookless cactus: (1) on alluvial river terraces of the Gunnison River from near Delta, Colorado, to southern Mesa County, Colorado; and (2) on alluvial river terraces of the Colorado River and in the Plateau and Roan Creek drainages in the vicinity of DeBeque, Colorado (Service 1990). (USFWS, 2010)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Predominately sexual (outcrossing) but can reproduce asexually (NatureServe, 2015)

**Lifespan**

Adult: 10-20 years (NatureServe, 2010)

**Breeding Season**

Adult: April to May (NatureServe, 2015)

**Reproduction Narrative**

Adult: Reproduction is predominately sexual, although individuals may sprout multiple stems. Flowering occurs in April-May, and fruits mature in May-June. The species appears to be predominantely outcrossing but is marginally self-compatible. Although no long-term demographic data is available, field observations suggest that plants may live for 10-20 years in good conditions (Ellen Mayo, Peggy Lyon pers. comm.) Population size may vary widely between years (Jim Ferguson, pers. comm.). Plants are typically sparsely distributed even in larger populations. Stems may fluctuate in size according to seasonal moisture availability, shrinking below the soil surface in dry times. Predation by a cactus borer beetle has been observed in Colorado populations, and may be very heavy in a localized area. Some herbivory by rodents has also been observed. (NatureServe, 2015)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Desert, forest/woodland, shrubland/chaparral, woodland - conifer (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs at elevations between 1200 and 2000 m (NatureServe, 2015)

**Environmental Specificity**

Adult: Moderate (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: The Colorado hookless catcus is found on exposed, gravel-covered, clay hills, saltbush or sagebrush flats, or pinyon-juniper woodlands at elevations from 1400 to 2000 m (Flora of North America Editorial Committee 2003). Populations occur primarily on alluvial benches along the Colorado and Gunnison Rivers and their tributaries. Sclerocactus glaucus generally occurs on gravelly, or rocky surfaces on river terrace deposits and lower mesa slopes. Exposures vary, but S. glaucus is more abundant on south-facing slopes. Soils are usually coarse, gravelly river alluvium above the river flood plains usually consisting of Mancos shale with volcanic cobbles and pebbles on the surface. Elevations range from 1200-2000 m. Associated vegetation is typically desert scrub dominated by shadscale (Atriplex confertifolia), galleta (Hilaria jamesii), black-sage (Artemisia nova), and Indian rice grass (Stipa hymenoides). Other important species include two similar spherical or cylindrical cactus species, strawberry hedgehog cactus ( Echinocereus triglochidiatus var. melanacanthus) and Simpson's pincushion cactus (Pediocactus simpsonii). Other important species in the plant community include the prickly pear cactus (Opuntia polyacantha), winterfat (Krascheninnikovia lanata), yucca (Yucca harrimaniae), snakeweed (Gutierrezia sarothrae), low rabbitbrush (Chrysothamnus viscidiflorus), sand dropseed (Sporobolus cryptandrus), and Salina wildrye (Elymus salinus) (USFWS 1990, Scheck 1994). Fire is not typically characteristic of S. glaucus habitat, but areas with large infestations of cheatgrass (Bromus tectorum) may build up sufficient fuel to carry fire into S. glaucus populations. (NatureServe, 2015). S. glaucus and S. dawsonii are endemic cactus species found in the Colorado and Gunnison River basins and their tributary canyons in Garfield, Mesa, Montrose, and Delta Counties in western Colorado. The species occur on alluvial benches and colluvial slopes from 4,500 to 7,200 feet (1,372 to 2,195 meters) in semi-arid high elevation desert. S. glaucus occurs in eight analytical units (AUs) in a range that extends from the Grand Valley, through the high desert at the foot of the Grand Mesa, and along the alluvial terraces of the Gunnison River and the Dominguez and Escalante Creek drainages to near Montrose. S. dawsonii occurs in two AUs along the Colorado River from DeBeque downstream toward the Grand Valley and along the Roan and Plateau Creek drainages (USFWS, 2022).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Ants and gravity appear to be the primary dispersal mechanisms (Peggy Lyon pers comm. 1998). Seed dispersal may be a limiting factor in the distribution of Sclerocactus glaucus. (NatureServe, 2015)

***Population Information and Trends***

**Population Trends:**

Unknown (NatureServe, 2015)

**Resiliency:**

To be resilient, AUs of both species require survivorship and recruitment at rates that are able to sustain AUs with pollinator connectivity between individuals and clusters of plants within the AU. Resilient AUs also contain enough individuals across each life stage (seed, seedling, and mature reproductive adult) to bounce back after experiencing environmental stressors such as intermediate disturbance, occasional drought, or grazing. Finally, individuals in both species of Colorado hookless cactus need certain habitat factors for resiliency. These include shallow exposed sandy or shale soils of sedimentary parent material or gravelly deposits of river alluvium; a semi-arid, high elevation desert climate (1,372-2,195 m) with 8-12 inches rain per year; and a period of deep cold during winter months to facilitate germination the following spring. (USFWS, 2022)

**Representation:**

Individuals and AUs inhabiting diverse ecological settings and exhibiting genetic or phenological variation add to the level of representation across the species' range. The greater diversity observed in Colorado hookless cactus genetics, habitats, and morphology, the more likely it is to be able to adapt to change over time. (USFWS, 2022)

**Redundancy:**

Colorado hookless cactus redundancy is influenced by the number of AUs across the landscape. More AUs across the range of Colorado hookless cactus increase the species' ability to withstand catastrophic events. (USFWS, 2022)

**Population Growth Rate:**

Unknown (NatureServe, 2015)

**Number of Populations:**

98 (USFWS, 2010). 8 AUs (USFWS, 2022)

**Population Size:**

>= 103,086 (USFWS, 2022)

**Population Narrative:**

The species has been documented at 98 element occurrences (EOs) totaling approximately 13,300 individuals (CNHP 2010b). Forty-two of the EOs have not been observed in over 20 years. Over 6,000 additional individuals were located recently in field surveys for a proposed electric transmission line and a proposed oil and gas wastewater evaporation facility north of Delta, Colorado (Bio-Logic 2008; 2009). These newly discovered individuals have not yet been incorporated into the CNHP database. Therefore, by combining the new survey data and the CNHP data, we estimate the total known population of Colorado hookless cactus at over 19,000 plants. (USFWS, 2010). Currently, S. dawsonii has a minimum of 31,867 plants distributed across two highly resilient AUs with a high survival rate and moderate to high habitat conditions across the range of the species. S. glaucus currently has a minimum of 103,086 plants distributed across eight AUs. Seven of the eight AUs are highly resilient; one is ranked moderate. Across their limited ranges, both species of Colorado hookless cactus are relatively abundant, which contribute to the high levels of resiliency in all but one AU. Redundancy for narrow endemic species is inherently limited; however, S. glaucus plants are distributed broadly across the range of the species in eight AUs, providing redundancy throughout its relatively small geographic range. With only two AUs located within a smaller range than S. glaucus, redundancy of S. dawsonii is much lower than that of S. glaucus. S. glaucus's relatively broad distribution and multiple highly resilient AUs make it better able to withstand catastrophic events than S. dawsonii. Representation is comparable among S. glaucus and S. dawsonii (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Mineral and energy development (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The 1990 Recovery Plan identified threats associated with mineral and energy development including: oil and gas, oil shale and tar sands, sand and gravel quarrying, gold dredging, and building stone collecting and quarrying. A gravel mining project proposed near Whitewater, Colorado, poses a threat to several Colorado hookless cactus individuals (BLM 2010). The BLM recently closed an area where recreational gold panners were causing disturbance in close proximity to a Colorado hookless cactus occurrence (BLM 2009b). Oil and gas development remains a meaningful factor in the long-term conservation of the Colorado hookless cactus. Thirty-six percent of the federally-owned potential habitat approximately 164,000 ac (66,000 ha) is leased for oil and gas development (Service 2010b). Increased surface disturbance from wells, roads and pipelines for oil and gas projects can result in the following impacts to S. and habitat. Oil and gas development fragments and destroys S. habitat (BLM 2005, 2008a). Each well disturbs approximately 1.5 ac (0.6 ha) of surface area (74 FR 47112, September 15, 2009). Increased erosion, soil compaction, and sedimentation can kill cacti (BLM 2005). Cactus seeds can be buried and lost due to erosion runoff from well-field facilities (BLM 2005). Increased surface disturbance increases airborne dust. Dust accumulation on cacti increases tissue temperature and reduces photosynthesis, thus decreasing plant growth, vigor,

and water use efficiency (Farmer 1993; Sharifi et al. 1997). Dust effects can extend up to 300 m from roads (Everett 1980). Energy development requires the addition of access roads in previously undeveloped areas. In most cases, these access roads are open to the public. The ORV trail use increases erosion, fugitive dust, soil compaction, sedimentation, and can crush cactus (Service 1990; BLM 2008a). Human access can result in illegal collection and the direct loss of individual plants (Service 1990; BLM 2005). Oil and gas development increases weed invasions because of the associated surface disturbance. Increased invasive weeds alter the ecological characteristics of cactus habitat, making it less suitable for the species (Service 1990; BLM 2008a).

**Stressor:** Utility corridors (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A BLM and Department of Energy designated Westwide Energy Corridor covers 70,142 ac (28,385 ha) of BLM land that is potential habitat for Colorado hookless cactus (Service 2010b; BLM 2008b). The BLM identified preferred corridors to limit the proliferation of additional rights-of-way across the landscape, but utilities are not limited to these corridors (BLM 2008b). Twenty-nine of the species’ 98 occurrences are at least partially located within this energy corridor (Service 2010b; BLM 2008b). Specific pipeline and transmission line routes within the energy corridor are not yet identified. The TransColorado (TransCO) gas pipeline resides in this corridor. Many of the 29 aforementioned occurrences were discovered during surveys for this project. The TransCO project resulted in transplantation of approximately 1,200 Colorado hookless cactus individuals. Monitoring documented a 19-percent mortality rate for the 129 monitored individuals between 1999 and 2003 (Bio-Logic 2008). Surveys for a new powerline north of Delta, Colorado (not in the designated energy corridor), located approximately 5,200 Colorado hookless cactus individuals (Bio-Logic 2008). Up to 100 individuals may be transplanted or destroyed during construction of this powerline in 2010 (Bio-Logic 2008). (USFWS, 2010)

**Stressor:** Invasive species (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasive weeds, including Bromus tectorum (cheatgrass) and Halogeton glomeratus (halogeton), are prevalent on BLM and private lands within the range of Colorado hookless cactus (CNHP 2010b). Invasive weeds alter the ecological characteristics of cactus habitat, making it less suitable for the species (Service 1990; BLM 2008a). In addition, invasive weeds are often able to out-compete native species under drought conditions (Everard et al. 2010). Several EO records include cheatgrass invasion as a threat, and BLM attributes downward trend at several locations to cheatgrass invasion (CNHP 2010b; BLM 2009a). (USFWS, 2010)

**Stressor:** Off road vehicle use (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Despite ORV use being common within Colorado hookless cactus habitat, there have been few documented impacts to the plants. Observers documented ORV use as a threat to 3 of the 98 EOs (CNHP 2010b). Additionally, illegal off road driving damaged Colorado hookless

cactus individuals during construction of the Collbran pipeline (WestWater Engineering 2009). The ORV use is expected to increase along with expected human population increases in the region in which Colorado hookless cactus is native and with increasing popularity and availability of improved ORVs. This is expected to result in an increase in damage to Colorado hookless cactus individuals and habitat (Service 1990). (USFWS, 2010)

**Stressor:** Water development (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The 1990 Recovery Plan identified water development as a threat to the species. It is likely that reservoir and irrigation canal development have impacted Colorado hookless cactus occurrences in the past; however, we have no documentation of those impacts. Two water reservoir projects known as Roan Creek and Sulphur Gulch have been proposed within potential and occupied habitat of Colorado hookless cactus. These potential reservoirs could permanently destroy plants and their habitat through project construction and inundation. After evaluation of numerous alternatives, the Roan Creek and Sulphur Gulch projects are no longer being considered (Bray and Drager pers. comm. 2008; Grand River Consulting Corporation 2009). Since the proposals have been withdrawn, these threats are not imminent. (USFWS, 2010)

**Stressor:** Collection (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The original listing of the Uinta Basin hookless cactus complex concluded that the cactus is prized among collectors and threatened by unregulated commercial trade (44 FR 58869, October 11, 1979). Collectors prefer larger, reproductive age individuals, leaving behind a younger, less reproductively fit population. We are not aware of illegal removal of Sclerocactus in Colorado prior to 2009. Three Colorado hookless cactus individuals were removed illegally in 2009 from sites proposed for a natural gas pipeline and a sewer pipeline in Mesa County, Colorado (Service 2010a; Glenne 2009). It did not appear that these plants were removed by collectors, but rather these were acts of vandalism. Additional damage to cacti occurred during project construction on the same natural gas pipeline (WestWater Engineering 2009). These incidents show that additional development increases risk to cacti of vandalism and removal by increasing human presence in areas previously rarely visited by humans. (USFWS, 2010)

**Stressor:** Livestock grazing and trampling (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Of the 450,000 ac (182,000 ha) of Colorado hookless cactus potential habitat on Federal lands, approximately 94 percent, 424,000 ac (172,000 ha) falls within grazing allotments. Moderate to heavy domestic livestock grazing has been observed to cause physical damage to Sclerocactus plants through trampling, but we have no evidence to suggest that cattle browse on individual Sclerocactus plants (Service 1990). A study on another federally listed cactus, S. wrightiae, found that cacti density increased more rapidly in a fenced plot excluded from cattle grazing than in an unfenced plot with a reduced cattle stocking rate (Clark and Clark 2007). Overgrazing (the continued heavy grazing beyond the recovery capacity of forage plants) by

domestic livestock can have a negative impact on North American xeric ecosystems (Jones 2000; Vallentine 1990). For example, overgrazing can facilitate the establishment of invasive species like Bromus tectorum (Masters and Sheley 2001), which are difficult to eradicate and tend to outcompete native vegetation, including cacti. (USFWS, 2010)

**Stressor:** Predation (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Another source of mortality is lagomorph and rodent browsing on Colorado hookless cactus. While there have been numerous observations of S. glaucus individuals being removed by desert cottontail rabbits (Sylvilagus audubonii) and unknown rodents (CNHP 2010b; BioLogic 2008; Clayton 2006), some of these plants have re-sprouted in subsequent years (Clayton 2010). Browsing likely goes unnoticed unless a marked individual is revisited within a 1- to 2-year period. We know very little about the magnitude of this threat. Parasitism by the cactus-borer beetle (Moneilema semipunctatum) is a significant but localized source of mortality to all Sclerocactus species on the Colorado Plateau, especially in larger, mature, reproducing individuals (Service 1990; 74 FR 47112, September 15, 2009). Additional studies are needed to determine the long-term, population-level effects of the cactus-borer beetle to Colorado hookless cactus. (USFWS, 2010)

**Stressor:** Herbicides and pesticides (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Colorado hookless cactus lives in or near areas that receive herbicide and pesticide treatments to remove undesirable species, such as cheatgrass and crop harming insects (Service 1990). Individual cacti are likely to be directly affected by herbicide use, and indirectly by effects of pesticides on pollinators (Service 1990). However, we cannot fully assess the magnitude of this threat, since the specific species that pollinate Colorado hookless cactus are currently unknown. (USFWS, 2010)

**Stressor:** Hybridizations (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Extinction due to hybridization, both natural and human influenced, can be a major concern for rare and endangered species (Denver Botanic Gardens 2009b). Colorado hookless cactus may hybridize with S. parviflorus (Heil & Porter 1987; Woodruff 2009; CNHP 2010b). The extent to which hybridization is occurring is unknown. Genetic research investigating this issue is essential for planning management and recovery efforts. The Denver Botanic Gardens has begun collecting floral tissue to examine the population genetic structure within and among the two population centers of Colorado hookless cactus and investigate the potential threat of introgression with S. parviflorus (Denver Botanic Gardens 2009b). (USFWS, 2010)

**Stressor:** Climate change, drought, and impacts to the vegetative community (USFWS, 2010)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** Climate change is likely to affect long-term survival of native species, including Sclerocactus, especially if longer or more frequent droughts occur. For the southwestern region of the United States, warming is occurring more rapidly than elsewhere in the country with an increase of 1.5°F (0.8°C) since 1979 (Karl et al. 2009). Under lower emission scenarios temperature is expected to increase 5°F (2.8°C) and under higher emission scenarios temperature is expected to increase 10°F (5.6°C) by the end of the century, from the 1979 baseline (Karl et al. 2009). Other future projections for the southwest include more intense and longer-lasting heat waves, an increased probability of droughts that are worsened by higher temperatures, heavier downpours, increased flooding, and increased erosion (Karl et al. 2009, pp. 129-134). The levels of aridity of recent drought conditions and perhaps those of the 1950s drought years may become the new climatology for the southwestern United States (Seager et al. 2007). Effects related to climate change (e.g., persistent or prolonged drought conditions, changes in community assemblages and the ability of nonnative species to succeed) may affect long-term persistence of Colorado hookless cactus. While the potential impacts of climate change could be significant, improved localized projections are needed to better understand this potential threat. In addition, invasive weeds are often able to out-compete native species under drought conditions (Everard et al. 2010). Drought conditions could further hinder BLM’s efforts to control invasive weeds and restore native vegetation, which is already difficult due to the extreme environment of the Colorado and Gunnison River basins (Service 1990; BLM 2005, 2008a). (USFWS, 2010)

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

**Delisting Criteria:**
Delisting criteria are not available.

**Recovery Actions:**
- Completion of a comprehensive survey throughout the species’ range. (USFWS, 2010)
- Surveys also should more accurately delineate the Colorado hookless cactus range relative to other Sclerocactus species. (USFWS, 2010)
- Locate possible population connectivity corridors. (USFWS, 2010)
- Continue ongoing monitoring efforts and expand monitoring to include a larger and more representative sample of occupied sites. (USFWS, 2010)
- Identify sites in urgent need of habitat protection, set protection priorities, and implement protective measures. In the long run, land management agencies should establish formal land management designations to provide for long-term protection of important populations and habitat. (USFWS, 2010)
- Oil and gas leasing and other mineral extraction activities should avoid occupied sites and other important habitat. (USFWS, 2010)
- Develop and implement standard conservation measures to minimize future project and use impacts. (USFWS, 2010)
- Coordinate with land management agencies, project proponents, and other partners early in the planning process to limit direct and indirect impacts of planned activities. (USFWS, 2010)

- Prevent the collection of Colorado hookless cactus plants from natural populations. (USFWS, 2010)
- Resolve the taxonomic status of Colorado hookless cactus regarding the species relationship with S. parviflorus. Secondarily, this study would assess genetic differences between Colorado hookless cactus populations. (USFWS, 2010)
- Continue research into Colorado hookless cactus life history and ecology, including pollinators. (USFWS, 2010)
- Study population dynamics and conduct a population viability analysis. (USFWS, 2010)
- Encourage investigations that project Sclerocactus species' vulnerability and response to climate change. (USFWS, 2010)
- Improve our understanding of livestock and native (e.g., rodent) grazing impacts. (USFWS, 2010)
- Monitor cactus-borer beetle (Moneilema semipunctatum) infestations, and study the relationship of episodic infestations with drought and other environmental factors. (USFWS, 2010)
- Monitor changes in invasive species prevalence and impacts on Colorado hookless cactus. Additionally, continue to explore approaches to minimize the risk posed by invasives and associated remediation actions. (USFWS, 2010)
- Make a final determination on the proposed the taxonomic revision splitting Sclerocactus glaucus into S. brevispinus, S. glaucus, and S. wetlandicus. We expect to make a final determination on this proposal in 2008. (USFWS, 2008)
- Issue a proposed and final rulemaking to reclassify S. brevispinus from threatened to endangered as described in our recent 12-month finding (72 FR 53211, September 18, 2007). (USFWS, 2008)
- Develop a recovery plan for each of the three species. As required by Section 4(f)(1)(B), each recovery plan should incorporate: (i) a description of such site-specific management actions as may be necessary to achieve the plan's goal for the conservation and survival of the species; (ii) objective, measurable criteria which, when met, would result in a determination, in accordance with the provisions of this section, that the species be removed from the list; and (iii) estimates of the time required and the cost to carry out those measures needed to achieve the plan's goal and to achieve intermediate steps toward that goal. (USFWS, 2008)
- Conduct range-wide inventories for each species. Once completed, continue and improve population monitoring for each species. (USFWS, 2008)

***Conservation Measures and Best Management Practices:***

- STATUS RECOMMENDATION Standard for Review Section 4 of the Act (16 U.S.C. Section 1533) and its implementing regulations (50 CFR part 424) set forth the procedures for determining whether a species meets the definition of "endangered species" or "threatened species." The Act defines an "endangered species" as a species that is "in danger of extinction throughout all or a significant portion of its range," and a "threatened species" as a species that is "likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range." The Act requires that we determine whether a species meets the definition of an "endangered species" or a "threatened species" because of any of the following factors: (A) The present or threatened destruction, modification, or curtailment of its habitat or range; (B) Overutilization for commercial, recreational, scientific, or educational purposes; (C) Disease or predation; (D) The inadequacy of existing regulatory mechanisms; or (E) Other natural or manmade factors affecting its continued existence. (USFWS, 2021)

# SPECIES ACCOUNT: *Sclerocactus mesae-verdae* (Mesa Verde cactus)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 11/29/1979; Southwest Region (Region 2) (USFWS, 2016)

**Physical Description**

The Mesa Verde cactus stems are usually singular, globose, 3.2-6.5 cm tall (1.5 - 3 in) and of equal diameter; central spine 0 (possibly 1-4); radial spines 8-11, 6-13 mm long (1/4-1/2 in), white, tan, straw or gray; flowers 2 cm in diameter (3/4 in), cream to yellow; fruit green, becoming brown with age and splitting open horizontally; seeds black. In late April a yellow or cream-colored flower blooms on top of the stem. (USFWS, 1984)

**Taxonomy**

Sclerocactus mesae-verdae and S. wrightiae have several morphological features in common: stem size, shape and color; flower shape and color; fruit dehiscence (not bearing scale leaves); and the ability to retract into the soil during periods of drought. S. mesae-verdae has 0-1 central spines, 8-11 radial spines, cream to yellow flowers with no fragrance, brownish-black seeds, while S. wrightiae has 4-6 central spines, 5-10 radial spines, cream to pink flowers with fragrance, and black seeds. (USFWS, 1984)

**Current Range**

Occurs only in parts of Montezuma County, Colorado and San Juan County, New Mexico. Mostly on Navajo Indian Reservation lands (Roth, pers. comm., 1998). (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual and asexual (USFWS, 2010)

**Lifespan**

Adult: ~50 years (USFWS, 2023)

**Dependency on Other Individuals or Species**

Adult: Pollen grain collected from the field averaged 91 percent viability (Cully et al. 1993) and the most frequent visitors and potential pollinators were small, solitary bees of the family Halictidae (Cully et al. 1993; Heil and Porter 1994; Colorado Natural Areas Program 2005; Navajo Nation Heritage Program 2004). Other common visitors included pleasing fungus beetles (Tritoma sp.) and blister beetles (Epicauta sp.), but it is still not known which insects are the effective pollinators for this cactus (Cully et al. 1993). (USFWS, 2010)

**Breeding Season**

Adult: Late April to early May (USFWS, 2010)

**Key Resources Needed for Breeding**

Adult: Repeated freezing and thawing (vernalization), seed coat scarification, and the proper temperature and moisture are required for successful germination (Service 1984). (USFWS, 2010)

**Reproduction Narrative**

Adult: Sclerocactus mesae-verdae is a perennial desert plant that grows slowly and has a lifespan of approximately 20 years (Colorado Natural Areas Program 2005). Stems begin producing flowers when they are about 2 cm (0.8 in) in diameter or about 8 years old and begin to flower each year after reaching 4 cm (1.6 in) in diameter (New Mexico State Forestry Division 2007). Flowers are diurnal, bloom from late April into early May, and open daily for up to five days (Heil and Porter 1994). Flowers possess both male and female organs (hermaphroditic) indicating self-compatibility, yet Heil and Porter (1994) suggest that self-fertilization rarely is found in the genus Sclerocactus. Tepedino (1998) found that a single plant can self-fertilize (selfing) using pollen from another flower on the same plant (geitonogamy) and produce viable seed, but not pollen from the same flower (autogamy). However, 50 percent less seed is produced from self-compatible fertilization when compared to the pollen donor coming from a flower on a nearby plant (xenogamy or outcrossing) (Tepedino 1998). Pollen grain collected from the field averaged 91 percent viability (Cully et al. 1993) and the most frequent visitors and potential pollinators were small, solitary bees of the family Halictidae (Cully et al. 1993; Heil and Porter 1994; Colorado Natural Areas Program 2005; Navajo Nation Heritage Program 2004). Other common visitors included pleasing fungus beetles (Tritoma sp.) and blister beetles (Epicauta sp.), but it is still not known which insects are the effective pollinators for this cactus (Cully et al. 1993). Repeated freezing and thawing (vernalization), seed coat scarification, and the proper temperature and moisture are required for successful germination (Service 1984). Seed dispersal distance and seed bank sampling found a total seed load around mature plants averaging 200 seeds within a 1 meter (m) (3.3 feet [ft]) radius with 80 percent of the seeds 0 - 3 cm (0 - 1 in) deep in the soil (Cully et al. 1993). Mesa Verde cactus, or Whoosh Diikoozih (O'Kane et al. 2022, p. 5), is a perennial desert plant that grows slowly and has an estimated lifespan of at least 50 years (Coles et al. 2012, p. 313). Mesa Verde cactus can reach maturity within 2 to 3 years and can reach a reproductive size in 7 to 11 years (Coles et al. 2012, p. 313). The Navajo Natural Heritage Program found during monitoring that stems lived an average of 4.33 years, however 27 stems (out of 270 stems) survived the entire study (2008-2019; 11 years) (USFWS, 2023)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Desert (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Open sunny areas (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Restricted to dry exposed hills and mesas at elevations about 1,400 to 2,000 m; sparsely vegetated areas (USFWS, 2010; NatureServe, 2015)

**Environmental Specificity**

Adult: Medium (USFWS, 2010)

**Tolerance Ranges/Thresholds**

Adult: Moderate (USFWS, 2010)

**Habitat Narrative**

Adult: Sclerocactus mesae-verdae are restricted to sparsely vegetated badlands of clay loam soils derived from upper Cretaceous Mancos shale in Colorado, and Mancos and Fruitland shale in New Mexico (Service 1984). Populations are located in a narrow strip of land between Cortez, Colorado, and Sheep Springs, New Mexico, at elevations ranging from 1,400 to 2,000 m (4,600 - 6,560 ft) (Heil and Porter 1994; Coles and Naumann 2003). These formations erode easily, forming low, rolling hills where plants are found on hilltops and benches, but less so in basins or swales (Cully et al. 1993; Coles and Naumann 2003). The soils are sodic (high alkalinity; pH 7.5 to 8), gypsiferous (poor permeability), and have shrink-swell tendencies which make harsh sites for plant growth (Potter et al. 1985). However, during severe hot or cold dry periods, individual plants shrink and retract back into soils which can minimize desiccation or dehydration (Heil and Porter 1994). Colorado State University soil lab results on Colorado Natural Areas Program plots (2001) revealed clay and silty clay loams in texture, with low water permeability. Sodium, calcium, selenium and iron levels are elevated, while organic matter, phosphate and nitrate levels are low. Cracks in the clay soil, where the seeds fall and may germinate, are apparently an important part of the plant's microhabitat. Soils are typically high in selenite. Vegetative associates, though low in total percent ground cover (5 to 18 percent), include Atriplex cuneata (valley saltbush) and A. corrugata (mat saltbush) in New Mexico, and A. corrugata, A. confertifolia (shadscale saltbush), A. gardneri (Gardner’s saltbush), and Artemisia spinescens (bud sagebrush) in Colorado (Cully et al. 1993; Coles and Naumann 2003). In both states, A. corrugata was consistently found to be the dominant shrub.(USFWS, 2010; NatureServe, 2015)

***Dispersal/Migration***

**Dispersal**

Adult: Moderate (USFWS, 2010)

**Dispersal/Migration Narrative**

Adult: Harvester ants (Pogonomyrmex sp.) and erosional processes (rain) are the most effective short-range seed dispersers; whereas, wind may be more important to long-range dispersal (Cully et al. 1993; Rojas-Arechiga and Vasquez-Yanes 2000). Seed predation is well known in desert areas with frugivores (fruit eaters) being another type of important dispersal agent. Mainly rodents, but also birds, lizards, and some mammals prey on fruits and seeds (Rojas-Arechiga and Vasquez-Yanes 2000). No long-range dispersal was observed by rodents or birds for this species (Cully et al. 1993; Colorado Natural Areas Program 2005; Navajo Natural Heritage Program 2005). (USFWS, 2010)

***Population Information and Trends***

**Population Trends:**

Long-term trends are unknown but short-term trends indicate a decline of 10-30% (NatureServe, 2015)

**Population Growth Rate:**
Slow growth and reproduce success rate (NatureServe, 2015)

**Number of Populations:**
78 (NatureServe, 2015)

**Population Size:**
10,000 individuals (NatureServe, 2015)

**Population Narrative:**
Slow growth and low reproductive success rate; the taking of a few plants can deplete/extirpate a population. There is insufficient data to characterize long-term population trends but short-term trends indicate a decline of 10-30%. Approximately 2000 individuals have been documented in element occurrence records (CNHP 2012, NHNM 2003), although the species is estimated to be represented by as many as 10,000 individuals (Coles 2003). A total of 78 occurrences have been documented, 22 in Colorado and 56 in New Mexico (CNHP 2012, NHNM 2003). Twenty of the occurrences report less than 10 individuals each. (NatureServe, 2015). Mesa Verde cactus is not distributed continuously throughout its range, distribution is instead sporadic and widely scattered. Mesa Verde cactus density within populations is low, rarely exceeding one plant per 10 square meters (108 square feet) (Coles et al. 2012, p. 312). Of the known Mesa Verde cactus populations, at least 80 percent of these occur on Navajo Nation lands, 15 percent on Ute Mountain Ute lands, and 5 percent on small blocks of Bureau of Land Management and New Mexico State trust lands (NMSFD 2020b, p. 2). Mesa Verde cactus are now known to occupy private land (BOR 2022, p. 18). At this time, not all potentially suitable habitat for Mesa Verde cactus has been surveyed (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Highway construction and right-of-ways for transmission lines (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Navajo Nation and BLM have consulted with the Service for various projects that have taken place or are planned to occur in areas with occupied or suitable habitat for S. mesae-verdae. We provide a list of consultations in order to convey the number and diversity of projects and to acknowledge the continuing compliance of the Navajo Nation and BLM with accounting for rare species. In each case, however, after the Service provided non-jeopardy opinions, we did not receive any further information regarding implementation of conservation measures, including post-construction surveys or progress reports. To ensure that the conservation measures are implemented and effective, and to apply adaptive management, if needed, to modify measures to assist the cactus, providing documentation of the outcome of these projects and other monitoring data would be very beneficial to the Service. By sharing information about the effects of projects, all parties managing S. mesae-verdae can be informed of what conditions are most favorable for this cactus and what conservation measures are the most worthwhile for promoting this species' recovery and moving toward delisting. There is a

need for a S. mesae-verdae multi-agency working group to share and disseminate information regarding this listed species to promote education, protection, and recovery. (USFWS, 2010)

**Stressor:** Off-highway vehicles (OHVs) (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The 1984 recovery plan correctly anticipated that OHV use would be one of the greatest human-caused threats to S. mesae-verdae. The use of OHVs appears to have increased within the Navajo Nation (Roth 2009, pers. comm.) and on BLM lands ((Jamison 2009, pers. comm.). This increase is most likely due to the recent energy boom and the resultant population boom within San Juan County; a 55 percent increase in population from 1980 to 2006 (http://wrdc.usu.edu/htm/publications/). National all-terrain and off-highway vehicles retail sales from 1993-2003 show a dramatic increase from 2,920 total vehicles sold in 1993 to a total of 8,010 vehicles sold by 2003 (Cordell et al. 2005). However, the perception of increased OHV traffic may be more of an issue of unmanaged/unregulated use where one vehicle could cause extensive and severe habitat damage with one trip through closed areas. When a vehicle runs over a cactus, the growing tip is often damaged resulting in a failure to flower and set seed as well as an increased vulnerability to desiccation, herbivory, and pathogens. Cacti can also be directly uprooted or irreversibly damaged from OHVs or any other form of forceful contact. In addition to these direct impacts to the cactus, indirect effects from OHV riding also occur such as damage or destruction of annual and perennial plants, destruction of fragile soil crusts, soil erosion and compaction, alteration of drainage patterns, formation of dust, and proliferation of weeds (Brooks 2009; Lei 2009). Erosion and denuding of plants on dry soils from unauthorized OHV use changes soil properties and alters the hydrological dynamics of an area, with impacts spanning from the microhabitat to the landscape scale. These factors increase run-off and decrease the infiltration of precipitation into soils, further diminishing water storage and accessibility to plant roots. Off-highway vehicle activity can also disturb fragile cyanobacterial-lichen soil crusts, a dominant source of nitrogen in desert ecosystems (Belnap 1996). Belnap (1996) showed that anthropogenic surface disturbances may have serious implications for nitrogen budgets in cold-desert ecosystems similar to those occupied by S. mesae-verdae. Soil crusts also appear to be an important source of water for plants, as crusts were shown to have 53 percent greater volumetric water content than bare soils during the late fall when winter annuals are becoming established (DeFalco et al. 2001). Once the soil crusts are disturbed, non-native plants may colonize, become established, and outcompete native perennial and annual plant species (DeFalco et al. 2001). Surface disturbance from OHV activity can cause erosion and large amounts of dust to be discharged into the air. Recent studies addressing surface dust impacts on gas exchanges of desert shrubs showed that plants encrusted by dust have reduced photosynthesis and decreased water-use efficiency, which may decrease primary production during seasons when photosynthesis occurs (Wijayratne et al. 2005; Sharifi et al. 1997). Sharifi et al. (1997) also showed reduction in maximum leaf conductance, transpiration, and water-use efficiency due to dust. These effects may impact desert plants including S. mesae-verdae. Impacts from constant OHV use, causing soil, vegetation, and hydrological disturbances, have the capacity to compound over time, particularly if the source of OHV impacts is located high in a drainage (Brooks and Lair 2005). Repeated OHV trail use leads to new routes that are not included in road databases (Brooks and Lair 2009). As a result, continual unauthorized OHV use, especially off-trail riding, can create conditions less and less supportive for a habitat specialist such as this cactus species. Furthermore, reduced moisture availability and ground cover from

OHV use can interact with other variables such as climate change or grazing, exacerbating drying conditions an already arid system. (USFWS, 2010)

**Stressor:** Coal mining (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** About 90 percent of known S. mesae-verdae habitat occurs in areas that lack coal reserves (Parker et al. 1977). The 1984 recovery plan reported that no coal mining was being actively pursued within occupied habitat, although several strip mining operations were within a few miles of the Waterflow cactus population (Service 1984). This cactus population was the only one known growing on the coal-bearing Fruitland formation (Service 1984). We are not aware of any effects resulting from coal mining on this species (Sivinski 2000). Thus, we believe that coal mining is not currently a threat and is not likely to threaten the species in the foreseeable future. (USFWS, 2010)

**Stressor:** Oil and gas exploration and production (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** About 70 percent of the known occupied S. mesae-verdae habitat is located on Navajo Nation lands. Navajo Nation lands contain significant deposits of coal, oil, and natural gas. Development of energy resources in the Four Corners Basin continues to increase (Energy, Minerals, and Natural Resources Department 2008). The Fruitland Coal formation of the San Juan Basin is the largest coal bed methane producer in the United States (Energy, Minerals, and Natural Resources Department 2008). These resources occur subsurface in ancient marine shale layers, primarily Fruitland and Mancos layers, which coincide with S. mesae-verdae habitat. Nearly all known cactus habitat has the potential to be affected by natural gas or oil exploration and development. Another mineral, a decomposed type of coal (humate), is also found under much of S. mesae-verdae habitat (Colorado Natural Areas Program 2004). Humate is used as a soil conditioner and additive to drilling mud which increases the potential for development. About 12.1 billion tons of humate occur within the San Juan Basin (McLemore et al. 2002). Ground disturbing impacts from these activities include the construction and maintenance of pipelines, power lines, and associated roads; the total clearing of all vegetation on an average of three acres for every oil or gas well pad and associated facilities; and associated commercial and residential development. These activities lead to long-term degradation, fragmentation, or loss of habitat, with impacts to S. mesae-verdae similar to those described above in the OHV section. Most S. mesae-verdae habitat occurs on the Mancos Formation, with the Rattlesnake, Shiprock-Gallup, Horseshoe-Gallup, and Hogback oil fields located within high quality habitat. Destruction of cactus habitat from these oil fields appears to be extensive (Roth 2008, pers. comm.); however, data quantifying the size of each oil field, number of cactus mortalities, and leasing of other areas for associated activities are not available. (USFWS, 2010)

**Stressor:** Commercial and residential development (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Commercial and residential development threatens S. mesae-verdae on private and Tribal lands (Service 2009). Since the species was listed, cactus habitat has been increasingly impacted from urban development on Navajo Nation lands (Navajo Natural Heritage Program 2004). Urban development is not allowed within a BLM ACEC or on New Mexico State trust lands. The status of urban development on Ute Mountain Ute lands regarding this cactus is unknown at this time. Impacts from urban development include habitat loss, fragmentation, and degradation, along with other factors relating to soil, vegetation, and hydrologic disturbances described in more detail in the off-highway vehicles section above. These impacts not only directly damage cacti, but also can make occupied and potentially usable habitat inhospitable to S. mesae-verdae and result in the decline of individuals and populations. Urban development, including homes, roads, power lines, pipelines, and waterlines; increased recreational activities, including use of OHVs; and commercial facilities have expanded in the proximity of Shiprock. In an effort to off-set the Navajo fairground project interfacing with the cactus, the Northern Navajo Fairground Conservation Area was established in 2001 to use for transplanting cacti that otherwise would be destroyed by the construction of the fairground. However, it is unknown at this time if signs and fences are in place to protect this area. (USFWS, 2010)

**Stressor:** Livestock grazing and trampling (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The 1984 Recovery Plan (Service) stated that livestock grazing was not believed to be a significant threat. Since that time, nearly all monitoring has documented disturbance of S. mesae-verdae by livestock. Livestock grazing occurs throughout the range of the cactus, and impacts from trampling, such as uprooted cacti, partially or entirely crushed cacti, and soil disturbance immediately adjacent to cactus individuals are regularly observed (Ecosphere Environmental Services 1985). Cattle have also been observed eating S. mesae-verdae (Service 1984; Ecosphere Environmental Services 1985). Livestock grazing continues to be permitted by the BLM within the Hogback ACEC (Bureau of Land Management 2003b). Navajo Nation staff noted heavy sheep and cattle grazing at the Sheep Springs population that historically supported S. mesae-verdae prior to 2004 (Navajo Natural Heritage Program 2004), but now appears to be extirpated (Roth 2008, pers. comm.). Three additional occupied areas on Tribal land were observed to have extensive livestock damage (Navajo Natural Heritage Program 2004). In Colorado, livestock trampling was also documented and believed to be the primary source of cactus mortality in 2005 (Colorado Natural Areas Program 2005). The 1984 Recovery Plan reported that when livestock are fenced in cactus habitat, trampling of the species could occur. High intensity grazing associated with fenced private or Tribal residences is likely to result in the permanent loss of cacti through trampling and soil compaction (Service 2009). On larger fenced acres, ranchers drive their trucks and OHVs off-road, tracking or herding their livestock (Jamison 2009, pers. comm.). Likewise, during capture of feral horse herds on the Navajo Nation, soils have become compacted within S. mesae-verdae habitat (Service 2009). Based on the increase in habitat degradation due to livestock trampling, whether it be compacted soils or vegetation displacement resulting in increased soil erosion and dust formation, we believe that livestock grazing and trampling has become a moderate threat to this species for the foreseeable future. (USFWS, 2010)

**Stressor:** Collectors (USFWS, 2010)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Cacti are desirable plants whose wild populations in the U.S. and Mexico have been subject to illegal collection and trade (Robbins 2003). Some cactus hobbyists, known as cactophiles, are well known for their passion and interest in rare cacti. Many of these collectors have illegally obtained certain species for their private collections (Robbins 2003). In summary, illegal collection leads to the direct loss of plants and has threatened some S. mesae-verdae populations. Cactus collecting will probably continue at some level into the foreseeable future, but such activities are difficult to document and we have not discovered any new information to suggest that cactus theft is increasing (CITES 2000; Robbins 2003; Martin 2009). Although illegal collection of S. mesae-verdae was considered a significant threat at the time of listing and during the development of the Recovery Plan, as evidenced by the second recovery criterion which directly addresses this threat, collecting appears to have decreased since the publishing of the Recovery Plan and is now considered a minor threat to the species for the foreseeable future. (USFWS, 2010)

**Stressor:** Predation (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** All Sclerocactus are susceptible to disease and predation, but only predation has been observed in this species. The longhorn cactus beetle (Moneilema semipunctatum) normally feeds upon Opuntia spp. However, during the 20022003 period of severe drought, the longhorn cactus beetle fed upon S. mesaeverdae and substantially reduced all of the monitored populations. Although the longhorn cactus beetle is a native species and S. mesae-verdae has likely evolved with it, this beetle has the potential to cause serious mortality in the foreseeable future with periodic atypical population eruptions. Native to the Great Plains and Intermountain West, a migratory, noctuid moth, the army cutworm (Euxoa spp), destroyed many S. mesae-verdae in the BLM Hogback ACEC study area during the drought of 2002-2003 (Bureau of Land Management 2003b). Numerous cacti also were reported killed by the army cutworm on Navajo Nation land (Roth 2008, pers. comm.). Since this insect is generally associated with agricultural crops which are found nearby BLM and Navajo Nation lands, but will also consume native plants, particularly grasses, the threat is still substantial. In 2003, a third type of cactus predator was observed in the Colorado (Navajo Natural Heritage Program 2004). Unfortunately, the identity of the predator was not determined, but the effects to the plant appear to be similar to those from the longhorn cactus beetle (Navajo Natural Heritage Program 2004). The Service believes that insect predators can be an ongoing, yet minor threat to S. mesae-verdae. However, during atypical drought episodes, the threat from these predators can be severe into the foreseeable future. (USFWS, 2010)

**Stressor:** Pesticide use (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Pesticides are considered a potential threat because they could directly harm a plant, but also could indirectly kill pollinators of S. mesae-verdae or their host plants (Service 1984). Herbicides are commonly used for noxious weed control, but no documentation has been provided on herbicide application occurring, and whether any S. mesae-verdae populations have

been directly or indirectly affected. On the other hand, agricultural use of pesticides has been reported on nearby BLM lands. Pesticides, particularly insecticides, are linked to bee declines (Kearns et al 1998; Kremen et al. 2002; National Academy of Sciences 2007), with the abundance and diversity of wild bee communities negatively correlated with increasingly intensive chemical applications of pesticides (Tuell and Isaacs 2010). Although the toxicity of pesticides to pollinators is challenging to quantify in a field setting and varies depending on the chemistry, quantity applied, degree of contact, area treated, and seasonal timing (Mineau et al. 2008; Tuell and Isaacs 2010), some pesticides cause immediate mortality to bees if applied upon crops while bees are actively foraging (Johansen 1977). Both wild and honey bee (Apis mellifera) declines have been found in areas adjacent to sprayed fields, suggesting a wider spatial impact to the pollinator community than just a targeted area (Kevan 1975; Kevan et al. 1990). Furthermore, depending on the seasonal timing of pesticide application, effects to pollinator communities may be chronic and cumulative, yet difficult to assess due to the different phenologies and nesting situations of pollinator species (Desneaux et al. 2007; Tuell and Isaacs 2010). Pesticide application, particularly aerial spraying, occurs in the local agricultural areas to control crop pests, including army cutworms (Euxoa spp). Most of the S. mesae-verdae populations are miles away and would not be impacted by drift (Sivinski 2000). However, a few cactus populations are situated near agricultural areas, such as the Waterflow population, which is close to an apple orchard and alfalfa field, yet it has been successfully setting fruit until the severe drought of 2002-2003. Due to the lack of information, we are uncertain whether pesticides directly or indirectly affect the survival of S. mesae-verdae. Thus, we do not consider pesticides to be a threat to this species in the foreseeable future. (USFWS, 2010)

**Stressor:** Climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Based on the unequivocal evidence of warming of the earth's climate from observations of increases in average global air and ocean temperatures, widespread melting of glaciers and polar ice caps, and rising sea levels recorded in the Intergovernmental Panel on Climate Change Report (IPCC 2007), climate change is now a consideration for Federal agency analysis (GAO 2007). The earth's surface has warmed by an average of 0.74 º C (1.3 º F) during the 20th century (IPCC 2007). The IPCC (2007) projects that there will very likely be an increase in the frequency of hot extremes, heat waves, and heavy precipitation events as a result of climate change. Increases in predatory insects are also predicted with climate change (Enquist and Gori 2008). This was documented for S. mesae-verdae during the drought of 2002-2003 with the unusual and extensive invasion of the longhorn cactus beetle and the army cutworm. The drought combined with concurrent insect infestations significantly reduced S. mesae-verdae populations and recovery has been extremely slow. Sclerocactus mesae-verdae is likely to have experienced and rebounded from periods of drought and cycles of insect predation in the past. However, should substantial climate change materialize with increased severity and frequency of drought, it would likely reduce the long-term survivorship of this species. Since the documented decline of S. mesae-verdae was concurrent with the drought of the early 2000s, the Service believes that climate change is a severe threat to this species in the foreseeable future. (USFWS, 2010)

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

Recovery Priority Number: 11C

**Delisting Criteria:**
1. Establish at least two restricted use areas for selected portions of S. mesaeverdae habitat on the Navajo Indian Reservation and on Bureau of Land Management (BLM) administered lands. (USFWS, 2010)

2. Provide S. mesae-verdae stock to trade outlets to help relieve the black market demand through the addition of 10,000 plants per year to commercial nurseries for 5 years. (USFWS, 2010)

**Recovery Actions:**
- Major actions listed in the recovery plan include species monitoring, management, and protection of the five known populations; establishment of at least two (additional) areas of restricted use; surveys of all potential species' habitat; development of a commercial artificial propagation program; and research into the distribution, population biology, and ecology of this species. (USFWS, 2010)
- Revise the recovery plan for this species to incorporate new information on biology, ecology, threats, and management recommendations. Objective and measurable recovery criteria for down and delisting of the species should be developed which addresses all listing factors relevant to this species. (USFWS, 2010)
- Recommend more stringent off-highway vehicle use restrictions and stronger enforcement of OHV laws in known and potential cacti habitat. (USFWS, 2010)
- Develop a S. mesae-verdae multi-agency working group to share and disseminate information regarding this listed species to promote education, protection, and recovery. (USFWS, 2010)
- Develop standardized survey and monitoring protocols for this species to be conducted annually by well trained personnel. Continue monitoring of known sites as well as adding new sites to provide a robust dataset for long-term trend analysis. (USFWS, 2010)
- Develop a mitigation banking requirement (a system whereby project proponents pay for plants to be preserved in an area suitable for their preservation as mitigation for losses incurred during projects). (USFWS, 2010)
- Implement and monitor new transplant projects with experimental manipulations (watering, shading, planting depth, etc.) and controls to determine required establishment needs. (USFWS, 2010)
- Provide legally grown seeds and plants of S. mesae-verdae to the commercial succulent trade, but law enforcement must remain vigilant against the theft of cacti throughout its range. (USFWS, 2010)
- Provide viable S. mesae-verdae seeds to a seed bank operating under the Center for Plant Conservation guidelines. (USFWS, 2010)
- Collect data on seed dispersal and growth past the germination stage, timing of seed set, and seedling establishment to more clearly define the vulnerable life history stages of this species. (USFWS, 2010)

- Determine microhabitat needs of this species ("nurse" plants, pollinators, precipitation needs - amount and timing, slope and aspect requirements, disturbance patterns, etc.) to further quantify potential habitat for a transplant and mitigation site. (USFWS, 2010)
- Collect data on the biology, demographics, ecology, and movements of the longhorn cactus beetle and the army cutworm to determine their long-term significance as predators of this species. (USFWS, 2010)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • If possible given workloads, conduct a Species Status Assessment to inform the next fiveyear review and to guide the development of a revised recovery plan to reflect current number of populations, population status and demographics, and status of threats. • We recommend stronger enforcement of off-highway vehicle laws in known and potential cacti habitat. • Conduct additional research on taxonomy and genetics of the Mesa Verde cactus across the range of the species. • Finalize species range map and continue to survey areas within the species' revised range to verify the presence or absence of individuals and suitable habitat. • Develop a Mesa Verde cactus multi-agency working group to improve collaboration, discuss annual monitoring results, and to promote protection and recovery. • Develop or adopt standardized survey and monitoring protocols range-wide for this species to be conducted annually by well trained personnel. Continue monitoring of known sites as well as adding new sites to provide a robust dataset for long-term trend analysis. • Implement and monitor new transplant projects with experimental manipulations (watering, shading, planting depth, etc.) and controls to determine required establishment needs. • Collect data on seed dispersal and growth past the germination stage, timing of seed set, and seedling establishment to clearly define the vulnerable life history stages of this species. • Determine microhabitat needs of this species ("nurse" plants, pollinators, precipitation needs - amount and timing, slope and aspect requirements, disturbance patterns, etc.) to further quantify potential habitat for a transplant and mitigation site. • Collect data on the biology, demographics, ecology, and movements of the longhorn cactus beetle and the army cutworm to determine their long-term significance as predators of this species. • Establish additional conservation areas for the Mesa Verde cactus. • Establish an off-site conservation program to develop captive propagation techniques that follow the Center for Plant Conservation best management practices. Conduct studies to evaluate the effectiveness of seed germination and seedling establishment. • Conduct studies on the reproductive biology of Mesa Verde cactus, including pollination, seed development, seed dispersal, and inbreeding depression. • Conduct additional studies on predation, impacts of invasive species to different life stages, and other emerging threats (USFWS, 2023).

# SPECIES ACCOUNT: *Sclerocactus wetlandicus* (Uinta Basin hookless cactus)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 09/15/2009; Mountain-Prairie Region (R6) (USFWS, 2016)

**Physical Description**

S. wetlandicus is a barrel-shaped cactus that ranges from 4 to 18 centimeters (cm) (1.5 to 7 inches (in.)) tall, with exceptional plants up to 30 cm (12 in.) tall. The stems have typically 12 to 15 ribs that extend from the ground to the tip of the plant. Along the ribs are areoles (small, cushion-like areas) with hooked spines radiating out (Heil and Porter 2004). There are two types of spines, radial and central, defined by the size and position on the plant (see Figure 1) (74 FR 47112, September 15, 2009). The 6 to 14 radial spines are located around the margin of the areole, extending in a plane parallel to the body of the plant. The radial spines are white or gray to light brown, and are 6 to 20 mm (0.24 to 0.8 in.) long. The one to five central spines (usually three) are 15 to 30 mm (0.5 to 2.0 in.) long, are generally longer than radial spines, and extend from the center of the areole. The central spines include abaxial and lateral forms. Abaxial spines are typically single and are noticeably bent at an angle usually less than 90 degrees. Lateral spines are usually present in pairs on either side of the abaxial spine, but are more or less straight and diverge from the abaxial spine at an acute angle (usually 20 to 50 degrees). The funnel-shaped flowers usually have pink to violet tepals (petal-like flower parts not differentiated into petals and sepals) with yellow stamens (the male reproductive organ of the flower), and are 2 to 5 cm (0.8 to 2 in.) long and 2 to 5 cm (0.8 to 2 in.) in diameter (74 FR 47112, September 15, 2009). The fruit is short, barrel-shaped, reddish or reddish grey when ripe, 7 to 12 mm (0.3 to 0.5 in.) wide, and 9 to 25 mm (0.35 to 1.0 in.) long (USFWS, 2010).

**Taxonomy**

The original listing rule for S. glaucus (44 FR 58868, October 11, 1979) included all hookless (straight central spines) Sclerocactus populations in western Colorado and northeastern Utah, and referred to them as S. glaucus per Benson (1966, pp. 50-57; 1982, pp. 728-729). This taxonomic classification is not supported by the results of more recent genetic and morphological research. Genetic studies (Porter et al. 2000), common garden experiments (Hochstätter 1993b; Welsh et al. 2003), and a reevaluation of the morphological characteristics of S. glaucus have led to separating this species into three distinct species: S. brevispinus, S. glaucus, and S. wetlandicus (Hochstätter 1993b; Heil and Porter 2004). The Flora of North America recognizes 15 species in the genus Sclerocactus, including these 3 species (Heil and Porter 2004). Comparative DNA sequences (Porter et al. 2000) infer common ancestry between S. brevispinus and S. wetlandicus, but infer S. glaucus is more closely related to S. parviflorus (Devil's claw cactus) and S. whipplei (Whipple's fishhook cactus). The common name for S. glaucus was changed to Colorado hookless cactus as the species is endemic to western Colorado. S. wetlandicus is now known as the Uinta Basin hookless cactus as this species occurs across Utah's Uinta Basin. S. brevispinus is now known as the Pariette cactus as it is limited to the Pariette Draw of the central Uinta Basin. The Uinta Basin hookless cactus complex will be used to refer to the combination of all three species previously listed as a single entity (USFWS, 2010).

**Current Range**

Known only from Duchesne and Uintah counties, Utah (Flora of North America Editorial Committee (2003).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Predominately insect pollinated (surrogate S. glaucus information) (USFWS, 2007)

**Breeding Season**

Adult: Flowering occurs in April-May, and fruits mature in May-June (surrogate S. glaucus information) (NatureServe, 2015).

**Reproduction Narrative**

Adult: Reproduction is predominantly sexual, although individuals may sprout multiple stems. Flowering occurs in April-May, and fruits mature in May-June. The species appears to be predominantely outcrossing but is marginally self-compatible. Ants and gravity appear to be the primary dispersal mechanisms (Peggy Lyon pers comm. 1998). Seed dispersal may be a limiting factor in the distribution of Sclerocactus glaucus (NatureServe, 2015). Information from S. glaucus is being used a surrogate information for S. wetlandicus due to the species similiarities and based on the following quote 'Because we lack life history data specific to S. wetlandicus, we have included life history data for S. glaucus, which should correlate to characteristics for S. wetlandicus' USFWS, 2010. Believed to be dispersed by heavy down-pours (Tepedino et al. 2010).; ABIOTIC; Water; (NatureServe, 2015). The species’ life history is poorly known, but it is thought to be a longlived perennial usually flowering after 3 or 4 years. A broad assemblage of native bees, and possibly other insects including ants and beetles, pollinates S. brevispinus (USFWS 1990, p. 7) (USFWS, 2007).

**Habitat Type**

Adult: Salt desert shrub (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred form NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred form NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits salt desert shrub communities and pinon-juniper woodlands on river benches, valley slopes, and rolling hills (Franklin 2005). Gravel-covered clay hills, desert grasslands, saltbush, and rabbitbrush flats (Flora of North America Editorial Committee 2003). (NatureServe, 2015). High ecological integrity of the population and site fidelity as well as low tolerance ranges are inferred based on the species habitat requirements of the species and the relatively small geographic area this species inhabits.

***Dispersal/Migration***

**Dispersal**

Adult: Believed to be dispersed by heavy down-pours (NatureServe, 2015)

**Dispersal/Migration Narrative**

Adult: Believed to be dispersed by heavy down-pours (Tepedino et al. 2010).; ABIOTIC; Water; (NatureServe, 2015)

***Population Information and Trends***

**Population Trends:**

Unknown

**Number of Populations:**

6 - 80 (NatureServe, 2015)

**Population Narrative:**

Approximately 8 occurrences observed since 1989 and 17 others last observed earlier (UTNHP 2009). (NatureServe, 2015). We do not have long-term status or trend population (USFWS, 2010). Low resiliency, redundancy and representation are inferred based on the relatively low number of known populations and the small geographic area this species is known to inhabit. data for S. wetlandicus (USFWS, 2010).

***Threats and Stressors***

**Stressor:** Oil and Gas Development and Associated Impacts (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The BLM is monitoring S. wetlandicus and neighboring Sclerocactus species, including impacts associated with oil and gas development. Initial results show that there may be impacts from oil and gas development (i.e., roads and well pads) on the survival and reproductive success of S. brevispinus (72 FR 53215, September 18, 2007), and similar effects could be expected for S. wetlandicus (USFWS, 2010).

**Stressor:** Collection (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Illegal collection is a significant threat to S. wetlandicus. The original listing of S. glaucus concluded that the cactus is prized among collectors and threatened by unregulated commercial trade (44 FR 58869, October 11, 1979). Collectors prefer larger, reproductive age

individuals, leaving behind a younger, less reproductive population. Approximately 40 percent of the potential habitat of S. wetlandicus is within 400 meters (1,312 feet) of a well (Service 2009). Such development facilitates human access and discovery by illegal collectors (72 FR 53216, September 18, 2007) (USFWS, 2010).

**Stressor:** Livestock Grazing and Trampling (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** A majority of S. wetlandicus potential habitat on BLM land is leased for grazing. At least 28 grazing allotments overlap with S. wetlandicus potential habitat, with both cattle and sheep grazing continuously and on deferred rotation. Livestock grazing results in S. wetlandicus mortality when livestock trample individual cacti (Service 1990; Utah Natural Heritage Program 2006; BLM 2008; 72 FR 53215, September 18, 2007). Overgrazing—the continued heavy grazing beyond the recovery capacity of forage plants (Vallentine 1990) - by domestic livestock degrades western ecosystem functions and structures (Fleischner 1994). Overgrazing can facilitate the establishment of invasive species like cheatgrass (Masters and Sheley 2001), which are difficult to eradicate and tend to outcompete native vegetation, including cacti. Invasive weeds (including Bromus tectorum and Halogeton glomeratus) are prevalent on BLM lands in the range of S. wetlandicus cactus and less so on tribal lands where grazing has been concentrated in areas outside of suitable cactus habitat (72 FR 53214, September 18, 2007) (USFWS, 2010).

**Stressor:** Predation (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Parasitism by the cactus-borer beetle (Moneilema semipunctatum) is a significant but localized source of mortality to all Sclerocactus species on the Colorado Plateau, especially in larger, mature, reproducing individuals (Service 1990; 72 FR 53216, September 18, 2007). Parasitism is identified as a threat to Sclerocactus plants; however, additional studies are needed to determine the long-term, population-level effects of the cactus-borer beetle to S. wetlandicus. Another source of mortality is lagomorph and rodent browsing. While there have been numerous observations Sclerocactus being removed by desert cottontail rabbits (Sylvilagus audubonii) and unknown rodents (Colorado Natural Heritage Program 2010b; BioLogic 2008; Clayton 2006), in subsequent years some of these plants have re-sprouted (Clayton 2010). Browsing likely goes unnoticed unless a marked individual is revisited within a 1- to 2-year period. We know very little about the magnitude of this threat (USFWS, 2010).

**Stressor:** Climate Change, Drought, and Impacts to the Vegetative Community (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Climate change is likely to affect long-term survival of native species, including S. wetlandicus, especially if longer or more frequent droughts occur. For the southwestern region of the United States, warming is occurring more rapidly than elsewhere in the country with an increase of 1.5°F (0.8°C) since 1979 (Karl et al. 2009). Under lower emission scenarios temperature is expected to increase 5°F (2.8°C) and under higher emission scenarios temperature is expected to increase 10°F (5.6°C) by the end of the century, from the 1979

baseline (Karl et al. 2009). Other future projections for the southwest include more intense and longer-lasting heat waves, an increased probability of droughts that are worsened by higher temperatures, heavier downpours, increased flooding, and increased erosion (Karl et al. 2009, pp. 129-134). The levels of aridity of recent drought conditions and perhaps those of the 1950s drought years may become the new climatology for the southwestern United States (Seager et al. 2007). Effects related to climate change (e.g., persistent or prolonged drought conditions, changes in community assemblages and the ability of nonnative species to succeed) may affect long-term persistence of S. wetlandicus. While the potential impacts of climate change could be serious, improved projections are needed to better understand this potential threat. S. wetlandicus mortality due to drought is well documented (Service 1990; 72 FR 53217, September 18, 2007). Many dead S. wetlandicus individuals were observed in the Uinta Basin after the severe drought of 1976 to 1977 (Service 1990). In addition, noxious weeds are often able to out-compete native species under drought conditions (Everard et al. 2010). Drought conditions could further hinder BLM’s efforts to control noxious weeds and restore native vegetation, which is already difficult due to the extreme environment of the Uinta Basin (Service 1990; BLM 2005, 2008) (USFWS, 2010).

**Stressor:** Herbicides and Pesticides (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of indivduals
**Narrative:** S. wetlandicus lives in or near areas that receive herbicide and pesticide treatments to remove undesirable species, such as noxious weeds and insect pests (Service 1990). Individual cacti are likely to be directly affected by these chemicals, and indirectly by effects on pollinators or by movement of contaminated soils (Service 1990). However, specifics of the species' pollination biology are currently unquantified (USFWS, 2010).

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** We are not aware of any city, county, or State laws, ordinances, or zone that provide for protection or conservation of the S. wetlandicus or its habitat. Removal, damage, or destruction of plants on private lands is not prohibited under the Act. Removal from Federal lands is prohibited without a permit, but can be allowed through consultation with the Service. The BLM sometimes authorizes adverse effects to the S. wetlandicus if it will not jeopardize the continued existence of the species. Conservation needs of S. wetlandicus are addressed through interagency consultation (section 7 requirements) typically between the Service, BLM, and Bureau of Indian Affairs. Through this process, conservation measures are implemented on a project-by-project basis to minimize the loss of individual cacti from oil and gas activities. These measures include preconstruction cactus surveys and a required buffer around individual cacti. For example, the Castle Peak/Eightmile Flat Oil and Gas Expansion Project Final Environmental Impact Statement included conservation measures to specifically protect S. wetlandicus and its habitat (BLM 2005). In addition to these project-specific protections, we need to establish consistent guidance and Resource Management Plan designations that provide adequate regulatory mechanisms over the longer term to protect large portions of the range of the S. wetlandicus (USFWS, 2010).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 8C

For Uinta Basin hookless cactus – The metapopulation has a stable or increasing growth trend (average lambda (λ) ≥ 0.95) over a minimum period of 10 consecutive years and predictive modeling (using data from the same 10-year monitoring period) indicates that the likelihood for long-term survival of the metapopulation is at least 95 percent over a 100-year period. In addition: a. At least 8 of the 11 core 2 areas have a stable or increasing growth trend (average lambda (λ) ≥ 0.95) over a minimum period of 10 years to demonstrate metapopulation stability. b. The eight core 2 areas evaluated should incorporate the principles of redundancy and representation by including core areas that represent the full distribution of the species (i.e., core areas from the furthest north, south, east, and west boundaries, representation from all habitat types, and range of elevation) (USFWS, 2023).

For Uinta Basin hookless cactus – The metapopulation maintains a size distribution that contains individuals in all size classes over a 5-year minimum period and where the largest size class maintains a stasis rate no less than 0.90. Size classes for Uinta Basin hookless cactus are defined as: class 1:< 21.2 mm; class 2: 21.2–51 mm; class 3: 51.1–80 mm; and class 4: >80 mm (Hornbeck 2020) (USFWS, 2023).

For Uinta Basin hookless cactus – Genetic diversity across the metapopulation is maintained at levels such that there is a high probability (95 percent) of two core 1 populations persisting over the long term (100 years) within each core 2 area (USFWS, 2023).

For Uinta Basin hookless cactus – Disturbance that contributes to the degradation and loss of habitat (e.g., roads, recreation, livestock) does not exceed established tolerance thresholds for each core 2 area (percent of habitat) (USFWS, 2023).

For Uinta Basin hookless cactus – Protected areas will be formally established by land managers for at least one genetically important population and at least one connectivity corridor (as identified using connectivity analysis) to provide long-term protection from anthropogenic threats. Methods may include but are not limited to Areas of Critical Environmental Concern (ACECs), Resource Management Plan special designations, Tribal resolutions, conservation agreements, and conservation easements (USFWS, 2023).

**Recovery Actions:**

- Priority 1 Actions 1. Monitor two core 1 areas within each core 2 area for Pariette cactus and eight core 2 areas for Uinta Basin hookless cactus to evaluate short- and long-term population trends across the metapopulation and support predictive modeling. Monitoring should be conducted for a minimum of 10 years (Recovery Criteria 1 and 2). 2. Reduce impacts from livestock, feral horses, and herbivores on a landscape scale (in all subpopulations) through herd management, grazing rotations and rest, and habitat improvements (Recovery Criterion 1). 3. Develop disturbance tolerance thresholds for each core 2 area (Recovery Criterion 4). 4. Formalize conservation measures with partners to be implemented with, and prior to, all surface disturbing projects. Conservation measures may be documented in a memorandum of understanding, resource management plan, conservation agreement, recreation management plan, travel management plan, or similar document (Recovery Criteria 1, 2, 3, 4, and 5). 5. Restore disturbed areas within core habitat so that new surface disturbance is less than the tolerated threshold identified in Recovery Action 3 (Recovery Criteria 1, 2, and 3). 6. Resurvey subsampled areas (targeted and repeat) to update abundance and population estimates (Recovery Criteria 1, 2, 3, 4, and 5) (USFWS, 2023).

- A Recovery Plan has not been published for this species.
- Priority 2 Actions 7. Evaluate current genetic diversity across the species range to identify subpopulations at risk, those needing protections, and those of high importance (Recovery Criterion 2). 8. Conduct a connectivity analysis to identify important gene flow corridors (Recovery Criterion 2). 9. Restore or improve connectivity corridors between core 1 and core 2 areas that are important for maintaining gene flow across the species range and limit new surface disturbance in important existing connectivity corridors (Recovery Criteria 2 and 3) (USFWS, 2023).
- Priority 3 Actions 10. Update disturbance calculations on an annual basis for each core area (Recovery Criterion 3). 11. Develop a predictive model to evaluate the long-term trend and projected survival probability of each species under likely future scenarios, including climate change (Recovery Criteria 1, 2, 3, 4, and 5). 12. Reestablish Sclerocactus individuals on restored sites and monitor effectiveness (Recovery Criteria 1, 2, and 4). 13. Establish areas for permanent protections that provide the greatest benefit towards maintaining the redundancy, representation, and resiliency of the species (Recovery Criteria 1, 2, 3, and 5). 14. Develop and implement management plans for each protected area (Criterion 5) (USFWS, 2023).

# SPECIES ACCOUNT: *Sclerocactus wrightiae* (Wright fishhook cactus)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/11/1979; Mountain-Prairie Region (R6) (USFWS, 2016)

**Physical Description**

Wright fishhook cactus (Sclerocactus wrightiae) is named for Dorde Wright Woodruff who discovered Wright fishhook cactus (L. Benson) in Emery County in 1961 (Benson 1982). The species is endemic to south-central Utah occurring in scattered clusters in Wayne, Emery, and Sevier counties. Wright fishhook cactus is a small, perennial globose shaped cactus mainly 6 – 12 cm long and 4 - 8 cm in diameter growing as a single plant with a branched taproot (Welsh et al. 2008). If damaged, the cactus may form multiple stems. Spines, both lateral and central, emerge from warty protuberances called tubercles. The large, lower central spine is hooked, a noticeable character that gives the cactus its common name of "fishhook." The flower is 3 to 4 cm in diameter, 3 to 4 cm long, white to cream or pink and fragrant. Sepaloids are green or green tinged with red or brown. Flowering occurs from late April through May and fruits are set in June. Fruits are barrel shaped and borne on the top of the cactus. Seeds are black, 2 mm long and 3.5 mm broad (Heil and Porter 1994). A distinguishing characteristic of the Wright fishhook cactus is the presence of magenta filaments with yellow anthers. Short spine length, round spines, early flowering time, small flower size, and magenta filaments help distinguish this species from other similar cacti (Heil and Porter 1994, Benson 1982).

**Current Range**

The overall range of the species has not changed significantly since the publication of the 1985 Recovery Plan (USFWS 1985). However, survey and inventory efforts have greatly expanded our knowledge of the distribution of the species within its range. We now know of more occupied sites that form a more continuous metapopulation than previously known. The known range of Wright fishhook cactus extends across approximately 993,705 acres (ac) (402,138 hectares (ha)) of Utah's western Emery County, southeastern Sevier County, and central Wayne County (USFWS, 2022)

**Critical Habitat Designated**

Yes;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Almost completely self-incompatible and pollination is accomplished mostly by native sweat bees

**Reproduction Narrative**

Adult: Wright fishhook cactus is almost completely self-incompatible and pollination is accomplished mostly by native sweat bees (Halictidae) (Tepedino 2000). Eight species of bees from one family (halictid bees) and two genera (Dialictus and Agapostemon) are known to visit Wright fishhook cactus (Tepedino 2000). Pollination is limited by the foraging distance of the ground nesting bees, which is strongly correlated to body size (Greenleaf 2005). The distance that ground nesting bees travel from their nests is difficult to determine but it is believed that they do not travel far; the maximum travel distance reported for the two genera that pollinate Wright fishhook cactus is approximately a quarter mile (400 m) (Tepedino 2000). Cross pollination is essential for Wright fishhook cactus to produce viable seeds; self-pollination would result in production of non-viable seeds. Little is known about the species' seed banks, seed viability, germination, dispersal, dormancy and establishment in the wild. Seeds fall directly from the base of the dry fruit onto the ground and most are believed to remain near the parent plant (USFWS 1985). Possible dispersal vectors include gravity, wind and water erosion, as well as insects and rodents (USFWS 1985, Kass 1990).

**Habitat Type**

Adult: Flat areas, low ridges and slopes

**Environmental Specificity**

Adult: Moderate (NatureServe, 2015)

**Habitat Narrative**

Adult: Wright fishhook cactus occurs on semi-barren sites on flat areas, low ridges and slopes in sparsely vegetated arid desert environments. They occur in a variety of vegetation types including desert scrub, desert grasslands, and open pinyon-juniper woodland communities. Wright fishhook cacti are generally found between 1,290 and 2,300 m (4,230 and 7,545 ft) and occur on a variety of geologic formations including Curtis, Mancos Shale, Morrison, Summerville, Dakota, Carmel, Entrada, and Moenkopi. Soils where the species is found include a broad range of textures, including clays, sandy silts, fine sands, loam and loamy sand. Soils generally have an overlying layer of fine and medium sized gravels or a cryptobiotic soil surface crust (USFWS 1985, Kass 1990). The overall range of the species has not changed significantly since the publication of the 1985 Recovery Plan. However, survey and inventory efforts have greatly expanded our knowledge of the distribution of the species across its range. We now know of more occupied sites and in some cases, more continuous populations than at the time of listing. The known range of Wright fishhook cactus extends across approximately 696,099 acres (ac) (281,701 hectares (ha)) of Utah's western Emery County, southeastern Sevier County, and central Wayne County. Wright fishhook cactus occurs primarily on lands managed by the BLM's Price and Richfield Field Offices and by the NPS at CRNP. More than 300 localities of Wright fishhook cactus have been documented from BLM and CRNP lands. A cactus locality consists of one or more individual cacti. There are 22 localities on lands managed by the BLM's Price Field Office, 256 localities on lands managed by the Richfield field office, and 55 localities on CRNP lands. Ninety-five percent of the Wright fishhook cactus range occurs within 22 active grazing allotments, including BLM, CRNP, SITLA, and private lands. Grazing is not permitted on the BLM North Caineville Mesa (2,200 ac (890 ha)) and a small section of the Factory Butte SRMA (approximately 1,300 acres (526 ha)). Although grazing is not permitted at Goblin Valley State Park, portions of the park are not fenced and are therefore accessible to livestock from adjacent lands. The CRNP section of the Cathedral grazing allotment was retired in 1999; however, livestock trail through the area each fall when moving between their summer and winter ranges. Our most recent range-wide population estimate is 4,500 - 21,000 individuals (USFWS 2008). Inventory efforts within CRNP during 2011 – 2013 documented 2,551 live individuals in 55 localities (CRNP 2014b). This should be considered a conservative number as counting and mapping efforts at each locality were limited to four person-hours, and therefore not all cacti at a locality were counted. Potential habitat is widely available in the vicinity of known localities of the species throughout its range, and because the species is a relative generalist, abundance of habitat is not considered a limiting factor in the conservation or survival of the species. Much of this additional potential habitat has yet to be surveyed. During the 2014 field season CRNP staff conducted 106 belt transects to gather presence/absence data on Wright fishhook cacti and Winkler cacti within suitable habitat that has not been previously inventoried (Clark 2014). These efforts located 546 previously unmapped Wright fishhook cacti. Although additional Wright fishhook cactus localities have been found since the species was listed, we cannot determine a trend. Previous surveys are not comparable because we do not have a measure of acreage surveyed or effort spent searching. The earliest estimates of 50,000 to 100,000 (Neese 1987, Kass 1990, Kass 2001a) are most likely not accurate because subsequent surveys do not support this estimate. In recent inventories conducted from 2011 and 2012, BLM and CRNP (BLM 2012a, CRNP 2012, CRNP 2013) found 10,724 individual cacti in 157 localities with the majority on BLM land. This number is likely to increase as inventories of the remaining known localities are made.

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

130

**Population Size:**

2,348

**Population Narrative:**

Wright fishhook cactus is a long-lived species that is slow to reach reproductive maturity. Individual cacti begin flowering when around 4 to 5 years old, producing flowers generally less than 50 percent of the time (Kass 2001a, Clark and Clark 2007). The highest reproductive rates are associated with large adult plants (>3.5 in [9.0 cm] in diameter), which flower between 75 and 100 percent of the time producing a disproportionately large amount of seeds (Kass 2001a, Clark and Clark 2007). Depending on environmental conditions, Wright fishhook cactus is estimated to grow an average of 0.2 ± 0.1 in (0.5 ±0.25 cm) in diameter within one year (Clark and Clark 2007) with seedlings growing at a faster rate than adults (Kass 2001a). Because of slow growth rates, the highest reproductive individuals may be at least 18 years old. Size class distribution of a population indicates its structure and stability, and can help to show vulnerabilities in each life stage. Between 1999 and 2008, Clark (2008a) collected size class data on Wright fishhook cactus collected at 130 of 151 sites surveyed. During these surveys, 2,348 cacti in the four size classes (excluding multiple stemmed plants) were recorded as follows: 10 percent seedlings, 37 percent juveniles, 52 percent young adults, and 2 percent old adults. Although it is likely that some seedlings were missed during this inventory effort, the percentage of old adults is likely accurate (Clark 2008a). Similar population structure results were reported from three demographic monitoring sites on BLM lands over a seven year period with most of the population in the young adult size class (Kass 2001a). Monitoring initiated at Factory Butte in 2009 also showed low numbers of seedlings (5 percent), higher numbers of juveniles (21 percent) and young adults (68 percent), and low numbers of older adults >8 cm in diameter (6 percent) (Clark 2009a). Overall, the majority of Wright fishhook cactus plants occur in the juvenile to young adult size classes throughout the range of the species (Kass 2001a, Clark and Clark 2007, Clark 2008a, Clark 2009a) with the largest and smallest size classes poorly represented. Low frequency in the occurrence in the smallest size classes indicates low levels of recruitment into the population. Demographic monitoring over a seven year period at three BLM Wright fishhook cactus monitoring plots reported a mortality to recruitment ratio of 2.5:1 in all plots (Kass 2001a). Low levels of recruitment are also reported in the Factory Butte area, where overall mortality was 8.9 percent between 2009 and 2010, and 6 percent between 2010 and 2011 (BLM 2012a). The mortality to recruitment ratio for both years was reported at 6:1 and 5:1, respectively (BLM 2012a). Low recruitment patterns and the small number of large older reproductive individuals may constitute a species wide pattern (Kass 2001a). For populations to persist in their environment, recruitment into the population must exceed mortality. Populations with a low percentage of seedlings or a low percentage of the highly reproductive individuals are potentially declining populations (Elzinga et al. 1998).

***Threats and Stressors***

**Stressor:**
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Threats to the species include damage to the habitat during mineral and gas exploration and the mining of coal, gypsum, bentonite and bentonite clay, uranium, vanadium, building stone and gravel. Livestock activity, such as trampling and uprooting of plants, is a threat. Off-road vehicle use causes damage. Illegal collecting is still a problem. The cactus apparently suffers from predation by the beetle Moneilema semipunctatum and perhaps other beetles. Small mammals such as Ord's kangaroo rat (Dipodomys ordii) and white-tailed antelope squirrel (Ammospermophilus leucurus) may eat the cactus. (NatureServe, 2015)

**Stressor:** Poaching (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Illegal collection of Wright fishhook cactus is a range-wide stressor that likely continues although the current scale of this effect is unknown. Wright fishhook cactus is desired in cactus collections and the Park has documented signs of scouting and poaching for the species, and illegal advertisements online. (USFWS, 2022)

**Stressor:** Drought (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Future climate projections for the southwest include more intense and longer-lasting heat waves, fewer cold periods, an increased probability of droughts that are worsened by higher temperatures, reduced snowpack, earlier snow melt and more frost-free days (Garfin et al. 2014, Melillo et al. 2014). Projections for precipitation changes are less certain than predictions for temperature and may increase in some areas and decrease in others (Garfin et al. 2014). However, it is expected that more precipitation will be in the form of rain versus snow, which can increase flooding of dry washes, and will occur as extreme precipitation events (Frankenson et al.

2018). As a desert species, Wright fishhook cactus has adapted to tolerate periodic drought conditions; therefore historic droughts patterns alone are not expected to cause a decline in species stability or trend. The ability to go dormant during drought periods and possessing contractile roots to retract low to the ground to reduce water loss and sun scald are two adaptive strategies that Wright fishhook uses during seasonal droughts. An analysis was attempted to distinguish between livestock effects and drought effects under current and future scenarios. However, due to the synergism between drought stress, livestock trampling, and herbivory, the degree to which drought plays a role in the population trend remains unclear (Hornbeck 2020b). (USFWS, 2022)

**Stressor:** Climate Change (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change was not identified as a threat at the time of listing or in the recovery plan. Wright fishhook cactus appears to be highly vulnerable to future climate conditions based on one evaluation that predicted considerable range loss for the species after 2040 (Krause 2010). Wright fishhook cactus was also ranked as “extremely vulnerable” to climate change using a climate vulnerability index and an evaluation of current verses future suitable habitat locations (Still et al. 2015). The species predicted vulnerability to future climate conditions using predictive models and the index were based on factors that include the species’ small current range, limited dispersal ability, and lack of overlap between current and future areas of suitable habitat (Krause 2010; Still et al. 2015). (USFWS, 2022)

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 5C

***Conservation Measures and Best Management Practices:***

- Recommended future actions: Based on recent discussions with conservation partners, we recommend the following future actions: 1. Work with partners to protect as much occupied and potential habitat as possible and improve habitat conditions for plants and pollinators by providing intact or restored habitat conditions; 2. Work with partners to restrict recreational use and restore degraded habitat areas to support the species and its pollinators; 3. Work with partners to collectseeds periodically from all populations to provide a genetically representative, off-site seed collection; 4. Establish a range-wide population trend monitoring program that is consistent and comparable on CRNP and BLM lands; 5. Continue existing livestock disturbance monitoring throughout the species range; 6. Continue existing OHV recreation disturbance monitoring and enforcement at FactoryButte SRMA; 7. Work with partners to improve species census data, especially within CRNP, and utilizing novel survey techniques such as drone surveys; 8. Work with researchers to develop a fine-scale species distribution model using censusimagery to identify favorable seedling microsites for seed additions and support future population augmentation efforts on BLM; 9. Work with partners and researchersto conduct a germination study on BLM and CRNP to inform population models and understanding of recruitment and population dynamics; 10.Continue to investigate propagation methods for the species to reduce plant and population losses and preserve genetic diversity; and 11.Work with researchers to develop an annual detectability estimate for the species based on population monitoring data to calculate the percentage of the population above ground and detectible for section 7 consultation effects analyses and population estimates.

# SPECIES ACCOUNT: *Scutellaria floridana* (Florida skullcap)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; Southeast Region (R4) (USFWS, 2015) 5/8/1992

**Physical Description**

A perennial herb, up to 4 dm tall. Stems are solitary or few, mostly erect or ascending. Leaves are opposite, narrowly linear, 2-4 mm long, the margins strongly rolled. Flowers are solitary in the axils of leaves and are bright lavender-blue with a whitish throat. (Based on Kral 1983.) (NatureServe, 2015)

**Taxonomy**

The rarest of several southeastern species in this genus. (NatureServe, 2015)

**Historical Range**

See current range/distribution.

**Current Range**

Known from the Apalachicola region of the Florida panhandle from Liberty, Franklin and Gulf counties. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: Perrenial (USFWS, 2009)

**Breeding Season**

Adult: Flowering is in May and June (Kral 1983) (USFWS, 2009).

**Reproduction Narrative**

Adult: The Florida skullcap is a perennial herb with quadrangular stems and opposite leaves. The flowers are solitary, with a bell shaped calyx and bright lavender-blue corolla. The corolla has two lips, the lower one being white in the middle. The stigma sticks out from under the flower hood with the anthers residing inside. Bumblebees, megachilids and halictids are probably important pollinators. Plants flower from mid-April through early July and are most prolific after a fire UUSFWS, 2009).

**Habitat Type**

Adult: Pine-palmetto flatwoods, wet prairies (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (Inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (Inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits dark, humus rich sands of pine-palmetto flatwoods, wet prairies, and savannahs. (Based on Kral 1983) Seepage slopes. (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species.

***Dispersal/Migration***

**Motility/Mobility**

Adult: Low (inferred from NatureServe, 2015)

**Dispersal**

Adult: Low (inferred from NatureServe, 2015)

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

19 protected populations (USFWS, 2024)

**Population Size:**

>100,000 total (USFWS, 2024)

**Population Narrative:**

Reported to respond positively to fire by sprouting and blooming. They stop flowering if not burned at least once every three years. Pollinator visits were infrequent in one study that examined who and when pollinators visited Scutellaria floridana. In addition, native bees were the primary pollinator, and factors that effect bee density could affect S. floridana density. Based on recent surveys within range and habitat of the species (NatureServe, 2015). Moderate resiliency, representation and redundancy are inferred based on number of populations and individuals as well as relatively large area in which this species is known to occur. Florida Natural Areas Inventory had estimated hundreds of thousands of flowering stems for multiple occurrences (Florida Natural Areas Inventory 2017-2023, A. Johnson, 2023, pers. comm). However, because of the clonal system for this species, stem counts alone are an imperfect proxy for abundance in S. floridana populations as one individual can be composed of dozens of stems with no clearly delineated shape or arrangement across the landscape (Hanko et al. 2023); clonal diversity in 12 studied populations showed that one to 16 clones were present in a single population. Scutellaria floridana is a perennial mint endemic to four counties in the Florida panhandle (Figure 1). It grows in fire-dependent habitats such as longleaf pine wet forests and wet meadows and has a strong response to fire (Negron-Ortiz 2023). It can also occur in appropriate habitats within road/transportation and/or transmission rights-of-ways that are maintained. There were originally 40 historically documented occurrences throughout this species range (Service 2009, 2019). Since points within 1 km are all considered part of one occurrence (NatureServe 2020), the 40 historical occurrences represent 29 Element Occurrences (hereafter EOs or occurrences; Service 2009, 2019). ⍰ Currently, there are 19 extant, protected EOs. These EOs continue to be threatened by urban development, timber farming, and fire suppression (USFWS, 2024)

***Threats and Stressors***

**Stressor:** Logging (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Pulpwood production in the outer Coastal Plain in the Apalachicola Basin The timber industry in North Florida became well established in the 1850s (FNAI 2005). It started in Franklin County in the 1870s and continued to be a prominent industry until the mid-1990s (Howell and Hartsell 1995). The St. Joe Timberland Company had close to a million acres in timber in the eastern region of the panhandle and they plan to continue to harvest and replant indefinitely. The Company also owned a paper mill in Port St. Joe until it was sold and shut down in 1999. According to J. Huffman (2009, pers. comm. to Negron-Ortiz) tree farming, i.e., privately owned forest managed (clearcutting, mechanical site preparation, and pine plantations) for timber production, is a primary threat since there still is a mill in Panama City (Bay County) and there are many thousands of acres of tree farms that are smothering out S. floridana (as in around the SJBSBP). Therefore, tree farming is a threat to this species (USFWS, 2009).

**Stressor:** Real estate development (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Urban development continues to threaten Florida skullcap. The St. Joe Timberland Company still owns the former extensive timber land in Northwest Florida, and now focuses on commercial and residential development along roadways and near or within business districts in the region. Urbanized land in Florida, statewide, is projected to double by 2060 along with doubling of the population to 36 million (http://www.1000friendsofflorida.org/PUBS/2060/01-Northwest-Florida). Several S. floridana's locations are found along U.S. and state roads. Construction activity may directly kill individual plants or convert habitat to unsuitable space; widening may convert native habitat to managed roadside; and culvert modification may change drainage patterns, which may change seasonal hydrology. Therefore, development, road widening and new roads continue to pose a threat to the species from direct habitat loss to severe habitat modification. As explained under C.1.e, this plant has unique habitat characteristics. Working together with partners on road maintenance activities, we can find possible alternatives that will support or maintain S. floridana (USFWS, 2009).

**Stressor:** Fire suppression (USFWS, 2009)
**Exposure:**
**Response:**

**Consequence:** Loss of habitat
**Narrative:** Suppression of fire continues to threaten the pineland and savanna's flora since fire is essential for the maintenance of flatwoods (Abrahamson and Hartnett 1990). Fire influences community structure and composition (Abrahamson and Hartnett 1990), and with insufficient frequency in longleaf pine communities, a woody midstory quickly develops (Glitzenstein et al. 1995), negatively affecting the understory diversity. Thus, fire suppression continues to be a threat to S. floridana. Lack of fire, and subsequent growth of shrubs (particularly encroachment of Cyrilla racemiflora L., commonly known as swamp titi) and saplings in the understory, in addition to shading by planted pines, inhibits this species emergence (Negrón-Ortiz, 2008, pers. observ.; FNAI 2008). Declining fire frequency reduces S. floridana abundance in areas where it was previously observed in great quantities (FNAI 2008). In recently burned areas, however, plant emergence is prolific within one year of the fire event (L. Keppner, 2008, pers. comm.). Several studies have shown that frequent prescribed fire regimes are important for maintenance of flatwoods diversity (Hiers et al. 2007). Therefore, frequent prescribed burnings, i.e., 1-3 yr interval, are needed to maintain optimal S. floridana populations. At present, the ANF utilizes a 3-5 yr interval burn rotation, Lathrop Bayou uses a 2-7 yr interval, and SJBSBP uses a 2-5 yr interval (USFWS, 2009).

***Recovery***

**Reclassification Criteria:**
Not available

Recovery Priority Number: 2C

**Delisting Criteria:**
For delisting the species, the goal is to adequately protect and manage 15 populations distributed throughout the species' historical range for 10 years. The plan states that these goals are by necessity only preliminary, and they will be refined (USFWS, 2009).

**Recovery Actions:**
- Protect and manage these plants outside Apalachicola National Forest (USFWS, 1994).
- Protect populations in Apalachicola National Forest and on other public lands (USFWS, 1994).
- Perform systematic and other studies (USFWS, 1994).
- Garden propagation and reintroduction (USFWS, 1994).
- Manage rights-of-way (USFWS, 1994).
- Complete a comprehensive census (e.g., the total number of individuals, number of flowering vs. non-flowering plants, and whether seedling recruitment is occurring) throughout the present distribution including all the historical locations to determine the population numbers and range (USFWS, 2009).
- Determine the levels and distribution of genetic diversity. Knowledge of the levels and distribution of genetic variation in species of conservation concern can be important for the development of efficient and effective conservation practices. For example, the identification of populations with rare alleles or with elevated levels of genetic diversity may lead to greater efforts for their preservation relative to less genetically unique populations (USFWS, 2009).

- Conduct surveys/inventories on potentially new sites. This action can include the use of species distribution modeling methods to initially determine potential sites, with subsequent validation or inspection of the sites for plants (USFWS, 2009).
- Conduct population studies. a. Studies on the viability of dry-stored seeds, the timing of germination, and whether a persistent seed bank is present should be addressed. b. Establish and implement monitoring to address demography. Plants should be monitored several times during the first 12-month period to assess the best monitoring schedule (e.g. annually, biannually). Data from monitoring should be evaluated through 5-year reviews. • Establish permanent plots on protected locations throughout the species' historical range. Priority for populations should include those sites that can be managed with fire. For each plot: o Estimate the density, and abundance of individuals. If possible, investigate basic ecological questions (e.g., pollinators; flowering period; annual variability in flowering; seed production). o Monitor the effect of fire (if the areas are burned) on density, fecundity, and size structure (USFWS, 2009).
- Manage ROWs Continue fostering conservation practices for utility and highway ROWs with the Forest Service, Talquin Electric, FDOT, and USFWS; a management plan should be developed and implemented (USFWS, 2009).
- The recovery plan should be updated to define objective measurable criteria and better address the five factors (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Estimate the levels of clonality and distribution of genetic diversity. Knowledge of the levels and distribution of genetic variation in species of conservation concern can be important for the development of efficient and effective conservation practices. Sampling should involve the established monitoring plots (see page 3 Recovery action 1) • By understanding clonality, the Service will be able to determine what is an individual and evaluate abundance. Specifically, we will be able to 1) relate flowering stems (both vegetative and flowering) to number of individuals in a given area, and 2) infer the effect of fire on flowering stems/individuals. • The identification of populations with rare alleles or with elevated levels of genetic diversity may lead to greater efforts for their preservation relative to less genetically unique populations. 2. Complete a comprehensive census (e.g., the total number of individuals, number of flowering vs. non-flowering plants, and whether seedling recruitment is occurring) throughout the present distribution including all the historical locations to determine the population numbers and range. Given the cryptic nature of this plant when it is not flowering, the density of surrounding vegetation and the number of locations, surveys are best recommended a ~5 weeks post-fire, if the fire is in the growing season; or in April or May if the fire was in Dec-Mar time period (A. Jonhnson, FNAI, 7/06/2019). A consistent and repeatable method should be employed. • Censuses are most critical for populations outside ANF. Surveys that have been accomplished following fire in the ANF (in the past 10 years by FNAI, Ann Johnson, and local botanists) have been extensive and thorough (A. Jenkins, FNAI, 6/27/2019). 3. Monitoring. It is recommended to set up more subplots and monitor both flowering and nonflowering individuals over time. • Population census data [e.g., the total number of individuals (flowering and nonflowering plants), and whether seedling recruitment is occurring] will help predict extinction risks and the smallest size at which a population can exist without facing extinction by using computer simulations known as population viability analyses. Emphasis should be given to clones and individuals with unique profiles identified by genetic study. If possible, investigate basic ecological questions [e.g., pollinators; flowering period; annual variability in flowering; seed production; and the effect of fire (if the areas are burned) on density, fecundity, and size structure]. See page 3 for details of ongoing investigations in the ANF. • A repeatable method should be employed. If the target population is small (e.g., 200 m2 ), it is recommended to walk the entire area and count each individual. If the target population covers a large area, then permanent marked transects should be established in key selected areas that reflect the larger area. 4. Conduct surveys/inventories on potentially new sites. This action can include the use of species distribution modeling methods to initially determine potential sites, with subsequent validation or inspection of the sites for plants. • FNAI developed occurrence-based suitable habitat model for S. floridana in 2011, and many new locations have been discovered since that time. Recommendation: Update the current model with most recent survey data (A. Jenkins, FNAI, 6/27/2019) and validate the model. 5. Manage ROWs Continue fostering conservation practices for utility and highway ROWs with the Forest Service, Talquin Electric, FDOT, and the Service; a management plan should be developed and implemented. 6. The recovery plan should be updated to define objective measurable criteria and better address the five factors. (USFWS, 2019)

- RECOMMENDED FUTURE ACTIVITIES 1. Address continued monitoring and management. a. Continue the long-term monitoring in the Apalachicola National Forest sites and set up plots in other sites such as St. Joseph Bay State Buffer Preserve, Tate’s Hell State Forest, and Lathrop Bayou. b. As sea levels rise, saltwater intrusion increases in duration, frequency, and spatial extent. To assess the effect of salinity on S. floridana, sites where intrusion of salt water occurs should be considered for long-term monitoring. c. Develop a stand-alone plan for managing listed plants at the Apalachicola National Forest and Tate’s Hell State Forest and integrate it to their Management Plans. 2. Conduct surveys/inventories on targeted sites. Based on Hanko et al. (2023), the genetic study showed that stem counts alone may not accurately reflect abundance in populations with low clonal richness; one individual can be composed of dozens of stems. It appears that on average, ten adjacent stems generally represent 1–2 unique individuals, suggesting that stem counts are usually equivalent to ten times the true population size. a. Gulf County. Thorough surveying of populations located on private lands (North Gulf Co., Fig. 1, sites with yellow and black symbols) is recommended to determine whether S. floridana and corresponding habitat are still present. This action is a priority for this species. b. In-depth investigation of clonal reproduction and management history of the four populations on public lands (Box-R Wildlife Management Area 1, Apalachicola National Forest 5, Tate’s Hell State Forest 1, and St. Joseph Bay State Buffer Preserve 1; Fig. 1) that possess very low genetic diversity and evidence of inbreeding. 3. Conduct surveys/inventories on potentially new sites (targeting recently burned sites). This action can include the use of species distribution modeling methods to initially determine potential sites, with subsequent validation or inspection of the sites for plants. 4. Manage Right-of-ways (ROWs) Continue fostering conservation practices for utility and highway ROWs with the Forest Service, Florida Department of Transportation, and the Service; a management plan should be developed and implemented. 5. Establish (or continue) frequent growing-season fire regimes (i.e., 3- to 5-year interval) on selected areas such as the Apalachicola National Forest, St. Joseph Bay State Buffer Preserve, Tate’s Hell State Forest, and Lathrop Bayou to maintain optimal conditions of populations. Re-visit sites shortly after a burn event, and mark and count individual ramets. Populations tend to be more evident after a fire event (Negron-Ortiz 2023) (USFWS, 2024).

# SPECIES ACCOUNT: *Senecio layneae* (Layne's butterweed (=Packera))

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 11/18/1996; Pacific Southwest (R8)

**Physical Description**

A perennial herb of the aster family (Asteraceae) that sprouts from a rootstock. Its mostly basal lance-shaped leaves are 8 to 24 centimeters (3 to 10 inches) long. The several flower heads are 4 to 6 centimeters (2 to 3 inches) wide. Each flower head has 5 to 8 orange-yellow ray flowers (the flowers usually located on the edge of the inflorescence of members of the aster family) and numerous yellow disk flowers (flowers in the center portion of an inflorescence of a member of the aster family). Senecio aronicoides (rayless groundsel), S. flaccidus var. douglasii (Douglas' groundsel), and S. vulgaris (common groundsel) also occur on gabbro-derived soils in the Pine Hill area (Wilson 1986). These Senecio species can variously be differentiated from S. layneae by a combination of life form, type of flower, number of flower heads, flower color, and pubescence. (USFWS, 2002)

**Taxonomy**

Kate Layne-Curran collected the type specimen for Senecio layneae in May 1883 from El Dorado County, California, on Sweetwater Creek, not far from Folsom. Edward L. Greene first described S. layneae in 1883 (Greene 1883). Although Asa Gray (1884) reduced S. layneae to a variety of S. fastigiatus, it currently is known as S. layneae (Barkley 1993). Senecio layneae is a member of the aureoid group of Senecio that is united by most of the following characters: perennial herbs arising from creeping rootstocks or a stout caudex; well developed basal leaves with cauline (arising from the upper part of the stem) leaves progressively reduced upward; leaf margins without callose denticles (hard teeth); thin branching fibrous roots; and haploid chromosome numbers 22 or 23, or derived from these numbers (Barkley 1988). The aureoid group of Senecio is now known by some as the genus Packera. The type population of S. layneae is now thought to be extirpated due to inundation by Folsom Lake. (USFWS, 2002) In the second edition of the Jepson Manual, the genus to which Layne's butterweed belongs was changed from Senecio to Packera (Baldwin et al. 2012). (USFWS, 2019)

**Historical Range**

In western El Dorado County that includes the Pine Hill formation and adjacent serpentine; a few other colonies occur in the Eldorado National Forest in El Dorado County, California. (USFWS, 2002)

**Current Range**

On the Pine Hill formation in western El Dorado County, California; a few known isolated occurrences in El Dorado, Nevada and/or Tuolumne Counties. (USFWS, 2019)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollinated (USFWS, 2002)

**Breeding Season**

Adult: Senecio layneae is a perennial herb that flowers from April to July (USFWS, 2019).

**Other Reproductive Information**

Adult: It is unclear whether the species has the ability to resprout from its caudex after disturbance (Marsh and Ayres 2002). Although the seed of this species seems to germinate in a wide range of soil conditions and adult plants grow in a wide range of slope, aspect, light and elevation levels (Williams 2014), it appears to have little or no persistent seedbank, a short seed dispersal distance (Williams 2014), and is also shade intolerant (Baad and Hanna 1987). It is likely the species functions as a fugitive species, depending on a short fire return interval to create a regeneration niche and a supply of the short-lived seed from a nearby reproducing population to colonize the patch (Marsh and Ayres 2002). Little else is known about reproductive biology, ecology, and demography of the species. (USFWS, 2019)

**Reproduction Narrative**

Adult: Senecio layneae is a perennial herb that flowers from April to July (California Native Plant Society 1994). Twenty-two plants from Cameron Park were used to determine whether the predominant breeding system was self-fertilizing or outcrossing (mating not involving inbreeding). Pollinators were excluded from the flower heads with fine mesh fabric. Open pollinated flower heads had an 8-fold increase in potentially viable seeds over flower heads where the pollinators had been excluded, indicating that the predominant breeding system for Senecio layneae is outcrossing (Marsh 2000) (USFWS, 2002).

**Habitat Type**

Adult: Chapparral (NatureServe, 2015)

**Environmental Specificity**

Adult: Moderate (inferred from USFWS, 2019)

**Habitat Narrative**

Adult: In addition to occurring on gabbro soils, Layne’s butterweed is also known to occur on serpentine soils.All serpentine sites, with the possible exception of the one in Shingle Springs, continue to support Layne’s butterweed. Persistence in at least two separate habitat/soil types benefits these species by increasing their degree of representation. (USFWS, 2019)

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Stable to increasing (USFWS, 2019)

**Number of Populations:**

45 populations;  6 extant; 36 presumed extant; 3 possibly extirpated (USFWS, 2019)

**Population Size:**

Greater than 9,100 individuals (USFWS, 2019)

**Additional Population-level Information:**

The 1996 listing rule did not present information on the abundance of the gabbro plant species (Service 1996, p. entire). As summarized in the 2019 review, annual surveys were carried out for all five species at the Pine Hill Preserve from 2007–2009 (Service 2019, p. 9). The 2009 surveys at the Pine Hill Preserve estimated over 9,820 Stebbins' morning glory, 55,350 Pine Hill ceanothus, 104 Pine Hill flannelbush, 21,000 El Dorado bedstraw, and 9,100 Layne's butterweed (BLM 2010 as cited in Service 2019, p. 9). Current abundance estimates were not available for other populations of the gabbro plant species due to infrequent surveying especially on private lands (Service 2019, p. 9). Since the 2019 review, periodic surveys continue to be completed by BLM and species experts (Klip et al. 2020; Ayres et al. 2020). The Diversity Database shows that additional survey data from 2017–2018 has become available for a limited number of occurrences: three occurrences of Pine Hill ceanothus, seven occurrences of El Dorado bedstraw, and one occurrence of Layne's butterweed (Diversity Database 2023). Appendix A presents the number of plants observed during the most recent survey of each occurrence of the gabbro plant species as recorded in the Diversity Database. New abundance estimates for Pine Hill Preserve are only available for Pine Hill flannelbush which was estimated to be between 300–400 individuals on the Pine Hill Unit, based on surveys done in 2019 (Ayres et al. 2023b). This abundance estimate is three to four times greater than the 2009 estimate. This increase in the estimated abundance of Pine Hill flannelbush is likely due to increased survey effort at Pine Hill preserve including survey effort in areas along the permitter of the Pine Hill Preserve and other areas that had not been surveyed previously (Klip et al. 2020, p. 65; Ayers in litt. 2023b). While new population estimates for the other gabbro species on the Pine Hill Preserve are not available, botanical surveys were conducted around the perimeter of Pine Hill from 2017–2019 in areas that had not been previously surveyed (Klip et al. 2020, p. 59). These surveys recorded 10 new patches of Pine Hill ceanothus, 6 new individuals of Pine Hill flannelbush, 16 new patches of El Dorado bedstraw, and 15 new patches of Layne's butterweed on Pine Hill (Klip et al. 2020, p. 65). Additional Pine Hill flannelbush individuals were found during rare plant surveys in 2019 on Pine Hill itself; on the peak and the sunny, southern slopes of Pine Hill and areas along Pinehill Road (Ayers in litt. 2023b). The overall paucity of survey data for the five gabbro plant species limits our ability to assess population trends (USFWS, 2024).

**Population Narrative:**

In general, a direct comparison of species abundance now versus at the time of listing is not possible due mainly to lack of abundance data at the time of listing. Contributing to that challenge is that there is not consistent current abundance data for many of the populations, especially those on private lands. However, given the increase in the number of populations of Layne's butterweed since listing, it is likely that overall abundance has increased for those species (CNDDB 2018). (USFWS, 2019). At the time of listing Stebbins' morning-glory, Pine Hill ceanothus, Pine Hill flannelbush, El Dorado bedstraw, and Layne's butterweed occurred primarily on the Pine Hill formation, an area of approximately 10,400 hectares (25,700 acres) in western El Dorado County, California, ranging in elevation from 138 to 628 meters (453 to 2,060 feet) (Service 1996, p. 54346). In addition, Stebbins' morning-glory and Layne's butterweed had "a few known isolated occurrences in El Dorado, Nevada and/or Tuolumne counties" (Service 1996, p. 54346). Between the listing of the species and the 2019 review, additional occurrences were discovered or introduced outside of Pine Hill Preserve (Service 2019, p. 6). Most notably, a few occurrences of Stebbins' morning glory were identified in Nevada County near Grass Valley, two occurrences of Layne's butterweed were found in Yuba and Placer counties, and two additional occurrences of Layne's butterweed were identified in Tuolumne County (Service 2019, p. 6). The 2019 review also noted that occurrences of Pine Hill flannelbush (Diversity Database occurrences 8, 9, 13, 14, 15) had been recorded in Nevada and Yuba counties but that the species identification had not yet been verified (Service 2019, p. 6). Recent morphological studies suggest that the flannelbush plants in Nevada and Yuba counties are unique from Pine Hill flannelbush (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Habitat loss and fragmentation (USFWS, 2002)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Historically, gold rush activities and clearing for agriculture reduced and fragmented habitat in western El Dorado County. More recently, vegetation on the Pine Hill formation has changed significantly due to commercial and residential development, road construction, and fragmentation. Commercial or residential developments have partially or completely destroyed occurrences of the species (California Natural Diversity Data Base 1998; California Department of Fish and Game 1990a, 1990b; G. Clark in litt. 1993). Proposed residential or commercial development within the Pine Hill formation threatens most of the remaining sites within the Pine Hill formation and adjacent serpentine in western El Dorado County, and either directly or indirectly will adversely affect most of the range of this species. Additionally, habitat fragments may be too small to support viable populations of animals serving as pollinators or seed dispersal agents for the species. Edge effects, which occur at the interfaces of any two or more habitat types, typically increase with habitat fragmentation and are more pronounced for natural communities bordered by human disturbances (USFWS, 2002).

**Stressor:** Altered fire regime (USFWS, 2002)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The primary overall threat is encroachment of native vegetation due to succession, even on lands in conservation ownership, in the absence of the natural fire regime. The long fire return interval due to fire suppression is preventing the formation of necessary clearings for Layne's butterweed establishment and possibly the scarification of seeds needed for germination. (USFWS, 2019a)

**Stressor:** Land use activities USFWS, 2002)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The increasing number of people and changes in land uses will continue to place an increasing strain on undeveloped areas through activities such as off-road vehicle traffic, unauthorized garbage dumping, and changes in the pattern of wildfires. Horse paddocking in rural residential areas within the central and northern portions of the Pine Hill formation

threatens this species. The horses, when confined, severely graze or trample most available vegetation. The herbaceous gabbro plants are especially likely to be grazed (J. Van Ess pers. comm. 1993). (USFWS, 2002)

**Stressor:** Invasive nonnative plants (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasive plants continue to present a minor threat to gabbro plant species. Populations within the Pine Hill Preserve are not significantly threatened by invasive plants and any small infestations identified are largely reduced or eliminated by mechanical means (BLM 2008). However, a population of Layne's butterweed at BLM's Red Hills Kanaka Point property in Tuolumne County is threatened by yellow starthistle (Centaurea solstitialis) and distaff thistle (Carthamus lanatus) (B. Brenneman, in litt. 2018b). (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**
Not applicable.

Recovery Priority Number: 5C

**Delisting Criteria:**
1. Secure and protect specified recovery areas from incompatible uses: Populations representing the range of the species including: (a) Cameron Park preserve south of Highway 50, (b)Cameron Park preserve north of Highway 50, (c) Pine Hill preserve, (d) Penny Lane preserve, (e) Salmon Falls/Martel Creek preserve, (f) occupied habitat on BLM lands in Yuba and Tuolumne Counties, and (g) occupied habitat on the Eldorado National Forest; along with adjacent unoccupied habitat and a 150-meter (500-foot) buffer. (USFWS, 2002)

2. Management plan approved and implemented for recovery areas, including survival and recovery of the species as the objective: For all populations and any occupied or unoccupied habitat identified as necessary for survival and recovery (see previous column) (USFWS, 2002).

3. Monitoring in all recommended preserves shows: (a) Stable or increasing with evidence of natural recruitment for a period of 60 years that includes normal disturbance. (b) Habitat monitoring of recommended preserves shows a mosaic of multiage class stands and habitat fragmentation has not appreciably increased (less than 5 percent) within any preserves over current (2000) conditions. (c) Spatially and temporally, the establishment of occurrences must be at least 10 percent greater than the extirpation of occurrences. (USFWS, 2002)

4. Other actions: (a) Ameliorate or eliminate threats (see Appendix H); (aa) Study importance of fire for management; (b) seeds of disjunct populations stored in at least two Center for Plant Conservation certified facilities. (c) Maintain metapopulation dynamics of at least 1 very large, 1 large, 7 medium, and 24 small occurrences throughout the Pine Hill formation; of at least 1 large, 2 medium and 5 small in western El Dorado County; of at least 2 medium and 4 small in Tuolumne County; and of at least 2 small in Yuba County. (USFWS, 2002)

**Recovery Actions:**

- 1. Develop and implement a cooperative program and participation plan. A cooperative program is needed to coordinate local public and private land use planning with State and Federal land use and recovery planning for gabbro species. A cooperative program needs to be developed focusing on western El Dorado County. A participation plan produced from this program will increase the chances of recovery for listed species. (USFWS, 2002)
- 2. Protect and secure existing populations. Natural lands that contain this species need to be protected in perpetuity. Protection of these lands includes identification and minimization of threats in perpetuity and application of appropriate and adaptive management (see Task 3) to ensure species survival and recovery. Natural lands that need protection can be categorized into two types: (1) blocks of land that contain occupied or potential habitat for two or more this species and (2) blocks of land that contain occupied or potential habitat for one this species. All potential preserve areas should be evaluated based on current mapping information and ground-truthed prior to purchase to confirm their value for recovery. (USFWS, 2002)
- 3. Manage Habitat Managing habitat is essential to the recovery of the listed species. Habitat management includes preparation and implementation of management plans for all areas inhabited by special status species being proposed for preservation, and periodic monitoring of populations in each of these areas. Within western El Dorado County, a multi-constituent committee should be formed to oversee the management of preserves located on the Pine Hill formation. The preserve management committee should include, at a minimum, representatives from the California Department of Fish and Game, U.S. Fish and Wildlife Service, Bureau of Land Management, El Dorado County, California Department of Forestry and Fire Protection, California Native Plant Society, American River Conservancy, and a private landowner representative. (USFWS, 2002)
- 4. Survey historical locations and other potential habitat where this species may occur. Recovery of listed species may often require relocating historic populations or locating new populations of these species. Historical locations should be surveyed to determine whether suitable habitat remains, the species persists at the sites, and/or the sites may be suitable for repatriation. Suitability of historical locations for repatriation would depend upon: (1) whether potential habitat exists, (2) the presence and magnitude of threats, and (3) whether the sites can be secured and managed for the long-term protection of the species. Surveys should also include other potential gabbro or serpentine habitat to determine whether undiscovered populations may exist. If new populations are discovered, they need to be protected and managed as discussed above. During the surveys, potential introduction sites should also be identified. (USFWS, 2002)
- 5. Conduct necessary biological research and use results to guide recovery/conservation efforts. - Develop propagation techniques for listed plant species for which enhancement, repatriation, or introductions would be appropriate. Geographic area research is outlined in the Recovery Plan. Species-specific research is described as follows: Habitat Survey Research: Serpentine soil areas off the Pine Hill formation in El Dorado County; Serpentine and Gabbro areas in Nevada County; Serpentine near Red Hills in Tuolumne . Reproduction and Demography Research: Including determining limiting life stages, seed production and survival in soil to determine appropriate fire return period, reproductive studies identifying pollinators, seed germination studies. . Genetics research. . Other Research Needs: Influence of disturbance and fire on seedling establishment; effects of grazing; metapopulation analysis; effects of fire; fire management techniques; determine efficacy of other types of disturbance regimes for species and habitat management; feasibility of

habitat restoration/ enhancement. . Management Actions Needed: Disturbance/ burning; general surveys; baseline monitoring; monitoring for trends of populations, success of management actions and threats at all populations identified for protection; monitoring for habitat fragmentation, major shifts in vegetation type, and tracking of occurrence establishment, and extirpation; seed banking for disjunct populations. (USFWS, 2002)

- 6. Undertake artificial enhancement, repatriation, or introduction efforts where necessary. Where it is deemed necessary, artificial enhancement, repatriation, or introduction efforts for sensitive plants should be undertaken. Prior to repatriation or introduction of sensitive plants, genetics studies are needed (see Task 5) to ensure that new populations will not disrupt unique local gene complexes. Plant repatriation or introduction efforts should be undertaken using collected seeds or plant propagules. (USFWS, 2002)
- 7. Determine possible prescribed burning management strategies and incorporate the strategies into the management plans (Priority 1). Possible prescribed burning management strategies need to be evaluated, peer reviewed, and incorporated into management plans. (USFWS, 2002)
- 8. Perform metapopulation-type analyses for this species (Priority 2). The results of a metapopulation-type analysis may be useful in clarifying uncertainties, data needs, and research, management priorities, and delisting criteria. Metapopulation-type analyses should be based on the results of monitoring and research. (USFWS, 2002)
- Dedicate more resources toward the investigation of best management approaches for the Pine Hill listed plant species, even at the cost of a temporary hiatus in land acquisition efforts. Investigation should be made into fire-related and non-fire related methods of disturbance to maintain listed plant species habitat. (USFWS, 2019)
- Once the best management strategy (in terms of technique, frequency, timing, and intensity) is determined at each site, implement these management practices to achieve and maintain a habitat mosaic that enables the attainment of recovery criteria for the species.

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of the gabbro plant species. Some of these recommendations have already been discussed in the recovery plan (Service 2002, pp. IV-1–IV22) and remain valid. All gabbro plant species 1. Further investigate the response of all five species to fire. Studies should focus on mortality, resprouting, and seedling recruitment following fire. 2. Dedicate more resources toward the investigation of best habitat management approaches for the gabbro plant species at the Pine Hill Preserve. Investigate fire-related and non-fire related methods of disturbance to maintain habitat for each of the gabbro plant species. a. Once the best management strategy (in terms of technique, frequency, timing, and intensity) is determined for each site, implement these management practices to achieve and maintain a habitat mosaic that enables the attainment of recovery criteria for each species. (USFWS, 2024)

# SPECIES ACCOUNT: *Sidalcea keckii* (Keck's Checker-mallow)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A slender, bristly-hairy, annual herb, 1.5-3.5 dm tall. A few deep pink flowers bloom April-May. (NatureServe, 2015)

**Taxonomy**

A distinct species in a genus of about 22 species of western North America. (NatureServe, 2015)

**Historical Range**

At the time of listing, the Mine Hill Sidalcea keckii population existed within a 0.73 acre area. The population occurred on a privately owned 700-acre parcel of land that was used for livestock 5 grazing. The occurrence of S. keckii at Mine Hill in Tulare County may have been extirpated when orange groves were planted on the property. (USFWS, 2012)

**Current Range**

Tulare and Fresno counties (NatureServe, 2015)

**Critical Habitat Designated**

Yes; 3/18/2003.

**Legal Description**

On March 18, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Sidalcea keckii (Keck's Checker-mallow) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes three critical habitat units (CHUs), in California (68 FR 12863-12880).

**Critical Habitat Designation**

The critical habitat designation for Sidalcea keckii includes three CHUs in Fresno and Tulare counties, California. This species critical habitat encompasses approximately 1,085 acres (ac) (438 hectares (ha)) (68 FR 12863-12880).

Unit 1: Piedra: Unit 1 is on the western slopes of Tivy Mountain in the Piedra area of southern Fresno County. It contains 206 ha (510 ac), of which 203 ha (503 ac) are privately owned and 3 ha (7 ac) are managed by the BOR (R. Faubion, pers. comm., 2002). Of the privately owned land, 77 ha (189 ac) of proposed critical habitat is on the Tivy Mountain Reserve which is owned by SFC and established for the conservation of Sidalcea keckii and other rare plants. SFC uses managed grazing as a tool to reduce competing non-native grasses from S. keckii sites, and monitors the plant as well (SFC 2001). Another 6.5 ha (16 ac) of this unit occurs on a conservation easement held by SFC on privately owned land adjacent to the reserve. Recent surveys of the areas containing documented populations of Sidalcea keckii were conducted in 1998, 2000, and 2001. In 1998, surveys coordinated by the BOR found 500 to 1,000 plants in the area (Cypher 1998). Surveys conducted in 2000 and 2001 by the SFC found eight separate patches of S. keckii growing on both Fancher and Cibo soils (C. Peck, in litt., 2002). This unit is essential to the conservation of the species because it is one of the two sites at which the species has been observed since the 1930s. When the number of populations or geographic distribution of a species are severely limited, as is the case when plants have only been observed recently at two locations, possible extinction or extirpation due to random events become a concern. Examples of random events that are a concern include fire and disease (Shaffer 1981, 1987; Primack 1993, Meffe and Carroll 1994). This unit is also essential because it includes the most northerly location known for S. keckii, and is the only location where above-ground plants with maroon-centered flowers have been documented (Cypher 1998).

Unit 2: Mine Hill: Unit 2 is about 3 km (2 mi) south of Success Dam and 5 km (3 mi) east of Porterville in Tulare County and contains 86 ha (213 ac), all of which are on privately owned land. Unit 2 encompasses a single known patch of Sidalcea keckii, which contained approximately 60 plants when last surveyed in 1992. At the request of the landowner, it has not been surveyed since that time. However, based on information from public comment, the standing population at Mine Hill may have been extirpated by conversion of the habitat to an orange grove. We currently do not know how much habitat may have been converted, although we believe that much of the habitat around the original population remains potentially viable and may contain a seed bank or standing plants. The Coarsegold rock outcrop soils of the area are best suited to rangeland (SCS 1982), which is the current use of the area where not converted to orchard. However the site is also zoned for mobile home development (R. Brady, Tulare County Planning Department, pers. comm., 1997). This unit is essential to the conservation of the species because it is presumably one of the two known locations where Sidalcea keckii plants have been observed since the 1930s. As is the case with Unit 1, when the number of populations or geographic distribution of a species are severely limited, possible extinction or extirpation due to random events become a concern. Examples of random events that are a concern include fire and disease (Shaffer 1981, 1987; Primack 1993, Meffe and Carroll 1994).

Unit 3: White River: Unit 3 is located near the town of White River in southern Tulare County. It contains 146 ha (362 ac), all of which is private land. Unit 3 contains the ‘‘type’’ location, specimens from which were used to first describe the species in 1940 (Wiggins 1940). This site is the only one not closely associated with serpentine rock, but contains the primary constituent elements that would support the species. This may be due to the presence of currently unknown and unmapped serpentine areas, or it may be due to an increased ability to compete on non-serpentine Cibo soils. As noted above, the White River site is one of the extremely few locations where Sidalcea keckii has ever been observed and may be occupied by a seed bank. Sidalcea keckii plants may still occur here, but none have been documented recently. Even if the species is not rediscovered at the White River site, we believe the site is essential to the conservation of the species. Because S. keckii has been observed at the site, it is the most appropriate site at which a reestablishment effort might be attempted. The combination of small range, few populations, and restricted habitat makes S. keckii susceptible to extinction or extirpation from a significant portion of its range due to random events, such as fire, disease, or other occurrences (Shaffer 1981, 1987; Primack 1993, Meffe and Carroll 1994). Such events are a concern when the number of populations or geographic distribution of a species are severely limited, as is the case with S. keckii. Establishment of a third location for S. keckii is likely to be an important component in reducing the risk of extinction due to such catastrophic events. This location also represents the southernmost extent of the known historical range of the species.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Sidalcea keckii critical habitat consists of two components (68 FR 12863-12880):

(i) Minimally shaded annual grasslands in the foothills of the Sierra Nevada Mountains containing open patches in which competing vegetation is relatively sparse; and

(ii) Serpentine soils or other soils that tend to restrict competing vegetation.

***Life History***

**Food/Nutrient Resources**

**Habitat Type**

Adult: Gressy slopes (Natureserve, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Serpentine soils (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from NatureServe, 2015)

**Environmental Specificity**

Adult: High (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Found on grassy slopes from 120 to 425 m elevation. The extant population is in a sparsely vegetation annual grassland on red or white-colored clay soils with 2-40 percent slopes. The clay substrates are thought to be derived from serpentine. (NatureServe, 2015)

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Decreasing (NatureServe, 2015)

**Population Growth Rate:**

Loss of populations because of development. Decline of 50-70% (NatureServe, 2015)

**Number of Populations:**

1 - 5 (NatureServe, 2015)

**Population Size:**

1 - 1000 individuals (NatureServe, 2015)

**Population Narrative:**

Loss of populations because of development. Decline of 50-70% Known historically from 3 populations in Tulare and Fresno counties, California, but the species has potentially been extirpated from each location. A new location discovered in 1998 had approximately. 900 individuals. Historical occurrence at White River near Glenville, Tulare County, California. (NatureServe, 2015). Low resiliency, representation and redundancy are based on the low number of known populations and restricted habitat requirements.

***Threats and Stressors***

**Stressor:** Agricultural conversion (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Agricultural development is listed as a threat to this species (USFWS, 2012).

**Stressor:** Potential development (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Critical Habitat Unit KECK-1 includes 205 acres of land protected by the Sierra Foothill Conservancy, federally managed lands, and some private land. There is a single unprotected parcel within the Piedra population that could potentially be developed (Stebbins 2004). However, there are no imminent plans for development at this time. The Service is not aware of any activities that would have caused destruction or modification habitat within Critical Habitat Unit KECK-1 since the last 5-Year Review in 2007 (USFWS, 2012).

**Stressor:** Grazing (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** At the time of listing, cattle (Bos taurus) grazing was discussed as a potential threat to the species; there has been no known change since the final listing. Cattle grazing may limit encroachment of non-native grasses (C. Peck, in litt., 2002; Weiss 1999). However, cattle have been observed to cause damage to S. keckii by eating or trampling it, although the damage was barely noticeable a week later (Cypher 1998). Increased grazing during months of flowering, seed-set, or seed maturation could potentially reduce local population viability and negatively affect long-term conservation of this species. Summary of Factor C: Diseases do not appear to be a threat at this time. Overgrazing by cattle may threaten the long-term conservation of this species (USFWS, 2012).

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Summary of Factor D: In summary, the Endangered Species Act is the primary Federal law that has provided protection for this species since the dates of its listing as endangered in

2000. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent their status under the Act. Therefore, we continue to believe other laws and regulations have limited ability to protect the species in absence of the Endangered Species Act (USFWS, 2012).

**Stressor:** Small population size (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Threat of extinction/lack of genetic variability
**Narrative:** Small population size increases the susceptibility of a population to extirpation from random demographic, environmental, and/or genetic events, affecting survival and reproduction of individuals (Shaffer 1981, 1987; Lande 1988; Groom et al. 2006). Small populations of annual species, such as Sidalcea keckii, may be more vulnerable to random environmental events such as extreme weather, disease, fire, or insect infestations (Shaffer 1981, 1987; Menges 1991; Groom et al 2006). For example, if a fire should occur before plants bloom or during the blooming season, the fire could destroy the individual plants as well as deplete the seed bank. The threat from random natural events has increased since S. keckii was listed because the plant now is found only at one location (USFWS, 2012).

**Stressor:** Altered fire regime (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** he absence of Sidalcea keckii from dense grasslands, even those on serpentine clay soils, suggests that it is a poor competitor (Stebbins 1992; J. Stebbins, pers. comm. 2001). Thus, aggressive, nonnative grasses such as Bromus madritensis ssp. rubens, and Bromus hordeaceus could potentially outcompete S. keckii if conditions changed to favor these grasses. For example, soil disturbances, increased availability of soil nutrients (e.g., nitrogen deposition) from cattle feces and other sources, and absence of fire may provide ideal conditions that would allow these nonnative grasses to outcompete S. keckii. Non-native grasses may generate increased fuel sources that could increase intensity of fires above the normal range of variability in serpentine grasslands that support S. keckii (E. Cypher, California Department of Fish and Game, pers. comm. 2006). However, an appropriate fire regime may reduce the presence of nonnative grasses and benefit serpentine endemic species such as S. keckii (Harrison et al. 2003) (USFWS, 2012).

**Stressor:** Climate change (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). However, predictions of climatic conditions for smaller sub-regions such as California remain uncertain. It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects. While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to

make accurate predictions regarding its effects to particular species at this time (USFWS, 2012).

***Recovery***

**Recovery Actions:**

- There is no approved final or draft recovery plan for the species (USFWS, 2012).
- Continue to protect property with suitable habitat for Sidalcea keckii. Acquisition of additional habitat through fee title or conservation easements is needed for the recovery of the species (USFWS, 2012).
- Survey additional serpentine and gabbro soil areas in Tulare and Fresno Counties to discover additional populations of Sidalcea keckii (USFWS, 2012).
- If additional populations of Sidalcea keckii are not discovered through systematic surveys, the species should be reintroduced into protected land within critical habitat units (USFWS, 2012).
- Continue monitoring the status and trend of Sidalcea keckii to determine whether this species is stable, increasing, or declining (USFWS, 2012).
- Continue genetic studies to confirm the species identity of plants preliminarily identified as Sidalcea keckii so that we can more accurately determine the actual number of populations, the geographic range, and types of habitats that support this species (USFWS, 2012).

***Conservation Measures and Best Management Practices:***

- The following recommendations for future actions are from the 2012 5-year review, scientific literature, and as a result of discussions with species experts. 1. Protect existing habitat in the San Joaquin Valley for Keck's checkermallow. 2. Conduct genetic evaluations to determine taxonomic status of Keck's checkermallow outside of the San Joaquin Valley. 3. Survey both extant and extirpated occurrences that have not been visited in the past few years to determine the status of these occurrences. Conduct yearly surveys at extant locations utilizing a standardized methodology to determine trends in the range-wide status as well as population/occurrence abundance. (USFWS, 2020)

# SPECIES ACCOUNT: *Sidalcea oregana ssp. valida* (Kenwood Marsh checker-mallow)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 11/21/1997; Pacific Southwest (R8)

**Physical Description**

A perennial herb in the mallow family (Malvaceae). The plants are 1 to 2 m (3 to 6 ft) tall. The leaves are rounded. Lower leaves have 5 to 7 shallow lobes; upper leaves are generally smaller and divided into 3 to 5 entire, lanceolate segments. The compound inflorescence consists of densely flowered, spike-like racemes 2 to 5 cm (0.8 to 2.0 in) long. Petals are 1.0 to 1.5 cm (0.4 to 0.6 in) long, notched at the apex, and deep pink-mauve. The flowers appear from late June to September. Sidalcea oregana ssp. valida differs from S. oregana ssp. eximia in having a hairless calyx. (USFWS, 1997)

**Taxonomy**

Edward L. Greene (1897) first described Sidalcea oregana ssp. valida in June, 1894, based on material he collected from Knight's Valley, Sonoma County, California. Since then, this taxon has been known as S. maxima (Baker), S. oregana var. spicata (Jepson), S. eximia (Baker) and S. spicata ssp. valida (Wiggins) (CNPS 1988b). C. L. Hitchcock (1957) studied the genus Sidalcea and recognized four subspecies, including S. oregana ssp. valida, a treatment accepted by Steven Hill (1993). (USFWS, 1997)

**Historical Range**

See current range/distribution.

**Current Range**

Freshwater marshes approximately 150 m (490 ft) in elevation, at Kenwood Marsh and Knight's Valley, Sonoma County, California.  (USFWS, 1997)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Flowers appear from late June to September (USFWS, 2009).

**Reproduction Narrative**

Adult: Flowers appear from late June to September (USFWS, 2009).

**Habitat Type**

Adult: Marsh (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits the edges of freshwater marsh. (NatureServe, 2015). High ecological integrity of the communit and site fidelity as well as low tolerance ranges are inferred based on the specific habitat needs of this species and the low number of known populations.

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2019)

**Number of Populations:**

2 (USFWS, 2019)

**Population Size:**

Varies from 24 to 500 per population (USFWS, 2019). 157 total in 2023 (USFWS, 2024)

**Additional Population-level Information:**

At the time of listing, two occurrences of Kenwood Marsh checker-mallow were known to exist with 130 plants between them. In 2018, biologists observed a small population (less than 100 individuals) at Deerfield Ranch Winery but no abundance survey was done (K. Symonds, pers. comm. 2018). Based on new observations from scientists and volunteers the threats to Kenwood Marsh Checker-mallow have marginally increased since the last status review. However, there has been no change to our understanding of threats to the species, or its distribution. (USFWS, 2019). 157 total in 2023 (USFWS, 2024)

**Population Narrative:**

There are two locations with extana populations: Kenwood Marsh and Deerfield Ranch Winery. During the previous status review (2009) there were two main sites within Kenwood Marsh where the Kenwood Marsh checker-mallow remained extant: at Deerfield Ranch Winery and on an adjacent property. Today, the only confirmed, extant population exists at the Deerfield Ranch Winery. Botanists have not surveyed the additional population at Kenwood Marsh for nearly 20 years (Service 2009) and the status of the plant remains unknown at this location. Likewise, no botanical surveys have been done at Knight’s Valley in 30 years. In 2009, only three colonies existed at the Deerfield Ranch Winery (USFWS; A. Rex, in litt. 2017). Kenwood Marsh checker-mallow abundance at this location has continued to decline in recent years (A. Rex, in litt. 2017; Appendix A). Over the past 25 years, the abundance at the winery has fluctuated from as many as 550 individuals, to as few as 24 (Appendix B; CNDDB 2018; USFWS 2009). (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Grazing (USFWS, 1998)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat/loss of individuals
**Narrative:** This species is adversely affected at both of its locations by reduced seed set resulting from cattle grazing (CNPS 1988b). Populations of Lilium pardalinum ssp. pitkinense have been enclosed with various types of wire fencing in an attempt to prevent grazing or browsing by cattle, horses, and deer, but most of the fences have failed to prevent grazing completely. The plants continue to suffer from herbivory by cattle, deer, and perhaps gophers and other herbivores, resulting in loss of flowers and seeds (L. Lozier, in litt. 1990). (USFWS, 1997)

**Stressor:** Water diversion (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Both permitted and unathorized water diversions are listed as a threat to this species (USFWS, 2009).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Regulatory mechanisms are deemed as inadequate to protect this species. Including those that require a 10-day advance notice to officials before private landowners change the land use in areas populated with this species. (USFWS, 2009).

**Stressor:** Small population size (USFWS, 1997)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The small population size of this plant species increases the susceptibility to extirpation from random events. Population sizes of 100 or fewer are known for one or more populations of Sidalcea oregana ssp. valida. This species may also be subject to increased genetic drift and inbreeding as a consequence of their small population sizes (Menges 1991, Ellstrand and Elam 1993). Increased homozygosity resulting from genetic drift and inbreeding may lead to a loss of fitness (ability of individuals to survive and reproduce) in small populations. In addition, reduced genetic variation in small populations may make any species less able to successfully adapt to future environmental changes (Ellstrand and Elam 1993). This species is threatened by potential loss of fitness and/or genetic variability associated with small population sizes. (USFWS, 1997)

**Stressor:** Naturally-occurring events (USFWS, 1997)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The potential for loss of the only population of Sidalcea oregana ssp. valida from naturally occurring events, because of the small population size, is exacerbated by drought and water diversions. In addition, this population is being encroached upon by invasive weeds, including yellow star-thistle and blackberry (A. Howald, pers. comm. 1993). One of the subpopulations was damaged by an off-road vehicle during maintenance of a local aqueduct, which passes through the marsh. The maintenance activity occurred late in the season when the soil was relatively dry, resulting in minimal damage to the plants. If such maintenance activities occur during a time when the soil is saturated, they pose a threat to the plants (A. Howald, pers. comm. 1993). (USFWS, 1997)

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change is listed as threat to this species. (USWS, 2009)

***Recovery***

**Reclassification Criteria:**
Not defined. A Recovery Plan has not been prepared. (USFWS, 2019)

Recovery Priority Number: 3C

**Delisting Criteria:**
Not defined. A Recovery Plan has not been prepared. (USFWS, 2019)

**Recovery Actions:**
- Not defined. A Recovery Plan has not been prepared. (USFWS, 2019)
- Removing thatch and invasive species from exclosures: Kenwood Marsh checker-mallows grow in full sun on the margins of riparian areas (K. Symonds, pers. comm. 2018). The species is currently threatened by thatch buildup from annual sedges, as well as invasive plants, both of which shade habitat (K. Symonds, pers. comm. 2018; R. Rex, pers. comm. 2018). Manual removal of invasive plants and thatch might be necessary to increase Kenwood Marsh checker-mallow survival. In 2018, Deerfield Ranch Winery staff and volunteers removed thatch and invasive plants from browsing exclosures (A. Rex, pers. comm. 2018). These efforts should take place annually to ensure the survival of Kenwood Marsh checker-mallow. (USFWS, 2019)
- Locate appropriate areas for new colony establishment: The Kenwood Marsh checker-mallow probably once existed in riparian zones between Kenwood Marsh and Knight's Valley. Today, the dispersal of this species is restricted by land-use conversion to agriculture and urban areas. However, there might be areas within the historical range where the species could be re-established with seeding and outplanting. Private landowners should be contacted and, if landowners are willing, a management plan should be developed and implemented by the Service or CDFW. Research and public outreach would be needed to determine the feasibility of establishing new colonies in the area. (USFWS, 2019)

- Population monitoring: Population estimates of Kenwood Marsh checker-mallow are sporadic (CNDDB; Appendix B). Establishing a protocol for continual, annual population monitoring would help us better understand the species needs and recovery potential. (USFWS, 2019)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of the Kenwood Marsh checker-mallow. Some of these recommendations have already been discussed in the previous status review (Service 2019, p. 3) and remain valid. 1. Continue surveys and develop a management plan for all exclosures at the Deerfield Ranch Winery. a. Establish a protocol for annual population monitoring. b. Verify a permanent conservation easement is in place for the property. c. Create a management plan with the cooperation of the landowner, conservation managers, the Department, and the Service. d. Evaluate management plan and adapt as necessary. 2. Manage competing vegetation: a. Remove/reduce invasive blackberry and native willow in the Willow exclosure at the Deerfield Ranch Winery to support latent seed germination and maintenance of Kenwood Marsh checker-mallow habitat. b. Remove thatch and competing vegetation annually in the Road exclosure. 3. Monitor hydrology and restore historical hydrology to the remaining portions of Kenwood Marsh and Knights Valley. a. Collect data on current hydrological conditions and inter- and intra-annual fluctuations. Compare to historical data if available. Restore historical flow and saturation to provide suitable habitat for Kenwood Marsh checker-mallow. 4. Reattempt out-planting at the Deerfield Ranch Winery exclosures 3, 4, and Willow if removal of competing vegetation does not result in germination of seed from the soil seedbank. 5. Build communication with the landowners of the Kenwood Marsh-West and the Knights Valley localities to survey those sites, secure protection, and create management plans. 6. Create permanent conservation easements at sites where the Kenwood Marsh checkermallow is known to occur. 7. Identify and consider permanently protecting locations within the Kenwood Marsh checker-mallow's historical range that contain suitable habitats for future outplantings. 8. Attempt outplanting at new locations on private and public land within the Kenwood Marsh checker-mallow's historic range. (USFWS, 2024)

# SPECIES ACCOUNT: *Sideroxylon reclinatum ssp. austrofloridense* (Everyglades bully)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 11/6/2017; Southeast Region (R4) (USFWS, 2017)

**Physical Description**

Everglades bully is a single to many-stemmed shrub, 3 to 6 feet (ft) (1 to 2 meters (m)) tall (Corogin and Judd 2014, pp. 410-412). The branches are smooth, slightly bent, and somewhat spiny. The leaves are thin, oval-shaped, 0.8 to 2 inches (in) (2 to 5 centimeters (cm)) long, evergreen, lance-shaped, and fuzzy on their undersides. The flowers are in axillary clusters. This subspecies is distinguished from the similar subspecies S. reclinatum ssp. reclinatum in Florida by its leaves, which are persistently pubescent (fuzzy) on their undersides, rather than smooth or pubescent only along the leaf midvein. In addition, the two subspecies are more reliably distinguished by differences in the micromorphology of the leaf epidermis. (USFWS, 2017)

**Taxonomy**

The genus Sideroxylon is represented by eight species in Florida. All of these plants were previously assigned to the genus Bumelia. Sideroxylon reclinatum, the Florida bully, is represented by three subspecies that range nearly throughout Florida and into neighboring states. The Everglades subspecies was first recognized by Whetstone (1985, pp. 544-547) as Bumelia reclinata var. austrofloridense, then transferred to the genus Sideroxylon (Kartesz and Gandhi 1990, pp. 421-427). Sideroxylon reclinatum ssp. austrofloridense was made a subspecies rather than a variety (Kartesz and Gandhi 1990, pp. 421-427); in plant nomenclature, the ranks of variety and subspecies are interchangeable. Sideroxylon reclinatum ssp. austrofloridense is used in the current treatment of the Florida flora (Wunderlin and Hansen 2016, p. 1). The online Atlas of Florida Vascular Plants (Wunderlin and Hansen 2016, p. 1), Integrated Taxonomic System (ITIS 2016, p. 1), NatureServe (2016, p. 1), and the Florida Department of Agriculture and Consumer Services (FDACS) (Coile and Garland 2003, p. 19) indicate that Sideroxylon reclinatum ssp. austrofloridense is the accepted taxonomic status. (USFWS, 2017)

**Historical Range**

The historical range of Sideroxlon reclinatum ssp. austrofloridense is limited to Collier, Miami-Dade, and Monroe Counties, Florida. In Miami-Dade County, the plant was known from central and southern Miami-Dade County along the Miami Rock Ridge, which extends from Long Pine Key in the Everglades northward through urban Miami to the Miami River. In Monroe County, the plant is known from Big Cypress National Preserve on the mainland, and was collected as far south as Key Largo, in the Florida Keys. In Collier County, the subspecies has been recorded only within Big Cypress National Preserve. The subspecies is apparently extirpated from Key Largo, and has not been found in surveys of pine rocklands on Key Largo, Big Pine Key, Cudjoe Key and Lower Sugarloaf Key. (USFWS, 2017)

**Current Range**

The current range of Sideroxylon reclinatum ssp. austrofloridense is in Miami-Dade and Monroe Counties, Florida, in Big Cypress National Preserve, the Long Pine Key region of Everglades National Park, and pine rocklands adjacent to Everglades National Park. The current range is approximately 42 mi (67.5 km). (USFWS, 2017)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 2017)

**Reproduction Narrative**

Adult: Little is known about the life history of Sideroxylon reclinatum ssp. austrofloridense, including pollination biology, seed production, or dispersal. Reproduction is sexual, with new plants generated from seeds. The subspecies produces flowers from April to May, and fruit ripens from June to July. (USFWS, 2017)

**Habitat Type**

Adult: Pine rockland habitat, marl prairie habitat, and within the ecotone between both habitats (USFWS, 2017)

**Dependencies on Specific Environmental Elements**

Adult: Periodic fire is extremely important to maintaining habitat for this subspecies (USFWS, 2017)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2017)

**Tolerance Ranges/Thresholds**

Adult: The plants can stand partial inundation with fresh water for a portion of the year, but do not tolerate salinity. (USFWS, 2017)

**Dependency on Other Individuals or Species for Habitat**

Adult: The species frequently has numerous stem galls, but these galls do not appear to cause mortality to the plant and may in fact be an important part of the subspecies' natural history. In addition, the stem galls are often inhabited by acrobat ants. (USFWS, 2017)

**Habitat Narrative**

Adult: Sideroxylon reclinatum ssp. austrofloridense grows in pine rockland habitat, marl prairie habitat and within the ecotone between both habitats. These habitats are maintained by regular fire, and are prone, particularly marl prairie, to annual flooding for several months during the wet season. The species also grows on the sunny edges of rockland hammock habitat, which is fire-resistant. Everglades bully occurs in sparsely vegetated, well-lit, open areas that are maintained by disturbance. (USFWS, 2017)

***Dispersal/Migration***

**Dispersal**

Adult: Unknown (USFWS, 2017)

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2023)

**Number of Populations:**

14 extant populations (USFWS, 2023)

**Population Size:**

10,000 to 100,000 plants, mostly occurring at Long Pine Key (USFWS, 2023)

**Population Narrative:**

The largest population occurs at Long Pine Key in Everglades National Park (ENP). The population at Long Pine Key is estimated at between 10,000-100,000 plants. Recent surveys of ENP have identified 14 occurrences of Sideroxylon reclinatum ssp. austrofloridense in Long Pine Key, expanding the known range in ENP. In Miami-Dade County, outside ENP, pine rocklands tracts are orders of magnitude smaller and exist in a matrix of agricultural, commercial, and residential development. Approximately 73 plants were observed at Larry and Penny Thompson Park, within the Richmond Pine Rocklands. Extant populations have been found at Quail Roost Pineland (two plants), Navy Wells Pineland Preserve (four plants), and Sunny Palms Pinelands (two plants). The subspecies has been observed in pine rocklands at Grant Hammock and Pine Ridge Sanctuary. The subspecies no longer occurs at the Nixon-Smiley Preserve. Surveys in the Gum Slough region of Lostmans Pines in Big Cypress National Park reported finding Sideroxylon reclinatum ssp. austrofloridense with limited distribution within the study area (USFWS, 2017). The Everglades bully currently has 14 extant populations on public and private lands in Miami-Dade and Monroe counties (Table 1). There is evidence that populations of Everglades bully are increasing within Everglades National Park (Bradley et al. 2013; Gann 2015; Lange, pers. comm. 2017), but insufficient survey data on private lands coupled with persistent threats to the species means it is unclear whether the overall species status is trending upwards (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Present or Threatened Destruction, Modification, or Curtailment of Its Habitat or Range
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat loss, fragmentation and degradation, and associated pressures from increased human population are major threats this species. These threats are expected to increase as remaining pine rocklands and other habitats are lost to development, placing these plants at greater risk. This species may be impacted when pine rocklands are converted to other uses or when lack of fire causes the conversion to hardwood hammocks or other unsuitable habitats. On public lands, including National Park Service lands and Miami-Dade County-owned lands, implementation of prescribed fire has not been sufficient because of legal constraints (permitting requirements) and inadequate funding. Any populations of this species found on private property

could be destroyed due to development. Although efforts are being made to conserve natural areas and apply prescribed fire, most pine rocklands remain in poor fire condition, and the long-term effects of large-scale and wide-ranging habitat modification, destruction, and curtailment will last into the future, while ongoing habitat loss due to population growth, development, and agricultural conversion continues to pose a threat to this species outside of conservation lands.

**Stressor:** Inadequacy of Existing Regulatory Mechanisms
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species is found on Federal, State and County lands. NPS regulations provide protection at Everglades National Park and Big Cypress National Preserve. These two sites continue to support the largest and best managed populations. State regulations provide protection against trade, but allow private landowners or their agents to clear or remove species on the Florida Regulated Plant Index. State Park regulations provide protection for plants within Florida State Parks. The Natural Forest Communities program in Miami is designed to protect rare and important upland (non-wetlands) habitats in south Florida; however, this regulatory strategy has several limitations that reduce its ability to protect this plant and its habitat. Although many populations of this species are afforded some level of protection because they are on public conservation lands, especially Federal lands, existing regulatory mechanisms vary in strength and scope, and do not provide substantive protection of habitat at this time. They have not led to a sufficient reduction of threats posed to these plants by a wide array of sources. (USFWS, 2017)

**Stressor:** Other Natural or Manmade Factors Affecting Its Continued Existence
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Threats from other natural or manmade factors to this species include nonnative, invasive plants; management practices (such as mowing); recreation (including off-road vehicle use), effects from small population size and isolation; limited geographic range; and stochastic events including hurricanes, storm surges, and wildfires. Additionally, this plant is particularly vulnerable to the effects of climate change, including sea level rise, as changes in the water table, increased soil salinity from partial inundation, and storm surge will likely result in vegetation shifts in the decades prior to the fully anticipated sea level rise. Some of these threats (e.g., nonnative species) may be reduced on public lands due to active programs by Federal, State, and County land managers. Many of the remaining populations of this plant are small and geographically isolated, and genetic variability is likely low, increasing the inherent risk due to overall low resilience of these plants. The threats act together to impact populations of this species. (USFWS, 2017)

***Recovery***

**Reclassification Criteria:**
Not defined.

Recovery Priority Number: 9

**Delisting Criteria:**
Not defined.

**Recovery Actions:**
- Recovery actions have not been defined.
- Conserve pine rocklands and suitable habitat through purchase or conservation easements.
- Provide regular prescribed burns to maintain suitable habitat conditions.
- Remove exotic plants and hardwoods to restore understories.
- Monitor and manage remaining small populations in Miami-Dade County.
- Locate new occurrences within Everglades National Park through additional surveys.
- Establish the limits of this species habitat requirements through additional surveys within Everglades National Park.
- Determine effects (positive or negative) from Everglades restoration and other hydrologic manipulations and changes through monitoring at Long Pine Key.

***Conservation Measures and Best Management Practices:***
- RECOMMENDED FUTURE ACTIVITIES Recovery Activities Through the course of this species status review, we recommend the following potential recovery activities. Restoration and protection of the pine rocklands, marl prairies, and rockland hardwood hammock habitats is critical to maintain populations of the species. This will ideally include increased fire management coupled with physical removal of invasive species. Removal of dense, woody invasive flora will prevent heightened burn temperatures and longer burn times, both of which increase Everglades bully mortality. More frequent prescribed fires will prevent tree encroachment and the succession of pine rockland habitat into hardwood forest. Further, we recommend working with private landowners to prevent the destruction of Everglades bully plants and to reintroduction. Monitoring / Research Activities We recommend extensive surveys on public and private lands to better understand the population trends in those areas. Of 14 extant populations, only the ENP colony has been sufficiently surveyed. There have also been no genetic studies on the Everglades bully, presenting a gap in our understanding of the species and its allelic richness. Further research should be conducted on the species response to development and fragmentation, pesticide use, and stochastic events and sea level rise which are expected to increase in frequency with climate change (USFWS, 2023)

# SPECIES ACCOUNT: *Silene spaldingii* (Spalding's Catchfly)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; Pacific Region (R1) (USFWS, 2016)

**Physical Description**

A perennial herb with stout stems, 2-8 dm tall. White flowers, forming a tight, leafy flower head, bloom from late June to August. (NatureServe, 2015)

**Taxonomy**

Spalding’s catchfly produce one to several vegetative or flowering stems that arise from a simple or branched persistent underground stem (caudex), which surmounts a long, narrow taproot. Plants range from 20 to 40 cm in height. Each stem typically bears 4 to 7 pairs of simple, opposite leaves that are 5 to 8 cm in length and 2 to 4 cm in width. Similar to the majority of plants in this family, Spalding’s catchfly has distinctly swollen nodes located where the leaves are attached to the stem. Reproductive individuals produce 3 to 20 cream to pink or light green flowers that are borne in a branched, terminal inflorescence. All green portions of the plant (foliage, stem, and flower bracts) are covered in dense sticky hairs that frequently trap dust and insects, giving this species the common name ‘catchfly’ (USFWS, 2016).

**Current Range**

Regional endemic restricted to remnants of the Poulouse Prairie grasslands of eastern Washington, northeastern Oregon, northern Idaho, and western Montana (barely extending into British Columbia, Canada) (NatureServe, 2015). The species is endemic to the Palouse region of south-east Washington and adjacent Oregon and Idaho, and is disjunct in northwestern Montana and British Columbia, Canada (USFWS, 2016).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Food/Nutrient Narrative**

Adult: All green portions of the plant (foliage, stem, and flower bracts) are covered in dense sticky hairs that frequently trap dust and insects, giving this species the common name ‘catchfly’ (USFWS, 2016).

**Breeding Season**

Adult: Flowering typically occurs from mid-July through August, but may occasionally continue into October (USFWS, 2016).

**Reproduction Narrative**

Adult: Plants (both vegetative and reproductive) emerge in mid- to late May. Flowering typically occurs from mid-July through August, but may occasionally continue into October. Rosettes are formed the first and possibly the second year, followed by the formation of vegetative stems.

Above-ground vegetation dies back at the end of the growing season and plants either emerge in the spring or remain dormant below ground for one to several consecutive years. Spalding's catchfly reproduces solely by seed. It lacks rhizomes or other means of reproducing vegetatively (USFWS, 2016). Silene spaldingii is a partially self-compatible, hermaphroditic perennial. Reproduction is apparently via seed only, as rhizomes or other means of vegetative propagation are lacking. Seeds appear to require cold stratification, so germination occurs mainly in the spring. Rosettes are formed the first year and flowering may occur during or after the second season. Flowers are protandrous (Lesica and Heidel 1996). Anthers mature and dehise pollen first. During this time, the styles are unexpanded, and the unexposed stigmatic surfaces are held well below the level of the anthers. After the anthers shrivel and fall from the filaments, the three styles expand and the stigmas become receptive. Each flower persists for two to several days, and two or more flowers may be in bloom on the same plant, so geitonogamous pollination is possible. This system promotes outcrossing while allowing the possibility of self-pollination (Lesica 1991; 1993). The bumblebee, Bombus fervidus, appears to be the only significant pollination vector for S. spaldingii throughout its range (Lesica and Heidel 1996). At least at some populations, S. spaldingii appears to be subject to pollinator limitations, inbreeding depression, and a large genetic load (Lesica 1991; 1993).; Silene spaldingii most frequently occurs in relatively intact climax or successionally advanced mesic grassland communities (Lorain 1991). It does not occur at sites where the native vegetation has been displaced by aggressive weeds. It is apparently tolerant of light to moderate grazing (Schassberger 1988). In areas where grazing occurs, it does not appear to be preferred by cattle, but these populations also are much smaller than those in mature grassland habitats. Lesica (1994) found that prescribed burning at a site in Montana increased growth, recruitment and flowering of Silene spaldingii.; Perfect; Predominantly outcrossing; SEXUAL; ABIOTIC; Self-dispersing; Hymenoptera; (NatureServe, 2015)

**Habitat Type**

Adult: Palouse Prairie (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: The 2007 Recovery Plan describes occupied habitat within five physiographic regions; 1) the Palouse Grasslands in west-central Idaho and southeastern Washington; 2) the Channeled Scablands in eastern Washington; 3) the Blue Mountain Basins in northeastern Oregon; 4) the Canyon Grasslands of the Snake River and its tributaries in Idaho, Oregon, and Washington; and 5) the Intermontane Valleys of northwestern Montana. These regions are distinctive from one another in climate, plant composition, historical fire frequencies, and soil characteristics. These differences are significant in that they may translate into differences in life histories, habitat trends, consequences of fire suppression, and types of weed control as they apply to conservation of catchfly (USFWS, 2016). Restricted to Palouse Prairies, sometimes extending into areas where the grasslands are intermingled with ponderosa pine (Pinus ponderosa) woodlands. Soils are almost always a productive, deep loess. Elevation range is 580-1,220 m. Silene spaldingii is restricted to Festuca idahoensis habitat types and phases throughout its range. These areas are often referred to as Palouse prairie. Sites are often near lower treeline, or near scattered ponderosa pine trees. Populations have been found on all aspects, but there seems to be a preference for northerly-facing aspects. It occurs at elevations ranging from about

1,900 to 3,600 feet, and on flat to steep slopes. Soils are almost always productive silt/loams (loess) that are moderately deep and sometimes gravelly (Gamon 1991; Lorain 1991). The soils are depositional materials from catastrophic floods of glacial Lake Missoula that extend from Montana across Idaho into eastern Oregon and Washington. (NatureServe, 2015)

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

~109 (USFWS, 2020)

**Population Size:**

~110,313 (USFWS, 2020)

**Population Narrative:**

At the time the Recovery Plan was developed in 2007, 99 populations of Spalding’s catchfly were reported (22 populations in Idaho, 11 in Montana, 17 in Oregon, 49 in Washington). The last 5-year review (2009) reported 10 new populations, adding 3 in Idaho, 2 in Oregon, and 5 in Washington, bringing the total number of populations to 109, with an estimated rangewide number of individual plants being just under 30,000. As noted above, Spalding’s catchfly also barely extends in to British Columbia, Canada. Photo credit: Jannis Jocius, Population Census at Wallowa Lake KCA. However, as this Recovery Plan applies only to populations within Idaho, Montana, Oregon and Washington, occurrences in British Columbia are not reported in this review. The number of known occurrences of Spalding’s catchfly has increased since 2009. We have evaluated new occurrences provided to us by the Idaho Fish and Wildlife Information System (IFWIS) database and additional reports from Idaho (Pekas et al. 2019 and Gray et al. 2010); the Montana Natural Heritage Program database; the Oregon Fish and Wildlife Office (OFWO) as adapted from the Oregon Biodiversity Information Center (ORBIC) database, and the Washington Natural Heritage Program database. Currently there are 139 occurrences in the United States: 49 in Idaho, 76 in Montana, 49 in Oregon, and 50 in Washington. The number of individual plants in each population ranged from one to thousands with the estimated total number of plants rangewide being approximately 110,313 individuals (8,142 in Idaho, 20,874 in Montana, 56,379 in Oregon, 24,918 in Washington). However, total plant counts are only rough estimates (unless noted otherwise). Exact plant counts are difficult because observed populations fluctuate drastically from one growing season to another, Spalding’s catchfly individuals can remain dormant or appear aboveground only briefly for one or more consecutive years, some plant counts at EOs only represent a portion of the occurrence, not all occurrence data includes a population census count, and at some occurrences plant counts are fairly dated. (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Development (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Human development (habitat loss) is listed as a threat to this species (USFWS, 2016).

**Stressor:** Grazing (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Habitat degradation
**Narrative:** Habitat degradation associated with adverse grazing and trampling by domestic livestock and wildlife is listed as a threat to this species (USFWS, 2016).

**Stressor:** Nonnative plants (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Invasions of aggressive nonnative plants are listed as threats to this species (USFWS, 2016).

**Stressor:** Loss of genetic variability (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Extinction/loss of genetic variability
**Narrative:** Loss of genetic fitness (the loss of genetic variability and effects of inbreeding) is a problem for many small, fragmented populations where genetic exchange is limited (USFWS, 2016).

**Stressor:** Fire frequency and seasonality (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Fire frequency and seasonality is listed as a threat to this species (USFWS, 2016).

**Stressor:** Off-road vehicle use (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals/habitat degradation
**Narrative:** Off-road vehicle use is listed as a threat to this species (USFWS, 2016).

**Stressor:** Herbicides (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Herbicide spraying and drift is listed as a threat to this species (USFWS, 2016).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 8C

**Recovery Actions:**

- Ongoing conservation efforts include research, Palouse Grassland conservation actions, invasive nonnative plant control, and land acquisition. Monitoring efforts continue, the technical team has worked towards developing a standardized monitoring protocol, and new monitoring has been initiated (USFWS, 2016).

***Conservation Measures and Best Management Practices:***

- Recommendations for Future Actions: The many conservation activities on-going for Spalding's catchfly should continue: • Continue working as a Technical Team to collaborate on recovery actions for this species, particularly at the KCAs. • Continue to pursue additional partnerships at areas identified as having potential to be KCAs. • Continue outplanting efforts in order to increase population numbers at KCAs with less than 500 plants (which includes investing in seed increase and grow-out of Spalding's catchfly plants and studying techniques such as direct seeding and site preparation techniques). • Continue the range-wide monitoring program at each of the KCAs and periodically analyze data sets. • Continue survey efforts to locate potential new populations or document population expansions at known locations. In addition to continuing those efforts, the following recovery actions should be made a priority (for funding and implementation) over the next 5 years: • Initiate development of Spalding's catchfly Habitat Management Plans at KCAs that currently are not covered. • Monitor, manage, and evaluate the response of Spalding's catchfly to site-specific stressors at KCAs, such as livestock, rodent activity, and insect herbivory; fire; potential loss of pollinators, and invasive nonnative plant species. • Prioritize the collection of quantitative invasive nonnative plant cover within KCAs. • Complete long-term seed banking at KCAs as well as smaller populations in order to preserve the breadth of genetic material across the species' range. (USFWS, 2020)

# SPECIES ACCOUNT: *Solidago houghtonii* (Houghton's goldenrod)

***Species Taxonomic and Listing Information***

**Commonly-used Acronym:** HOGO

**Listing Status:** Threatened; 07/18/1988; Great Lakes-Big Rivers Region (R3) (USFWS, 2016)

**Physical Description**

A perennial herb. Stems are frequently tufted or clumped, up to 7.5 dm high. Leaves become linear upwards on the stems. The inflorescence is a terminal, more-or-less flat-topped cluster of relatively few, large flower heads, each consisting of about 6-9 pale to bright yellow ray flowers and several yellow disk flowers. The branches of the inflorescence are smooth, but the stalks of the flower heads are finely but distinctly hairy. Blooms in August. (NatureServe, 2015)

**Taxonomy**

FNA (vol. 20, 2006) transfers Oligoneuron houghtonii to Solidago houghtonii. The disagreements concerning the origin of S. houghtonii and, more importantly, the true identities of populations within the currently circumscribed range, argue strongly for considering the species in the broad sense now (USFWS, 1997; NatureServe, 2015)

**Current Range**

Solidago houghtonii is primarily an endemic of the Upper Great Lakes region, occurring principally on the northern shores of Lakes Michigan and Huron in Michigan and Ontario; peripheral range extends north to Canadian shores of Georgian Bay, also 1 disjunct site in New York. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Dependency on Other Individuals or Species**

Adult: Jolls' preliminary findings from the 1993 research indicate that S. houghtonii is self-incompatible and thus dependent on insect vectors for successful pollination. Potential pollen vectors include bees (Hymenoptera), butterflies (Lepidoptera), flies (Diptera), moths (Lepidoptera), and wasps (Hymenoptera). (USFWS, 1997)

**Breeding Season**

Adult: August to October (USFWS, 1997)

**Reproduction Narrative**

Adult: Flowering occurs primarily in August and early September but may occur as early as late July and not uncommonly well into October. Fruiting and seed dispersal appears to occur mostly from August through November and undoubtedly later (MNH 1993). Jolls' preliminary findings from the 1993 research indicate that S. houghtonii is self-incompatible and thus dependent on insect vectors for successful pollination. Potential pollen vectors include bees (Hymenoptera), butterflies (Lepidoptera), flies (Diptera), moths (Lepidoptera), and wasps (Hymenoptera). (USFWS, 1997)

**Habitat Type**

Adult: Terrestrial and palustrine (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Bog/fen, herbaceous wetland, riparian, barrens, sand/dune (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Prefers cool, moist areas (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Found in sparsely vegetated areas at elevations between 100 and 400 m (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow. Specialist or community with key requirements common. (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Medium (USFWS, 1997)

**Habitat Narrative**

Adult: Solidago houghtonii occurs primarily along the northern shores of Lakes Huron and Michigan and is restricted to calcareous beach sands, rocky and cobbly shores, beach flats, edges of marl ponds, and especially the shallow, trough-like interdunal wetlands that parallel shoreline areas (MNEI 1993). Much less commonly, S. houghtonii occurs in wet prairie-like habitats in Lower Michigan and locally in a New York marl fen. It also occurs on seasonally wet limestone pavement, which is the species’ more typical habitat in the eastern portion of its range. S. houghtonii was collected from open limestone pavements in moist rock crevices (D.F. Brunton 3352, CAN). In sand dune areas, it tends to occur on the lee side of low foredunes and on low stabilized dunes adjacent to interdunal wetlands, especially in moist to saturated sands within and around interdunal depressions. The restriction of S. houghtonii to calcareous sands and dolomitic limestone areas of the Niagaran Escarpment suggests that the species requires a relatively high amount of calcium and magnesium (and possibly sodium and potassium) in its substrate. Dune sands in the region of the Niagaran Escarpment generally have a calcareous component of about 1 to 5 percent that is composed primarily of ground mollusk shells (Collins 1989). The sands in which it grows are circumneutral (pH 7.0) to alkaline (pH 8.0) and may occasionally have a thin covering of organic material (Collins 1989). Solidago houghtonii usually occurs where there is a relatively low density of competing vegetation at elevations between 100 and 400 meters. The species’ apparent establishment in the better drained portions of dunes, such as along the backside of foredunes, may indicate it has some resistance to desiccation. Often associated with Solidago ohioensis, Lobelia kalmii, and other calciphiles; occasionally associated with two other rare species: Pitcher's thistle (Cirsium pitcherii) and dwarf lake iris (Iris lacustris). (USFWS, 1997; NatureServe, 2015)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Fruiting and seed dispersal appears to occur mostly from August through November and undoubtedly later (MNH 1993). In researching the ecology of S. shortii, Buchel6 et al. (1991) found their data suggested no persistent seed bank for the species. In examining numerous other studies concerning the phenology of Solidago seed dispersal and germination, they concluded there is a good possibility that members of this genus produce seeds that remain viable for no more than one year, resulting in transient seed banks. (USFWS, 1997)

***Population Information and Trends***

**Population Trends:**

Unknown. Inferred from information (USFWS, 2020)

**Species Trends:**

Unknown. Inferred from information (USFWS, 2020)

**Population Growth Rate:**

Slowly declining (NatureServe, 2015)

**Number of Populations:**

~90 (NatureServe, 2015)

**Population Narrative:**

Long-term population trends suggest declines of 30-70%, whereas short-term trends indicate a decline of <30% to relatively stable. There are approximately 90 occurrences known (Penskar et al. 1996). (NatureServe, 2015). Recent status assessment efforts for a portion of the U.S. populations (45 out of 76 EOs) show many (28 out of 45) stable or increasing HOGO populations, with several locations having well over 10,000 flowering individuals (Leopold and Weber 2019). However, high lake levels, shoreline development, invasive plant species, recreation, and deer browse represent stressors to HOGO that need further evaluation (Leopold and Weber 2019) (USFWS, 2020).

***Threats and Stressors***

**Stressor:** Narrow habitat range (USFWS, 1997)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Solidago houghtonii, like several of its associated endemics, is particularly vulnerable to extirpation because of its restriction to narrow shoreline habitats ofthe Great Lakes. In a 1981 status survey, D.C. Nepstad considered habitat destruction to be the greatest threat to populations of S. houghtonii and cited the desirability of shoreline areas for residential housing and the escalating pressure for this type of development as a principal cause of this habitat destruction. The rate of residential development continues to accelerate, and it is highly unlikely that there will be any abatement of this trend in the near future. Nepstad (1981) also noted that some major occurrences of S. houghtonii have been considerably altered and fragmented by private development such that their long-term viability has been severely diminished. This has

been a view supported by subsequent field surveys (MNFI 1993).There are many causes of habitat alterations that have adversely affected S. houghtonii populations. Construction of beach retaining walls and other emergency erosion control measures (e.g. rip-rap and bulkhead installation) prevents or inhibits dune formation. Excessive foot and off-road vehicle (ORV) traffic destabilizes dune and beach flats. Marina construction, road construction, sand mining, and home and cottage construction where improved lake views are desired, have resulted in leveling of dune ridges (Collins 1989). Driveway installation or permitted work performed by utilities and railroads near interdunal wetlands have fragmented colonies and altered the hydrology. Residential development further potentially threatens habitat by altering hydrology with the placement and construction of septic systems whose nutrient loading degrade adjacent interdunal wetlands. Finally, both foot and ORV traffic have caused the direct destruction of plants. (USFWS, 1997)

**Stressor:** Modification of groundwater (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Disjunct populations, located in calcareous fens and dependent upon calcium rich groundwater flowing through them, face additional threats. Modifications or contamination of the groundwater could cause these sites to become unsuitable for Houghton's goldenrod and could lead to extirpation of this species. As such, this species could be also be threatened by off-site activities. (USFWS, 2011)

**Stressor:** Invasive species (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasive species control efforts are underway in three of the four Michigan State Parks with Houghton's goldenrod. New York has had limited success with control efforts at Bergen Swamp. Common reed grass (Phragmites australis) is the non-native invasive species most likely to affect Houghton's goldenrod at Bergen Swamp (Drake, pers. comm. 2010), although encroachment by false brome (Brachypodium sylvaticum) may pose a threat to Houghton's goldenrod also (Steve Young, NYNHP, pers. comm., 2010). Almost all occurrences are threatened by the increase in invasive plant species, such as baby's breath (Gypsophila paniculata), Phragmites australis, purple loosestrife (Lythrum salicaria) and false brome (Brachypodium sylvaticum). If not removed or controlled, these invasive species may threaten the Houghton's goldenrod habitat by outcompeting native species, shading the habitat or altering the hydrology. (USFWS, 2011)

**Stressor:** Climate change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change models predict the climate of the Great Lakes region will grow warmer and drier over the next century, with precipitation increasing in winter and decreasing in summer (AMEC 2006; Anton Reznicek, University of Michigan, pers. comm. 2004; Kling et al. 2003). Average temperatures in the Great Lakes region could increase by 3 to 7°C in winter and 3 to 11°C in summer by the year 2100. While average annual precipitation could increase by 10–20

percent, significant changes in the seasonal precipitation cycle are likely, with winter and spring rain increasing and summer rain decreasing by up to 50 percent (Kling et al. 2003). A warmer, drier summer will affect surface and groundwater levels, as well as soil moisture, which is projected to decrease by 30 percent in summer (Kling et al. 2003). Increased water temperatures will also result in decreased ice cover that when combined with an expected intensity of winter storms, will leave coastal areas more vulnerable to the effects of winter storms and flooding (Fang and Stefan 2000; AMEC 2006), altering Houghton's goldenrod habitat. A warmer climate could also bring about a northward shift and an even greater increase in invasive species that may be more problematic in the dunes and lakeshore systems, thus increasing competition with native plant species (Malcolm et al. 2002; AMEC 2006; Penskar, pers. comm. 2009). (USFWS, 2011)

**Stressor:** Roads and highways (USFWS, 1997)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Several S. houghtonii occurrences in Michigan are within or along rights-of-way administered by MDOT. Records in the MNFI show that there are at least 11 occurrences partially within or along MDOT rights-of-way, representing nearly 20 percent of the known occurrences in Michigan. Kim D. Herman (1988) notes that S. houghtonii is more vulnerable to disturbance than two other endemics of Great Lakes shorelines, dwarf lake iris and Pitcher's thistle, because of its restriction to narrow bands of interdunal wetland habitats, many of which occur between coastal roads and lakeshores. In some of these sites, highways may be severely fragmenting S. houghtonii populations or preventing them from expanding and colonizing suitable habitat available further inland. Herman (1988) further states that the MDOT activities which resulted in the most adverse effects to this species and other Great Lakes endemics are projects along two major State roadways, US-2 and US-23, located in the Upper Peninsula and Lower Peninsula, respectively. These activities included culvert extensions, pavement recycling, shoulder widening, and other types of safety work. (USFWS, 1997)

**Stressor:** Road maintenance (USFWS, 1997)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A number of common road maintenance activities, including emergency repairs on eroding shoreline areas, herbicide application, mowing, road salting, shoulder grading, snow removal, and tree removal, have affected populations of S. houghtonii (Herman 1988). A number of illegal activities which have occurred on or near MDOT rights-of-way have also affected this species and its habitat. Illegal use of sites by commercial fishermen and encroachments by ORV operators and other recreationists have had adverse effects (MNFI 1993). (USFWS, 1997)

**Stressor:** Off-road vehicles (ORVs) (USFWS, 1997)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat damage resulting from ORV traffic is one of the major threats to S. houghtonii. The restriction of this species to a very limited, narrow expanse of shoreline habitat renders it particularly vulnerable to destruction and habitat fragmentation. Off-road-vehicles are in

widespread use and are very difficult to exclude from most kinds of natural areas, particularly beaches and coastal dunes. Their use and resulting effects on these sites are well documented throughout Michigan (MNFI 1993). Off-road-vehicle traffic or evidence of it has been observed in areas of exemplary S. houghtonii occurrences, such as Crow River Mouth (Mackinac County), Grass Bay (Cheboygan County), and Wilderness State Park (Emmet County) (MNFI 1993), and probably occurs in many and perhaps most other sites throughout the range of the species. (USFWS, 1997)

**Stressor:** Natural disturbances (USFWS, 1997)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The restriction of S. houghtonii to low-lying, linear coastal zone habitats also causes it to be highly susceptible to natural disturbance. Rises in lake levels, such as the record highs attained in 1986, may severely reduce population numbers throughout the entire range of the species (Voss 1987). It is thus very important that destructive human activities are minimized or eliminated so as not to exacerbate the effects of natural disturbance (Voss 1987). (USFWS, 1997)

**Stressor:** Artificial stabilization of lake levels (USFWS, 1997)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** It is unlikely that the range of S. houghronii will expand because of the accelerating habitat loss and fragmentation due to development, increasing human-caused habitat disturbance, and the restriction of nearly all individuals of the species to shores of the Great Lakes. Therefore, essential habitat must be protected. Any artificial stabilization of Great Lakes levels could markedly change the natural dynamics of shoreline habitats and be highly detrimental to S. houghtonii, as well as to many other sensitive species and significant natural communities. Stabilization of the Great Lakes at low water levels might initially benefit S. houghtonii by temporarily exposing maximum suitable habitat. However, unless lake levels are continually lowered, stabilized S. houghtonii habitat is likely to be altered and will become unsuitable through plant succession. As a relatively poor competitor restricted to dynamic shoreline areas, this species depends on the cyclical fluctuations of the Great Lakes. It suffers local extirpations during high water years, but later exploits and colonizes newly exposed habitat as it becomes available again. (USFWS, 1997)

**Stressor:** Over-collection (USFWS, 1997)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Like many rare species, S. houghtonii can potentially be over-collected by individuals with legal collecting permits, such as those who desire specimens for herbaria in which this taxon is poorly represented. Despite the good intentions of removing live plants for propagation and exhibition in rare plant collections, such activities, if done excessively or without proper permits, also represent a threat to populations. Permits granted for the taking of this species should be issued only after careful consideration and consultation with appropriate, knowledgeable individuals. Permits should stipulate that collections may be made only when an occurrence (i.e., a “population’.’) would not be significantly diminished or adversely affected by removal of

individuals. (USFWS, 1997)

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

Recovery Priority Number: 8C

**Delisting Criteria:**
1. Protect a minimum of 30 of the most viable occurrences of Houghton’s goldenrod and preserve the species’ essential habitat and the natural environmental processes that maintain it. (USFWS, 1997)

**Recovery Actions:**
- Protect all known occurrences, with priority given to the most viable occurrences and the species’ essential habitat. (USFWS, 1997)
- Survey suitable habitat for additional occurrences and verify the status of historic occurrences. (USFWS, 1997)
- Educate and notify land managers and the public. (USFWS, 1997)
- Monitor occurrences for population demographics, viability, and threats. (USFWS, 1997)
- Conduct biosystematic research throughout the species’ range. (USFWS, 1997)
- Report survey results and habitat and population conditions to the Michigan Natural Features Inventory and the East Lansing Field Office and update element occurrence records. (USFWS, 2011)
- Plan and implement regular surveys and monitoring of occurrences, including better documentation of habitat conditions and populations trends. (USFWS, 2011)
- Reassess ranks of known occurrences. (USFWS, 2011)
- Provide education and outreach to stakeholders and the public. (USFWS, 2011)
- Monitor approach of non-native species and control as appropriate. (USFWS, 2011)

***Conservation Measures and Best Management Practices:***
- RECOMMENDATIONS FOR FUTURE ACTIONS: • Conduct a Species Status Assessment to inform the next 5-year review • Develop written agreements and management plans for protection on public lands (Recovery plan task: 1.12) • Plan and implement regular surveys and monitoring of occurrences, including better documentation of habitat conditions and populations trends. (Recovery plan tasks: 2.22, 4) o In particular, surveys are needed for sites not visited in 2015-2016 in Michigan. Information on the Ontario populations would also be helpful in evaluating the species’ status. • Reassess ranks of known occurrences. (Recovery plan task: 2.24) • Promote landowner involvement in a registry program. (Recovery plan task: 14.143) • Develop strategies to protect occurrences and sites from ORV damage. (Recovery plan task: 13.131) (USFWS, 2020)

# SPECIES ACCOUNT: *Solidago shortii* (Short's goldenrod)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 9/5/1985; Southeast Region (Region 4) (USFWS, 2016)

**Physical Description**

A perennial herb with one to several erect or ascending stems 0.5 to 1.3 m tall, arising from a creeping rhizome. Stems are terete in cross section, slightly ribbed, and minutely scabrid-puberulent at least above the middle. Leaves are alternate, crowded, 5-10 cm long and 0.6 to 1.5 cm wide. Individual leaves are firm, oblong-lanceolate to narrowly elliptic, remotely serrulate and glabrous on both sides. The leaves are largest near the middle of the stem and become progressively smaller towards the inflorescence. Lower leaves are reduced and usually absent during flowering time. The inflorescence is terminal and ranges from racemose to paniculate with divergent, secund branches. Heads are 10-14 flowered on puberulent stalks usually 5 mm or less in length. The involucre is 4-6 mm long and 3 mm wide with imbricate, coriacious and glabrous phyllaries. Ray florets number from 4 to 8 and are 2.5-3.0 mm long. The corollas are elliptic-linear with bright yellow ligules about 2 mm long. The disc florets are also bright yellow with a short tube, funnel form throat and five linear spreading lobes about equaling the throat in length. The white papus is capillary and about 2 mm long. Achenes are cuneate-cylindric, about 2 mm long, and pale brown with appressed, silky pubescence (USFWS, 1988).

**Taxonomy**

In the Aster family (Asteraceae)(USFWS, 1988).

**Historical Range**

Historically known from Jefferson, Robertson, Nicholas, and Fleming Counties in Kentucky (USFWS, 1988).

**Current Range**

Known from Robertson, Nicholas, and Fleming Counties in Kentucky (the vicinity of Blue Licks, Kentucky) and along the Blue River in Harrison County, Indiana (USFWS, 2007).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect (USFWS, 1988)

**Breeding Season**

Adult: Flowers from mid-August to early November (USFWS, 1988).

**Key Resources Needed for Breeding**

Adult: Insects for pollination, probably bees (USFWS, 1988)

**Reproduction Narrative**

Adult: Flowers from mid-August to early November, and fruits mature several weeks after the flowers whither. Specific pollinators have not been documented; sweat bees have been observed visiting the flowers. Germination rates in the field are unknown (USFWS, 1988).

**Habitat Type**

Adult: Terrestrial (USFWS, 1988)

**Habitat Vegetation or Surface Water Classification**

Adult: A variety of dry, mostly open habitats, in full sun or partial shade (USFWS, 1988).

**Dependencies on Specific Environmental Elements**

Adult: Natural disturbance (USFWS, 1988)

**Environmental Specificity**

Adult: Very narrow. Specialist or community with key requirements scarce. (NatureServe, 2015)

**Habitat Narrative**

Adult: Habitat is full sun or partial shade in a variety of dry, mostly open habitats. These include limestone cedar glades, open eroded areas, edges of dry, open oak-hickory woods, cedar thickets, pastures, old fields, power rights-of-way, and rock ledges along highway rights-of -way. This species does not appear to compete well and does best in areas with a low density of other plants. It will not grow in full shade (as in closed canopy woods). Soils are described as flaggy, silty clay texture with 20-30% rock fragments, and slightly acid to moderately alkaline, with slow permeability and rapid runoff (USFWS, 1988). In the long term, it appears that the species can survive only in early successional, short-term habitats (resulting from some disturbance), natural openings associated with animal movements or rock outcrops, or dynamic rocky shorelines along rivers (Indiana occurrence) (USFWS, 2007).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Although goldenrod fruits are normally wind dispersed, there is no evidence that this species is expanding its range by this method. It has been suggested that bison may be a dispersal vector (USFWS, 1988).

***Population Information and Trends***

**Population Trends:**

Stable to declining (USFWS, 2007)

**Species Trends:**

Decline of 10-30% (NatureServe, 2015)

**Number of Populations:**

20 (USFWS, 2023)

**Population Size:**

1 - 1000 individuals (NatureServe, 2015)

**Adaptability:**

The plant is clonal and is capable of persisting after some disturbance. Survivorship curves are typical of other herbaceous perennials (Walck et al. 1999b). Does not produce a long-lived seed bank (Walck et al. 1999a) (NatureServe, 2015).

**Population Narrative:**

Based on the results of numerous surveys and investigations over the past 25 years, the current distribution of S. shortii is restricted to 13 occurrences within a 2-mile radius of Blue Licks Battlefield State Resort Park in Fleming, Nicholas, and Robertson counties, Kentucky and one occurrence along the Blue River in Harrison County, Indiana (Harrison-Crawford State Forest). Despite numerous, intensive searches of similar habitats, only two occurrences (one within Sho1i's Goldenrod SNP in Fleming County, Kentucky and the Indiana occurrence) have been discovered since completion of the recovery plan in 1988. At present, eight Kentucky occurrences (numbers 1, 2, 5, 7a, Sa, 11, 12a, and Short's Goldenrod SNP) and the Indiana occurrence appear to be stable, and some level of protection has been achieved for all but one of these occurrences (number 11). The remaining Kentucky occurrences have shown declines in the number of stems and surface area since 1989 (Smith et al. 2004; Buchele et al. 1989). The reason for these declines is unknown, but competition from exotics and land-clearing activities on private property appear to be the primary causes (USFWS, 2007). Currently, the species is known from 20 extant occurrences, including 12 Blue Licks occurrences (two occurrences are now considered extirpated); 3 introduced occurrences near Claysville in Harrison County, Kentucky; 1 introduced occurrence along the Licking River in Robertson County, Kentucky; 3 introduced occurrences at Clay Wildlife Management Area in Fleming and Nicholas counties, Kentucky; and 1 occurrence along the Blue River, Greenbrier Knob Nature Preserve, in Harrison County, Indiana (Homoya and Abrell 2005) (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Kentucky occurrences are most threatened by competition from exotics such as crown vetch, tall fescue, and other species described above, habitat disturbance on private property, and highway and powerline maintenance activities. The Indiana occurrence is most threatened by competition from exotics. The potential raising of the Ohio River's pool level is a possible threat but is unlikely to occur (USFWS, 2007).

**Stressor:** Overutilization for commercial, recreational, scientific, or educational purposes (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Recent park improvements in Blue Licks Battlefield State Resort Park are expected to increase the recreational use of the park and could lead to adverse impacts to S. shortii individuals if recreational activities (e.g., hiking) are not directed away from S. shortii occurrences. The species' small range and low number of individual plants makes it vulnerable to overcollecting for scientific purposes. Plants within Blue Licks Battlefield State Resort Park cannot be collected without a permit from the Kentucky Department of Parks and KSNPC; these permits are only issued for valid scientific purposes. Plants occurring on private property are not afforded this protection. The Indiana occurrence is also potentially threatened by recreational use (trampling by fishermen, canoeists, hikers). At present, though, recreational use does not appear to be a significant threat in Indiana. In addition, these plants occur on state property and cannot be collected without a permit (USFWS, 2007).

**Stressor:** Predation (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Over-grazing by cattle on private property has the potential to adversely affect the species by eliminating flower production, but this effect has not been observed directly (USFWS, 2007).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Occurrences at Blue Licks Battlefield State Resort Park are protected from unauthorized taking; permits administered by the Kentucky Department of Parks and KSNPC are only issued for valid scientific purposes. Portions of occurrences 7a and 12a are protected through an MOU between KSNPC and KYTC (KSNPC 1989) that restricts habitat disturbance within these road rights-of-way. The Indiana occurrence occurs on state property (Harrison-Crawford State Forest) and is also protected from unauthorized taking. No such protection is available for occurrences located on private property in Kentucky or Indiana (USFWS, 2007).

**Stressor:** Other natural and manmade factors affecting its continued existence (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The species has been reduced to a small number of occurrences with a limited number of individuals. Consequently, the species is vulnerable to natural or human-induced factors (fire suppression) that might directly destroy individuals and further reduce population size (Federal Register 1985). Natural (secondary) succession can eliminate potential habitat for S. shortii through changes in vegetational composition. As old-field habitats and closed canopy woodlands develop, potential S. shortii habitat is lost (USFWS, 2007).

***Recovery***

**Reclassification Criteria:**

1. Adequate protection is obtained for the nine high priority occurrences and the habitat they occur in (USFWS, 1988).

2. Protected occurrences are determined to be self-sustaining and maintaining current population levels or above (USFWS, 1988).

3. Species biology and ecological requirements are sufficiently understood to determine and implement long-term management strategies (USFWS, 1988).

Recovery Priority Number: 8

**Delisting Criteria:**
1. Adequate protection is obtained for the nine high priority occurrences and the habitat they occur in (USFWS, 1988).

2. Protected occurrences are determined to be self-sustaining and maintaining current population levels or above (USFWS, 1988).

3. Species biology and ecological requirements are sufficiently u understood to determine and implement long-term management strategies (USFWS, 1988).

4. At least nine additional protected occurrences, equal in size and significance to the high priority occurrences mentioned above, are discovered in the vicinity of the Blue Licks population or at a currently unknown location (USFWS, 1988).

**Recovery Actions:**
- Protect existing occurrences and essential habitat. Prioritize occurrences for protection. Contact landowners and negotiate highest or most appropriate level of protection possible (USFWS, 1988).
- Conduct systematic searches for additional occurrences and populations. Identify potential habitat. Conduct ground searches (USFWS, 1988).
- Conduct studies of life history and ecological requirements. Delineate existing occurrences and establish permanent study plots. Analyze physical habitat and characterize habitat factors. Study phenology, pollination, and seed dispersal. Perform ex situ germination study and long-term demographic study. Determine management practices and develop recommendations to maintain health, vigor, and survivability of species (USFWS, 1988).
- Develop management plan and implement recommended management practices if determined beneficial. Conduct controlled burns, if determined beneficial. Remove overstory and/or aggressive competing vegetation if determined beneficial. Implement controlled rotational grazing system, if determined beneficial. Monitor results of management practices and re-evaluate needs as data on management results are obtained (USFWS, 1988).
- Maintain viable seeds. Collect and deposit seeds into seed banks. Make seeds available to organizations or institutions for propagation (USFWS, 1988).
- Continue management and monitoring of naturally occurring and reintroduced occurrences in Kentucky and Indiana, with consideration of intensified management at selected sites (USFWS 2017).
- Consider expansion of reintroduction efforts, with careful consideration of seed origin and genetics (USFWS 2017).

- Investigate and compare the genetic diversity/structure of Kentucky and Indiana populations, including the reintroduced occurrences in Harrison County, Kentucky (USFWS 2017).
- Investigate potential impacts of the bacterial leaf spot observed on occurrences in the Blue Licks area of Kentucky (USFWS 2017).
- Explore the potential threat posed by the horticultural cultivar S. shortii ‘Solar Cascade’ (USFWS 2017).
- Continue searches for new occurrences in the Blue Licks area, especially near known buffalo traces (USFWS, 2007).
- Conduct searches for new occurrences in riparian outcrop habitats of central Kentucky and southern Indiana or in upland areas of the region with suitable habitat (USFWS, 2007).
- Continue to investigate the life history and ecological requirements of the species (e.g., seedling establishment, seed and pollen dispersal distances) (USFWS, 2007).
- Continue to pursue permanent protection (through registry agreements, easements, or land purchases) of occurrences located on private property (USFWS, 2007).
- Expand the size of extant occurrences through habitat management and augmentation (USFWS, 2007).
- Establish viable occurrences in areas within the historical range that have suitable habitat, especially the Blue Licks Area of Fleming, Nicholas, and Robertson counties; develop criteria for establishing experimental populations in Kentucky (USFWS, 2007).
- Acquire potentially suitable but currently unoccupied habitat for the species where the species can be introduced and managed (USFWS, 2007).
- Continue implementation of management actions for permanently protected occurrences; develop a management strategy for the Indiana occurrence (USFWS, 2007).
- Revise the recovery plan (USFWS, 2007).

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES Recovery Activities • Continue to pursue permanent protection (through registry agreements, easements, or land purchases) of occurrences under private ownership • Expand the size of extant occurrences through habitat management and augmentation • Establish viable occurrences in areas within the historical range that have suitable habitat, especially the Blue Licks area of Fleming, Nicholas, and Robertson counties, Kentucky, and the Falls of the Ohio area in Clark and Floyd counties, Indiana, and Jefferson County, Kentucky. • Develop criteria for establishing experimental populations in Kentucky • Acquire potentially suitable but currently unoccupied habitat for the species where the species can be introduced and managed • Continue implementation of management actions for permanently protected occurrences; work with Indiana DNR and the Indiana ES Field Office to develop a management strategy for the Indiana occurrence • Revise the recovery plan Monitoring and Research Activities • Continue searches for new occurrences in the Blue Licks area, especially near known buffalo traces • Conduct searches for new occurrences in riparian outcrop habitats of central Kentucky and southern Indiana or in upland areas of the region with suitable habitat • Continue to investigate the life history and ecological requirements of the species (e.g., seedling establishment, seed, and pollen dispersal distances) • Study the species’ population genetics (USFWS, 2023)

# SPECIES ACCOUNT: *Spigelia gentianoides* (Gentian pinkroot)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 12/26/1990; Southeast Region (R4)

**Physical Description**

This small perennial herbaceous species possesses a single, erect, sharply ridged stem 10-30 centimeters (cm) (3.9-11.8 inches (in.)) long. The leaves are opposite, sessile, and in pairs at right angles to the next set of leaves. The leaves are largest at the top of the stem, 3-5 cm long, with lower leaves smaller. Flowers are borne in a short, few-flowered, terminal, determinate cyme. The flower consists of a narrow corolla tube of about 2.5-5 cm long, with five triangular lobes, each 5-6 mm long. The corolla is pale to dark pink; slightly darker at the margins of the lobes for the var. gentianoides. The stamens are within the flower, and the pollen grains are deposited along the bristles of the style (secondary pollen presentation). At anthesis , the corolla lobes of var. gentianoides are partially open, occasionally fully reflexed; whereas the corolla lobes of var. alabamensis are always fully reflexed. The green sepals are 4-6 cm long. The fruit is a capsule with two conspicuous round lobes. Peak flowering season occurs between May and June, however, plants have been seen flowering as early as April and as late as October. In a greenhouse, individual flowers last 2 to 5 days before wilting. Most seeds can be collected in June or July. (USFWS, 2012)

**Taxonomy**

At the time the Recovery Plan was issued, the species was comprised of two varieties located in Jackson and Calhoun counties (Florida), and Geneva and Bibb counties (Alabama). Morphological and molecular studies reassessed the appropriate ranks of these varieties and elevated variety  alabamensis to species (USFWS 2018, Weakley et al. 2011). Consequently, Spigelia gentianoides alabamensis is now a different species. (USFWS, 2019) Spigelia gentianoides  var. gentianoides was first collected in north Florida by Alvan Wentworth Chapman in 1837, probably from the west side of the Apalachicola River, in either Jackson or Calhoun counties. He identified the plant as S. floridana, later Alphonse de Candolle (1845) established the current epithet, S. gentianoides.  S. gentianoides alabamensis was first found in 1992 by James R. Allison (Georgia Natural Heritage Program, Georgia Department of Natural Resources) with Timothy Stevens, Jim Rodgers, and Debbie Rodgers while exploring the Little Cahaba River in Bibb County, Alabama. (USFWS, 2012)

**Historical Range**

Var. gentianoides:  Washington, Calhoun, and Jackson counties in Florida, and Geneva County in Alabama. Var. alabamensis:  Bibb County, Alabama. (USFWS, 2012)

**Current Range**

Spigelia gentianoides var. gentianoides is present in Washington, Calhoun, and Jackson counties in Florida, and Geneva County in Alabama. Spigelia gentianoides var. alabamensis is present in Bibb County, Alabama. (USFWS, 2019)

**Critical Habitat Designated**

No;

*Life History*

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Abiotic, Biotic, Self-pollination

**Breeding Season**

Adult: Peak flowering season occurs between May and June; However, plants have been seen flowering as early as April and as late as October. (USFWS, 2018)

**Other Reproductive Information**

Adult: Spigelia gentianoides can be propagated vegetatively and from seeds. Affolter (2005) successfully propagated S. alabamensis: by transplanting entire plants from the field to well drained potting mix; from stem cuttings, and by germinating seeds using cold stratification (2°C) or gibberellic acid (500-1000 ppm) treatments. Eight weeks of cold stratification provided excellent germination rates. (USFWS, 2018)

**Reproduction Narrative**

Adult: Secondary pollen presentation, a mechanism presenting the pollen on a structure other than the anther, appears to be present in S. gentianoides (Negrón-Ortiz, 2007, pers. observ.) and S. alabamensis; pollen was observed in the short bristles of the style. At the Geneva SF population, small Halictidae bees (sweat bees) were observed entering and exiting the flower of the S. gentianoides. (USFWS, 2018)

**Habitat Type**

Adult: Terrestrial (USFWS, 2012)

**Habitat Vegetation or Surface Water Classification**

Adult: well drained upland pinelands (var. gentianoides); glades (var. alabamensis) (USFWS, 2012)

**Dependencies on Specific Environmental Elements**

Adult: Fire-dependent ecosystems (USFWS, 2012)

**Spatial Arrangements of the Population**

Adult: Solitary individual or in small clumps (USFWS, 2012)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2012)

**Habitat Narrative**

Adult: Spigelia alabamensis is found in glades (open, almost treeless areas within woodland) that have developed over an ancient rock formation known as Ketona Dolomite. The Ketona formation contains a pure form of dolomite, crystalline in texture with only about 2% of siliceous impurities (Garland 2008). The glades vary in size from about 0.1 to 5 hectares with soil high in magnesium and calcium, low in phosphorus and potassium, and a pH ranging from 7.4 to 7.6 (Grossman et al. 1994). The topography varies from flat to sometimes very strongly sloping.

There are patches of exposed rock and thin-soiled areas dominated by grasses and other herbaceous vegetation. The plants in these glades are exposed to extreme heat and drought. At these sites, plants are quite abundant, and mainly found in small clumps adjacent to rocks. (USFWS, 2018)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: The mechanism of seed dispersal is unknown, but the fruit does not appear to be adapted for long-distance dispersal (USFWS, 2009).

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2018)

**Number of Populations:**

7 (USFWS, 2023)

**Population Size:**

Var. gentianoides: ~3,900 individuals; var. alabamensis: unknown ("seems to be abundant") (USFWS, 2023)

**Additional Population-level Information:**

Very narrow distribution, low population density. (USFWS, 2018)

**Population Narrative:**

Spigelia gentianoides var. gentianoides is currently restricted to seven extant sites within four counties west of the Apalachicola River: Calhoun, Jackson, and Washington counties in Florida, and Geneva County in Alabama. These sites support about 3,900 plants. The species was originally recorded from nine sites but two sites are considered extirpated. Of the seven extant sites, two new were noted in 2013. Spigelia alabamensis (S. gentianoides var. alabamensis, sensu Gould 1996) is restricted to the Ketona Dolomite formation and glades of Bibb County, AL. This species seems to be abundant but the current number of individuals at these glades is unknown; therefore, population trends are also unknown for S. alabamensis. Some of the 17 glades where this species is found are owned and protected by TNC. (USFWS, 2018). Currently, it is restricted to seven extant locations within four counties west of the Apalachicola River: Calhoun, Jackson, and Washington counties in Florida, and Geneva County in Alabama (Fig. 1, Table 1). As of 2018, these sites supported about 3,900 plants. The species was originally recorded from nine locations, but two are considered extirpated (Fig. 1, Service 2012). Of the seven extant locations, two new were noted in 2013 (FNAI 2017). The extant locations are located on both public and private lands in fire-dependent longleaf pine-wiregrass and pine-oak-hickory ecosystems (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Habitat loss or modification (USFWS, 2018)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Conversion of much of the upland forest land in the four counties to pulpwood plantations (clearcutting, mechanical site preparation, and pine plantations) has possibly extirpated other populations. Clearcutting and/or selective thinning are of concern since typical silviculture operations often result in soil disturbance and compaction. In particular, site preparation practices resulting in soil disturbance, change in canopy cover from tree harvest, and change in fire frequency and seasonality are of concern. Land conversion coupled with disruption of pre-historical and historical fire regimes of the longleaf pine-wiregrass ecosystem is responsible for the rapid decline of the ecosystem where S. gentianoides is found. Several studies have shown that frequent prescribed fire regimes are important for maintenance of longleaf pine-wiregrass ecosystem (Hiers et al. 2007). Prescribed burnings at 3 – 5 year intervals seem to maintain optimal S. gentianoides populations. However, areas at Apalachee WMA are on a 2-year fire rotation where the largest population of S. gentianoides appears to be stable (A. Jenkins, FNAI, 8/15/2018, pers. comm.). However, it is unknown 1) if frequent fires is detrimental to recruitment, and 2) the implications of fire seasonality to S. gentianoides survival. Habitats converted to pine plantation, and managed without fire have created a shaded canopy. In addition, pine plantation management induces severe soil disturbance. According to Kral (1983), S. gentianoides would not survive the mechanical site preparation used in pine monoculture. This observation seems accurate due to the fragile nature of these plants, but the population located at the Spigelia Preserve seems to have survived, at least over the short term, after cutting and planting. Nevertheless, the population exhibited a decline immediately after the last timber harvest. Similarly, the population in Jackson Co. on land owned by Guy Anglin emerged in a former pine plantation. Urban development also threaten S. gentianoides. Conversion of much of forest land to residential development has possibly extirpated many populations. More than a third of Florida's land is projected to be developed by 2070 along with a growth of about 33.7 million residents–almost 15 million more people than in 2010 (University of Florida GeoPlan Center 2017). Spigelia alabamensis is restricted to one county in northern Alabama. It is found in 17 glades, and TNC owns and protects about a dozen larger glades and some smaller glades. Populations on private property are threatened by future development for home-sites, agriculture, logging of associated hardwoods, recreational facilities, or other purposes. (USFWS, 2018)

**Stressor:** Disease or Predation (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Neither diseases nor predation are currently known to be major threats to S. gentianoides or S. alabamensis. However, minor herbivore damage was noted at Three Rivers SRA and Geneva SF (B. Chowdhury, AU, 6/11/2018, pers. comm.) populations. (USFWS, 2018)

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Endangered Species Act (Act) of 1973, as amended prohibits the removal of federally listed threatened and endangered plants or the malicious damage of such plants on areas under federal jurisdiction, or the destruction of endangered plants on non-federal areas in

violation of state law or regulations or in the course of any violation of a state criminal trespass law. However, the Act does not provide protection for plants on non-federal lands unless it is in violation of state law. In Florida. S. gentianoides is listed as endangered under the Preservation of Native Plant Flora of Florida Act (PNPFF Act) (Rule: 5B-40.0055, Section 581.185-187, Florida Statutes; https://www.flrules.org/gateway/RuleNo.asp?ID=5B-40.0055). The PNPFF Act addresses the protection of endangered, threatened, or "commercially exploited" plants (http://www.sfrc.ufl.edu/Extension/florida_forestry_information/planning_and_assistance/threatened_and_endangered_species.html). The removal of protected plants from a property, whether for transplant, sale, or any other purpose, requires both the written permission of the landowner and a permit from the Florida Department of Agriculture and Consumer Services. In Alabama, the Alabama State Constitution provided the necessary authority to add plants to Alabama's section 6 cooperative agreement. Department of Conservation and Natural Resources has a policy to protect, conserve and increase the wildlife of the state [Ala. Code 9-2-2 (1)], but provides little direction as to how this is to be accomplished. While the state's Natural Heritage Program maintains lists of non-game species considered endangered, threatened, of special concern or poorly known, it does not apply penalties for taking listed species or for altering their habitats. The Nongame Wildlife Program, which was started in 1984, helps administer endangered and threatened species projects on federally and state-listed species, and also issues scientific collecting permits to enable a wide range of projects and collect the data for fishes, amphibians, reptiles, birds, and mammals (USFWS, 2018)

**Stressor:** Non-native plant interactions (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Currently, non-indigenous plants within or near extant populations of S. gentianoides do not pose a threat. However, Lygodium japonicum (Thunb. ex Murr.) Sw. (Japanese climbing fern) and Lonicera japonica Thunb. (Japanese honeysuckle) have been found in the vicinity of S. gentianoides, and both are becoming problematic in areas of the Southeast. (USFWS, 2018)

***Recovery***

**Reclassification Criteria:**
Downlisting of S. gentianoides from endangered to threatened status will be considered when (Criterion 5 was removed per USFWS 2019): (USFWS, 2012; USFWS, 2019)

1. Extant populations and newly discovered sites are identified and mapped (USFWS, 2012; USFWS, 2019).

2. Inventories (i.e., the total number of individuals, number of flowering vs. non-flowering plants, presence of pollinators, and whether seedling recruitment is occurring) have been conducted across the species' historic sites and/or on new locations; (USFWS, 2012)

3. Monitoring programs and management protocols on selected populations (e.g., largest populations) are established for 15 years to track threats to the species and its habitat (e.g., control exotic species, minimize site disturbance, urban development); (USFWS, 2012)

4. For var. alabamensis: the extant populations (including subpopulations at the Ketona Glades, Bibb Co., Alabama) located on public land are stable. (USFWS, 2012)

6. Research on key aspects related to demography (e.g., density, effect of fire on seedling establishment), reproductive biology, and seed ecology is accomplished (USFWS, 2012)

7. Viable germplasm representing > 50% of the populations for each variety is maintained in ex-situ. (USFWS, 2012)

Var. gentianoides: (1) sizes of populations in the Apalachee WMA, Three Rivers State Park, Calhoun Spigelia Preserve in Florida and the Geneva State Forest in Alabama are increased via prescribed burns until plant numbers are stabilized over a period of 15 years; (2) at least one new population is found, and; (3) at least one population is re-established within the historic range, specifically at sites where the plants are currently known to be extirpated. (USFWS, 2012)

Var. alabamensis: (1) 50 % the Bibb Co. glades known to support the variety on private land are protected through conservation agreements, easements, and/or land acquisition. (USFWS, 2012)

Recovery Priority Number: 2

**Delisting Criteria:**
The following Delisting Criteria are applicable to var. gentianoides: (USFWS, 2019)

1. Existing core populations [Apalachee WMA, TNC Spigelia Preserve, Three Rivers SRA, Rock Hill TNC Preserve, and Geneva SF] are restored and properly managed, and monitoring demonstrates that the populations are stable or increasing over multiple prescribed burn cycles, evidenced by a type of natural recruitment and/or multiple size-classes (addresses Factors A, D, and E). (USFWS, 2019)

2. At least five (5) new populations are discovered or established within the historic range of the species on lands protected by a conservation mechanism. These populations should exhibit stable or increasing trends over multiple prescribed burn cycles, evidenced by a type of natural recruitment and/or multiple size-classes (addresses Factors A and E). (USFWS, 2019)

3. Threats to S. gentianoides and its habitat (e.g., exotic species, site disturbance, urban development, hurricanes) have been managed and reduced to ensure the persistence of S. gentianoides into the foreseeable future (addresses Factors A, D, and E). (USFWS, 2019)

Delisting criteria for var. alabamensis have not been developed. (USFWS, 2012)

**Recovery Actions:**
- 1. Protect, manage, and secure existing populations and habitat. The distribution of Spigelia gentianoides is limited to a few areas in Northwest Florida extending into central Alabama (Fig. 2), thus it is important to secure and stabilize current and any newly discovered populations to prevent further decline of this plant. (USFWS, 2012).
- 2. Conduct surveys/inventories. Inventotory of current and new populations; field surveys and species distribution modeling to determine survey sites. (USFWS, 2012).

- 3. Establish new occurrences within the historic range of var. gentianoides, specifically in the sites where the plants are known to be extirpated (USFWS, 2012).
- 4. Maintain the species ex-situ in a protected facility. Ex-situ populations will serve as an important component for storage of germplasm and reintroducing S. gentianoides populations within the species range. (USFWS, 2012).
- 5. Conduct long-term monitoring and research; establish and implement a long-term monitoring program on selected sites, to include population biology/demographic studies and phenological studies. Conduct research into reproduction, pollination ecology, and breeding systems. Conduct reserach on seed bank, germination, and seedling survival. Conduct taxonomic and genetic studies. (USFWS, 2012)
- 6. Outreach: Develop and distribute information to the general public about S. gentianoides, how to protect and manage it for its recovery, and how lands can be managed to benefit the plant along with meeting landowner needs. Promote the implementation of the recovery actions via private landowners, academia, and public agencies. (USFWS, 2012)
- 7. Review and track recovery progress. (USFWS, 2012)
- Recommended Action from 2018 5-Year Review: Establish protection and management agreements with landowners. (USFWS, 2018)
- Recommended Action from 2018 5-Year Review: Conduct surveys/inventories on each known population. For each extant population, the following data should be collected once a year: the total number of individuals, number of flowering vs. non-flowering plants, presence of visitors to the flowers, and whether seedling recruitment is occurring. (USFWS, 2018)
- Conduct a long-term study using populations distributed throughout the species' historical range Recommended Action from 2018 5-Year Review: for 10 years to document both distribution and abundance changes. Observations of flowering and fruiting are important and should be integrated with variables such as plant size and seedling data. Since gentian pinkroot occurs in fire prone habitats, the effect of this disturbance (including winter vs. growing season prescribed fire, fire frequency, intensity, duration, and timing) on survival and fecundity should be also monitored. Such studies should be conducted on large populations. Plants should be monitored several times during a 12-month cycle (e.g., flowering and fruiting seasons) the first year, then annually or biannually over an extended number of years. (USFWS, 2018)
- Recommended Action from 2018 5-Year Review: Investigate if there is a soil seed bank persistence of S. gentianoides seeds throughout the species' geographic range. (USFWS, 2018)
- Recommended Action from 2018 5-Year Review: Conduct germination studies and investigate whether seedling recruitment is occurring. (USFWS, 2018)
- Recommended Action from 2018 5-Year Review: Monitoring and managing for invasive species: Frequent inventories or surveys of the Florida populations for invasive plant species should be established, which will help with the early detection and eradication of small patches of exotic invasive plants within the sites. This is an ongoing action for the Three Rivers SRA population conducted by the Park staff. (USFWS, 2018)
- Recommended Action from 2018 5-Year Review: Conduct surveys/inventories on potentially new sites in Northern Florida and Alabama. This action can include the use of aerial photographs and species distribution n models to determine potential sites, with subsequent field inventory of the site using a consistent, statistically valid, repeatable inventory method. If new populations are discovered, protection should be sought. (USFWS,

2018)

- Recommended Action from 2018 5-Year Review: Reintroduce plants within the historic range, specifically in the sites where the plants have been extirpated. (USFWS, 2018)
- Recommended Action from 2018 5-Year Review: Conduct reproductive studies Since site disturbance occurs within the populations of S. gentianoides, it may pose problems to pollinator diversity (Kevan and Phillips 2001). Therefore, it is important to determine which insects are pollinators, and understand the value and pollinators' requirements so that actions can be taken to incorporate specific management or protection plans. Knowledge of the type of mating systems is essential for conservation of rare plant taxa because mating systems affect genetic diversity within and among populations (Navarro and Guitian 2002). Therefore, floral morphological analysis and experimental hand-pollinations are all recommended. (USFWS, 2018)
- Recommended Action from 2019 Amended Recovery Plan: Conduct research on key aspects related to (1) demography (e.g., density, effect of fire on seedling establishment), (2) reproductive biology, (3) levels and distribution of genetic diversity, (4) seed ecology to facilitate better understanding of this species' biology and potential impacts of threats such as low density, and changes in fire regime and (5) effects of catastrophic events such as hurricanes on populations and habitat of S. gentianoides (addresses Factor E, and resiliency, and inform representation). (USFWS, 2019)
- Recommended Action from 2019 Amended Recovery Plan: The effects of forest management practices (e.g., logging) on long-term persistence of S. gentianoides is assessed and a standardized monitoring technique is in place (addresses Factor D and resiliency). (USFWS, 2019)
- Recommended Action from 2019 Amended Recovery Plan: Inventories (i.e., the total number of individuals, number of flowering vs. non-flowering plants, presence of pollinators, and whether seedling recruitment is occurring) have been conducted across the species' historic sites and/or on new locations where appropriate habitat exists (addresses Factors A and D). (USFWS, 2019)
- Recommended Action from 2019 Amended Recovery Plan: A living collection of viable germplasm, collected from genetically distinct sites, is maintained in protected facilities (ex-situ) for research, recovery, and public outreach (addresses Factors A and E, and representation). (USFWS, 2019)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIVITIES 1. Establish protection and management agreements with landowners. 2. Conduct surveys/inventories on each known population. For each extant population, the following data should be collected once a year: the total number of individuals, number of flowering vs. non-flowering plants, presence of visitors to the flowers, and whether seedling recruitment is occurring. 3. Conduct a long-term study using populations distributed throughout the species' historical range for 10 years to document both distribution and abundance changes. Observations of flowering and fruiting are important and should be integrated with variables such as plant size and seedling data. Since gentian pinkroot occurs in fire prone habitats, the effect of this disturbance (including winter vs. growing season prescribed fire, fire frequency, intensity, duration, and timing) on survival and fecundity should be also monitored. Such studies should be conducted on large populations. Plants should be monitored several times during a 12-month cycle (e.g., flowering and fruiting seasons) the first year, then annually or biannually over an extended number of years. 4. Investigate if there is a soil seed bank persistence of seeds throughout the species' geographic range. 5. Conduct germination studies and investigate whether seedling recruitment is occurring. 6. Monitoring and managing for invasive species, Frequent inventories or surveys of the Florida populations for invasive plant species should be established, which will help with the early detection and eradication of small patches of exotic invasive plants within the sites. This is an ongoing action for the Three Rivers SRA population conducted by the Park staff. 7. Conduct surveys/inventories on potentially new sites in Northern Florida and other suitable habitats. This action can include the use of aerial photographs and species distribution models to determine potential sites, with subsequent field inventory of the site using a consistent, statistically valid, repeatable inventory method. If new populations are discovered, protection should be sought. 8. Reintroduce plants within the historic range, specifically in the sites where the plants have been extirpated. 9. Determine the long-term impacts of hurricanes and salvage logging on S. gentianoides populations. 10. Assess impacts of a reduced fire interval (2-year compared to longer 3- to 5-year interval) on populations of S. gentianoides including seed bank, seed germination, and recruitment. Specifically, to assess populations at Apalachee WMA and Geneva SF. (USFWS, 2023)

# SPECIES ACCOUNT: *Spiraea virginiana* (Virginia spiraea)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 06/15/1990; Northeast Region (Region 5) (USFWS, 2015)

**Physical Description**

Colonial shrub up to 1.2 m high; largest stems 3-4 cm in diameter, dark gray, often arching or nearly horizontal; young stems upright, greenish-yellow to reddish-brown; branching often profuse in older specimens; leaves alternate, very variable in shape, size and degree of serration, generally mucronate-tipped, glaucous beneath, simply and singly serrate to entire, ranging from ovate to lanceolate; flowers 6 mm wide, bright to creamy white in tightly packed corymbs; corymbs variable in size, ranging from 5-22 cm, wide; follicles small, 2.0 mm long, 1.5 mm wide; seeds rarely produced. Fruit is a follicle. Flowering in June and July. Fruiting in August and September. (NatureServe, 2015)

**Taxonomy**

The two varieties sometimes recognized (var. serrulata and var. virginiana) are not maintained by Kartesz (1994 and 1999), nor are they recognized by any Heritage Program in the species' range, or by the U.S. Fish and Wildlife Service. Spiraea virginiana is distinguished from most other Spiraea by its creamy white flowers in corymbs, and its leaves which have an acute apex (Weakley 2004). (NatureServe, 2015)

**Historical Range**

Known historically in Pennsylvania. (NatureServe, 2015)

**Current Range**

Pennsylvania and Ohio south to Georgia and Tennessee. Records for Pennsylvania are historic. It occurs on streams that drain into the Ohio River and primarily within the Appalachian (Cumberland) Plateau and Blue Ridge physiographic regions, with at least one outlier in the Bluegrass Region of Kentucky. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Asexual (vegetative) and sexual (NatureServe, 2015)

**Breeding Season**

Adult: June to July (NatureServe, 2015)

**Key Resources Needed for Breeding**

Adult: The species’ flowers are visited by a host of insects, most commonly beetles. Identified insects, which are common and widespread, include flower long—horn beetles, a flower beetle, and a soldier beetle (R.L. Hoffman pers. comm.). (USFWS, 1992)

**Reproduction Narrative**

Adult: Although this element may flower profusely, it is clonal and almost exclusively reproduces vegetatively. Sexual reproduction will occur when genets are placed in close proximity but is rare in the native habitat (D.W. Ogle, pers. comm., 1996). Flowers bloom in June and July. The species' flowers are visited by a host of insects, most commonly beetles. Identified insects, which are common and widespread, include flower long—horn beetles, a flower beetle, and a soldier beetle (R.L. Hoffman pers. comm.). (USFWS, 1992)

**Habitat Type**

Adult: Riverine, Palustrine, and terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: High gradient, herbaceous wetland, riparian, scrub-scrub wetland, bare rock/talus/scree (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Found at elevations between 850 to 2,400 feet (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Colonies (USFWS, 1992)

**Environmental Specificity**

Adult: Very narrow. Specialist or community with key requirements scarce. (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: High (USFWS, 1992)

**Habitat Narrative**

Adult: Spiraea virginiana is found along the banks of high gradient sections of second and third order streams, or on meander scrolls and point bars, natural levees, and other braided features of lower reaches (often near the stream mouth). Leopold et al. (1964) theorized that such areas are slow—changing, dependable aspects of the equilibrium in river systems. If this is true, the S. virginiana populations located there may be relatively stable; otherwise, they may be highly susceptible to extirpation. The habitat of this species is in oft-disturbed early successional areas, and its associates are determined by availability to recolonize after disturbance. A rangewide list of associates would run to several hundred, usually disturbance—adapted, species. A list of these species compiled from a sample of element occurrence records is found in Rawinski (1988) (USFWS, 1992).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seeds seem to be rarely produced. The seeds are very small (> 2 mm long x ca. 0.5 mm wide) and could be dispersed by wind or water. (USFWS, 1992)

***Population Information and Trends***

**Population Trends:**

Short-term trends indicate a decline of 10 to 30% (NatureServe, 2015)

**Adaptability:**

Moderate (USFWS, 1992)

**Population Narrative:**

The current range of Virginia spiraea is generally unchanged since the 1992 recovery plan, occurring in 7 states (Georgia, Kentucky, North Carolina, Ohio, Tennessee, Virginia, West Virginia) within the Ohio and Tennessee River basins; the species remains extirpated from Pennsylvania and Alabama. One EO with historic documentation has been rediscovered (Cheoah River, North Carolina) and 38 additional EOs (32 of them extant as of 2019) and 74+ sub-EOs have been discovered due to searches of rivers/streams with suitable habitat in known drainages, surveys of rivers/streams with known occurrences, and incidental finds when surveying for other species. However, 11 EOs became presumed extirpated (F or X rank) since 1992 when the species' recovery plan was completed. (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Impoundments (USFWS, 1992)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Impoundments are a double threat to the species: clones are not only destroyed by rising water, but the impoundment may also serve as a "death trap" for propagules washed down-stream. The probability of being washed into a suitable habitat may decrease from slim to none, thus breaking any possible continuity in downstream motility. (USFWS, 1992)

**Stressor:** Road-building and water release regulation (USFWS, 1992)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A site on the Cheoah River in Graham County, North Carolina was probably destroyed by road-building and water release regulation (erosion control) below a dam. (USFWS, 1992)

**Stressor:** Industry development (USFWS, 1992)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Areas along Hominy Creek in Buncombe County, North Carolina have been extensively developed by industries. (USFWS, 1992)

**Stressor:** Watershed management (USFWS, 1992)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Cumulative and more subtle problems could occur from lack of watershed management and uncontrolled development of rivers. Bowles and Apfelbaum (1989) illustrate the effects of stochastic environmental events on another riverine species and graphically describe necessary conditions for survival. “Extinction possibility is increased by low disturbance, which favors plant succession and competition, or by high disturbance, which exceeds levels of ... population maintenance.” (USFWS, 1992)

**Stressor:** Reproduction and genetics (USFWS, 1992)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** “Weak points” in the species’ biology may be a threat to its survival. Paucity of sexual reproduction dramatically decreases the intrinsic rate of reproduction and the dispersal potential of the plant’s small seeds. Genetic “fixation” of the clonal material may have adverse effects on the future breeding potential of the species, and the small number of genetically different individuals may constitute a threat. (USFWS, 1992)

**Stressor:** Insect predation (USFWS, 1992)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Various insect pests have been seen on virginiana plants. Aphids of several types cluster at the rapidly growing shoot tips. Most of these are tended by ants, which move the aphids from place to place on the same plant, or from plant to plant. Aphids are most common on plants growing away from the water’s edge. On the beneficial side, lady bug beetles are regularly seen on these same stem tips. In another case, K. Walton (pers. comm.) identified a copper underwing moth caterpillar, a common and widespread species, that was doing damage in one population. However, for the most part, there is little evidence of anything other than local damage by insect pests. (USFWS, 1992)

**Stressor:** Introduced plants (USFWS, 1992)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Introduced alien plant species (e.g., Polygonatum cuspidatum, Liqustrum sinense, Spiraea japonica, and Rosa multiflora) are another, almost uncontrollable, detriment. (USFWS, 1992)

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

Recovery Priority Number: 8

**Delisting Criteria:**
1. Three stable populations are permanently protected in each drainage where populations are currently known. (USFWS, 1992)

2. Stable populations are established on protected sites in each drainage where documented vouchers have been collected. (USFWS, 1992)

3. Potential habitat in the states with present or past collections has been searched for additional populations. (USFWS, 1992)

4. Representatives of each genotype are cultivated in a permanent collection. (USFWS, 1992)

**Recovery Actions:**

- Protect existing populations and essential habitat through landowner cooperation and land acquisition. (USFWS, 1992)
- Search for additional populations. (USFWS, 1992)
- Conduct site-specific habitat manipulation as needed to maintain populations. (USFWS, 1992)
- Distinguish between N and n individuals and identify genetically different populations. (USFWS, 1992)
- Maintain cultivated sources for reproduction studies as well as conservation and reintroduction activities. (USFWS, 1992)
- Study the species' environmental tolerances and habitat characteristics. (USFWS, 1992)
- Re-establish populations within the historic range of the species. (USFWS, 1992)
- Inform land owners and managers about the plant's recovery needs. (USFWS, 1992)
- Monitor populations and evaluate effectiveness of recovery efforts. (USFWS, 1992)
- Protect existing populations and essential habitat. (USFWS, 1992)
- Conduct rangewide searches in areas of suitable habitat for additional populations. (USFWS, 1992)
- Conduct site-specific manipulation to maintain existing populations. (USFWS, 1992)
- Distinguish between N and n individuals. (USFWS, 1992)
- Maintain representative material from each known genotype in permanent cultivation. (USFWS, 1992)
- Investigate the species environmental tolerances and habitat characteristics. (USFWS, 1992)
- As appropriate, reintroduce S. virginiana in additional drainage systems within the species' historical range. (USFWS, 1992)
- Develop an information packet for landowners and land managers. (USFWS, 1992)
- Evaluate the effectiveness of protection and management programs and redirect efforts as necessary. (USFWS, 1992)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Clarify recovery criteria 1 and 2 to support consistent evaluation and to reflect current information. Specifically, both recovery criteria should be clarified in terms of population assessment measures (e.g., what factors determine a "stable" population) and definition of "population." In addition, the definition of "drainage system" should be clarified as it relates to this species' recovery and definition of a population. Recommendations for specific recovery actions and priority number (1-3, based on priority number definitions in the Virginia spiraea recovery plan [Service 1992]): 1. Continue genetic analysis of Virginia spiraea across its range and within collections to determine genotypes and ploidy numbers, which will help guide potential propagation efforts and determine which localities/genotypes should be added to cultivated collections to provide genetic representation [Priority 1]. 2. Develop specific guidance on the treatment of invasive species that threaten this species and recommendations for habitat management to increase viability of the populations, in particular EOs with C or D ranks. Include invasive species specialists and encourage practical application of invasive species and habitat management in populations across the range [Priority 1]. 3. If deemed necessary based on the genetic analysis, develop a rangewide propagation and reintroduction plan [Priority 2]. 4. Coordinate with natural resource agencies to complete rangewide review and revision, if needed, of the Virginia spiraea species distribution model to help identify potential suitable habitat [Priority 2]. 5. Conduct comprehensive surveys of potential habitat in streams/rivers with known occurrences and no known occurrences, but identified in a species distribution model, to find new populations. Efforts should focus within the Blue Ridge and Appalachian Plateau physiographic provinces, where almost all EOs occur [Priority 2]. 6. Conduct surveys of extant EOs that have not been surveyed for more than 10 years to verify presence and update their EO ranks [Priority 2]. 7. Determine if there is suitable habitat in areas where the species has been historically documented or extirpated and search these areas. Some areas that should receive priority ranking for survey work include, but are not limited to: Cypress Creek, AL; Youghiogheny River, MD and PA; Little River, TN; Hominy Creek, NC; Monongahela River, WV; and New River, WV [Priority 3]. 8. Coordinate with natural resources agencies and Service Field Offices to develop methods and resolve nomenclature for accurately counting/measuring individual plants, population size, and populations to provide consistency and allow objective assessment of populations. Also coordinate to define appropriate ecological units (e.g., HUC units) to assist with organizing populations as it relates to species' recovery [Priority 3]. 9. Coordinate with natural resource agencies and NatureServe to utilize consistent definitions of EO and EO rank for Virginia spiraea across the range to allow analysis of population trends and consistent assessment of status [Priority 3]. 10. Develop educational materials for local government and public use aimed at increasing public awareness of the species, in particular in areas where development and recreational activities may impact Virginia spiraea [Priority 3]. (USFWS, 2021)

# SPECIES ACCOUNT: *Streptanthus albidus ssp. albidus* (Metcalf Canyon jewelflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

An annual herb, up to 1+ m tall. Basal leaves are narrow, coarsly toothed, the upper leaves not toothed and becoming linear. Flowers (April-July) are borne in leafless terminal clusters; they have have white to whitish-green sepals and white petals with purple-brown veins. The erect, flattened seed pods are 3-8 cm long. (NatureServe, 2015)

**Taxonomy**

Streptanthus albidus ssp. albidus (Metcalf Canyon jewelfiower) was first collected in 1887 by Volney Rattan, a botany teacher and author, from hillsides a few miles south of San Jose (Greene 1887). Edward Greene described Streptanthus albidus ssp. albidus in 1887 (Greene 1887); later he redefined the limits of Euclisia, formerly a subgenus of Streptanthus, treating it as a genus in its own right (Greene 1904). Streptanthus albidus ssp. albidus, as a member of the Euclisia group, was included in this change. Jepson (1925) returned Euclisia to subsection status, and later authors followed his treatment. Jepson (1925) also treated Streptanthus albidus ssp. albidus as a subspecies of Streptanthus glandulosus. Kruckeberg published a revision of the Streptanthus glandulosus complex in which he recognized the close relationships among Streptanthus glandulosus, Streptanthus albidus, and Streptanthus niger (Kruckeberg 1958). In this paper, he notes that the “sharp genetic discontinuity between Streptanthus albidus and all other populations, coupled with the morphological distinctness and regional restriction of Streptanthus albidus warrant the restoration of this Greeneian species.” He recognized two subspecies: Streptanthus albidus ssp. albidus and Streptanthus albidus ssp. Perarnoenus (Kruckeberg 1958). Recent research affirms the distinctiveness of Streptanthus albidus ssp. albidus. Streptanthus albidus ssp. peramoenus, and Streptanthus niger (M. Mayer. in litt., 1998) (USFWS, 1998).

**Current Range**

Santa Clara county, California. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Streptanthus albidus ssp. albidus flowers April to June (Kruckeberg 1977) (USFWS, 1998).

**Reproduction Narrative**

Adult: Streptanthus albidus ssp. albidus flowers April to June (Kruckeberg 1977). No detailed data on its reproductive biology or demography are available. Nine populations totaling approximately 20,000 to 25,000 plants have been recorded (McCarten I992b) (USFWS, 1998).

**Habitat Type**

Adult: Outcrops

**Spatial Arrangements of the Population**

Adult: clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits serpentine outcrops with shallow soils (NatureServe, 2015). High ecological integrity and site fidelity as well as low tolerance ranges are inferred based on this species restricted habitat requirements and geography.

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

9 (USFWS, 2023)

**Population Size:**

Highly variable (USFWS, 2023)

**Population Narrative:**

Known from 22 total occurrences, but only nine presumed extant (NatureServe, 2015). When we listed the subspecies in 1995, we estimated there were a total of 20,000 to 25,000 plants, based on estimates by McCarten (1992, pp. 4–6) for 8 of the 9 populations recognized at that time (Service 1995, p. 6676). The majority of those plants (15,000) were in Occurrence 4 (McCarten 1992, p. 6), which has since been determined to consist of most-beautiful jewelflower rather than Metcalf Canyon jewelflower (Vondracek 2021, p. 1). When we published our last status review in 2013, additional population estimates were only available for four unspecified occurrences (Service 2013, p. 14). Three of those estimates were published in 1989 and one in 2006. The four occurrences were highly variable in abundance, with counts of 27, 40, 1,000, and 5,000 plants (due to a typographical error, we reported the last count as

4,000 rather than 5,000 in our last review, but still indicated the total count as 6,067 (Service 2013, p. 14)). Three of the counts (27, 1,000, and 5,000) appear to be for Occurrences 2, 12, and 4, respectively (Diversity Database 2009, pp. 1, 3, 8). It is unclear which occurrence the fourth count (for 40 plants) refers to (Diversity Database 2009, entire). As discussed above, Occurrence 4 (with 5,000 of the 6,067 total plants) actually consists of most-beautiful jewelflower (Vondracek 2021, p. 1), and so would no longer count towards total abundance. Currently, Occurrence 2 is the largest occurrence, both by area and by number of plants. It consists of several subpopulations within 0.25 miles of each other, both within Metcalf Canyon and extending about a mile north and half a mile south of the canyon, encompassing about 200 acres in all (Diversity Database 2022). Total number of plants in the occurrence varied, with upwards of 14,000 in 2013, over 250,000 in 2014, upwards of 10,000 in 2015, and 5,000-plus in 2016 (Diversity Database 2023, p. 1). Occurrence 12 had 710 plants in 2013, about 1,675 the following year, upwards of 1,000 in 2015, and about 300 in 2016 (Diversity Database 2023, p. 4). Occurrence 17 had about 75 plants in 2013, 730 the following year, about 500 in 2015, and about 1,000 in 2016. Occurrences 15 and 18, on the Silver Creek Preserve, have survey counts starting prior to our last status review and continuing for several years after, although the counts for both occurrences were often combined. Table 1 shows the combined counts for Silver Creek Preserve. Although we lack total abundance estimates for Metcalf Canyon jewelflower across its range, there is nothing to indicate it has decreased since our last status review. Counts from year to year in the same locations have been highly variable, making it difficult to discern trends. Seedbanks likely contribute to the high variability from year to year by allowing plants to sprout in good years from seed left over the course of several years (Niederer and Whittall 2017, p. 60). The length of time that seeds remain viable in a seedbank is unknown and would provide an appropriate subject for research (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Development (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** t the time of listing, there were 13 documented sites, 9 of which still harbored plants. Two occurrences were known from herbarium records only. One of the historical records was visited in 1990, but no plants were found. Strepanthus albidus ssp. albidus was last observed at the other historical site in 1895. One population consisting of approximately 9,000 plants, approximately 45 percent of all known plants, occurred on the proposed site of the Cerro Plata residential and golf course project (also known as Ranch on Silver Creek Development). Although no direct destruction of any plants were planned at the time of listing, it was thought that construction activities, human disturbance, and habitat fragementation would result in significant impacts to the population. There was a proposed Valley Christian School and South Valley Christian Church that would destroy 61 percent of the 2,700 plants occurring on the site. The remaining 7 populations were also threatened by impending or potential development. The Ranch on Silver Creek Development (Cerro Plata) has been constructed since the time of listing. Although all direct impacts to Strepanthus albidus ssp. albidus were avoided as described in the biological opinion (Service 2000), the populations within the 580 acre parcel are intermixed with residential homes, golf course, and facilities. Ten years of monitoring (2001-2010) of the preserved populations within the on-site Hassler Ranch Preserve show that the Plant Conservation Areas are still occupied by Strepanthus albidus ssp. albidus. The total area occupied

within the Plant Conservation Areas has increased slightly by 3.65 acres. The numbers of plants have drastically reduced from 75,000 plants in 1998 to an average of 11,266 plants over 10 years (2001-2010). This is a reduction of 85% percent of the baseline prior to construction of the Silver Creek Development. One location at Tulare Hill was covered by fill during construction of a housing development (CNDDB 2012). Three sites within the Metcalf Energy Center Ecological Preserve are proposed for reintroduction (Whittall 2011). The reintroduction plan includes monitoring and preparation of a management plan (USFWS, 2013).

**Stressor:** Predation (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Herbivory was observed on approximately 8 individuals of Streptanthus albidus ssp. albidus at the Metcalf Motorcycle County Park. The herbivory was likely due to invertebrate herbivores since aphids and Pierid caterpillars have been observed in the populations there previously (Whittall, 2011) (USFWS, 2013).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** In summary, the Endangered Species Act is the primary Federal law that provides protection for these species since their listing as endangered in 1995. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent its status under the Act. Therefore, we continue to believe other laws and regulations have limited ability to protect the species in absence of the Endangered Species Act (USFWS, 2013).

**Stressor:** Nitrogen deposition (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** A relatively recently identified threat is nitrogen deposition into grasslands from air pollution sources and the resultant increase in productivity of the soils has facilitated increased invasion of nonnative species (ICF 2012). The main effect for Santa Clara Valley dudleya and Metcalf Canyon jewelflower is their vulnerability to annual grass overgrowth. Nonnative annuals are much less dominant in serpentine areas, although increasing nitrogen deposition from air pollution has increased the productivity of serpentine soils and allowed a greater number of nonnatives to invade (Evens and San 2004; Harrison et al. 2003; Weiss 1999). Santa Clara Valley dudleya (Dudleya setchellii) lives on rock outcrops and is relatively immune from grass invasions except when extremely tall grasses smother small rock outcrops. The species persists on medium to large rock outcrops in ungrazed areas. Metcalf Canyon jewelflower can be a poor competitor against dense annual grasses, and some degree of grazing appears necessary to maintain populations (ICF 2012). Livestock grazing is an important management tool to combat increased invasive nonnative plants in serpentine grasslands due to atmospheric nitrogen deposition (Weiss 1999) (USFWS, 2013).

**Stressor:** Climate change (USFWS, 2013)

**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** ICF (2012) summarized the potential effects of climate change to serpentine plant species and its relationship to the proposed permitted activities during the Santa Clara Valley Habitat Plan's proposed 50 year permit span. Serpentine plant distribution is restricted to highly specialized and localized habitat requirements that include species-specific microclimate conditions coincident with serpentine soil occurrence. Restriction to serpentine soils limits species range and distribution to this soil type. Climate change could change microclimate conditions so that species can no longer persist within their current range. Increase in favorable microclimate conditions could lead to an expansion of distribution and increase in abundance, both in terms of number of populations and number of plants within each population. Change in timing or intensity of seasonal events could have an effect on pollinator reproductive and plant flowering periods leading to phonological mismatches. The Santa Clara Habitat Plan (ICF 2012) includes a conservation strategy reserve design to reduce species vulnerability and provides opportunities for species and natural communities to adapt in response to climate changes (USFWS, 2013)

**Stressor:** Grazing (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Although grazing is extremely useful for addressing threats from competition and nitrogen deposition, an incompatible grazing regime can also constitute a threat in its own right. A study of simulated grazing impacts on the closely related most-beautiful jewelflower found that jewelflowers can be clipped in half in early May with either no effect or a positive effect on growth and seed production, but that clipping close to the ground produces negative impacts (Weiss et al. 2007, pp. 7, 37). A comparison of grazed and ungrazed introductory plots on Tulare Hill (Occurrence 27) showed negative effects from grazing throughout the growing season, with the biggest impacts beginning in late April (Niederer and Whittall 2017, p. 34). This is the time when jewelflower plants start producing flowers and seeds and thereby become more attractive to cattle. As summer progresses jewelflowers are targeted even more by cattle, because they remain green and stand out against the drying grass (Niederer and Whittall 2017, p. 50). The reproductive stage of the Metcalf Canyon jewelflower lasts through November (Niederer and Whittall 2017, p. 34), so the largest threat from grazing is likely to occur from late April through November (USFWS, 2023).

**Stressor:** Climate change (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In our last status review we noted that climate change could have either positive or negative effects, depending on how it affects microclimate conditions in occupied serpentine areas (Service 2013, pp. 26–27). Microclimate conditions refer to the set of atmospheric conditions typical for a small area. We note here that climate change could also produce indirect impacts by increasing variation in weather conditions, thereby elevating the likelihood of atypical conditions such as droughts or unusually heavy precipitation (Ault 2014, pp. 7529, 7545; Williams et al. 2015, p. 6819; Berg and Hall 2015, pp. 6324, 6332). Either of these effects could lead to

negative impacts on Metcalf Canyon jewelflower, depending on grazing and topography at a given occurrence. High-precipitation years would tend to encourage growth of annual grasses, which would then compete with Metcalf Canyon jewelflower unless held in check by grazing or other methods (WRA 2019, p. 23). High precipitation could also cause landslides which could bury or undermine Metcalf Canyon jewelflower growing on steep slopes, particularly at roadcut occurrences such as 12, 26, and portions of Occurrence 2. Droughts would tend to restrict growth of competing nonnative grasses but could result in increased grazing damage if adequate forage elsewhere was unavailable during summer months. More serious droughts could also directly impact the ability of Metcalf Canyon jewelflowers to grow and reproduce, and any such droughts that lasted several years might tend to deplete the jewelflower seedbank at a given location (USFWS, 2023).

**Stressor:** Hybridization with most-beautiful jewelflower (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The southeastern end of the Metcalf Canyon jewelflower range meets and somewhat overlaps the northwestern end of the most-beautiful jewelflower range in an area southeast of Metcalf Canyon (Whittall et al. 2023, p. 50). Because the two jewelflowers can interbreed (ICF 2012, p. 7-69; Valley Habitat Agency 2020b, p. 34), there is a potential, that we have not previously considered, for one or more southern Metcalf Canyon jewelflower occurrences to be lost due to takeover of the areas by hybrids. It is also likely that the proposed Metcalf Canyon jewelflower occurrences in the CROSP are hybridized to some extent, which must be considered when deciding whether they constitute Metcalf Canyon jewelflower occurrences (see below). Hybridization could be occurring in three ways: (1) due to short flights of pollinating insects between plants of different subspecies that essentially occupy the same occurrence in areas of range overlap; (2) due to long-distance flights of pollinating insects between separate occurrences of each subspecies; and (3) by transport of seeds from occurrences of one subspecies to another via the coats or manure of cattle. This would be followed by cross pollination between the resulting plants growing in the occurrence (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
Secure and protect specified recovery areas. Occupied habitat along with adjacent unoccupied habitat and a 150-meter (500- foot) buffer at nine known sites. Management plan approved and implemented for recovery areas, including survival of the species as an objective. For all populations and any occupied or unoccupied habitat identified as essential to survival.

Recovery Priority Number: 3C

**Delisting Criteria:**
Secure and protect specified recovery areas. 18 populations representing entire historic range of the species.  from incompatible uses:

**Recovery Actions:**

- Population monitoring in specified recovery areas shows: Downlist: Stable or increasing for a period of 20 years that include the normal precipitation cycle (or longer if suggested by the

results of demographic monitoring). Delist: No decline after downlisting; if declining, determine cause and reverse trend.
- Preserve, protect, manage, and monitor Dudleya setchellii CNDDB occurrence number 43. Occurrence number 43 was found in the year 2005, subsequent to listing of the species and the Recovery Plan. The occurrence represents the most southwesterly extent of its current known range (USFWS, 2013).
- Confirm if the historic and current westernmost and southernmost occurrences for Streptanthus albidus ssp. albidus are valid. Perform additional surveys in suitable habitat around CNDDB number 6 and 21 to confirm if the range of the species is smaller than previously understood (USFWS, 2013).
- Conservation measures should include focus on preserving, monitoring, and managing pollinator fauna as it appears to be essential for any significant fruit set in Streptanthus albidus ssp. Albidus (USFWS, 2013).
- Streptanthus albidus ssp. albidus plant numbers can fluctuate drastically from year to year (Whittall 2011). Reliable methods should be developed to evaluate when a population should be considered as stable and viable. The methods should include ways to measure and evaluate natural and human influenced variables

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of the Metcalf Canyon jewelflower. 1. Research should be conducted into the length of time that Metcalf Canyon jewelflower seeds can remain viable in the soil. This would support estimates regarding the ability of a population to rebound from multiple years of poor conditions, and to maintain genetic diversity. 2. Work with the landowner of the Silver Creek Preserve (Occurrences 15 and 18) to establish and fund an endowment for long-term management of the habitat and ongoing monitoring of the jewelflower population. 3. Grazing should be considered as a management tool at all known occurrences to control invasive grasses. If grazing is not feasible, the extent of competition with non-native grasses in the area should be monitored so that the importance of, and options for, weed abatement can be considered. 5. Monitoring of both direct grazing impacts to jewelflower plants, and of residual dry matter (RDM) should be implemented at Occurrence 27 at Tulare Hill, as described in the 2021 annual monitoring report for the site (Weiss et al. 2021, pp. 26, 93). This will provide better information on how much grazing the site can support, and over what time periods, before it changes from beneficial to detrimental for the jewelflower. 6. Efforts should continue to develop tests (including genetic tests) allowing consistent and accurate differentiation of Metcalf Canyon jewelflowers, most-beautiful jewelflowers, and hybrids of the two. This will allow biologists to investigate the extent to which hybrids may be spreading through Metcalf Canyon jewelflower occurrences, particularly in the southern portion of the range. It will also allow biologists to confirm the Metcalf jewelflower occurrences tentatively identified in the CROSP. 7. Research should be conducted into the ease of transport and subsequent germination of Metcalf Canyon jewelflower and most-beautiful jewelflower seeds on the coats, or in the digestive tracts, of cattle. 8. Now that the reintroduction effort to establish Occurrence 27 at Tulare Hill appears successful, additional new populations should be created using the knowledge gained. For instance, seeding densities for such new populations should be high, and seeding efforts should be conducted over multiple years (Weiss et al 2021, p. 93). Provisions should also be taken to limit grazing impacts to the extent possible, such as by seeding in areas less accessible to cattle, or by establishing a grazing plan that applies adaptive management techniques to monitor post-April grazing impacts and adjust grazing limits accordingly. 9. The discovery of up to eight possible new populations in the CROSP (Niederer et al. 2017, p. 19) suggests there may be additional undiscovered natural populations within the subspecies' range. Additional surveys should be conducted to either establish or provisionally rule out their presence in currently unsurveyed areas, as well as to monitor the occurrences in the CROSP. Population numbers can occasionally drop to zero and then rebound from seeds, so a single negative survey would only rule out an area provisionally. 10. A final survey of the area in the general vicinity of Occurrence 19 at Communications Hill should be conducted, preferably early in the growing season, over at least two years spanning a wide range of precipitation levels, to rule out the possibility of any jewelflower plants persisting at or near the location. 11. The Recovery Priority Number for this subspecies is currently 3C. The "C" indicates a potential conflict with development or with other forms of economic activity (48 FR 4304). Although the Valley HCP removes development as a likely source of conflict, there may be other forms of economic activity such as grazing that remain in potential conflict at some occurrences. At this point, the potential for such conflicts remains unclear. We recommend reconsidering this issue in our next status review (USFWS, 2023).

# SPECIES ACCOUNT: *Streptanthus bracteatus* (Bracted twistflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened

**Physical Description**

Bracted twistflower (Streptanthus bracteatus) is a herbaceous annual plant of the Mustard Family (Brassicaceae) currently reported from five counties of south-central Texas. The seeds germinate in response to fall and winter rainfall, forming basal rosettes (clusters of leaves that radiate from the root crown); the young plants resemble radish seedlings. The waxy bluish-green basal leaves, up to 15 centimeters (cm) (5.9 inches (in)) long, have broadly lobed margins. Flower stalks emerge the following spring bearing showy lavender-purple flowers; often these stalks are un-branched and 46 to 61 cm (18 to 24 in) tall, but may reach 137 cm (54 in) in height, and have several long branches. The lower stem leaves have an elongated heart shape and the upper leaves are progressively shorter, ultimately reduced to very short, triangular bracts (modified leaves) at the base of each flower stem. Thin seed pods, known as siliques, are up to 12 cm (4.7 in) long and 4 millimeters (mm) (0.15 in) wide; they mature and dry during the summer, finally splitting open to release flattened seeds with narrow wings. The foliage withers as the fruits mature, and the plants die during the blazing heat of summer.

**Taxonomy**

Family: Brassicaceae (mustards). About 100 species of Streptanthus have been described, although many of these have more recently been placed in Caulanthus, Boechera, Thelypodium, or other genera (Tropicos 2011a, pp. 12). Gray (1848, p. 146) described Streptanthus bracteatus as a new species, based on specimens collected by Ferdinand Lindheimer near New Braunfels, Texas, in 1846. Kuntze (1891, p. 933, cited in Tropicos 2011c, p. 1) classified this taxon as Erysimum bracteatum (A. Gray) Kuntz. Nevertheless, the Flora of North America (Al-Shehbaz 2011, p. 706), Tropicos (2011b, p. 1), the Integrated Taxonomic Information Service (2011, p. 1), the International Plant Names Index (2011, p. 1), and the Plants Database (Natural Resources Conservation Service 2011, p. 1) treat this taxon as a valid species with the name Streptanthus bracteatus. Pepper (2010, p. 14) concluded that S. bracteatus is a morphologically and evolutionarily distinct species; its closest extant relative is the broadpod jewelflower, S. platycarpus, a west Texas endemic. Poole et al. (2007, p. 470) list bracted twistflower and bracted jewelflower as common names for this species. While the latter is also used by the Plants Database, the botanists and conservation organizations who work with this species primarily use the former name. For the purposes of this document, we will refer to Streptanthus bracteatus as bracted twistflower.

**Historical Range**

U.S., Texas. Historic collection records where the species has not been observed since 1989: Comal, Bandera/Kerr, Real, Bexar counties.

**Current Range**

U.S., Texas. Bexar, Hays, Medina, Travis, and Uvalde counties. Endemic to a small area of the Edwards Plateau of Texas.

**Critical Habitat Designated**

Yes; 5/11/2023.

**Legal Description**
We, the U.S. Fish and Wildlife Service (Service), determine threatened species status under the Endangered Species Act of 1973 (Act), as amended, for the bracted twistflower (Streptanthus bracteatus), a plant species from Texas. In addition, we designate critical habitat for the bracted twistflower. In total, approximately 1,596 acres (646 hectares) in Uvalde, Medina, Bexar, and Travis Counties, Texas, fall within the boundaries of the critical habitat designation. This rule applies the protections of the Act to this species and its designated critical habitat.

**Critical Habitat Designation**
Critical habitat units are depicted for Bexar, Medina, Travis, and Uvalde Counties, Texas.

**Primary Constituent Elements/Physical or Biological Features**
The physical or biological features essential to the conservation of bracted twistflower consist of the following components:

(i) Karstic, dolomitic limestones underlain by less permeable limestone strata, where perched aquifers seep to the surface along slopes. These are often found within 2 kilometers of the exposed boundary of the Edwards or Devils River and Glen Rose geological formations

(ii) Native, old-growth juniper-oak woodlands and shrublands along the Balcones Escarpment

(iii) Herbivory from white-tailed deer and introduced ungulates of such low intensity that it does not severely deplete populations prior to seed dispersal

(iv) Tree and shrub canopy gaps that allow direct sunlight to reach the herbaceous plant layer at least 6 hours per day

(v) Viable populations of native bee species and the abundant, diverse forb and shrub understory that support them

**Special Management Considerations or Protections**
When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features which are essential to the conservation of the species and which may require special management considerations or protection. The features essential to the conservation of this species may require special management considerations or protections to reduce the following threats: Habitat loss due to urban and residential development, increased woody plant cover, severe herbivory by native and introduced ungulates, and trampling and erosion from recreational use. Management activities that could ameliorate these threats include (but are not limited to) juniper thinning, prescribed fire, fencing to exclude deer and other herbivores, herd management of local ungulate populations, and protection from foot and bicycle traffic. These management activities will protect the physical and biological features essential for the conservation of the species by reducing herbivory, maintaining open canopies, protecting the habitat from trampling and erosion, and conserving diverse shrub and forb understory vegetation that supports the species' native bee pollinators.

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: 1 year (annual) (USFWS, 2021)

**Breeding Season**

Adult: Bloom April and may continue to May and early June

**Reproduction Narrative**

Adult: Bracted twistflower has an annual lifespan, meaning that it completes its entire life span within one year. It may also be considered a winter annual or biennial, since the seeds germinate in the fall of one calendar year, and the emerging plants reach maturity, produce seeds, and die during the summer of the following year. Zippin (1997, p. 222) determined that from 79 to 90 percent of seed germination occurs during the months of October and November. The plants form a rosette of radially-arranged basal leaves (Figure 1.1) that develop during the fall and winter; during this time, the plants store nutrients and water in a tap root. Positive identification is somewhat difficult during the rosette stage, since bracted twistflower resembles other members of the Mustard family, including rock cress (Arabis petiolaris) (Damude and Poole 1990, p. 6). (USFWS, 2021)

**Habitat Type**

Adult: Primarily in oak-juniper woodlands and associated openings on slopes and in canyon bottoms with shallow, well drained, gravelly clays and clay loams over limestone. Often found amid dense shrub growth where some protection from browsing animals is afforded, but is not ideal habitat.

**Habitat Vegetation or Surface Water Classification**

Adult: Forest/Woodland; Shrubland/Chaparral, Woodland - Mixed

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2014)

**Habitat Narrative**

Adult: Bracted twistflowers are best adapted to sites with less than 50 percent cover of woody plants, and that severe herbivory by dense populations of white-tailed deer has largely extirpated the plant from its optimal habitats. It may persist for a time in the protection of dense thickets, or it may gradually decline. In addition, the germination of seeds and reproduction of bracted twistflower in the wild appears to respond to as-yet unknown triggers. This compels us to consider how historic vegetation changes may have affected bracted twistflower populations. Bray (1904, pp. 14, 22) described a very apparent, ongoing transition of Edwards Plateau uplands from grassland to woodland at the beginning of the twentieth century. At that time, the well-watered canyons supported dense forests with trees over 500 years old; stunted but continuous forest covered hills and bluffs; sparse trees were found on loose, stony slopes in the eastern Edwards Plateau (precisely where bracted twistflower populations currently occur); and trees were then invading the open prairies on the level plateau divides (uplands), which previously were free of woody vegetation (Bray 1904, pp. 1415). He attributed this change to overgrazing and the consequent depletion of grasses, erosion, and cessation of wildfires, and stated that open prairies had been converted to dense oak scrub in a span of 25 years (Bray 1904, pp. 1415, 2223). These historic descriptions support a hypothesis that bracted twistflower is a relict of a woodland-grassland ecotone (transition zone) that occurred at or near the confluence of loose, stony slopes and prairie uplands. This savanna, in the broad sense of the term, would have been influenced periodically by wildfires of varying intensity and frequency. Some Streptanthus species, such as S. heterophyllus (San Diego wild cabbage), germinate following wildfires (Moreno and Oechel 1991, pp. 19992000), thus, fire may also be a trigger of bracted twistflower emergence.

***Dispersal/Migration***

**Dispersal**

Adult: Seeds disperse by gravity (Fowler et al. 2012, p. 1512), although other mechanisms, such as water flowing over the soil, may also occur. The foliage withers as the fruits mature, and the plants die during the blazing heat of summer (USFWS, 2023).

***Population Information and Trends***

**Population Trends:**

Decreasing (USFWS, 2023).

**Number of Populations:**

13 EOs (=populations); 9 with intact habitat, 4 with degraded or partially destroyed habitat (USFWS, 2014). 14 extant populations (USFWS, 2023).

**Population Size:**

~6,200 individuals (USFWS, 2014)

**Population Narrative:**

Of the 16 EOs (Element Occurrences=geographic sites) observed since 1989, 9 EOs remain with intact habitat, 2 EOs are partially intact, 2 are on managed rights-of-way, and 3 sites have been developed and the populations are presumed extirpated. Only 7 of the intact EOs and portions of 2 EOs, representing 2,502 individuals (33 percent of the maximum populations observed since 1989), are on protected natural areas. Four EOs with 3,708 individuals (48 percent of the maximum populations) are intact but vulnerable to development and other impacts. Five EOs have been partially or completely developed, resulting in the loss of 1,449 individuals (19 percent of the maximum populations). Two EOs were destroyed in 2012 and 2013 (USFWS, 2014). The maximum populations observed at these EOs range from a few up to about 2,000 individuals; in 2012, a pulse year for many populations, 1,463 individuals were observed at 14 extant EOs. Since 1989, two EOs have been eradicated and four others have been mostly destroyed by residential development. We estimate that 33 percent of the potential population has been lost due to habitat development during this time. Populations on many of the remaining habitats have also declined. We recognized bracted twistflower as a candidate for listing under the Endangered Species Act (ESA) on October 26, 2011 (76 FR 66370). Additionally, on July 31, 2014, we received a petition to list the species (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Urban development
**Exposure:** Degradation and destruction of habitat
**Response:**
**Consequence:**
**Narrative:** The greatest threat to bracted twistflower is habitat loss due to urban and residential land development (McNeal 1989, p. 17; Damude and Poole 1990, p. 51; Zippin 1997, p. 229; Fowler 2010, p. 2; Pepper 2010, p. 5). Our analysis of the 16 EOs reported since 1989 indicates that 3 have been extirpated, portions of 2 have been extirpated, 2 are in disturbed habitat, and 9 are intact. Of the intact EOs, 2 are vulnerable to development, and 7 intact EOs and portions of 2 EOs, representing 33 percent of the maximum populations recorded since 1989, occur in protected natural areas. The Rough Hollow population in Hays County was discovered in 2010; by 2012, the site had been bulldozed. The Cat Mountain population in Travis County, which was a core reservoir of the species genetic diversity (Pepper 2010, p. 12), was located on private land that was sold in 2011 (Bracted Twistflower Working Group 2010, pp. 34; Stewart 2012); this site was completely bulldozed in 2013 (Fowler 2014, p. 16). Habitat loss is an imminent threat throughout the species range to the populations not on protected natural areas and is likely to continue.

**Stressor:** White-tailed deer, small mammals, exotic ungulates
**Exposure:** Browsing
**Response:**
**Consequence:**
**Narrative:** Severe herbivory by white-tailed deer is a major, imminent threat to bracted twistflower throughout the species' range, except where populations are protected from deer by fencing or intensive herd management (hunting) (McNeal 1989, p. 17; Damude and Poole 1990, pp. 5253; Dieringer 1991, p. 341; Zippin 1997, pp. 39197, 227; Leonard 2010a, pp. 3643; Fowler 2014, pp. 17, 19) and is exacerbated by the extremely high deer densities in the Edwards Plateau of Texas (Zippin 1997, p. 227). The foliage of bracted twistflower is very palatable to many browsing animals, including squirrels (Fowler 2010, p. 7), and even humans (Kral 1990 cited in Damude and Poole 1990, p. 51). Exotic ungulate species such as aoudad (Ammotragus lervia), which have been widely introduced on game ranches and now exist in self-sustaining feral populations in central Texas, present an additional potential threat (Damude and Poole 1990, pp. 52 - 53). It is also likely that bracted twistflower populations were impacted during historic periods of poor rangeland management in central Texas, particularly by herds of goats and sheep.

**Stressor:** Woody plant density
**Exposure:** Decreased habitat
**Response:**
**Consequence:**
**Narrative:** Changes in vegetation structure and composition, specifically the increased density of woody plant cover, appear to be detrimental to bracted twistflower (Pepper 2010, p. 5). The species benefits from higher light intensity and duration than it receives in many of the extant populations; its persistence in dense thickets may be due to increased herbivory of the plants growing in more open vegetation (Leonard 2010a, p. 63; Ramsey 2010, p. 22). The positive reproductive response of bracted twistflower to higher light levels is consistent with the hypothesis that it may also be a fire-adapted species (Fowler 2010, pp. 3, 10). Bray (1904, pp.

1415, 2324) documented the rapid transition of grasslands to woodlands in the Edwards Plateau occurring more than a century ago; he attributed this change to over-grazing, the depletion of grasses, and the cessation of wildfires. We conclude that bracted twistflower habitats were probably influenced by frequent wildfires and that the frequency of wildfires has decreased greatly since pre-settlement times; therefore, bracted twistflower may be a fire-adapted species, and the lack of wildfire may have contributed to its decline. The increase in density of woody plant cover has occurred incrementally over a span of decades, but affects most bracted twistflower populations, including those on protected natural areas, and may also have caused a gradual decline in population sizes. In addition, optimal vegetation management of bracted twistflower populations may be incompatible with the management of nesting habitat of the endangered golden-cheeked warbler.

**Stressor:** Powdery mildew fungus
**Exposure:** Disease infestation
**Response:**
**Consequence:**
**Narrative:** Bracted twistflower is highly susceptible to attack from a powdery mildew fungus (Ascomycota, family Erysiphaceae) which may be more severe when plants grow in dense, shaded thickets (Ramsey 2010, p. 21; Leonard 2010a, p. 53). The species of fungus has not yet been identified; it may be an introduced pathogen to which bracted twistflower has no resistance (Bracted Twistflower Working Group 2010, p. 2). We do not yet know the magnitude of this threat. However, Fowler (2014, p. 17) found that, contrary to expectation, the incidence of powdery mildew was positively associated with reproductive output (plants with greater degrees of powdery mildew infestation produced more viable seed).

**Stressor:** Recreation
**Exposure:** Erosion and trampling
**Response:**
**Consequence:**
**Narrative:**

**Stressor:** Land use changes (USFWS, 2021)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A major threat to bracted twistflower is habitat loss due to urban and residential land development (McNeal 1989, p. 17; Damude and Poole 1990, p. 51; Zippin 1997, p. 229; Fowler 2010, p. 2; Pepper 2010, p. 5). As described in Section 2.4, 82 percent of bracted twistflower EOs are within 2 km (1.2 mi) of the Edwards/Devils River and Glen Rose geological formations. This narrow crescent along the eastern and southern edges of the Edwards Plateau follows the Balcones Escarpment. Along this escarpment are many springs that provide good quality water from the Edwards Aquifer. Since potable surface water is scarce in many parts of Texas, colonists built towns along the escarpment during the 18th and 19th centuries. These towns have now grown into cities, including Georgetown, Austin, San Marcos, New Braunfels, and San Antonio; collectively known as the Interstate 35 corridor, this is one of the fastest-growing urban complexes in the U.S. Consequently, urban development has consumed all or most of the habitat at six EOs. Figure 10 shows the known populations of bracted twistflower overlaid on projected urban growth along this corridor by 2050 (Hill Country Alliance 2018)—a visual demonstration

that additional populations and habitats are threatened by urban development and other land use changes. (USFWS, 2021)

**Stressor:** Changes in the structure and composition of vegetation and in wildfire frequency (USFWS, 2021)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Laboratory and field experiments conducted by Fowler (2010, pp. 10–11), Leonard (2010a, p. 63), and Ramsey (2010, p. 20) demonstrated that growth and reproduction of bracted twistflower benefits from higher light intensity and duration than it receives in many of the extant populations; its persistence in dense thickets may be due to increased herbivory of the plants growing in more open vegetation (Leonard 2010a, p. 63; Ramsey 2010, p. 22). Some Streptanthus species, such as S. heterophyllus, germinate in response to wildfire (Moreno and Oechel 1991, pp. 1999 to 2000). One trial showed that bracted twistflower seed germination is enhanced by exposure to karrikins, substances produced by burned vegetation that stimulate germination of many fire-following plants (Flematti et al. 2004; Stewart 2012c, d, e). The positive reproductive response of bracted twistflower to higher light levels and its germination response to karrikins are consistent with the hypothesis that it may also be a fire-adapted species (Fowler 2010, pp. 3, 10; see discussion in Sections 2.3, 2.4, and 3.2). Bray (1904, pp. 14–15, 23–24) and Fonteyn et al. (1988, p. 79) documented the rapid transition of grasslands and savannas in the Edwards Plateau to dense juniper thickets beginning around 1850; they attributed this change to over-grazing, the depletion of grasses, and the cessation of wildfires. An alternate viewpoint concluded that pre-settlement juniper forests were extensive, and that fire frequency has not decreased in the last 150 years, in the Balcones Escarpment region of the Edwards Plateau (O'Donnell 2019, pp. 35–36). Nevertheless, we conclude that the preponderance of evidence supports the hypothesis that bracted twistflower habitats were periodically renewed by frequent wildfires in pre-settlement times and that the frequency of wildfires has subsequently decreased; bracted twistflower is likely to be a fire-adapted species adapted to woodland edges and openings, and the lack of wildfire may have contributed to the deterioration of its habitat and to the decline of its populations. Woody plant cover has increased in density incrementally over a span of decades andaffects most bracted twistflower populations, including those on protected natural areas. (USFWS, 2021)

***Recovery***

**Recovery Actions:**

- Search for new populations on public conservation land as well as private lands (with landowner permission).
- Provide technical guidance and material support to private landowners who voluntarily wish to conserve the species on their land.
- Manage the existing populations on protected natural areas more rigorously, including installation of deer exclosures, closing illicit foot and mountain bike trails, enforcing applicable regulations that protect the habitats on public property, and conducting public outreach.
- Maintain less than 50 percent cover of woody plants at occupied habitats to the extent allowed under the existing habitat management plans or applicable regulations.

- Protect multiple populations within each area of the species genetic diversity in Medina and Travis counties.
- Investigate the species ecology and optimal habitat requirements, particularly the fire ecology, geology, and associated vegetation structure.
- Conduct pilot reintroductions to determine effective methods of population reintroduction and augmentation. Reintroduction and augmentation must use seeds from ecotypes adapted to the sites. Avoid translocating propagules of an ecotype into sites that support a genetically distinct ecotype.
- Collect seeds from extant populations for seed bank storage and propagation. Propagate plants from the representative genetic ecotypes (genotypes that are specifically adapted to a specific ecological area) and produce seed for experimental and reintroduction efforts (to prevent excessive collection from wild sources and depletion of the soil seed bank at extant populations).

# SPECIES ACCOUNT: *Suaeda californica* (California seablite)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

An evergreen shrub that forms low mounds, leafy with fleshy, narrow leaves, each 5-35 mm long. The tiny flowers (2-3 mm across) are borne July-October. (NatureServe, 2015)

**Taxonomy**

Suaeda californica was first described by Sereno Watson in 1874, based on type material collected by Bolander and Kellogg in San Francisco Bay tidal marshes. Amos Heller published the name Dondia californica in 1898, recognizing the genus name used by Michel Adanson in 1763. However, the name Suaeda has been conserved (Abrams 1944). Munz (1959) recognized several previously recognized taxa as subspecies of S. californica, and described the range as extending from San Francisco Bay south to Lower (Baja) California. Ferren and Whitmore (1983) noted that much of what had been identified as S. californica in southern California was a distinct taxon, which they named S. esteroa. Further study revealed that the only extant populations of Suaeda that resemble the type specimen of S. californica are those that occur in the vicinity of Morro Bay. In his revision of the genus, Ferren (1993) recognized S. californica as a full species (USFWS, 2013).

**Historical Range**

See Current

**Current Range**

Extirpated from the San Francisco Bay area; now known only from Morro Bay, San Luis Obispo County. May have once occured in Sonoma County as well (Skinner and Pavlik 1994). Does NOT occur in southern California or Baja California - plants of these areas are referable to S. esteroa &/or S. taxifolia (Skinner and Pavlik 1994, USFES 1994). (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Wind pollinated? (USFWS, 2013)

**Breeding Season**

Adult: Flowers typically appear from May to October, but mostly in late summer. Occasional flowers may be found at other times of the year, sometimes emerging as early as late spring (McMinn 1939, Baye pers. observ.) (USFWS, 2013).

**Reproduction Narrative**

Adult: Suaeda californica produces seeds throughout its lifespan. Reproduction appears to be entirely by seed (sexual); there are no known reports of natural regeneration from vegetative fragments. The spread of individual plants can be extensive, and sometimes resembles clonal populations. However, they have not been observed to spread clonally. Vegetative stem cuttings of S. californica treated with synthetic auxins (hormones) are easily rooted for artificial propagation (P. Baye pers. observ. 1991-1999). Reproductive maturity may in some cases be reached in as little as one year (P. Baye unpubl. data 1998). Flowering occurs on portions of the current year's shoot growth, usually on lateral branches of older wood. Flowers typically appear from May to October, but mostly in late summer. Occasional flowers may be found at other times of the year, sometimes emerging as early as late spring (McMinn 1939, Baye pers. observ.). Differences in flowering phenology may be an indication of genetic variation. One entire colony of Suaeda californica on Pickleweed Island, Morro Bay, was observed to flower precociously in April, while adjacent plants and all other colonies were entirely vegetative (P. Baye unpubl. data 2000). The longevity of individual plants is unknown, but large woody plants in stable substrate appear to live for over a decade. Very little information is available on the breeding system of Suaeda californica; however, a predominantly outcrossing breeding system would be expected for this wind-pollinated, often colonial, shrub. Abundant seed (many hundreds per plant) is produced on fruiting plants at Morro Bay. The ability of isolated plants in cultivation to produce seed (P. Baye pers. observ. 1998) suggests that at least some individuals possess a degree of self-compatibility. Abundant seed set occurred spontaneously in outdoor container-grown nursery plants at the Golden Gate National Recreation Area nursery in San Francisco in 1998. These seeds were viable and produced vigorous seedlings (E. Heimbinder pers. comm. 1999). Based on observations by marsh ecologist Peter Baye, abundant seedling establishment at Morro Bay appears to be episodic, corresponding to storm events that cause both vegetation gaps and deposits of driftline debris with seeds. Seedlings were widespread and abundant along the backbarrier shoreline following the erosive winter storms of 1998. Many thousands of seedlings and multiple-branched juvenile plants had established in the erosion zone in driftlines and litter rafts by late April 1998. Seedlings rooted in debris rafts without roots in the marsh substrate were subject to high mortality. No evidence of long distance dispersal and colonization was observed. Re-survey of the extensive 1998 seedling colonies in April of 1999 and 2000 revealed only regeneration of remnant mature shrubs that survived erosion. No juvenile or young mature plants were detected, indicating extremely high mortality of the post-storm cohort of seedlings. In contrast, the colonies of mature Suaeda californica at the north end of Morro Bay were mostly unaffected by the 1998 storm. These narrow, dense colonies acted as a significant refugia for survival and seed production during the catastrophic mortality that affected most of the population along the bayshore of the central sand spit (USFWS, 2013).

**Habitat Type**

Adult: Salt marsh (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from  NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species is restricted to the upper intertidal zone of a coastal salt marsh along the perimeter of a bay (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species and the relatively low number of known populations.

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seeds of Suaeda californica are somewhat hard-coated, and are enclosed in fleshy calyces that become spongy and buoyant upon drying, and which remain attached to the fruits after dehiscence and dispersal (USFWS, 2010).

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

Nine (USFWS, 2013)

**Population Size:**

1 - 1000 individuals (NatureServe, 2015); ~500 (NatureServe, 2015)

**Population Narrative:**

< 500 genetic individuals estimated by McLeod (1991) as cited in USFWS 1994. (NatureServe, 2015). USFWS (2013) notes that there are nine known occurrences of this species 5 naturally occurring in Morro Bay and 4 re-introduced locations in San Francisco Bay. Low Resiliency, representation and redundancy are inferred based on the low number of occurrences and individuals as well as the small geographic range this species inhabits.

***Threats and Stressors***

**Stressor:** Alteration and Loss of Habitat (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The historical rarity of Suaeda californica in San Francisco Bay may have been due in part to the natural rarity of its sandy high marsh and beach habitat, but its extirpation seems related to the early spread of urban and port development over the East Bay shoreline from Richmond to Alameda, centered around Oakland (P. Baye pers. comm. 2004). This heavily urbanized area was the center of both the bay's sandy shorelines and S. californica distribution. Oakland and Alameda Marshes were filled and urbanized before the 20th century, eliminating populations there, but it was the destruction of Bay Farm Island for the construction of the

Oakland International Airport in the 1950s and 1960s that probably destroyed the only remaining viable population in San Francisco Bay. Other species with affinity for sandy tidal marsh edges, such as Atriplex californica, were also described as occurring either along sandy beaches or sandy marsh edges within San Francisco Bay (Brewer et al. 1880, Jepson 1911, Greene 1894). These, too, have become extirpated. The Morro Bay population has suffered little habitat loss compared with San Francisco Bay, and has relatively abundant habitat there, despite declines following El Niño winter storm erosion. However, it is subject to strong fluctuations in abundance due to natural disturbances, particularly dune migration and shoreline erosion, and its regeneration following disturbance is vulnerable to numerous threats. Though the population has in the past been threatened by strong residential and commercial real estate development pressures on the east shore of Morro Bay, centered at Baywood Park and Los Osos, these pressures have been reduced drastically (J. Vanderweir pers. comm. 2009). Loss of habitat and individuals, and failed regeneration after natural catastrophes could cause extirpation of this population. Other threats include interference by non-native vegetation, trampling, oil spills, sea level rise associated with climate change, excessive dune mobilization, and alteration of shoreline dynamics due to stabilization and shoreline repair projects (USFWS, 2013).

**Stressor:** Recruitment failure (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals/Weakening population
**Narrative:** Trampling of seedlings in Morro Bay may contribute to the failure of Suaeda californica regeneration following catastrophic shoreline erosion caused by major storms. Trampling results from both recreational activities (hiking) and by black-tail deer (Odocoileus hemionus) populations on the sand spit, and represents a relatively infrequent threat. However since seedling recruitment is episodic and local, impacts to seedlings (which are difficult to detect) could be severely detrimental at times. This is indicated by tracks and footprints along the Morro Bay shoreline in a devegetated zone nearly 0.5 meter (0.55 yd) wide (P. Baye pers. observ. 1997-1999). As recreational pressure on the Morro Bay shoreline increases with local residential population and increased visitor use at Montaño de Oro and Morro Bay State Parks, this impact is likely to become more severe (USFWS, 2013).

**Stressor:** Competition with non-native species (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Exotic invasive vegetation, primarily Carpobrotus edulis X chilensis hybrids (iceplant), Eucalyptus globulus (blue gum), and Cupressus macrocarpa (Monterey cypress; a native to the Monterey peninsula only), cause significant damage to Suaeda californica by direct interference and indirect adverse habitat modification. Carpobrotus edulis establishes clonal colonies in adjacent uplands above saline influence, and can encroach by transporting nonsaline soil moisture from portions of the clone above the high tide line (P. Baye unpubl. data 1997). Most stands of S. californica along the perimeter road to Morro Beach State Park have been partially smothered by C. edulis, which grows through and over the S. californica colonies there. Carpobrotus edulis impacts are particularly significant for seedling regeneration along the backbarrier shore of Morro Bay spit. As the sandy backbarrier shoreline retreats into dense continuous stands of C. edulis on the dunes, C. edulis overhangs the erosional scarp and forms a canopy that drapes over the base of the scarp and upper shoreline. This sharply reduces or

eliminates open seedling habitat for S. californica—its regeneration niche. It may also inhibit regeneration of storm-eroded remnants of S. californica. Therefore, spread of C. edulis along the dunes of the backbarrier shoreline is likely to reduce population resilience of S. californica. In fact, removal of C. edulis near S. californica populations has had a striking effect of recovery of the later (Baye in litt. 2009). Heavy leaf litter and canopy shade from non-native trees, Cupressus macrocarpa and Eucalyptus globulus, are detrimental to seedling habitats for Suaeda californica, and apparently cause decline in vigor of remnant stands of mature plants (e.g., near the entrance of Morro Bay State Park and in Baywood Park). Degradation of the ecological niche for seedling regeneration is probably a more severe long-term threat to the viability of the S. californica population than local disturbance of existing mature colonies. Stands of S. californica have been damaged directly by broken and fallen limbs of E. globulus adjacent to Morro Beach State Park (P. Baye unpubl. data 1997-2000). The persistence of suitable and restorable habitat for reintroduction of Suaeda californica to San Francisco Bay is also threatened by non-native vegetation. In San Francisco Bay, the spread of invasive Spartina (Daehler and Strong 1996) caused the conversion of open mudflat into stabilized tidal marsh that traps sediment and moderates estuarine wave energy. This invasive vegetation intercepted alongshore transport of sand in the middle and lower intertidal zone, and inhibited the wave deposition of the sandy higher elevation marsh-beach ecotone that is important for establishment of S. californica. Invasive Spartina eradication efforts have likely eliminated the further spread of the species which could have precluded the long-term viability of S. californica reintroduction (USFWS, 2013).

**Stressor:** Dredging (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Navigational dredging may threaten stands of Suaeda californica that have colonized the marina shoreline at Morro Bay State Park. Dredging of the inlet channel steepens the subtidal shore profile, probably resulting in shoreline erosion along the unarmored eroding south shore of the interior shoreline of the marina, which could threaten the S. californica colony there. The marina subpopulation of S. californica is particularly significant to the species' conservation because it is highly sheltered from storm wave erosion that threatens the main population along the spit's backbarrier shoreline (USFWS, 2013).

**Stressor:** Predation (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** In the absence of natural predators, hunting, or management in Morro Bay, deer populations are likely to forage intensively along the backbarrier shoreline where seeps provide fresh water, soft herbaceous vegetation, and flat travel corridors (USFWS, 2013).

**Stressor:** Small number of populations (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Extirpation
**Narrative:** Suaeda californica is vulnerable to extinction in the wild largely because it has been reduced to a very small number of populations distributed in a very narrow zone of the Morro

Bay and San Francisco Bay shorelines. In Morro Bay, most of the colonies occur along the erodible backbarrier shore of the Morro Bay sand spit, which is susceptible to erosion by occasional extreme storm tides and high wind-generated waves, and rapid burial by migrating dunes. Severe storm erosion occurred along this shoreline in the winter of 1997-1998, creating an extensive erosional scarp in the narrow S. californica zone. The population has not yet rebounded from this event. Although this was a natural catastrophe and rebound may occur in time, erosion events may become a recurrent threat if climate change increases storm intensity, frequency, and sea level rise rates (USFWS, 2013).

**Stressor:** Climate change (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat/extirpation
**Narrative:** Extreme local fluctuations of climate (winter storms, high winds, summer drought) may be associated with global climate change. A series of severe winter storms followed by years of drought could cause catastrophic reproductive failure of the species. Global climate change and associated sea level rise may also cause long-term changes in the stability of sand beach and dune shorelines (SCOR Working Group 1991), such as those of Morro Bay spit. Suaeda californica occurs in abundance only where the backbarrier shoreline is adjacent to dune scrub vegetation that stabilizes dunes. It is sparse or absent where bare mobile dunes retreat over the backbarrier shoreline. Many of the remaining colonies are being encroached on by mobile dunes, and are not expected to survive more than a few years. The formation of new “marsh coves” (potential S. californica habitat) in the lee of stabilizing dunes may occur in the future, but none are foreseeable now. A combination of shoreline retreat and increased dune movement could significantly reduce the largest subpopulation of S. californica. Accelerated sea level rise and shoreline retreat could also force conflicts between natural movement of the Suaeda californica zone on the east shore of Morro Bay and landowner needs. Where costly residential developments are threatened by shoreline retreat, response typically involves armoring (structural stabilization) of the shoreline (e.g., revetments, seawalls, rip-rap, etc.). Currently, S. californica appears to be able to migrate with the slowly retreating shorelines of eastern Morro Bay (Baywood Park, heron rookery) (USFWS, 2013).

**Stressor:** Oil spills (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat/extirptation
**Narrative:** Oil spills and clean-up operations may have significant adverse effects on Suaeda californica populations at Morro Bay, particularly on seedlings. Spilled oil tends to accumulate near the high tide line, the narrow marsh zone in which S. californica is largely restricted. Oil would probably cause high mortality of seedlings and juvenile plants during years of seedling regeneration by coating and smothering small plants with oil, and possibly by direct toxicity. Oil clean-up operations involving mechanical removal (raking, excavation) of oiled sand would also cause significant disturbance of S. californica habitat. Direct toxic effects of oil on older woody S. californica are uncertain, but are probably less damaging than effects of clean-up operations (USFWS, 2013).

**Stressor:** Rust Disease (USFWS, 2023)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Researchers collected and identified a new species of rust fungus (Uromyces rebeccae) on California seablite plants from Morro Bay (Bruckart et al. 2020, pg. 546). In general, rust disease on plants may cause leaf chlorosis (yellowing), withering, and premature abscission (falling off). Heavy rust infestation reduces overall vigor and extreme cases may kill plants (Royal Horticultural Society 2023, website). Rust disease on California seablite is a new threat to the species (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 8

1. Within the Morro Bay Recovery Unit, dunes are revegetated with native species to achieve natural shoreline stability consistent with that which existed in historic dune systems. (USFWS, 2023)

2. Eradication of iceplant (Carpobrotus edulis) is conducted throughout habitat for California seablite at the Morro Bay Recovery Unit. (USFWS, 2023)

3. Habitat supporting at least three populations in the Central/South San Francisco Bay Recovery Unit must exist on land in conservation ownership or under conservation management. (USFWS, 2023)

4. To provide sufficient resilience to stochastic events, all conditions under downlisting criteria 1 through 3 (above), have been met and have resulted in at least the following: a. Number of populations: a minimum of three populations must occur in the Morro Bay Recovery Unit and a minimum of three populations must occur in the Central/South San Francisco Bay Recovery Unit. A population shall be any concentration of plants separated by greater than 1.9 km (1.2 miles) from other such concentrations of plants, with no intervening locations observed over a period of five years. b. Number of plants: minimum – for five consecutive years of monitoring, the three populations in the Morro Bay Recovery Unit must total a minimum of 3,000 individuals. c. For five consecutive years of monitoring, the three populations around the San Francisco Bay must total a minimum of 1,500 individuals. (USFWS, 2023).

**Delisting Criteria:**
1) protection of the population at Morro Bay to ensure its long-term survival (USFWS, 2013).

2) re-establishment of suitable habitat with new populations in San Francisco Bay, the historical range of the species

**Recovery Actions:**

- 1. Any person collecting information on Suaeda californica as part of field surveys or research should be encouraged to submit occurrence information to the CNDDB to provide a more comprehensive picture of this species distribution and status throughout its range (USFWS, 2010).

- 2. Potential re-introduction sites for Suaeda californica within the San Francisco Bay area and other sites within its historic range should continue to be evaluated by the Service (USFWS, 2010).
- 3. Land managers and the Service should work cooperatively to begin population surveys in all potentially suitable and legally-accessible habitat along the central coast to determine if there are yet undiscovered occurrences of Suaeda californica and to update the status of known occurrences (USFWS, 2010).
- 4. The CDPR and the Service should continue monitoring of existing outplanting efforts and seek to identify additional sites for outplanting of Suaeda californica on Federal, State, or otherwise conserved lands along the coastline in San Luis Obispo County (USFWS, 2010).
- 5. Establish site-specific and species monitoring protocols to identify potential impacts of sea-level rise and storm surge associated with climate change. This will assist in determining the effects of projected sea level rise and increased storm surge events on Suaeda californica and its habitat (USFWS, 2010).
- 6. The CDPR and Morro Coast Audubon Society should develop and implement active nonnative invasive species eradication programs for those occurrences of Suaeda californica under their management authority. Post-eradication, sites should be evaluated for their potential to re-establish occurrences of S. californica (USFWS, 2010).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Obtain access (if possible) to all known/mapped California seablite occurrences to conduct monitoring surveys of the status, abundance, approximate size and age of plants observed, and evaluate threats at these locations. Include estimates of numbers of individuals present, global positioning system (GPS) mapping of occupied spatial area, ecological setting, co-occurring and co-dominant vegetation, presence of natives versus nonnative plant species, timing of phenology, soils and hydrological data, and observations of potential insect pollinators. Update information in resource agency databases (CNDDB) to ensure that these data remain accurate and current. 2. Develop site-specific, comprehensive management plans for California seablite occurrences designed to ameliorate the species threats, and ensure that progress towards achieving the recovery criteria outlined in the recovery plan is made, so that the criteria are ultimately met. 3. Ensure that partners at all occurrences conduct invasive weed reduction and elimination activities, with special attention toward eradication of ice plant. If necessary, dune restoration efforts should also occur, focusing on outplanting of native species to achieve natural shoreline levels of stability and curtail erosion. 4. Conduct experimental research on the species population genetic structure. Assess the genetic constitution of colonies within Morro Bay and levels of connectivity between them. Then compare these data with outplanted colonies in the San Francisco Bay Area to determine if genetic diversity in the species is maintained, if new variations occurred, and other potential effects from outplanting. Genetics work to assess the overall ability of California seablite to withstand stochastic events also needs to occur. 5. Continue experimental research on the reproductive biology of the species. In particular, we need to better understand California seablite’s capacity to both outcross and self, the degree that it is utilizing these different pathways in the wild, identify insect pollinators (if they are being used), and the possible implications of these factors on the species recovery. 6. Make accessions for conservation seed banking throughout the species range, so all occurrences are represented in the collections. Conduct seed bulking of accessions that may serve as a source for recovery efforts, and a backup in the event of stochastic loss and local extirpation. (USFWS, 2023)

# SPECIES ACCOUNT: *Thalictrum cooleyi* (Cooley's meadowrue)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 02/07/1989; Southeast Region (R4) (USFWS, 2017)

**Physical Description**

A small, rhizomatous, perennial herb with erect to lax stems, up to 1 m tall. Loose clusters of flowers are borne in June. The unisexual flowers lack petals, but the sepals are white, pale yellow, or pale green with lavender filaments. The leaves are narrow and lance-shaped. The fruits are single-seeded and winged. Phenology: Flowers appear mid to late June and fruit mature in August or September (NatureServe, 2015).

**Taxonomy**

Thalictrum cooleyi is distinguished from other such members of the genus, Thalictrum revolutum in particular, by the combination of leaflet narrowness (4 to 26 times as long as wide), lack of lobing in the majority of the leaflets, and absence of hairs, glands, or papillae on lower leaflet surfaces, petioles, peduncles, and achenes (Park 1992) (USFWS, 1994).

**Historical Range**

Three historic North Carolina populations--Brunswick, Columbus, and Pender Counties--are assumed extirpated, because recent surveys showed habitat destruction at the sites and no plants were found (North Carolina Natural Heritage Program 1992). Cooley's meadowrue has been reported from New Hanover County, North Carolina (Radford et al. 1968), but without documentation (USFWS, 1994).

**Current Range**

All of the known Thalictrum cooleyi populations occur in the Coastal Plain Province in NC, GA, and FL (USFWS, 2009).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual, wind- and insect-pollinated (NatureServe, 2015)

**Breeding Season**

Adult: Flowering in June (Radford et al, 1968) (NatureServe, 2015)

**Reproduction Narrative**

Adult: Flowering in June (Radford et al, 1968). The winged, single-seeded fruits mature in August and September (Lowe et al. 1990), but the seed life is presumably short. A dioecious species, Thalictrum cooleyi has separate male and female flowers that are wind- and insect-pollinated (NatureServe, 2015).

**Habitat Type**

Adult: Pine Savanna (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Wetlands/intermittent fire (NatureServe, 2015; USFWS, 1994); soil pH 5.8-6.6 (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (Inferred from NatureServe, 2015 and USFWS, 1994)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (Inferred from NatureServe, 2015 and USFWS, 1994)

**Site Fidelity**

Adult: High (NatureServe, 2015)

**Habitat Narrative**

Adult: Sunny, moist places such as open, savanna-like forest edges and clearings, wet savannas over calcareous clays, and ecotones between wet savannas and non-riverine swamp forests. Soils are basic, sandy loams. Also on roadsides and power line rights-of-way in former savannas. It grows on circumneutral soils in wet pine savannas, grass-sedge bogs, and savanna-like areas, often at the border of intermittent drainages or swamp forests. Boggy savannah-like borders of low woodlands, roadside ditches, and power line rights-of-way. Usually associates with some type of disturbance, e.g., clearings, the edges of frequently burned savannas, power line right-of ways which are maintained either by fire or mowing, and roadside edges. Typically on Grifton soil. This plant is found on fine sandy loams that are at least seasonally (winter) moist or saturated and are only slightly acidic (pH 5.8-6.6). Sufficient moisture is critical to plant vigor and reproductive effort. This plant occupies a narrow hydrological niche, where soil is moist to saturated but water does not stand above the soil surface. This species occurs in moist to wet bogs and savannas and savanna-like openings on circumneutral soils and is dependent upon some form of disturbance to maintain the open quality of its habitat. Currently, artificial disturbances, such as power line and road right-of-way maintenance, and plowed firebreaks, are maintaining some of the openings historically provided by naturally occurring periodic fires (Murdock 1989).This species grows in circumneutral soil in moist to wet savannas and savanna-like areas kept open by frequent fire or other disturbance. "This borderline type of habitat would have been disturbed historically by naturally occurring savanna fires moving through at 1- to 5-year intervals, clearing litter from the soil surface and causing the cyclical advance and retreat of woody growth. A typical population of Cooley's meadowrue has robust reproductive plants among shrubs and in adjacent open savanna and repressed individuals in nearby dense shade" (Boyer 1994) (NatureServe, 2015; USFWS, 1994). Low tolerance range and clumped spatial arrangement are inferred based on the specific habitat needs of this species and the relatively low number of populations (NatureServe, 2015; USFWS, 1994).

***Dispersal/Migration***

**Motility/Mobility**

Adult: Low (USFWS, 1994)

**Dispersal/Migration Narrative**

Adult: Possibly propagate by breaking off and dispersal of vegetative parts in aquatic habitat (USFWS, 1994).

***Population Information and Trends***

**Population Trends:**

Decreasing (NatureServe, 2015)

**Species Trends:**

Stable (USFWS, 2009)

**Number of Populations:**

19 (USFWS, 2020)

**Population Size:**

1 - 1000 total individuals (NatureServe, 2015)

**Population Narrative:**

Thalictrum cooleyi is intrinsically vulnerable in several ways. It is rhizomatous, so the number of ramets is far greater than the number of genets. It is dioecious, so the populations where only one sex persists are particularly vulnerable. It produces few seeds and apparently does not have a seed dispersal mechanism (USFWS 1989). (NatureServe, 2015) The total number of individuals is estimated at between 1 and 1000 and the number of populations between 6 and 20. In addition, the short-term population trend indicates a decline of 10-30% (NatureServe, 2015). Low representation, resiliency and redundancy are inferred based on species specific habitat needs, low number of populations and fragmentation of suitable habitat (NatureServe, 2015). In the 2008 Recovery Data Call, the status of Thalictrum cooleyi was listed as stable. Between 2005 and 2007, NCNHP staff or other knowledgeable botanists have visited 12 of 25 North Carolina subpopulations (representing 10 populations) of Thalictrum cooleyi. As of 2008, there were 9 extant populations in NC; 2 in GA; and 1 in FL (USFWS, 2009). In summary, several new EOs have been found in NC, including one entirely new population and four EOs that expand the size of a known population. One new discovery is a county record for New Hanover County, NC; however, it is located within a few hundred feet of the boundary with Pender County, where this species has been known since listing. One new population was discovered in Worth County, GA. Currently, state natural heritage programs recognize 19 extant populations (10 in NC, 8 in GA and 1 in FL). Of these, 10 populations (6 in NC, 3 in GA and 1 in FL) have some level of protection, and are either owned and/or managed for conservation by state agencies or private conservation organizations. (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Agriculture (USFWS, 1994)
**Exposure:**

**Response:**
**Consequence:** Loss of habitat
**Narrative:** USFWS (1994) notes that land clearing for agriculture is a threat to this species.

**Stressor:** Succession (USFWS, 1994)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** USFWS (1994) notes that succession (due to lack of disturbance/fire) is a threat to this species.

**Stressor:** Forestry (USFWS, 1994)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** USFWS (1994) notes that forestry/logging is a threat to this species.

**Stressor:** Mining and Development
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** USFWS (1994) notes that mining and development are threats to this species.

**Stressor:** Draining (USFWS, 1994)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** USFWS (1994) notes that draining (for development/road construction) is a threat to this species.

**Stressor:** Road construction (USFWS, 1994)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** USFWS (1994) notes that highway construction is a threat to this species.

**Stressor:** Inadequacy of regulatory mechanisms (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** There are no known populations on federal lands (USFWS, 2009).

***Recovery***

**Reclassification Criteria:**
Not available

Recovery Priority Number: 2

**Delisting Criteria:**
Cooley's meadowrue (Thalictrum cooleyi) will be considered for delisting when there are at least 16 self-sustaining, geographically distinct populations in existence that are protected to such a degree that the species no longer qualifies for protection under the Endangered Species Act (see criteria below). A self-sustaining population is a reproducing population that is large enough to maintain sufficient genetic variation to enable it to survive and respond to natural habitat changes. The number of individuals necessary and the quantity and quality of habitat needed to meet this criterion will be determined as one of the recovery tasks (USFWS, 1994).

**Recovery Actions:**
- Protect existing populations and essential habitat. Develop interim research and management plans in conjunction with landowners and managers. Search for additional populations and potential habitat. Rank populations for focus of protection efforts. Evaluate habitat protection alternatives (USFWS, 1994).
- Determine and implement management necessary for long-term reproduction, establishment, maintenance, and vigor. Determine population size, stage-class distribution and sex ratios for all populations. Study abiotic and biotic features of the species' habitat. Conduct long-term demographic studies. Determine the effects of past and ongoing habitat disturbance. Define criteria for self-sustaining populations and develop appropriate habitat management guidelines based upon the data obtained from Tasks 2.2 through 2.4. Implement appropriate management techniques as they are developed from previous tasks. Develop techniques and reestablish populations in suitable habitat within the species' historic range (USFWS, 1994).
- Maintain and expand cultivated sources for the species and provide for long-term maintenance of selected populations in cultivation (USFWS, 1994).
- Revisit known populations that have not been visited in the past three years; monitor the habitat condition of each site including threats; discuss conservation options with landowners where appropriate; update Natural Heritage Program files with this information (USFWS, 2009).
- Search for additional populations (USFWS, 2009).
- Prioritize known sites for protection (USFWS, 2009).
- Protect additional populations (USFWS, 2009).
- Develop management plans for all protected populations (USFWS, 2009).
- Develop monitoring protocols, initiate long term population monitoring and determine the criteria for sustaining populations (USFWS, 2009).
- Conduct research on general biology of the species including life history and reproductive biology (breeding systems, seed production and seedling survivorship) (USFWS, 2009).
- Compare, genetically, the populations of questionable taxonomy in Georgia with those known from North Carolina and Florida (USFWS, 2009).
- Work with North Carolina Botanical Garden to conserve seeds and develop propagation protocols (USFWS, 2009).

***Conservation Measures and Best Management Practices:***
- RECOMMENDATIONS FOR FUTURE ACTIONS The recommended actions listed in the 2009 5-year review (page 10 and 11 above) remain important to the conservation and recovery of Thalictrum cooleyi. Since the 2009 5-year review, progress has been made on several recommendations for

future actions. For example, the Service and East Carolina University professors and graduate students have visited most of the known populations in NC and provided updated information to the NCNHP. According to GADNR and FLNAI records, half of the known populations in GA and the single FL population have been visited since the last 5-year review and natural heritage program records have been updated. Surveys for new populations of Thalictrum cooleyi have resulted in the discovery of one new population in New Hanover County, NC and one new subpopulation was discovered near a known population in Pender County, NC. In addition, a new population was discovered in Worth County, GA. Additional surveys across the range of the species are needed and may result in the discovery of new populations. Such surveys could be guided by species distribution modeling. Researchers at East Carolina University recently conducted research on various aspects of the life history and reproductive biology and genetics of Thalictrum cooleyi. Their research also increased our knowledge of the propagation and culture of this species which will be used to guide future restoration efforts. (USFWS, 2020)

# SPECIES ACCOUNT: *Thelypodium howellii spectabilis* (Howell's spectacular thelypody)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; Pacific Region (R1) (USFWS, 2016)

**Physical Description**

Howell's spectacular thelypody is an herbaceous biennial that reaches approximately 60 cm (24 inches) tall, with branches arising from near the base of the stem. The basal leaves are approximately 5 cm (2 inches) long with wavy edges and are arranged in a rosette. Stem leaves are shorter, narrow, and have smooth edges. It is a root forming plant and is pollinated by insects. Flowers appear in loose spikes at the ends of the stems. Flowers have four purple petals approximately 1.9 cm (0.75 inches) in length, each of which is borne on a short stalk. Fruits are long, slender pods (Kagan 1986). The plant begins actively growing in April, flowers in May, fruits in June and goes dormant in August (USFWS, 2016).

**Current Range**

Endemic to the northeastern corner of Oregon, occurring in the Baker-Powder River valley in Baker and Union Counties (Fish and Wildlife Service 1999). Generalized current range of about 175 sq. km.

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollinated (USFWS, 2016)

**Breeding Season**

Adult: Flowers in May (USFWS, 2016)

**Reproduction Narrative**

Adult: It is a root forming plant and is pollinated by insects. Flowers appear in loose spikes at the ends of the stems. Flowers have four purple petals approximately 1.9 cm (0.75 inches) in length, each of which is borne on a short stalk. Fruits are long, slender pods (Kagan 1986). The plant begins actively growing in April, flowers in May, fruits in June and goes dormant in August (USFWS, 2016).

**Habitat Type**

Adult: Wet alkaline meadows (USFWS, 2016)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2016)

**Habitat Narrative**

Adult: The thelypody occurs in wet alkaline meadows in valley bottoms, usually in and around woody shrubs that dominate the habitat on the knolls and along the edge of the wet meadow habitat between the knolls. Soils are pluvial-deposited alkaline clays mixed with recent alluvial silts, and are moderately well-drained (Kagan 1986). Associated species include Sarcobatus vermiculatus (greasewood), Distichlis stricta (alkali saltgrass), Elymus cinereus (giant wild rye), Spartina gracilis (alkali cordgrass), and Poa juncifolia (alkali bluegrass) (Kagan 1986). The thelypody may be dependent on periodic flooding since it appears to rapidly colonize areas adjacent to streams that have flooded (Kagan 1986). Abundance fluctuates widely from year to year in response to annual climate and soil moisture (USFWS 2010, p. 4). Thelopody is readily consumed by cows. Thus, thelopody is typically only found under shrubs in areas that are intensively grazed during the growing season (USFWS 2010). In addition, this taxon does not compete well with encroaching weedy vegetation such as Dipsacus fullonum (teasel) (Davis and Youtie 1995) (USFWS, 2016).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2016)

**Number of Populations:**

5 natural populations (13 sites). 1 introduced population (USFWS, 2023)

**Population Size:**

10,000 - 100,000 individuals (USFWS, 2016)

**Population Narrative:**

This taxon was thought to be extinct until rediscovered by Kagan in 1980 near North Powder (Kagan 1986a). The Recovery Plan identifies 11 different occurrences that are grouped into five separate “populations” The labeling of these geographically-clustered occurrences as “populations” is a loose application of the term, since we do not know the extent of genetic interchange among occurrences. The 2008 update of the Oregon Natural Heritage Information Center’s (ORNHIC) database documents 15 Howell’s thelypody occurrences (USFWS 2010). The known occurrences vary substantially in size and plant abundance. Some are small patches just several hundred square feet in size, while others extend over 10 to 20 acres. One additional population has been established since the subspecies was listed. Staff from ODA’s Native Plant Conservation Program translocated thelypody plants to three locations near Baldock Slough on a property that has a permanent conservation easement through the Wetland Reserve Program (Currin et al.2008). All of the known thelypody occurrences are on private land and many are not accessible for monitoring. Since Federal listing in 1999, population monitoring efforts have focused on three sites where there are mechanisms in place that allow for thelypody monitoring: 1) the Haines Rodeo Grounds site, 2) the Miles Ranch Easement, and 3) the Baldock Slough introduction site (USFWS 2010). At all of the monitored sites, the number of flowering plants tends to vary widely from year-to-year. The amount of early spring precipitation appears to be an important driver of annual abundance, with high precipitation levels correlated with increased plant abundance. The biennial habit of thelypody also appears to play a role, with spikes in abundance tending to occur every two years (J. Stephenson, USFWS, pers. comm., 2015). In one ½-acre plot at the Haines Rodeo Grounds that was intensively monitored from 2008 to 2010, thelypody abundance fluctuated from 3,011 plants in 2008 to 25,600 plants in 2009, and back down to 3,135 plants in 2010 (EcoWest Consulting 2011). As this is a protected site, no livestock grazing or other land use activities occur that might negatively affect plant development. The inherent year-to-year variability in plant numbers make it difficult to assess long-term population trends, particularly since quantitative surveys are not conducted every year (J. . Stephenson, USFWS, pers. comm., 2015). During good years, the Haines Rodeo Grounds population is quite large (> 50,000 plants in 2009), however few plants were found during qualitative surveys in June 2014 leading to concerns that this population is declining. There is concern that the spread of invasive weeds, particularly cheatgrass, is outcompeting thelypody in this area. There is less quantitative survey data for the Miles Ranch Easement, but it is also a large population in good years (> 35,000 plants in 2009). The Baldock Slough introduced population contained approximately 400 plants in 2009, distributed in 7 small areas. By 2013, plants were found at only 3 of the 7 areas, and a survey in June 2014 tallied only 20 plants in those 3 remaining areas (D. Trochlell, Natural Resource Conservation Service, pers. comm. 2014). The other known thelypody locations are all located on private lands have either very limited or no access to the occupied sites (USFWS 2010). Where occurrences are visible from public roads, occasional presence/absence surveys have been done in June/early July (when flowering plants are highly visible) to document that the occurrence is still extant, while the less visible sites have not been observed in many years. Much uncertainty remains given the inability to access and monitor the majority of populations on private lands that have no special management protections. However, the overall status of thelypody has improved since listing because additional populations have been found and 3 populations have some protections in place for thelypody. The protection of these sites and some modest progress in developing compatible livestock grazing management practices have moved these subspecies further away from the threat of extinction (USFWS 2010) (USFWS, 2016). Surveys 0 Additional population information was collected in 201 1 (Oregon Department of Transportation 2013), where State highway crews documented approximately 35 plants growing on the side of Highway 84. This population had been documented previously in 2009, 1997 and 1996, is within the previously described range, and is located 0.15 miles from another population. 0 USDA-NRCS conducted a survey of seven sites on June 25, 2014. In four of the . seven experimental sites where the Oregon Department of Agriculture Native Plant Conservation Program had conducted transplants in 2002 and 2007, no T howellii ssp. spectabilis were found. USDA-NRCS attributed this decline to a competition from nonnative species including intermediate wheatgrass (Thinopyrum intermedium) and whitetop (Cardaria draba), which were thought to be outcompeting T. howellii ssp. spectabilis (U.S. Department of Agriculture- Natural Resource Conservation Service 2014) (USFWS, 2018). Research 0 In 2014, EcoWest Consulting Inc. and the USFWS finished an experiment titled “The influence of Population Dynamics, Grazing, and Precipitation Patterns on the Restoration of a Threatened Riparian Mustard to Former Habitat” (2014). Thelypodium howellii ssp. spectabilis was the subject of this Before/After Control/Impact (BACI) design study, which began in 2008 and concluded in 2014. The results of the study were largely inconclusive due to the life history and moisture and soil sensitivity of T. howellii ssp. spectabilis, which resulted in highly variable results. However, the researchers suggest that changes in grazing practice to late season grazing after post-seed dispersal may allow these plants to expand into other areas (USFWS, 2018). Howell’s spectacular thelypody, a biennial plant in the mustard family, continues to occur within the geographic area identified in the recovery plan - the Powder Valley between North Powder, Haines, and Baker City in Union and Baker Counties, Oregon. The recovery plan described five Figure 1: Map of Howell's spectacular thelypody populations. Marshall and Brown (2021). Used with permission. natural populations, consisting of 13 sites (Figure 1), plus one introduced population at Baldock Slough (not mapped – located between North Baker and North Powder populations) (USFWS, 2023).

### *Threats and Stressors*

**Stressor:** Development (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Habitat loss due to urban and agricultural development is listed as a threat to this species (USFWS, 2016).

**Stressor:** Habitat degradation (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Habitat loss/habitat degradation
**Narrative:** Habitat degradation due to livestock grazing and hydrological modification is listed as a threat to this species (USFWS, 2016).

**Stressor:** Grazing (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals
**Narrative:** Consumption by livestock is listed as a threat to this species (USFWS, 2016).

**Stressor:** Herbicides (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of indivduals
**Narrative:** Use of herbicides or mowing during the growing season is listed as a threat to this species (USFWS, 2016).

**Stressor:** Competition (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Competition with exotic species such as teasel (Dipsacus fullonum), bull thistle (Cirsium vulgare), Canada thistle (C. canadensis), and yellow sweet clover (Melilotus officinalis) is listed as a threat to this species (USFWS, 2016).

### *Recovery*

**Reclassification Criteria:**
Recovery Priority Number: 8

**Delisting Criteria:**

The thelypody recovery plan calls for the protection of five self-sustaining thelypody populations throughout its extant and historic range. Each of the five populations should have management plans providing for the plant's long-term protection and have stable or increasing trends for 10 years. Currently, three populations of thelypody receive some level of protection from development and are managed for conservation (USFWS 2010). The Haines Rodeo Grounds is a purchased mitigation site specifically for thelypody conservation, and has a completed management plan for this species. The other two sites (the Miles Ranch Easement and the Baldock Slough introduction site) are easements managed for wetlands protection. While the Baldock slough will remain protected in the Wetland Reserve Program, it is not clear if the reintroduced population will become self-sustaining. In addition, there are also three small roadside populations managed by ODOT under a State Management Area. In the past, there were two populations on private lands near North Powder that were managed via conservation easements: the BLM has managed a population for several years until about 2006, and the TNC managed another population for 15 years. At this time there are no agreements for the management of these two populations and their status is unknown (USFWS, 2016).

**Recovery Actions:**

- Landowner Outreach — Work with local officials in Baker and Union counties to develop a Thelypody Conservation Proposal that includes participation incentives that would then be taken to landowners in thelypody habitat for their consideration. Such a proposal would likely include provisions for establishment of pastures with special management elements for thelypody conservation (e.g., rest or reduced grazing during the growing season) (USFWS, 2018).
- Grazing Research — Continue controlled studies to determine the response of thelypody to livestock grazing outside the plant's primary growing season, as well as the potential to use grazing as a tool to control competing vegetation (USFWS, 2018).
- Manage Haines Rodeo Grounds Site — Work with the Baker County Road Department to reinitiate implementation of the management plan for this site. Of particular concern at this site is control of competing vegetation in thelypody-occupied areas (USFWS, 2018).
- Management Plan for Miles Easement — Finalize a management plan for the Miles Easement and actively pursue its successful implementation (USFWS, 2018).
- Succeed at Baldock Slough — Continue the effort to successfully establish a the lypody population at Baldock Slough. Control of invasive weeds will need to be a key component of this effort (USFWS, 2018).
- Monitoring Plan — Develop and use a practical, standardized methodology for monitoring thelypody populations so that we can obtain comparable data across sites and across years. This methodology would also serve as the basis for a subsequent Post Delisting Monitoring Plan, satisfying one of the delisting criteria in the Recovery Plan (USFWS, 2018).
- All of the General Plant Conservation Measures (Section 3.13.1) apply for thelypody. In additional, livestock grazing will not be used to control or remove invasive and non-native vegetation at project sites occupied by Howell's spectacular thelypody, unless approved by the local Service office (USFWS, 2016).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: ⍰ Stakeholder engagement and landowner outreach – Create a stakeholder group, in cooperation with ODA, to increase communication and action on thelypody conservation programs and promote community interest and involvement in the protection of this rare plant, and to help inform management plans. Partner with local officials in Baker and Union counties to develop a Thelypody Conservation Proposal that includes participation incentives that would then be taken to landowners in thelypody habitat for their consideration.  Management of Haines Mitigation Site – Work with Baker County to update and reinitiate implementation of the management plan for this site and reinitiate its implementation. Of particular concern at this site is control of competing vegetation in thelypody-occupied areas.  Management Plan for Miles Easement – Develop and finalize a management plan, in cooperation with ODA and the land owner, for the Miles Easement and actively pursue its successful implementation. Prioritize monitoring of this site.  Regular monitoring at a subset of sites – Future monitoring should include a full thelypody population count (or sampling where appropriate) and mapping at least every two to four years at a subset of strategically selected sites. This will aid in understanding year to year population variability and population stability, along with changes in the spatial distribution of plants in wet versus dry conditions. Vegetation monitoring transects at Haines Mitigation Site (re-surveyed in 2023) should be repeated to better understand the changing plant composition over time.  Succeed at Baldock Slough – Continue the effort to successfully establish a thelypody population at Baldock Slough. Site preparation and control of invasive weeds, especially whitetop (Lepidium draba), will need to be a key component of this effort.  Continue the Seed-Increase Program – Continue to collect wild thelypody seed and bulk the seed by growing it over the full life cycle (i.e., 2 years to flower and set seed) in a greenhouse setting. Seeds should be collected following both wet and dry years to increase genetic diversity and resilience of the species to climate variability. Consideration should be given to the life expectancy of thelypody seeds, as viability may decrease with time. Seed should be collected from multiple sites and grown at more than one facility to improve representation and redundancy.  Introductions on protected land – Explore options for population introduction at protected sites. Seek out potential sites that support the associated alkali plant community and have adequate hydrology. An analysis of soil composition and hydrology, along with invasive species management and site preparation, is recommended prior to population introduction.  Research unknowns and emerging issues - Climate change is an emerging threat for most rare species, and Howell’s spectacular thelypody may be particularly at risk due to its need for moisture and small geographical range. Research needs include determining what constitutes a “stable” population, including year to year variation in population size and distribution, and response to precipitation, temperature, and groundwater. Research seed viability and longevity (both in storage and in the wild), and continue research into grazing effects.  Consider updating the recovery plan – After implementing the above recommendations and reviewing monitoring data and new research, consider whether to update the 2002 recovery plan using the new 3-part planning process (USFWS, 2023).

# SPECIES ACCOUNT: *Thymophylla tephroleuca* (Ashy dogweed)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 07/19/1984; Southwest Region (R2) (USFWS, 2016)

**Physical Description**

Ashy dogweed is endemic to South Texas and occurs in open flat areas of shrubby grasslands and deep sandy pockets of fine sandy loam soils. Ashy dogweed is a short, woody-based, perennial sub-shrub plant, growing 3.9 – 11.8 inches in height and belongs to the Asteraceae (sunflower) family. It has mostly alternate, linear leaves with ashy-white pubescence due to fine, short hair glands that emit a pungent odor when crushed (U. S. Fish and Wildlife Service 1988). Flower heads are yellow to bright yellow and flowering typically occurs between March and May; however, such events are dependent on rainfall (USFWS 1984) and can occur as early as February (Correll and Johnston 1979). Ashy dogweed is an obligate out-crosser that has non-specialist pollinators from members of the families Buprestidae (beetles), Bombyliidae (bee flies), and Megachilidae (bees) (Dodson 2001, Williamson 2002, Poole et al. 2007).

**Current Range**

Several ashy dogweed populations are considered meta-populations based on relative distance between sites. Surveys conducted in the years since listing have identified five other extant populations in addition to the one known at the time of listing. These populations have increased the known range of the species from Webb to southern Zapata County. The loss, fragmentation and/or alteration of habitat may be increased at these meta-population sites as opposed to plants in populations that are farther apart. Ashy dogweed was first recorded in Starr County in 1932, near Rio Grande City, but is now considered extirpated from this area. This species was federally listed as endangered on July 19, 1984 and a recovery plan for the species was completed in 1988. At the time of listing, the ashy dogweed population was estimated to be 25 acres in size and contained approximately 1,300 individuals (USFWS 1984, 1987). Since then five additional populations have been found and the species' known range has expanded from Webb County into Zapata County, Texas (USFWS 2011). One of the six extant populations is partially on state-owned ROW lands that are maintained by TxDOT. The five remaining populations are found on private lands and three of the land owners have entered into Voluntary Conservation Agreements with TPWD (USFWS 2011). No critical habitat has been designated for ashy dogweed.

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

Adult: Flower heads are yellow to bright yellow and flowering typically occurs between March and May; however, such events are dependent on rainfall (USFWS 1984) and can occur as early as February (Correll and Johnston 1979). Ashy dogweed is an obligate out-crosser that has non-specialist pollinators from members of the families Buprestidae (beetles), Bombyliidae (bee flies), and Megachilidae (bees) (Dodson 2001, Williamson 2002, Poole et al. 2007).

**Habitat Type**

Adult: Grasslands

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Fine sand or sandy-loam soils on level or rolling grasslands that are often shrub-invaded. Freer mixed brush thorn woodland. Mesquite-Acacia thorn woodland. (NatureServe, 2015). Ashy dogweed is endemic to South Texas and occurs in open flat areas of shrubby grasslands and deep sandy pockets of fine sandy loam soils.

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

6 (USFWS, 2022)

**Population Narrative:**

Several ashy dogweed populations are considered meta-populations based on relative distance between sites. Surveys conducted in the years since listing have identified five other extant populations in addition to the one known at the time of listing. These populations have increased the known range of the species from Webb to southern Zapata County. The loss, fragmentation and/or alteration of habitat may be increased at these meta-population sites as opposed to plants in populations that are farther apart. Ashy dogweed was first recorded in Starr County in 1932, near Rio Grande City, but is now considered extirpated from this area. This species was federally listed as endangered on July 19, 1984 and a recovery plan for the species was completed in 1988. At the time of listing, the ashy dogweed population was estimated to be 25 acres in size and contained approximately 1,300 individuals (USFWS 1984, 1987). Since then five additional populations have been found and the species' known range has expanded from Webb County into Zapata County, Texas (USFWS 2011). One of the six extant populations is partially on state-owned ROW lands that are maintained by TxDOT. The five remaining populations are found on private lands and three of the land owners have entered into Voluntary Conservation Agreements with TPWD (USFWS 2011). No critical habitat has been designated for ashy dogweed. At the time of the 5-year status review in 2011, six extant populations were known (Service, 2011). Three occur on private lands and one large extant meta-population partially occurs along the TXDOT U.S. Highway 83 right-of-way (ROW) on both state- and privately-owned lands (USFWS, 2022).

***Threats and Stressors***

**Stressor:**
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Primary threats to the survival of the ashy dogweed have been identified as certain ranching activities, including invasion by non-native grasses planted to improve range conditions. Oil and gas development, highway development and roadside projects, and climate change (e.g. more frequent and/or extended droughts) also threaten the species.

**Stressor:** Habitat Loss
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat loss for ashy dogweed has been largely due to the introduction of non-native pasture grass during the conversion of native rangeland to improved pasture; overgrazing; and ground disturbance activities associated with urban development, construction or improvement of highways and utility transmission systems necessary to support urban infrastructures

**Stressor:** Introduction of non-natives
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Many areas in South Texas are dominated by the introduced buffelgrass (Pennisetum ciliaris), an aggressive, exotic grass. Kleberg bluestem grass (Dicanthium annulatum), used for erosion control on roadway ROWs, also invades natural areas and is present at all ashy dogweed sites although not as extensively as buffelgrass (USFWS 2011).

**Stressor:** Drought
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Drought conditions can reduce plant populations and population size, decreasing genetic variability and viability, thus reducing the species ability to cope with a wide range of environmental stressors (USFWS 2011).

**Stressor:** Grazing
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Seedling establishment can be decreased by chaining, blading, dozing and disking activities that cause deep soil disturbance, along with surface compaction (Williamson 2002) potentially caused by heavy grazing pressures (USFWS 1988). Dodson's (2001) and Williamson's (2002) research suggests that some disturbance may be important for this species' colonization, spread, and/or growth; however, the level of preferred disturbance is unclear.

**Stressor:** Highway construction and improvements
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Highway construction and improvements may adversely impact ashy dogweed populations (USFWS 2011). Since the largest, extant meta-population of ashy dogweed occurs along US 83, roadway improvement projects, highway maintenance, and potential urban

development have the potential to continue to impact the species.

**Stressor:** Development
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The potential for development exists on private lands. An increase in development projects may increase the rate at which these populations are exposed to disturbance activities.

**Stressor:** Pesticides
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The use of herbicides to maintain ROW and control noxious weeds could directly harm a plant and could indirectly kill ashy dogweed pollinators or their host plants (USFWS 2011). Pesticide application to control crop pests, particularly aerial spraying and drift impacts, could also potentially impact populations if they are situated near agricultural areas.

**Stressor:** Oil and Gas Activity
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** When ashy dogweed was listed in 1984, oil and gas activity was not mentioned as a threat to the species. Since 1984, oil and natural gas activities have steadily increased in both Webb and Zapata counties impacting land cover and soils with the development of oil wells, well pads, oil and gas roads, vehicular traffic and/or hydraulic fracturing (“fracking”). The Environmental Protection Agency (EPA) is conducting a study examining the pollution effects of fracking on ground and surface water. Oil and gas activities do not currently occur within the US 83 ROW, but do occur on private lands and are considered significant threats to the ashy dogweed (USFWS 2011).

**Stressor:** Climate Change
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change is considered to be a potential threat to ashy dogweed. “Warming of the climate system is unequivocal, as is now evident from observations of increases in global average air and ocean temperatures, widespread melting of snow and ice, and rising global average sea level” (Intergovernmental Panel on Climate Change (IPCC) 2007). For the next two decades a warming of about 0.2°C (0.4°F) per decade is projected. After that time, temperature projections increasingly depend on specific emission scenarios (IPCC 2007). Various emissions scenarios suggest that by the end of the 21st century, average global temperatures are expected to increase 0.6°C to 4.0°C (1.1°F to 7.2°F) with the greatest warming expected over land (IPCC 2007). Localized projections suggest the southwest United States may experience the greatest temperature increase of any area in the lower 48 states. The IPCC describes the likelihood that hot extremes, heat waves, and heavy precipitation events will increase in frequency. There is also high confidence that many semi-arid areas like the western United States will suffer a decrease in water resources due to climate change (IPCC 2007). Climate change may act alone

or synergistically with the invasion of non-native invasive species to increase their spread and their ability to out-compete native varieties (Archer and Predick 2008). Temperature and precipitation changes, along with increases in atmospheric carbon dioxide and nitrogen, can enhance dispersal pathways for non-natives (Smith et al. 2000), allowing exotic plants to invade new areas and causing range reductions or possibly local extirpations of rare plant populations. Invasion of ashy dogweed habitat by buffelgrass has been described earlier. Due to its limited geographic distribution, and the fact that the largest number of individual plants occur in one meta-population, ashy dogweed is vulnerable to localized catastrophic events, such as flooding or drought, as well as to broader climate changes that could decrease suitable habitat, while simultaneously making conditions conducive to further exotic grass invasion. Extended periods of drought, becoming more common in South Texas also play a role in fire ecology by increasing the frequency, and potentially severity, of fires. Ashy dogweed's response to fire is unknown. However, most of the invasive grass species in south Texas appear to be positively fire adapted, so consequences of increasing drought conditions may include increasing the competiveness of these non-natives (Kuvlesky et al. 2002). Intensified and more frequent fire regimes can allow exotic grasses to form dense monocultures, including in areas where native species are able to persist. The increased amount of biomass and understory produced by these non-native grasses adds to the fuel load, and combined with a lack of precipitation forecast by potential climate change, could affect fire regime characteristics in ashy dogweed habitat including frequency, intensity, extent, type, and seasonality of fires (USFWS 2011). Climate change may also alter pollinator phenology (USFWS 1988). Since ashy dogweed appears to be insect pollinated, alterations in environmental conditions related to climate change, including precipitation and temperature, could alter the phenology of ashy dogweed such that the current blooming and fruiting patterns may not match the timing of pollinators that currently visit these plants, thereby stalling pollination (Sherry et al. 2007). Although it is reasonable to assume that ashy dogweed may be affected by climate change, we lack sufficient certainty to know how climate change will affect the species, and if so, to what extent.

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 5

**Recovery Actions:**

- The primary objective of the recovery plan for ashy dogweed is to protect this species and its habitat from further destruction from human activities and to establish healthy populations in their natural habitat at levels that would allow the species to be down-listed to threatened and eventually delisted (USFWS 1987).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The Service finds that impacts to the species from loss, fragmentation and/or alteration of habitat are continued threats to ashy dogweed. Current populations conditions remain unchanged and appear stable since the previous 5-year status review (Service, 2011). A complete evaluation of the biology through genetic studies, species monitoring on private lands and involvement with private landowners is recommended (USFWS, 2022).

# SPECIES ACCOUNT: *Trifolium amoenum* (Showy Indian clover)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest Region (R8)

**Physical Description**

An annual herb, 1-6 dm tall, hairy and often robust. Leaves are divided into 3 egg-shaped leaflets. Flowers (April-June) are purple with white tips and are borne in dense, round or oval heads, 2-3 cm long (NatureServe, 2015).

**Taxonomy**

A distinct species in a genus of about 300 species, most abundant in north temperate regions (NatureServe, 2015)

**Historical Range**

Historically in Alameda, Mendocino, Marin, Santa Clara, Solano, Sonoma, Napa counties, California (NatureServe, 2015)

**Current Range**

Currently believed extant only in Marin (native) and Sonoma (reintroduced) counties (NatureServe, 2015).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Self pollination and outcrossing (NatureServe, 2015)

**Reproduction Narrative**

Adult: Mating system appears to include both cross-and self-pollination, as extant plants were found to have a higher level of heterozygosity than would be expected in a predominantly self-pollinating species (Knapp and Connors 1999 cited in USFWS 2007).; Mixed selfing and outcrossing (NatureServe, 2015).

**Habitat Type**

Adult: Grasslands (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Serpentine soil (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species is typically in low, wet swales in grasslands. Also on grassy hillsides at up to about 400 m elevation. Per the California Dept. of Fish and Game (2000): Open, sunny sites, sometimes on serpentine soil in coastal bluff scrub and valley and foothill grassland; most recently seen on a roadside that had been graded and on an eroding cliff face. Possibly requires disturbance-created openings for germination (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species and the low number of populations and individuals.

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Decreasing (NatureServe, 2015)

**Number of Populations:**

2 (USFWS, 2023)

**Population Size:**

1 - 1000 individuals (NatureServe, 2015)

**Population Narrative:**

Historically known from 25 sites but probably extirpated at all but 1 of these (although some viable seed may remain in seedbanks and may germinate if conditions are right). Loss of habitat to urbanization and agriculture was probably the primary reason for the extirpation of so many populations. Even since 1997 when this species was listed as Endangered, much habitat potentially suitable for restoration has been altered and is now unsuitable due to urbanization, agricultural operations, and changes in the biological community and hydrological conditions (USFWS 2007). Decline of >90% The one native occurrence had about 225 plants when it was discovered in 1996 (California Dept. of Fish and Game 2000). Had been thought extinct until the early 1990s. A single plant was found in 1993 at a site in Sonoma County, but that site has now been developed and the species is considered extirpated there. However, seeds were collected from the plant prior to its extirpation and were subsequently multiplied. In 2006, some of those seeds were used to establish experimental populations at two sites in Sonoma County and at several sites at Point Reyes National Seashore (Marin County). It is as yet unknown whether any of the experimental sowings will persist (USFWS 2007). Another population, the only native population currently extant, was discovered in 1996 in Marin County. In 1997, seed from those plants was used to establish a small experimental population (approximately 20 seedlings) at

Bodega Marine Laboratory (Sonoma County) (USFWS 2007). The Bodega experimental population had persisted as of 2007, but its long term fate is unknown (USFWS 2007) (NatureServe, 2015). NatureServe (2015) also notes that the short-term trend for this species is a decline of 10% and the long-term trend is a decline of 90%. Low resiliency, representation and redundancy are inferred based on the low number of known populations and individuals. The species was considered extinct until 1993 when a single plant with the “erect” phenotype was discovered on privately owned property in Occidental, Sonoma County. Following the species’ discovery in Occidental, the locality site was developed, and the species is now extirpated from this site. Another native population with the “prostrate” phenotype was discovered in 1996 in Dillon Beach in Marin County on privately-owned property. The Dillon Beach population was the only known population at the time of listing (Service 1997, p. 55806). At the time of the Service’s previous 5-year review for the species in 2012 the Dillon Beach population was still extant, and the Service and its partners had established an outplanted population at Point Reyes National Seashore as well as another outplanted population at the Bodega Marine Reserve in Sonoma County that was extirpated by the time of the 2012 5-year review (Service 2012, p. 3). Currently, the distribution of the species is unchanged from the species’ previous 5-year review in 2012. Specifically, only the Dillon Beach and Point Reyes National Seashore populations, both possessing the “prostrate” phenotype, are known to remain in the wild (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Urbanization (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Urbanization is listed as a threat to this species (USFWS, 2012).

**Stressor:** Agriculture (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Conversion of land to agriculture is listed as a threat to this species (USFWS, 2012).

**Stressor:** Erosion (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In addition to the threat from erosion of the hillside, in a 2010 annual report, Dr. Connors states the possibility of an earthquake that could result in a significant portion of the Dillon Beach population being lost in a landslide since it is very close to the eroding cliff (Connors 2010) (USFWS, 2012).

**Stressor:** Trampling (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A small trail providing local homeowners with access along the bluffs runs directly through the population. Although current use of the trail does not appear to threaten the

population, any increase in use or expansion of the trail could adversely affect the population (Connors 2006) (USFWS, 2012).

**Stressor:** Herbivory (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbivory by gophers and voles is listed as a threat to this species (USFWS, 2012).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The State's authority to conserve plants is comprised of four pieces of legislation: The California Endangered Species Act (CESA), the Native Plant Protection Act (NPPA), the California Environmental Quality Act (CEQA), and the Natural Community Conservation Planning Act (NCCPA). Trifolium amoenum is not listed under CESA, therefore neither that Act nor the NPPA apply to this review. The California Environmental Quality Act (CEQA) (chapter 2, section 21050 et seq. of the California Public Resources Code) requires government agencies to consider and disclose environmental impacts of projects to not only federally listed species, but also to those considered "rare" by other agencies or professional associations. Trifolium amoenum, although not state listed, is considered a List 1B plant by the California Native Plant Society. Any impacts to T. amoenum would be subject to evaluation through CEQA. The CEQA also requires the avoidance or mitigation of those impacts, where possible. Under CEQA, public agencies must prepare environmental documents to disclose environmental impacts of a project and to identify conservation measures and project alternatives. Through this process, the public can review proposed project plans and influence the process through public comment. However, CEQA does not guarantee that such conservation measures will be implemented. Currently there are no completed regional or county-wide Habitat Conservation Plans per the Federal Endangered Species Act (HCPs) or Natural Community Conservation Plans (NCCPs) per the Natural Community Conservation Planning Act at any of the known occurrences (USFWS, 2012).

**Stressor:** Non-native exotic plants (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The most significant long-term threat to the Dillon Beach 10 population is invasion by the non-native Carpobrotus edulis (iceplant or sea fig). This plant, which competes for habitat with Trifolium amoenum, was planted for fire and erosion control in the adjacent yard and reached the T. amoenum population for the first time in 1999. Dr. Connors has developed an agreement with that landowner on an iceplant control program involving both hand-pulling and herbicide (Roundup) application (Connors 2006). Though the landowners do not follow any practices that would be harmful to the population, the status of iceplant removal is unknown. Other invasive competitors already present at the site, including Lolium multiflorum (Italian ryegrass) and Plantago lanceolata (English plantain), may gain in population size or density at the expense of T. amoenum (Connors 2006, in litt.). In addition, the non-native grass Holcus lanatus (velvet grass) is not currently at the site but has invaded many coastal bluff plant communities in the area. It could be a strong invader of the T. amoenum population if it became established at

the Dillon Beach site (Connors 2006) (USFWS, 2012).

**Stressor:** Small population size and few populations (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** As discussed in the listing rule (Service 1997) and the 2007 5-year review, the conservation biology literature commonly notes the vulnerability of taxa known from one or very few locations and/or from small populations (e.g., Shaffer 1981, 1987; Primack 1998; Groom et al. 2006). In these situations, genetic diversity can become dangerously low. Also, as Dr. Connors reports, annual plants like clovers naturally fluctuate annually, likely due to regional patterns in amounts and timing of rainfall (Connors 2010). Yearly fluctuations in the Dillon Beach population have been large, with occasional 15 to 20-fold changes between subsequent years. Seedling density was high and quite similar in 2007, 2009 and 2010, but much lower in 2008 (Connors 2010). Seed production has been even more variable. Trifolium seeds are typically long-lived in suitable soils, and the importance of a seedbank in sustaining this T. amoenum population has been demonstrated by the strong rebounds of the population in 2007 and 2009 (Connors 2010). However, if several years of low germination in a small population are followed by a disruption to or removal of the seedbank, genetic diversity may be further diminished. That Trifolium amoenum occurs in small numbers and at few locations has not changed since the time of listing or the last 5-year review. Therefore, threats associated with these factors remain. The combination of a single native population, small range, and restricted habitat makes this species highly susceptible to extinction or extirpation due to random events, such as flood, drought, disease, or other occurrences (USFWS, 2012).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 2

Urbanization and land development. A1 The species persists in at least five total geographically-widespread populations (including the current Dillon Beach and Point Reyes National Seashore populations), as defined above. Each population possesses a minimum mean geographic coverage of 0.41 acre with a minimum density of 17 seedlings per square meter in survey transects over a five-year period including at least one below-average rain year for the population locality. This observation period must contain a below-average rain year in order to demonstrate the population’s ability to withstand this frequent stressor. (USFWS, 2025)

Erosion and geological events. A2 For each of the five populations described in Downlisting Criterion A1 above, there is a site-specific monitoring plan in place to monitor the effects of erosion on the population. (USFWS, 2025)

Trampling. A3 For each of the five populations described in Downlisting Criterion A1 above, there is a site-specific monitoring plan in place to monitor the effects of trampling and recreational activity on the population. (USFWS, 2025)

Non-native invasive species. A4 For each of the five populations described in Downlisting Criterion A1 above, there is a site-specific monitoring plan in place to monitor the effects of nonnative invasive species on the population. (USFWS, 2025)

**Delisting Criteria:**
A1 The species persists in at least five total geographically-widespread populations (including the current Dillon Beach and Point Reyes National Seashore populations). Each population possesses a minimum mean geographic coverage of 0.41 acre with a minimum density of 17 seedlings per square meter in survey transects over a ten-year period including at least two below-average rain years for the population locality. As in the downlisting criteria above, this observation period must include at least two below-average rain years to demonstrate the population's ability to withstand this frequent stressor. (USFWS, 2025)

A2 The geographic breadth of at least five total populations meeting the specifications described in Delisting Criterion A2 above are protected from incompatible uses through a formal agreement with the landowner such as a conservation easement or Conservation Benefit Agreement with the Service. (USFWS, 2025)

Erosion and geological events. A3 A site-specific management plan to control the effects of erosion on the species is developed and implemented for any populations threatened by erosion (e.g. the Dillon Beach population). (USFWS, 2025)

Trampling. A4 A site-specific management plan to control the effects of trampling and recreational activity on the species is developed and implemented for at least five populations meeting the specifications of Delisting Criterion A1 above (USFWS, 2025).

Non-native Invasive species. A5 A site-specific management plan to control the effects of non-native invasive species on the species is developed and implemented for at least five populations meeting the specifications of Delisting Criterion A1 above. (USFWS, 2025)

**Recovery Actions:**
- No approved final or draft recovery plan for Trifolium amoenum has been completed or is in preparation. (USFWS, 2012).
- 1) Complete and implement a recovery plan for T. amoenum which outlines specific recovery criteria and recovery tasks (USFWS, 2012).
- 2) Continue to monitor known populations of T. amoenum so as to discern population sizes and the differences between natural and unnatural population fluctuations (USFWS, 2012).
- 3) Conduct range-wide surveys to identify additional populations for protection and outcrossing purposes (USFWS, 2012).
- 4) Expand the genetic base of the Occidental population, currently used for reintroduction experiments, to prevent further loss of evolutionary potential and the possibility of deleterious effects associated with inbreeding. Any additional plants found as a result of (3) above should be used to expand the genetic variability. If no additional individuals are identified, the Dillon Beach population should be used. Much care must be used during this process, however, as phenotypic difference between the two populations are likely adaptive. Through "controlled introgression", a small proportion of the non-local Dillon Beach source seed could be mixed into the Occidental population over time, such that local adaptive variation is maintained while promoting adequate levels of within population genetic variation (Knapp and Connors 1999) (USFWS, 2012).

- 5) Reintroduce both growth forms into suitable habitat. The two forms of T. amoenum should be treated separately in any reintroduction efforts, however, because these forms have morphological differences which may be adaptive. The establishment of a self-sustaining population in a preserved area would greatly increase the likelihood of recovery of this species. Suitable habitats might be found at the Bodega Marine Laboratory or on State or Federal lands in the area (USFWS, 2012).
- 6) Conduct research into (a) the role of herbivory, (b) whether the presence of gophers is beneficial or detrimental, (c) reasons for interannual variability in population numbers and seed productivity, (d) the tolerance of T. amoenum to different soil types, and (e) the effect of disturbance regimes on T. amoenum, among other topics (USFWS, 2012).
- Action 1. Protect and manage existing populations of showy Indian clover (Priority 1). 1-1 Identify and execute opportunities to protect existing populations on private lands (i.e. the Dillon Beach population) through a formal agreement with the landowner such as a conservation easement or Conservation Benefit Agreement with the Service. 1-2 Identify and execute opportunities to protect existing populations on private and public lands by developing and implementing management plans for erosion and recreation effects on the species. (USFWS, 2025a)
- Action 2. Increase the number of existing showy Indian clover populations and the number of plants within each population (Priority 1). 2-1 Partner with local landowners and agencies to identify suitable areas for species outplanting and population augmentation. 2-2 Work proactively with partners to address regulatory issues which may arise from outplanting or population augmentation efforts. 2-3 Develop and implement greenhouse experiments as described in Action 5 below to identify key habitat needs of the species for germination and survival. 2-4 Partner with botanical gardens to multiply seed for outplanting and population augmentation. 2-5 Implement outplanting and population augmentation efforts, including population monitoring as described in Action 3 below. (USFWS, 2025a)
- Action 3. Conduct range-wide and long-term monitoring of showy Indian clover populations (Priority 2). 3-1 Identify partners to develop and implement a long-term monitoring program for showy Indian clover populations to observe trends in population abundance. 3-2 Identify and mark suitable long-term monitoring transects within each known population. 3-3 Survey monitoring transects both early and late during the flowering period (i.e. before and after seed set) to identify demographic trends in seedling mortality for each population each season. 3-4 Monitor the status of threats to populations such as invasive plants, erosion, and recreational use to inform management of these threats. (USFWS, 2025a)
- Action 4. Conduct rangewide field surveys (Priority 3). 4-1 Partner with local landowners and agencies to identify areas which contain suitable habitat for the species and obtain survey access to these areas. 4-2Conduct surveys of suitable habitat areas during the species' flowering season to identify any remaining wild populations. This action would also support recovery activity 2-1 above (identification of suitable areas for species translocation). (USFWS, 2025a)
- Action 5. Perform research on the fundamental biology of showy Indian clover throughout its known range (Priority 3). 5-1 Perform research on the specific habitat needs of the species. Specifically, research should address questions on the effects of grazing and herbivory on the species as well as the habitat needs of the species. 5-2 Perform research on how the habitat needs of the "erect" phenotype differ from the "prostrate" phenotype. 5-3 Perform experimental crosses to determine the "erect" phenotype's ability to cross with the "prostrate" phenotype. (USFWS, 2025a)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1) Continue to monitor the Dillon Beach and Point Reyes National Seashore populations and implement management strategies to address threats to these populations. 2) Identify potential outplanting areas suitable for both the “prostrate” and “erect” phenotypes of the species and outplant additional “prostrate” and “erect” populations. 3) Collect fresh seed to re-invigorate the species’ seed multiplication program and continue to store seed from the “erect” and “prostrate” forms in service of future outplanting efforts. 4) Conduct research into improving outplanting success rates such as identifying optimal soil geology and chemistry. 5) Perform breeding crosses and genetic analyses of “prostrate” and “erect” individuals to determine whether the differing phenotypes of the species reflect reproductive isolation. (USFWS, 2022)

# SPECIES ACCOUNT: *Trifolium trichocalyx* (Monterey clover)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest Region (R8)

**Physical Description**

A prostrate, spreading annual herb. The prostrate branches are sometimes only 3-4 cm long, but can reach 30 cm under favorable conditions. Flowers are borne in heads, 4-14 mm wide, the pale purple petals barely extending beyond the bristly calyces. Blooms April-June. (NatureServe, 2015)

**Taxonomy**

Trifolium trichocalyx (Figure 7) was first collected by Amos A. Heller in 1903 following a fire 2 years earlier "in sandy pine woods about Pacific Grove" (Heller 1904). The species was described by Heller the following year (Heller 1904). Laura F. McDermott considered the taxon a variety of T. oliganthum in her treatment of the genus (McDermott 1910), although this classification was not recognized in subsequent floras. Axelrod (1982) reported at least one researcher who suggested that Monterey clover was a sporadic hybrid between T. microcephalum and T. variegatum and recommended removing it from the list of Monterey endemic taxa. This view was challenged by V. Yadon (in litt. 1983) who had grown T. trichocalyx and observed it consistently producing up to seven seeds per pod, while both putative parent plants were two-seeded taxa. Trifolium trichocalyx has continued to be recognized as a distinct species by Abrams (1944), Munz and Keck (1959), Howitt and Howell (1964), and Isely (1993), and we accept it as such (USFWS, 2004).

**Historical Range**

Monterey clover was historically only known from a 206 acre area in Monterey County (Figure 1) (Service 2009, p. 2) on land that is now largely owned and managed by the Del Monte Forest Conservancy and the Pebble Beach Company. In 2011, Monterey clover was identified along logging roads during botanical surveys for a timber harvest plan in Mendocino County, approximately 200 miles (mi) north of the historical range (USFWS, 2025).

**Current Range**

Monterey clover) is known from only one area (Huckleberry Hill) covering approximately 16 hectares (40 acres) on property owned by the Pebble Beach Company on the Monterey Peninsula. During 1996, two locations in the Huckleberry Hill area with a total of 22 plants were located (USFWS, 2004). In 2011, Trifolium trichocalyx was identified along logging roads in Mendocino County. Additional populations have since been found in Mendocino but the population sizes and area remain restricted. (USFWS, 2019). Monterey clover occurs in the understory of Monterey pine (Pinus radiata) forest in Monterey County (Service 2009, p. 6) and along logging roads in mixed forest of coast redwood (Sequoia sempervirens), Douglas fir (Pseudotsuga menziesii), and tanoak (Notholithocarpus densiflorus) in Mendocino County (Heise et al 2012, p. 167). The common element between the two locations is recent disturbance that results in low canopy cover and reduced competition for light from other species both native and non-native. The disturbance regime has been based on fire cycles (Service 2004, pp. 37-38) in Monterey County, while in Mendocino County the disturbance regime has resulted from the construction and use of logging roads (Service 2020, pp. 7-8). It is possible that Monterey clover is more widespread in both Monterey and Mendocino Counties but has gone undetected either from lack of surveys or presumed absence based on habitat type. The variation in associated species between the two locations suggests that habitat requirements may not be as strict as previously described (USFWS, 2025).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Trifolium trichocalyx flowers between April and June (USFWS, 2004).

**Reproduction Narrative**

Adult: Trifolium trichocalyx appears to regenerate in large numbers during spring following a fire that removes the dense vegetative cover that shelters its seed bank. Trifolium trichocalyx populations will decline as shrubs and seedlings overshadow the plants as the forest begins to recover following a fire. Trifolium trichocalyx appeared after the 1901 fire and again after the 1987 fire, thus possibly harboring a seed bank capable of surviving more than 90 years. Recent studies indicate light as the only germination requirement (Doak et al. 2000). However, seeds buried in the soil at Huckleberry Hill may require different germination cues than those seeds used in germination experiments because experimental seeds were never buried (Doak et al. 2000). Trifolium trichocalyx flowers between April and June. Small bees are likely pollinators as they are with other Trifolium clover species, although no pollinators were observed in previous studies (Jones and Stokes Associates 1996). Additionally, scarification may stimulate some Trifolium trichocalyx to bloom between fires (V. Yadon in litt. 2002) (USFWS, 2004).

**Habitat Type**

Adult: Pine forest (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Fire dependent (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (NatureServe, 2015)

**Site Fidelity**

Adult: High (NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits openings in and edges of Monterey pine forest. Ephemeral: plants persist for a few years following fire or other vegetation removal, but are shaded out or outcompeted after that. Soils are poorly drained, coarse loamy sands. < 100 m elevation (NatureServe, 2015).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Trifolium trichocalyx becomes scarce when the forest canopy closes, persisting primarily as a seed bank in the soil while shade and competition increase during succession of the forest community (USFWS, 2004).

***Population Information and Trends***

**Population Trends:**

Increasing in new locations, decreasing in other locations (USFWS, 2025)

**Number of Populations:**

2 (USFWS, 2025)

**Population Size:**

Thousands (USFWS, 2025)

**Population Narrative:**

The Service considers there to be two populations of Monterey clover, one population in Monterey County and another in Mendocino County with multiple sublocations (Figure 1). The sublocations in Mendocino County relate to monitoring areas for timber harvest plans rather than biological or geographical boundaries. In Monterey County, Monterey clover is under surveyed and information on abundance since listing in 1998 is sparse. We do not break out sublocations for the Monterey population because of the lack of abundance information coupled with inaccurate historical spatial data. Despite multiple survey attempts through 2022, no Monterey clover have been observed in Monterey since 2016 when only 23 individuals were identified (McCabe 2017, pp. 2-6) (Table 1). Prior to 2016, Monterey clover was only documented in 1987 (several hundred to a thousand) and in 1996 (22) (Service 2004, p. 37). The lack of observations may be due to a lack of continuous survey effort but may also reflect a stabilization of the habitat from lack of disturbance that results in higher canopy cover and greater understory competition inhibiting germination and growth (USFWS, 2025).

***Threats and Stressors***

**Stressor:** Urban and recreational (e.g., golf courses) development (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The Recovery Plan (Service 2004) identifies the most significant threat to the species has been the loss of potential habitat from urban and recreational (e.g., golf courses) development. At the time of listing, less than 20 percent of the historical Monterey pine forest on the Monterey Peninsula was estimated to remain, much of it in fragmented and increasingly isolated stands (Jones and Stokes Associates 1994 in Service 1998). Jones and Stokes Associates

(1996) estimated that habitat for the species has declined approximately 69 percent, from 1,754 acres (710 ha) to 539 acres (218 ha) as of 1996. Of locations mapped for the species, the majority of occurrences appear to be within the Huckleberry Hill Natural Reserve and Morse Reserve; however, individuals have been identified adjacent to the south of the Huckleberry Hill Natural Reserve. A number of plants are presumed to have been extirpated when the Poppy Hills Golf Course was developed in 1980 (Service 2004). The Service is unaware of any potential habitat losses since the species was listed in 1998 (USFWS, 2009).

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** At the time of listing, regulatory mechanisms thought to have some potential to protect Trifolium trichocalyx included: (1) listing under the California Endangered Species Act (CESA); (2) the California Environmental Quality Act (CEQA) and the National Environmental Policy Act (NEPA); (3) the California Coastal Act; and (4) local land use laws, regulations, and policies. The listing rule (63 FR 43100) provides an analysis of the level of protection that was anticipated from those regulatory mechanisms. This analysis appears to remain currently valid. Trifolium trichocalyx was listed as endangered by the State of California in 1979. As such, projects that would affect Trifolium trichocalyx are subject to CESA and CEQA requirements. The lead CEQA agency with primary authority or jurisdiction over a project is responsible for conducting a review of the project and to consult with other agencies concerned about resources affected by the project. However, required biological surveys are not always adequate to identify the presence of Trifolium trichocalyx, as the species is not visible above ground while it exists as seed banks. In addition to the laws and regulations discussed above, local county regulations may also benefit Trifolium trichocalyx. This species occurs within a portion of the Monterey Peninsula included in the California Coastal Zone. The Del Monte Forest Land Use Plan of 1984 was developed to comply with the Coastal Act’s requirement that all counties prepare a plan for those portions of the Coastal Zone within their jurisdiction. Once the Del Monte Forest Land Use Plan was certified by the CCC, development permits within the Del Monte Forest coastal zone became the responsibility of the County of Monterey. The County of Monterey also has designated certain areas, including a portion of where Trifolium trichocalyx is known to occur, as ESHAs. Although the County of Monterey recognizes the importance of these areas, protection of listed species through the California Coastal Act and local land use designations is dependent upon the review of the lead agency involved. Additionally, while no development projects have been implemented in the area where Trifolium trichocalyx occurs since the time of listing, State and local regulations may not protect the species from indirect impacts that occur from such threats as changes in hydrology in adjacent areas and the spread of nonnative species (USFWS, 2009).

**Stressor:** Alteration of fire frequency (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat/loss of populations
**Narrative:** At the time of listing, the alteration of natural fire cycles was identified as a significant threat to the species’ survival. The species is only known to occur within an area bordered by residential development and Pebble Beach Company facilities (e.g., golf courses, structures). This fact combined with the limited remaining habitat makes this species extremely susceptible to

stochastic events. Trifolium trichocalyx seed banks within the Huckleberry Hill area are apparently viable after an extended period of time; however, due to fire suppression, the normal fire cycle in Monterey pines has been lengthened. Due to the lack of knowledge on the species, it is unknown what effect the lack of a natural fire regime will have on seed viability. In the absence of fire, or a reasonable habitat disturbance alternative, this species could become extirpated at certain locations or potentially be rendered extinct (CDFG 2005) (USFWS, 2009).

**Stressor:** Small numbers of individuals and populations (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of genetic diversity
**Narrative:** Conservation biology literature discusses that small populations are threatened by inbreeding depression (Ellstrand and Elam 1993). Small populations can have significantly lower germination rates than larger populations of the same species due to high levels of homozygosity (Menges 1991). Based on historical records, we believe that urban and recreational development on the Monterey Peninsula has already reduced the distribution of this species in the area where it occurs. Indirect effects from urbanization in the Huckleberry Hill area could include changes in hydrology, vegetation, and an increase in nonnative species. While any one of these factors may not be enough to threaten the survival of Trifolium trichocalyx independently, its limited range and the cumulative and synergistic effects of all of these factors combined could be a threat to the survival and recovery of the species (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). Recently, the potential impacts of climate change on the flora of California were discussed by Loarie et al. (2008). Based on modeling, they predicted that species’ distributions will shift in response to climate change, specifically that the species will “move” or disperse to higher elevations and northward, depending on the ability of each species to do so. Species diversity will also shift in response to these changes with a general trend of diversity increases shifting towards the coast and northwards with these areas becoming de facto future refugia. However, predictions of climatic conditions for smaller sub-regions such as California remain uncertain. It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects. While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to Trifolium trichocalyx at this time (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:**

***Recovery***

**Reclassification Criteria:**
1. At least five viable populations (i.e., populations that are stable or increasing based on a minimum of 12 years of monitoring) occur in suitable habitat. One of these populations is the Huckleberry Hill population (USFWS, 2009).

2. All five of the sites are on land that is protected from human-induced disturbance (i.e., development, recreation) that would negatively affect growth or reproduction of the plants. Funds must be available for appropriate long-term management. As determined by research, protected habitat must be of adequate size (large enough to support a functioning ecosystem [e.g., species present to support seed dispersal and pollination, areas that support fluctuating distributions, areas that harbor suitable unoccupied habitat for population expansion]) and configuration to ensure that ecosystem and community processes and associated species (e.g., hydrologic regime, fire, food webs, pollinator fauna, Monterey pine forest communities) are maintained, and that an adequate diversity of sites exist for population expansion and for colonization of new areas as microhabitat conditions change (USFWS, 2009).

3. The Huckleberry Hill population and four additional viable populations (as described in 1 above) have been managed so as to allow regeneration of plants and replenishment of the seed bank found in the soil within protected habitat (USFWS, 2009).

4. A seed bank has been established at a recognized institution certified by the Center for Plant Conservation (USFWS, 2009).

Recovery Priority Number: 5C

**Delisting Criteria:**
Delisting Criterion 1) threats are reduced or eliminated so that protected populations are capable of persisting without significant human intervention or perpetual endowments are secured for management necessary to maintain the continued existence of the species. We currently do not know what the specific habitat needs are for this species. To the best we know now, the most outstanding management need currently is: a) integrate, or find a replacement for, a fire regime as a means of revitalizing declining or senescing colonies; and b) research on soil seed bank dynamics and conditions for germination. (USFWS, 2019).

Delisting Criterion 2) unoccupied habitat in the area has been assessed for its suitability for reintroduction efforts; the area in Mendocino County where colonies were discovered in 2011 should be assessed, as well as the Monterey Peninsula area. Also, two additional, new populations are established and protected where appropriate. (USFWS, 2019).

Delisting Criterion 3) all protected populations remain viable for at least 10 years to demonstrate long-term viability under a range of environmental conditions. Assuming that habitat was being managed to incorporate a fire regime to increase openness and to release fire-adapted seed, we would then expect above-ground population size to fluctuate annually, based on response to amount and timing of rainfall (e.g. see Fox et al. 2006). Therefore, a period of 10 years should be long enough to include most of the variability in rainfall that occurs in this region (Zedler & Black 1989; NOAA 2018). (USFWS, 2019).

**Recovery Actions:**

- No other populations have been discovered or re-introduced within the known historic range of the species; therefore, this criterion has not been met. Ensuring that five viable populations occur in suitable habitat may be relevant; however, the complexities associated with identifying discrete populations of this ephemeral plant make it difficult for us to measure this criterion. This criterion may need to be revised in future recovery plans and could be based on preserving all or portions of the species remaining potential habitat (USFWS, 2009).
- As discussed above, we currently have no appropriate method for measuring five viable populations of the species; therefore, this criterion may need to be revised in future recovery plans. The majority of Trifolium trichocalyx occurrences are within areas that have been permanently protected by easements (i.e., Huckleberry Hill Natural Reserve and Morse Reserve). However, we believe that any further development in the Huckleberry Hill area of the Monterey Peninsula would directly reduce the species remaining habitat. Undeveloped areas within the vicinity of Huckleberry Hill that are not protected by easements are important for potential expansion of the species, and we believe they require protection. Additionally, funds dedicated for long-term management of the species in protected areas have not been committed. This criterion has not been met (USFWS, 2009).
- As stated in criteria (1) and (2) above, we have no suitable method to determine five distinct populations of this ephemeral species. Currently, the areas where Trifolium trichocalyx is known to occur is not being managed to allow regeneration of plants and replenishment of the seed bank. This criterion has not been met (USFWS, 2009).
- Currently Trifolium trichocalyx seed is being stored at the Plant Genetic Resources Conservation Unit located on the Griffin Campus of the University of Georgia. Additionally, Trifolium trichocalyx seed is being stored at the U.S. Department of Agriculture's National Center for Genetic Resource Preservation in Fort Collins, Colorado. This criterion is relevant and up-to date. This criterion has been met (USFWS, 2009).
- 1. Work with Pebble Beach Company, Del Monte Forest Foundation, Pebble Beach Community Services District, and Pebble Beach residents to develop and implement a fire management plan that would mimic natural fire regimes within the Huckleberry Hill area. If a burn management plan is not implemented, burn box experiments should be conducted to determine where the species occurs within the Huckleberry Hill area (USFWS, 2009).
- 2. Surveys for Trifolium trichocalyx should be conducted following fires and/or following substantial scarification of potential habitat on the Monterey Peninsula (USFWS, 2009).
- 3. Experiment with establishment of new populations in similar habitat on the Monterey Peninsula or at Point Lobos State Reserve. If these efforts are successful, attempts to establish other populations could be undertaken on the Monterey Peninsula (USFWS, 2009).
- 4. Germination trials should be conducted that mimic natural soil conditions and germination cues to establish more clearly the conditions needed to facilitate germination (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: The following actions are recommended based on the current 5-Year Review: 1. Annual surveys should be conducted within the historical range in Monterey County with attention given to areas where disturbance within the past 5 years is known to have occurred. 2. Annual surveys for populations in Mendocino County continue with attention given to frequency of use and any management actions taken. 3. Potential suitable habitat is identified and surveyed in areas between the northern and southern boundaries. 4. Seed from both populations are collected and stored within a seed bank. 5. Germination and outplanting strategies should be developed if an adequate amount of seed can be collected. Outplanting and monitoring should be attempted at potentially suitable habitat in both Mendocino and Monterey Counties. (USFWS, 2020)

- RECOMMENDATIONS FOR FUTURE ACTIONS: The following actions are recommended based on the current 5-Year Review: 1. Conduct regular annual surveys in Monterey and Mendocino Counties where the species is known to occur. Surveys should include estimates of abundance, spatial information, associated species, threats, description of disturbance drivers, and general habitat conditions/land use. 2. Conduct surveys for Monterey clover in areas where there is suitable habitat in both Monterey and Mendocino Counties. Logging roads within suitable habitat, both active and inactive, as well as dirt access roads or hiking paths may offer relatively easy survey targets. 3. Identify and survey potential suitable habitat in areas between the northern and southern populations. 4. Collect seed from Monterey, Big River, and Garcia Section 11 store within a conservation seed bank. 5. Develop germination and outplanting strategies if an adequate number of seed can be collected. Design and implement outplanting and monitoring experiments at potentially suitable habitat in both Mendocino and Monterey Counties. (USFWS, 2025)

# SPECIES ACCOUNT: *Verbena californica* (Red Hills vervain)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 10/14/1998; California/Nevada Region (R8) (USFWS, 2016)

**Physical Description**

A perennial herb, 3-7.5 dm tall, that produces spikes of blue to purple flowers. Blooms May-September. (NatureServe, 2015)

**Taxonomy**

Verbena californica is a narrowly distributed biennial or perennial herb belonging to the vervain family (Verbenaceae). Verbena californica was first discovered in 1938 in Tuolumne County, California (Moldenke 1942) (USFWS, 2008).

**Current Range**

Currently, the entire range of Verbena californica is presumed to be an area of about 77 square kilometers (30 square miles) or 12 kilometers (7.5 miles) by 6.4 kilometers (4 miles). Within this narrow range, the total area occupied by the populations is estimated to be 50 hectares (124 acres) (CNDDB 2011). Verbena californica grows at elevations between 255 and 400 meters (837 to 1,310 feet) (CNDDB 2011). Most of the sites are within the expanded Red Hills Area of Critical Environmental Concern (ACEC) that now consists of about 4,042 hectares (9,988 acres, about 15.6 square miles) of public land south of the historic town of Chinese Camp in Tuolumne County (BLM 2011) (USFWS, 2012).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Formerly, the species was thought to also reproduce vegetatively through rhizomes, but Knox (1998) found no evidence of rhizomes when she dug up plants. In nature, seed germination has been observed as early as mid-October and probably continues throughout the winter (Knox 1998). The progress of seedling maturation has not been reported. Plants mature and can begin flowering by late May, with flowering continuing through September (Stone 1992; Tibor 2001) (USFWS, 2012).

**Reproduction Narrative**

Adult: Knox (1998) determined that soil moisture was the primary factor influencing the distribution and reproduction of this species. Underground springs were responsible for maintaining summer water flow in the stream reaches she studied. Nine of the total 11 V. californica occurrences are along streams in Pinus sabiniana (foothill pine) woodlands (USFWS, 2008). Seeds apparently are the primary means of reproduction for Verbena californica. Formerly, the species was thought to also reproduce vegetatively through rhizomes, but Knox (1998) found no evidence of rhizomes when she dug up plants. In nature, seed germination has been observed as early as mid-October and probably continues throughout the winter (Knox 1998). The progress of seedling maturation has not been reported. Plants mature and can begin flowering by late May, with flowering continuing through September (Stone 1992; Tibor 2001). Flowering begins at the bottom of the flower cluster and progresses upward through the season (Stone 1992). Dates of seed formation in nature have not been reported, although transplants grown in an outdoor garden had mature seeds present in July (Knox 1998). Considering that each flower can produce as many as four seeds, Knox (1998) estimated that potential seed production at her three study sites ranged from 282 to 1,245 seeds per plant. The lowest estimate was at an atypical site in a meadow with compacted soils and severe competition (Knox 1998). Seed dispersal mechanisms are not known for V. californica (USFWS, 2012). Availability of pollinating insects is important for reproduction. Pollination of Verbena californica has not been studied in great detail, but insects visiting the flowers, and possibly transferring pollen, include butterflies, flies, beetles (Stone 1992), and bees (Moldenke 1972). The most frequent visitors according to Stone (1992) were butterflies in the genus Ochlodes (woodland skippers; family Hesperiidae). However, Moldenke (1972) reported only bees visiting the flowers of V. californica in 1970 and 1971, including two species of leafcutting bees (family Megachilidae), Anthidium edwardsii and Chalcidoma angelarum, and two cuckoo bees (family Anthophoridae), Anthophora urbana and Melissodes lupina (USFWS, 2012).

**Habitat Type**

Adult: Woodland/grassland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Serpentine substrates (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species occurs along intermittent and perennial streams with serpentine substrates. 260-400 m elevation. Cismontane woodland, valley and foothill grassland / mesic, usually serpentine seeps or creeks; elevation 260-400m (California Native Plant Society 2001) (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the species limited number of populations and the species specific habitat requirements.

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seed dispersal mechanisms are not known for V. californica (USFWS, 2012).

***Population Information and Trends***

**Population Trends:**

Decreasing (USFWS, 2012)

**Number of Populations:**

15 presumed occurrences (USFWS, 2022)

**Population Size:**

2500 - 10,000 individuals (NatureServe, 2015)

**Population Narrative:**

The abundance of Verbena californica is much the same today as it was when it was listed and 15 sites are presumed extant (A. Franklin in litt. 2007; CNDDB 2011). However, other sites may have been extirpated in the past without having been documented. We believe that current populations likely have been fragmented and reduced in size from those that existed historically (USFWS, 2012). Low resiliency, redundancy and representation are inferred based on this species specific habitat needs and low number of populations. The current species distribution of Red Hills vervain is an area of about 82 square kilometers (32 square miles) or 9.7 kilometers (6 miles) by 8.6 kilometers (5.3 miles) in and around the Red Hills of Tuolumne County, similar to what we described in our 2012 review (Service 2012, p. 4). See Figure 1 for a map of distribution. Within this narrow range, the total area occupied by the species is estimated to be 85 hectares (210 acres) (Diversity Database 2021). At the time of listing, the species was known from nine occurrences across a range of about 16 kilometers (10 miles) (Service 1998, p. 49023). One of the described occurrences is known only from an herbarium specimen collected in 1972 and no details on habitat, population size, or threats are available (Diversity Database 2021). Similar to our 2012 5-year review, for the purposes of this 5-year review we do not consider this specimen an extant occurrence. At the time of our 2007 and 2012 5-year reviews, there were 11 and 15 presumed extant occurrences, respectively (Service 2007, p. 4; Service 2012, p. 5). The number of extant Diversity Database occurrences of Red Hills vervain has not changed since the 2012 5-year review (i.e., there are 15 presumed extant sites). Of these, nine occurrences have been verified since the 2012 5-year review and further fieldwork is necessary to determine the status of the other six occurrences. At the time of listing, about 85% of Red Hills vervain were on private lands (Service 1998, p. 49023). Now, most of the sites are protected within the Red Hills Area of Critical Environmental Concern that consists of about 4,042 hectares (9,988 acres, about 15.6 square miles) of public land south of the historic town of Chinese Camp in Tuolumne County. The Red Hills Area of Critical Environmental Concern is managed by the Bureau. The Bureau designated the southern 1,821 hectares (4,500 acres) of the Red Hills as an Area of Critical Environmental Concern in 1985, which was then expanded to its current range in 1993 (Service 2012, p. 11). The purpose of the designation is to protect the unusual serpentine soils and the rare or listed species that rely on the habitat, including rare plants, Red Hills roach (Hesperoleucus symmetricus ssp.), and bald eagles (Haliaeetus leucocephalus) (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Recreational gold mining (USFWS, 2012)

**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Placer gold mining, which includes panning and dredging along streams, is a potential threat to occurrences of Verbena californica on lands administered by the BLM (J. Willoughby, BLM, in litt. 1990; California Department of Fish and Game 1993; A. Franklin, in litt. 2007). In the course of gold panning, the plants themselves can be trampled or dislodged and soil can be compacted. Currently, the California Department of Fish and Game is prohibited by court order from issuing suction dredge permits. Panning of gold along streams is still allowed (USFWS, 2012).

**Stressor:** Adjacent development (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Hydrological changes remain a threat to the Andrew Creek occurrence. Although the Verbena californica population is no longer threatened directly by residential development, runoff from the proposed houses and golf course on the table land above the drainage may affect the riparian area. Lowering of the water table that feeds springs in the riparian area is also a concern (California Department of Fish and Game 2005). The direct threat from housing development has decreased since listing. The Verbena californica habitat that was formerly on private land within the Andrew Creek drainage became public land in 2000. The acquisition was a cooperative effort among the BLM, the Tuolumne County Land Trust, the Trust for Public Lands, the California Wildlife Conservation Board, the Packard Foundation, and the California Department of Transportation (A. Franklin, in litt. 2002). In 2004, the Tuolumne County Land Trust acquired part of the Big Creek population with funding from the California Department of Transportation (E. Cypher, California Department of Fish and Game, pers. comm. 2006, 2007) (USFWS, 2012).

**Stressor:** Grazing (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals/degradation of habitat
**Narrative:** Currently, grazing on the BLM lands in the Red Hills occurs within two leases, one of which has Verbena californica. This lease is for 72 animal unit months over 1,178 acres within the Red Hills ACEC. Monitoring of V. californica, which began in 1998, uses a comparison of 2 grazed and 2 ungrazed (fenced) plots to evaluate grazing effects (BLM 2007b). No clear pattern of grazing effects has emerged from monitoring, i.e., it is not clear that the grazed or ungrazed plots are resulting in greater viability (BLM 2007b). However, grazing clearly does impact plants of V. californica. Clipped stems of V. californica have been observed both in the experimental plots and in other areas subjected to grazing. Trampling damage has been observed especially for the wet ground where V. californica occurs. Because the phenology of V. californica is relatively late, the grazing period was moved forward and now ends on April 15. We determined that the grazing program may adversely affect V. californica. No new grazing leases will be authorized in the Red Hills (BLM 2007b; Service 2007); however, the existing leases still remain (Peggy Cranston, Wildlife Biologist, Mother Lode Field Office, BLM, pers. comm. 2012) (USFWS, 2012).

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2012)

**Exposure:**
**Response:**
**Consequence:** Loss of habitat/Loss of individuals
**Narrative:** The Endangered Species Act is the primary Federal law that provides protection for this species since its listing as threatened in 1998. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent its status under the Act. Therefore, we continue to believe other laws and regulations have limited ability to protect the species in absence of listing under the Endangered Species Act (USFWS, 2012).

**Stressor:** Climate change (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The global average temperature has risen by approximately 0.6 degrees Celsius (1 degree Fahrenheit) during the 20th Century (IPCC 2001, 2007; Adger et al. 2007). There is an international scientific consensus that most of the warming observed has been caused by human activities (IPCC 2001, 2007; Adger et al. 2007), and that it is “very likely” that it is largely due to manmade emissions of carbon dioxide and other greenhouse gases (Adger et al. 2007). Ongoing climate change (Inkley et al. 2004; Kerr 2007; Adger et al. 2007; Kanter 2007) likely imperils Verbena californica and the resources necessary for its survival. Since climate change threatens to disrupt annual weather patterns, it may result in a loss of its habitat and/or increased numbers of its predators, parasites, and diseases. Where populations are isolated, a changing climate may result in local extinction, with range shifts precluded by lack of habitat, or in the case of plants the inability to disperse to newly suitable habitat at a rate equal to advance of newly unsuitable habitat caused by the change in environmental conditions (USFWS, 2012).

**Stressor:** Non-native plants (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:**

**Stressor:** Small populations (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Small populations may also be subject to increased genetic drift and inbreeding (Menges 1991; Ellstrand and Elam 1993). Populations that are continually small in size are particularly susceptible to genetic changes due to drift. However, drift may also cause genetic changes with populations that occasionally fluctuate to small sizes (e.g., undergo population bottlenecks). Increased homozygosity (reduced genetic variation) resulting from genetic drift and inbreeding may lead to a loss of fitness (ability of individuals to survive and reproduce) in small populations. In addition, reduced genetic variation in small populations may make any species less able to successfully adapt to future environmental changes (Ellstrand and Elam 1993) (USFWS, 2012).

**Stressor:** Recreational activities (USFWS, 2012)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Red Hills have mostly been used for recreation. Until 1991, the main recreational uses were target-shooting, off-road vehicle driving, camping, hunting, hiking, horseback riding, nature study, wildflower viewing, and hobby prospecting. In 1991, to protect the fragile biological resources of the area, target shooting and off-road vehicle use were prohibited on public land in the Red Hills (BLM 2009). Presently the main recreational activity in the Red Hills is equestrian use. Hiking, mountain biking and spring wildflower viewing are other popular activities (BLM 2007b). Overnight camping is no longer allowed within the Red Hills ACEC (BLM 2008) (USFWS, 2012).

**Stressor:** Herbivory and trampling (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Currently, the primary threats to Red Hills vervain throughout its range include: herbivory and trampling during unmanaged cattle grazing (USFWS, 2022).

**Stressor:** Drought (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Drought is listed as a primary threat to this species (USFWS, 2022).

**Stressor:** Fire, flash floods, competition with nonnative plants (USFWS, 202)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Currently, the primary threats to Red Hills vervain throughout its range include: herbivory and trampling during unmanaged cattle grazing, drought, fire, flash floods, competition with nonnative plants, recreation, gold mining, and climate change (USFWS, 2022).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 14

**Recovery Actions:**

- No recovery plan or outline has been completed for this species (USFWS, 2012).
- Work with the BLM to revise the Red Hills ACEC management plan to include new data, new listings of species under the Endangered Species Act, newly acquired lands, and other lands added to the ACEC because of newly developed resource information (USFWS, 2012).
- Encourage the BLM to withdraw habitat from mining patents (USFWS, 2012).
- Establish reliable baseline data for monitoring plant occurrences. Monitor the status and trend of Verbena californica in order to track any threats, and to estimate current population sizes, the number and distribution of populations, and whether the species is stable, increasing, or declining (USFWS, 2012).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of Red Hills vervain. Some of these recommendations have already been discussed in previous 5-year reviews (Service 2007; Service 2012) and remain valid. 1. Verify Red Hills vervain occurrences recorded in the California Natural Diversity Database, especially occurrences with a currently unknown status, that have not been surveyed in the previous ten years, and/or that are on private land. 2. Establish reliable baseline data for monitoring Red Hills vervain occurrences. Monitor the status and trend of occurrences to (a) track any threats, (b) estimate current population sizes and the number and distribution of populations, and (c) determine whether the species is stable, increasing, or declining. 3. Research the hydrology of watersheds and streams in the Red Hills Area of Critical Environmental Concern to predict how climate change will impact water availability to Red Hills vervain. Monitor seasonal and yearly changes to stream flows. 4. Mitigate cattle grazing impacts on Red Hills vervain by maintaining the fence demarcating the boundary between the Red Hills Area of Critical Environmental Concern and private ranch lands at Diversity Database occurrence #12. Continue to monitor Diversity Database occurrence #8 for grazing impacts. 5. Determine the extent of impact of nonnative grasses on Red Hills vervain. Work with the Bureau to continue to monitor and control yellow star thistle, especially those adjacent to Red Hills vervain. Determine whether and where Red Hills vervain is impacted by Bermuda grass and panic grass to establish a management plan. 6. Create a management plan for recreational activities in the Red Hills Area of Critical Environmental Concern to mitigate the impact of recreational activities, including hiking, mountain biking, and equestrian use, on Red Hills vervain. Work with the Bureau to identify appropriate actions, such as signage and fencing to limit access to sensitive habitat areas. 7. Identify potential locations for outplanting and translocation of Red Hills vervain based on known habitat preference information, in case these activities are necessary due to irreversible change to current habitat, such as those due to climate change. 8. Determine length of seed viability in storage. Currently, Red Hills vervain seeds are stored at the University of California Botanical Garden at Berkeley (USFWS, 2022)

# SPECIES ACCOUNT: *Warea amplexifolia* (Wide-leaf warea)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 05/29/1987; Southeast Region (R4)

**Physical Description**

Warea amplexifolia is an annual herb in the mustard family (Brassicaceae). Plants may be 30 to 100 cm tall and the stalk may be unbranched or, more often, branching midway up the stem. Leaves are alternate, from 2 to 5 cm long, and 1 to 3 cm wide, smaller as they ascend the stalk, with a rounded apex and entire margin. On young plants, the leaves are slightly folded along the midrib, tipped upward, and the lobes at the base of leaves reach around the stem. This characteristic has led to one of the common names for the species, clasping warea. The heart-shaped clasping leaf bases and its pale green, slightly glaucous leaves readily distinguish W. amplexifolia from the three other species in its genus in Florida. The characteristic leaves can be used in field identification even if the plants are not flowering. The pale lavender flowers of W. amplexifolia vary in individuals from almost white to almost purple. Flowers appear at the ends of the branches in spherical clusters about 5 to 6 cm across. Superficially, the flowers look like small versions of the garden cleome (Cleome hasslerana), a member of the family Capparaceae. The inflorescences are dainty, and in the field the flowering plants look almost fluffy. Individual flowers are about 1.5 cm across, with four petals and six long stamens. Warea amplexifolia is also readily identifiable in seed, even as the stalk turns brown and the leaves wither, by the clusters of narrow down-curving seed pods, from 5 to 7 cm long. The pods split longitudinally, with small black seeds on either side of the center membrane. (USFWS, 1999)

**Taxonomy**

Warea amplexifolia was originally described by Thomas Nutall in 1822 from a specimen collected in central peninsular Florida by N.A. Ware. Nutall at first placed this plant in the genus Stanleya, but in 1834 transferred it to the genus Warea and provided an amplified description that accommodated specimens from the Florida panhandle. The panhandle specimens were later recognized as a distinct species, Warea sessilifolia, by Nash. Shinners (1962) proposed a new name for the peninsular species, Warea auriculata, but most authors consider W. amplexifolia the correct name (Payson 1922, Channel and James 1964, Judd 1980). (USFWS, 1999)

**Historical Range**

Judd (1980) believed the former range of W. amplexifolia included Lake County, western Orange County, extreme northwestern Osceola County, and northern Polk County, Florida. (USFWS, 1999)

**Current Range**

Endemic to the Lake Wales Ridge of central Florida in Lake, Orange, and Polk counties (USFWS, 2017)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (Produces seeds) Abiotic (wind), Biotic (Hymenoptera; Lepidoptera) (USFWS, 1999)

**Lifespan**

Adult: Annual (USFWS, 1999)

**Breeding Season**

Adult: Flowering occurs from mid-August to early October, and fruiting occurs from late September to mid-November (USFWS, 1999)

**Reproduction Narrative**

Adult: Warea amplexifolia flowers from mid-August to early October, and fruiting occurs from late September to mid-November. Senescence occurs just before the fruit matures, and the population overwinters as seeds. The showy flowers are pollinated by various Hymenoptera (bees) and Lepidoptera (butterflies). Reproduction is exclusively sexual, with seeds probably released from the pods by wind action. The small seeds generally fall near the parent plant (FWS 1986). Experimental propagation to field plots at Bok Tower Gardens suggests that the number of flowering plants is related to the amount of rainfall during the December prior to the growing season. They also found that plants grew from seeds that had been sown into the experimental plots 2 to 4 years earlier, which indicates that seed banking in the soil is important in this species (Bok Tower Gardens 1994). (USFWS, 1999)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Oak sandhills and sand pine-scrub oak scrub (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Sunny openings with exposed sand in longleaf pine/turkey oak sandhills and sand pine-scrub oak scrub. (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/Specialist (NatureServe, 2015)

**Habitat Narrative**

Adult: Warea amplexifolia is endemic to high pine ecosystems of Florida. The high pine refers to the hilly portions of the ecosystem rather than the stature of the pines themselves. The undulating xeric sand ridges supporting the high pine are known as sandhills and the entire community is referred to by the same term. Sandhills are maintained under natural conditions by frequent patchy summer fires sparked by lightning. The resulting habitat condition is an open, often sparse over-story plant assemblage of longleaf pine (Pinus palustris), longleaf pine/turkey oak (Quercus laevis), or live oak/bluejack oak (Q. geminata/Q. incana) with an open, park-like understory. The ground cover consists of perennial grasses and forbs interspersed with deciduous clonal oaks (Myers 1990). Warea amplexifolia occurs on welldrained, sterile, yellow sands and is typically widely scattered in the sunny openings of the sandhills. (USFWS, 2017)

***Dispersal/Migration***

**Motility/Mobility**

Adult: Moderate (NatureServe, 2015)

**Dispersal**

Adult: Abiotic (wind) (NatureServe, 2015)

**Dispersal/Migration Narrative**

Adult: Seed is dispersed by wind (NatureServe, 2015)

***Population Information and Trends***

**Number of Populations:**

9 naturally occurring (USFWS, 2022)

**Population Size:**

over 10,000 individual plants (USFWS, 2017)

**Population Narrative:**

The most recent data suggest there are over 10,000 plants in the 9 extant natural populations (Peterson 2016); however, the Warea Tract in Lake County and the Ocklawaha property (Ocklawaha North EOR #28 and Ocklawaha South EOR #30) in Marion County typically account for greater than 95% of the plants range-wide. Lake Griffin State Recreation Area historically had a larger population, but the recent surveys suggest the population appears to be declining. The remaining six populations generally have low population numbers. (USFWS, 2017). Nine extant populations that were documented in the previous 5-year review (2017) still persist. Four populations occur on public lands while the remaining five are in private ownership. Current plant counts for these locations are not included in this reporting. The Florida Forest Service Warea Tract in Lake County and the Ocklawaha Corridor in Marion County (Duke Energy and private ownership) are the largest populations and account for ~95% of the plants range-wide (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Habitat destruction or modification
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat destruction, modification, and degradation on private lands remain the primary threat to the species range-wide. Populations occurring on private lands remain subject to habitat destruction or fragmentation due to development. In addition, the absence of habitat management on private lands results in unsuitable conditions for the species to successfully

flourish and reproduce. Publicly owned conservation lands typically are afforded controlled access and may even have enforcement personnel on-site to prevent destructive activities. These lands also have management plans to create, restore, or maintain desirable habitat conditions; however, budget shortfalls and staffing constraints may preclude beneficial activities in some years. Also, depending on the management plan for various public lands, not all public conservation lands where the species occurs are specifically managed to benefit W. amplexifolia. The management is often a balance of the multiuse activities occurring on the sites and prioritized accordingly to available budget and respective mission (e.g. state park, state forest, county or city utility property, etcetera). Currently, four of the extant populations (Lake Griffin State Recreation Area, Warea Tract, Sugarloaf Mountain, and Schofield Sandhill) occur on public lands, four populations (Ferndale Ridge, Bissett Property, Mountain Lake Estates, and Ocklawaha North and South) are under private ownership, and one population (Twin Lakes) occurs on private property and in a road/utility easement. (USFWS, 2017)

**Stressor:** Inadequacy of existing regulatory mechanisms
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Florida Administrative Code 5B-40 (Preservation of Native Flora of Florida) provides the Florida Department of Agriculture and Consumer Services (FDACS) with limited authority to protect plants on State and private lands (primarily from the standpoint of illegal harvest). Warea amplexifolia is listed as an Endangered Plant under this statute, which requires anyone wishing to "willfully harvest, collect, pick, remove, injure, or destroy any plant listed as endangered growing on the private land of another or on any public land or water" to "obtain the written permission of the owner of the land or water or his legal representative" (FAC 5B-40.003(1)(a)). A permit is also required to transport "for the purpose of sale, selling, or offering for sale any plant contained on the endangered plant list which is harvested from such person's own property" (FAC 5B-40.003(1)(c)). (USFWS, 1999)

**Stressor:** Other natural or manmade factors
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Drought, fire suppression, and invasive plant species encroachment continue to negatively affect W.amplexifolia populations. The Intergovernmental Panel on Climate Change (IPCC) concluded that warming of the climate system is unequivocal (Pachauri et al. 2014). Effects associated with changes in climate have been observed including changes in arctic temperatures and ice, widespread changes in precipitation amounts, ocean salinity, and wind patterns and aspects of extreme weather including droughts, heavy precipitation, heat waves, and the intensity of tropical cyclones (Pachauri et al. 2014). Species that are dependent on specialized habitat types, limited in distribution, or at the extreme periphery of their range may be most susceptible to the impacts of climate change (Byers and Norris 2011; Anacker et al. 2012). However, while continued change is certain, the magnitude and rate of change is unknown in many cases. The magnitude and rate of change could be affected by many factors (e.g., circulation patterns), but we have no additional information or data regarding these factors with respect to W.amplexifolia. There is evidence that some terrestrial plant populations have been able to adapt and respond to changing climatic conditions (Franks et al. 2013). Both plastic (phenotypic change such as leaf size or phenology) and evolutionary (shift in allelic frequencies)

responses to changes in climate have been detected. Both can occur rapidly and often simultaneously (Franks et al. 2013). Relatively few studies are available, however, that (1) directly examine plant responses over time, (2) clearly demonstrate adaptation or the causal climatic driver of the responses, or (3) use quantitative methods to distinguish plastic versus evolutionary responses (Franks et al. 2013). (USFWS, 2017)

***Recovery***

**Reclassification Criteria:**
1. When 10 geographically distinct, self-sustaining populations are protected and managed (USFWS, 1993).

Recovery Priority Number: 2C

**Delisting Criteria:**
1. When 20 such populations are protected and managed, and each has been monitored for at least 8 years. Recovery will require a minimum of 10 years (until 2003), if establishment of new populations is prompt and obviously successful (USFWS, 1993).

**Recovery Actions:**

- Determine current distribution of W. amplexifolia. Conduct surveys of W. amplexifolia. Maintain distribution of known populations and suitable habitat in GIS database. Use GIS to map existing populations and to assess the species? status and trends over time. The database should contain information on locations, population sizes, and status. This information should also be used for project review, in land acquisition activities, and to coordinate updates with the FNAI database. Currently, the Lake Wales Ridge Ecosystem Working Group and Archbold Biological Station are proposing to map the entire central ridge. This information would show potential habitat for scrub and high pine endemics based on their habitat needs. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding areas has been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases is isolated. (USFWS, 1999)
- Continue research on life history characteristics of W. amplexifolia. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species more specific biological information is needed. (USFWS, 1999)
- Continue monitoring the existing populations of W. amplexifolia. Evaluate the effectiveness of the monitoring protocol used to assess population trends for W. amplexifolia. Monitor and detect changes in demographic characteristics., such as growth, survival, and mortality. Monitor the effects of various land management actions on W. amplexifolia. Continue to work with private landowners. Monitor introduced plants. (USFWS, 1999)
- Provide public information about W. amplexifolia. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery

of W. amplexifolia and other rare species require a self- sustaining, secure, number of natural populations. (USFWS, 1999)

- Habitat-Level Recovery Actions: Prevent degradation of existing habitat. Secure habitat through acquisition, landowner agreements, and conservation easements. Manage and enhance habitat. Restore areas to suitable habitat. Conduct habitat-level research projects. Monitor habitat/ecological processes. Provide public information about scrub and high pine and their unique biota. (USFWS, 1999)
- Revise the current recovery plan to include objective and measurable recovery criteria that are related to reducing and/or eliminating threats to W. amplexifolia as well as updated on the species distribution and ecology (USFWS, 2007).
- Provide funding and technical support for further research on: The effects of prescribed burning and other management tools on W. amplexifolia. Continue working with public managers to increase the management on their sites. Additional life history needs. Information is needed on how W. amplexifolia plants and seeds are affected by years of drought. Genetic inbreeding depression. This information will help us determine what constitutes a stable population. The most appropriate methodology to germinate seeds, grow seedlings, and successfully out-plant seedlings to native habitats. The various pollinators (e.g. Hymenoptera and Lepidoptera), as well as how different species assist with seed dispersal (USFWs, 2007).
- Encourage non-Federal agencies to protect and manage habitat under the Partners for Fish and Wildlife Program (USFWS, 2007).
- Update the range-wide survey, that was completed by Dr. Jack Stout in 200, on all known and potential sites occupied by W. amplexifolia and determine population size. Current distribution information is needed to determine where plants currently exist and to prioritize recovery actions (USFWS, 2007).
- Consider reintroduction and monitoring of W. amplexifolia on additional publicly owned lands with suitable habitat. Prior to reintroduction, research on the microhabitat needs of W. amplexifolia should be considered. Reintroduction of W. amplexifolia could help to increase the number of populations on protected sites and augment populations where needed (USFWS, 2007).
- Acquisition and management of the remaining known populations on private lands. Areas within the Ocklawaha and Ferndale Ridge developments where native sandhill habitat still exists would be the primary areas to target near-term. (USFWS, 2017)
- Active management of the four natural populations on public lands to maintain or create openness of the habitat and to control the invasive plant species encroachment. (USFWS, 2017)
- Yearly monitoring of the natural populations and the introduced populations on public lands will be necessary to accurately determine future population viability. (USFWS, 2017)
- Continued research on life history, biology, and ecology (population genetics, seed germination, spatial seedling recruitment patterns, demography, pollination biology, microhabitat factors, etcetera). (USFWS, 2017)
- Update range-wide survey to determine number of extant populations and individual plant abundance at each location. (USFWS, 2017)
- . Continue population introductions and population augmentations. (USFWS, 2017)
- Compare sites with long-term data sets from different locations within close proximity to one another and their associated management to increase the understanding of the ecological conditions that influence population abundance. (USFWS, 2017)

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES • Acquisition and management of the remaining known populations on private lands. Areas within the Ocklawaha and Ferndale Ridge developments where native sandhill habitat still exists would be the primary areas to target near-term. • Active management of the four natural populations on public lands to maintain or create openness of the habitat and to control the invasive plant species encroachment. • Update range-wide survey to determine number of extant populations and individual plant abundance at each location. • Continue collaboration with Duke Energy Corporation on compatible habitat management activities within the Ocklawaha Corridor population occurring in their right-of way (USFWS, 2022).

# SPECIES ACCOUNT: *Warea carteri* (Carter's mustard)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 2/20/1987; Southeast Region (R4)

**Physical Description**

Warea carteri is an annual herb, 0.2 to 1.5 m tall with erect green stems. The plants usually have many slender, ascending branches forming an open, rounded crown. The leaves lack stipules and are arranged alternately on the stem. Lower leaves are lost by the time the plant flowers. Leaf size and shape varies with age and position on the plant. At the time of flowering, leaf petioles range from 0.8 to 3.9 mm with blades 1to 3 cm long. Towards the tips of stems, the leaves are smaller and narrowly elliptical to almost linear, while closer to the bases of stems and branches, the leaves are larger and oblanceolate or spatulate. All leaves are rounded at the tip, their margins entire, and their bases attenuate to cuneate. The lower leaves can also be undulate, margined or lobed. The many inflorescences of W. carteri are dense, rounded racemes with many flowers (60 or more). The flowers are radially symmetric, with four white linear-oblanceolate sepals, about 4.5 mm long, and curved toward the center of the flower at the tip. The four petals are white, about 6.0 mm long, with more than half their length in the form of a slender claw. The petal’s blade is nearly round with irregular margins. The six spreading stamens are irregularly subequal in length and arise from a nectar-producing floral disc. The ovary is superior, cylindric, about 2.3 mm long, and raised on a slender stalk (gynophore) about 2 mm long. The sessile stigma has two lobes. W. carteri is protandrous: the anthers begin to dehesce within an hour or two after the flower has opened. The stigmas are receptive until 2 to 4 days afterwards, by which time the stamens on that flower have dropped. Warea carteri’s fruit is a silique, long, slender pod divided lengthwise by a partition (septum). The pod is flattened, cylindrical in cross-section and gently curved along its length, which is 4 to 6 cm long and 1.5 mm wide. The pod is borne on a gynophore, which is a stalk-bearing pistil 5 to 6 mm long,above a spreading pedicel, which is around 8.5 mm long.The pod carries numerous oblong seeds, each 1.5 mm long (Kral 1983). Fruits split apart passively to shed the seeds. (USFWS, 1999)

**Taxonomy**

Warea carteri was named by Small in 1909. A review of the genus by Channel and James in 1964 retained Small’s treatment of the species. There are no scientific synonyms (Nauman 1980). Common names for the species include Carter’s mustard, Carter’s warea, and Carter-warea. (USFWS, 1999)

**Historical Range**

Carter's mustard was once found in Miami-Dade County, Florida, as well as Lake, Polk, and Highland Counties, Florida. Extirpated from extirpated from Miami-Dade County.

**Current Range**

On the Lake Wales Ridge in Lake, Polk, and Highlands counties, Florida (USFWS, 2019).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Self-pollinating

**Breeding Season**

Adult: Flowering occurs in September and October. Fruiting occurs in October and November (USFWS, 1999)

**Other Reproductive Information**

Adult: Large fluctuations observed in above ground population size suggest the possibility that seed banking plays a significant role in W. carteri's biology. Environmental cues necessary for germination were explored experimentally at Archbold Biological Station. Moisture and light were found to be necessary for germination. The use of an oak leachate did not significantly affect germination. Some seeds stored in dry, dark conditions for 2 years germinated, demonstrating the potential of W. carteri's seeds to remain dormant at least that long. Fire-related cues such as heat do not stimulate germination, but germination does require light and seeds may remain dormant for more than 2 years. (USFWS, 1999)

**Reproduction Narrative**

Adult: Experiments have demonstrated that Warea carteri is self-pollinating, autogamous, and self-compatible (Evans et al., in press). Autogamy and self-compatibility allow isolated or sparsely distributed individuals to reproduce. Natural levels of fruit- and seed-set are quite high, with a fruit-set of 62 percent, and seed-set of 50 percent (Evans et al. in press). Self-pollinated flowers showed significantly lower fruit- and seed-set, 41 percent fruit-set and 28 percent seed-set. This indicates that insect-mediated pollination is important in keeping fruit- and seed-set high, and individual fecundity high. Pollinators appear to be the limiting factor in fruit and seed production. Because aboveground populations fluctuate wildly, autogamy helps ensure fecundity and may be a key life history trait. Germination in W. carteri occurs in late winter through early spring (January-March). Flowering occurs in September and October. Fruiting occurs in October and November, and dispersal follows in November and early December (Kral 1983). Preliminary observations of insect activity on W. carteri indicate it is a generalist with respect to pollination. A great diversity of insects visit the flowers, including native solitary bees, bumblebees, syrphids (known as hoverflies or bee-flies), wasps, flies, beetles, etc. Within-plant movements by insects appear to predominate over among-plant movements. Because of this, and in combination with the close proximity of male and female flowers in an inflorescence, self-pollination probably is a regular method of reproduction in this species. (USFWS, 1999)

**Habitat Type**

Adult: Upland sandy areas; xeric, shrub-dominated habitats

**Environmental Specificity**

Adult: Moderate (inferred from USFWS, 1999)

**Habitat Narrative**

Adult: Carter’s mustard is found almost exclusively in upland areas and is a soil generalist, being found on yellow, gray, or white sands (Menges et al. 2007). It is found primarily in sandhills and scrubby flatwoods, and often at the ecotone between these two vegetation types. In the northern part of its range, most sites are on sandhill. This is also true for sites at Tiger Creek Preserve, a site in the central part of its range, which supports the greatest number of plants. At this site, the species is found in both high-quality, frequently burned sandhill, as well as in overgrown sandhill that could also be termed xeric hammock (Menges in litt. 2008d). Near the south end of its range (e.g., ABS), Carter’s mustard is fond primarily in scrubby flatwoods, often just downhill from a ridge of yellow sand (Menges in litt. 2008e). These habitats have a range of fire return intervals from 2 to 15 years (Menges 2007). Although Carter’s mustard has a large populations after fire, it can also recover from a persistent soil seed bank after many years or even decades without fire (Menges in litt. 2008f). Although preferring post-fire or disturbed sites, Carter’s mustard is not a gap specialist. Plants often grow among dense shrubs in scrubby flatwoods or shrubby sandhill sites.

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: There are no obvious specialized forms of seed dispersal in W. carteri. The siliques do not open explosively; rather, the external walls of the fruit peel away from the central septum as the fruit slowly dries, exposing the mature seeds inside. The seeds drop passively to the ground or they may be flung a bit further if the plant is brushed. It’s not likely that seeds are moved by wind once they reach the ground. Collection or movement of seeds of W. carteri by ants or other animals has not been studied, but there are no obvious specialized structures on the seed that would encourage such movement. (USFWS, 1999)

***Population Information and Trends***

**Number of Populations:**

50 known occurrences (USFWS, 2019)

**Population Narrative:**

The most recent FNAI Element Tracking Summary (FNAI 2015) reported 50 known occurrences for Carter's mustard, of which 41 were found on 12 managed areas. Historical populations in Brevard and Miami-Dade Counties are believed extirpated. Although Carter's mustard has large populations after fire, it can also recover from a persistent soil seed bank after many years or even decades without fire . Carter's mustard populations fluctuate widely from year to year. For burned populations especially, these fluctuations are biennial (peak every two years) and dampen over time. Fires usually initiate cycles, with the largest population sizes occurring the year following fire. (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** This species is restricted to xeric scrub habitats in one or more of the interior Central Florida counties of Polk, Highlands, Hendry, Osceola, and Lake, where habitat destruction from development continues to occur and development pressure remains high. Areal extent of post-Columbian xeric upland habitat loss on the Lake Wales Ridge is estimated to exceed 85 percent (Weekley et al. 2008a). Increasing pressure from population growth is likely to result in further loss of these habitats going forward. Carr and Zwick (2016) analyzed existing land use and landscape patterns to identify areas (including central Florida) most likely for development to accommodate a growing human population. They suggests that Florida's 2070 population will be early 15 millionpersons greater than in 2010, for an estimated total of 33,721,828. Using these figures, they estimated relative losses to agriculture, open space, and conservation to other land uses. If trends continue, they estimate 34 percent of land will be developed by 2070, up from 19 percent in 2010. At the same time, conservation lands will increase less than 1 percent (from 9,269,000 acres in 2010 to 9,525,000 acres by 2070). Overall, loss of habitat to development, primarily on private lands, will likely continue in Central Florida, eliminating populations and reducing the area of suitable habitat for these species. Therefore, habitat on protected lands are critical for the recovery of this scrub plants. (USFWS, 2019)

**Stressor:** Lack of adequate fire management
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire is necessary to maintain the scrub habitats upon which this species depends. Historically, lightning-induced fires were a vital component in maintaining native vegetation within the scrub community. Fire suppression started on a regional scale on the Central Florida ridges about 80 years ago. Due to the extent of residential and agricultural development throughout Central Florida, fire has all but disappeared from the region as a widespread, natural phenomenon. Prescribed fire is a crucial management component for maintenance of all scrub habitats. Because of the difficulties of applying prescribed fire on an ever-increasing urban landscape, imperiled species on unmanaged sites will almost certainly disappear over time (Turner et al. 2006). In managed areas, prescribed fire is essential to manage habitats and restore or maintain suitable conditions for scrub species. (USFWS, 2019)

**Stressor:** Limited geographic range.
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species occurs occur within a relatively limited geographic range in Central Florida. The limited geographic range in combination with the loss of habitat has resulted in a highly fragmented landscape where the remaining scrub areas and their residing species have become more and more isolated from each other, thereby making resiliency, redundancy, and representation more challenging to achieve. The effects of habitat fragmentation on species richness have been exhaustively studied (MacArthur and Wilson 1967, Diamond 1975, 1978; Simberloff and Abele 1976, 1982; Zimmerman and Bierregaard 1986). For most taxonomic groups, large habitat patches in close proximity to each other provide for the greatest species diversity and minimize extinction probabilities. On the contrary, small patches that are isolated are less likely to preserve species that would otherwise be common in the mosaic of communities that existed before isolation. Since at least the Pleistocene, Florida scrub has been characterized by an insular, discontinuous distribution, but the degree of habitat fragmentation

seen today is unprecedented and certainly will contribute to increases in extinction rates among scrub-dependent plants and animals. (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**

1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations required to assure 95 percent probability of persistence for 100 years (USFWS, 1999)

2. When these populations, within the historic range of W. carteri are adequately protected from further habitat loss, degradation, and fire suppression (USFWS, 1999)

3. When these sites are managed to maintain the scrubby flatwoods and turkey oak dominated high pine to support W. carteri (USFWS, 1999)

4. When monitoring programs demonstrate these sites support sufficient population sizes, are distributed throughout the historic range, and are sexually reproducing at sufficient rates to maintain the population (USFWS, 1999)

Recovery Priority Number: 2

**Delisting Criteria:**

1. At least 40 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)

2. Populations (as defined in criterion 1) in yellow sand scrub or scrubby flatwoods habitats are distributed across the known range of the species. (USFWS, 2019)

3. Populations are protected and managed via a conservation mechanism to a degree that enough suitable habitat is present for the species to remain viable for the foreseeable future. (USFWS, 2019)

**Recovery Actions:**

- Determine current distribution of W. carteri. Some portions of W. carteri’s range have been well surveyed, yet a total distribution has not been ascertained for this species. A thorough survey is needed to determine the distribution for this species. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties has been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Conduct research on life history characteristics of W. carteri. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species’ more specific biological information is needed. (USFWS, 1999)
- Monitor existing populations of W. carteri. (USFWS, 1999)
- Provide public information about W. carteri. It is important for the recovery of this species that governmental agencies, conservation organizations, and private landowners be

appropriately informed about this species. (USFWS, 1999)

- Habitat-level Recovery Actions: Prevent degradation of existing habitat. Restore areas to suitable habitat. Conduct habitat-level research projects. Monitor habitat and ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • Better land management is needed so that protected populations remain extant. Periodic burning is recommended to ensure that aboveground populations are replenished before seed banks decline. Adaptive management can be used based on data collected on Carter’s mustard responses to various fire regimes. • Data on management activities (e.g., fire, mechanical treatments) should be gathered in management units where level 2 monitoring is being done. These can serve to link information specific to those units, including population size and trends, with detailed demographic models that are keyed to management (e.g., prescribed fire). • Detailed demographic data from three sites (Quintana-Ascencio et al. 2008) could be used as the basis of a population viability analysis that addresses questions such as how Carter’s mustard responds to different fire regimes and what is the prognosis for populations of different sizes. They could also be used to make specific predictions for populations where there were estimates of population sizes. • For some or all managed sites, collection of additional data on population sizes (level 2 monitoring). These data are being collected at two sites (LWRSF and TNC Tiger Creek Preserve. For Carter’s mustard, level 2 monitoring will have to be concentrated in September and October, when plants are visible and more easily counted. • More data on the response of Carter’s mustard to management activities such as roller chopping, mowing, gyro-tracking, logging, and chain-saw felling. • If significant unprotected populations of Carter’s mustard are discovered, these populations should be protected by land purchase or management agreements. (USFWS, 2021)

# SPECIES ACCOUNT: *Ziziphus celata* (Florida ziziphus)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 8/28/1989; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

Ziziphus celata is a spiny shrub that averages between 0.5 to 1.5 m in height, but can grow to over 2 m. Plants occur in groups of stems, arising from what are assumed to be connected root systems. The primary branches are jointed and bent, and give rise to short, straight, spiny, branchlets. The oblong-elliptic to obovate leaves are alternate and deciduous. The leaves are characterized by rounded tips, cuneate bases, and entire margins. The upper leaf surface is dark glossy green, while the underside is a dull light green. Leaves vary from 4.5 to 21 mm in length, and from 3 to 13 mm in width. Fragrant Z. celata flowers are small, axillary, and solitary, but are tightly bundled on short shoots. Flowers are perfect, with five greenish-yellow sepals, and five white petals clasping five stamens; however, three-and four-merous flowers have been observed (Race and Weekley 1996). The bright yellow drupes range from 10 mm to 20 mm long, and 3 mm to 10 mm wide (Judd and Hall 1984, DeLaney et al. 1989, Race and Weekley 1996). (USFWS, 1999)

**Taxonomy**

Ziziphus celata was originally collected near Sebring in 1948. A second specimen was collected in 1954, perhaps from the same site as the original specimen, but the location of the latter collection is unknown. The plant remained unidentified and unnamed until 1984, when Judd and Hall (1984) named the original herbarium specimen Ziziphus celata. When it was named, the Florida ziziphus was thought to be extinct. However, it was rediscovered in 1987 at a site in Polk County (DeLaney et al. 1989). (USFWS, 1999)

**Historical Range**

See Current Range.

**Current Range**

Florida ziziphus is known only from a few sites on the Lake Wales Ridge in southern Polk and northern Highlands counties, in Florida. (USFWS, 2019)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollinated; Asexual (USFWS, 1999)

**Breeding Season**

Adult: Begins to flower in late December or early January and flowering continues through late February (varying by site and year), while the branches are still bare.

**Other Reproductive Information**

Adult: Research on the genetics, reproductive biology, and demography of Florida ziziphus for over a decade has quantified limited genetic variation in the wild populations. Breeding system experiments have demonstrated that Florida ziziphus is self-incompatible and that most genotypes are also cross-incompatible. The combination of limited genetic variation and a limited range of mating types explains why most populations are self-sterile. Demographic research has shown that populations are stable with high survival but variable levels of clonal recruitment. Without augmentation, most populations are predicted to undergo slow decline in numbers (Menges 2012). (USFWS, 2019)

**Reproduction Narrative**

Adult: Ziziphus celata is deciduous, losing its leaves in late fall. It begins blooming in late December or early January and blooming continues through late February (varying by site and year), while the branches are still bare (Burkhart et al. 1997). Fruits begin to develop in March, with new leaves forming at the same time or soon after. The fruits ripen in May or early June. No seedlings have been found in the wild, so it is not known whether the seeds germinate in the summer or later in the year. Common pollinators (bees and flies) have been observed visiting the flowers, although it is not known if these are pollinators of Ziziphus. No viable seeds have been observed in the wild. Natural fruit set has been observed twice in the wild, but few fruit were produced, and of those all aborted before maturity. Lack of sexual reproduction may be due to the absence of compatible genotypes at a given site and/or the age of the above ground stems (Burkhart et al. 1997). Ziziphus celata spreads asexually by sending shoots up from its roots. These additional stems give Z. celata a clump-like appearance, where individual plants in the clump are not distinguishable. Like other members of its genus, Z. celata is capable of parthenocarpic production of fruit, but it differs from others in its genus by not being dichogamous, having pistils and stamens that mature at different times to prevent self-fertilization (Burkhart et al. 1997). (USFWS, 1999)

**Habitat Type**

Adult: Oak-hickory scrub

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2019)

**Habitat Narrative**

Adult: Florida ziziphus is a thorny clonal shrub found only on yellow sand xeric habitats that historically supported longleaf pine/wiregrass sandhills and similar vegetative communities. Most Florida ziziphus habitat has been converted to citrus groves and cattle ranches. (USFWS, 2019)

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

13 wild, 3 introduced (USFWS, 2024)

**Population Narrative:**

Florida ziziphus is known only from a few sites on the Lake Wales Ridge in southern Polk and northern Highlands counties. Only four of the 14 known populations occur in publicly protected sites. Most populations are self-sterile due to limited genetic diversity and the isolation of population. The most recent FNAI Element Tracking Summary (FNAI 2015) reported 10 known occurrences for Florida ziziphus, of which 5 are protected at 4 different managed areas. In addition, four new populations have been established since 2008. Florida ziziphus has been reintroduced using.transplants and seeds to four sites, including The Nature Conservancy's Tiger Creek Preserve, the Lake Wales Ridge State Forest, and the Lake Wales Ridge NWR. (USFWS, 2019) In 2009 there were 14 extant populations. Since that review, the monitoring schedule for the plant has been altered to be less frequent than previously, and the most recent survey data are from 2021. As of 2021, there are 13 extant wild populations and 3 introduced populations (Table 1; Heron pers. comm 2024). This is a reduction from the 16 documented wild populations because three of those located on private lands have been extirpated (Herron pers. comm 2024). Several of the extant wild populations also occur on private land and are at risk of loss. These populations are vital to recovery, as plants on public property represent a small fraction of genetic diversity. The Masterpiece site (including the Masterpiece North and South populations), which has a conservation easement, supports over half of known plants and much of the genetic diversity in this species. Most populations on privately owned sites have declined steadily over the past decade (Smith et al. 2013) and will continue to decline without efforts to promote sexual reproduction (Ellis et al. 2007). The recent transfer of the Gulfstream/Mitigation site to the Service has also aided in the conservation of Florida ziziphus. This parcel is now known as the Arbuckle unit and is part of the Everglades Headwater National Wildlife Refuge. Several translocations of Florida ziziphus have occurred (Table 2; for details, see David and Herron 2023). Only one plant remains from the initial augmentation at one of the Avon Pines sites, and it is unclear whether the second augmentation has yet resulted in sexually mature and reproducing plants. Two larger augmentations at Arbuckle Everglade Headwaters National Wildlife Refuge in 2003 and 2006 have been successful in flowering, producing fruit, and producing one second generation seedling. However, survival has been relatively low in this disturbed sandhill (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Habitat destruction or modification
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species is restricted to xeric scrub habitats in one or more of the interior Central Florida counties of Polk, Highlands, Hendry, Osceola, and Lake, where habitat destruction from development continues to occur and development pressure remains high. Areal extent of post-Columbian xeric upland habitat loss on the Lake Wales Ridge is estimated to exceed 85 percent (Weekley et al. 2008a). Increasing pressure from population growth is likely to result in further loss of these habitats going forward. Carr and Zwick (2016) analyzed existing land use and landscape patterns to identify areas (including central Florida) most likely for development to accommodate a growing human population. They suggests that Florida's 2070 population will be early 15 millionpersons greater than in 2010, for an estimated total of 33,721,828. Using these figures, they estimated relative losses to agriculture, open space, and conservation to other land uses. If trends continue, they estimate 34 percent of land will be developed by 2070, up from 19

percent in 2010. At the same time, conservation lands will increase less than 1 percent (from 9,269,000 acres in 2010 to 9,525,000 acres by 2070). Overall, loss of habitat to development, primarily on private lands, will likely continue in Central Florida, eliminating populations and reducing the area of suitable habitat for these species. Therefore, habitat on protected lands are critical for the recovery of this scrub plants. (USFWS, 2019)

**Stressor:** Lack of adequate fire management
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species occurs occur within a relatively limited geographic range in Central Florida. The limited geographic range in combination with the loss of habitat has resulted in a highly fragmented landscape where the remaining scrub areas and their residing species have become more and more isolated from each other, thereby making resiliency, redundancy, and representation more challenging to achieve. The effects of habitat fragmentation on species richness have been exhaustively studied (MacArthur and Wilson 1967, Diamond 1975, 1978; Simberloff and Abele 1976, 1982; Zimmerman and Bierregaard 1986). For most taxonomic groups, large habitat patches in close proximity to each other provide for the greatest species diversity and minimize extinction probabilities. On the contrary, small patches that are isolated are less likely to preserve species that would otherwise be common in the mosaic of communities that existed before isolation. Since at least the Pleistocene, Florida scrub has been characterized by an insular, discontinuous distribution, but the degree of habitat fragmentation seen today is unprecedented and certainly will contribute to increases in extinction rates among scrub-dependent plants and animals. (USFWS, 2019)

**Stressor:** Limited geographic range
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire is necessary to maintain the scrub habitats upon which short-leaved rosemary, Avon Park harebells, Garrett's mint, scrub mint, snakeroot, Highlands scrub hypericum, scrub blazing star, Lewton's polygala, wireweed, sandlace, Carter's mustard, and Florida ziziphus depend. Historically, lightning-induced fires were a vital component in maintaining native vegetation within the scrub community. Fire suppression started on a regional scale on the Central Florida ridges about 80 years ago. Due to the extent of residential and agricultural development throughout Central Florida, fire has all but disappeared from the region as a widespread, natural phenomenon. Prescribed fire is a crucial management component for maintenance of all scrub habitats. Because of the difficulties of applying prescribed fire on an ever-increasing urban landscape, imperiled species on unmanaged sites will almost certainly disappear over time (Turner et al. 2006). In managed areas, prescribed fire is essential to manage habitats and restore or maintain suitable conditions for scrub species, including short- leaved rosemary, Avon Park harebells, Garrett's mint, scrub mint, snakeroot, Highlands scrub hypericum, scrub blazing star, Lewton's polygala, wireweed, sandlace, Carter's mustard, and Florida ziziphus. (USFWS, 2019)

**Stressor:** Fire suppression or lack of adequate fire regime (USFWS, 2024)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** Fire suppression is a continuing threat to the habitat of Florida ziziphus. In studies of Florida ziziphus introduced to one sandhill site, Menges et al. (2008) found that resprouting oaks encroached with negative effects on plant survival. The number of oaks increases under fire suppressed conditions. Fire return intervals for Florida ziziphus should be in the 5- to 20-year range (Menges et al. 2020), however most private property owners do not apply prescribed fire at this frequency. Fire suppressed conditions will likely continue on most private sites, to the detriment of potential Florida ziziphus habitat. Prescribed fire implementation on some public lands is behind schedule due to insufficient resources coupled with logistical obstacles. Smoke, public safety, and property liability issues, along with public perceptions relating to aesthetics still pose obstacles to implementing prescribed fire (USFWS, 2024).

**Stressor:** Invasive plants (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Non-native invasive plant species are a threat to Florida ziziphus at sites, especially those that are adjacent to modified landscapes and those that have been converted to pasture. In pastures, the dominant groundcover of pasture grasses may be a factor in the lack of recruitment from seeds in the few reproductive populations, but this has not been investigated. In addition, non-native vines pose a threat and can grow over Florida ziziphus. These vines compete for sunlight, space, water, and nutrients and may cause a decrease in the survival and reproductive success of Florida ziziphus. Invasive plants are managed at the protected sites and are not a significant threat to Florida ziziphus at these sites (USFWS, 2024).

**Stressor:** Paucity of recruitment from sexual reproduction (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Few fruits and seedlings have been documented in populations. Because populations are fragmented and beyond likely pollination distance, crosses among populations only occur when plants are brought together or manually pollinated. The destruction of unprotected populations on private land could result in additional loss of genotypes critical to conservation and recovery of the species. In particular, if the remaining genetic diversity drops, sexual reproduction may become impossible further threatening the species (USFWS, 2024)

**Stressor:** Climate change (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Effects of climate change on the habitat of Florida ziziphus are not known. Increases in temperature and changes in precipitation patterns could be important in the future. Forecasts of more severe droughts and higher rainfall between droughts could mean that fires would be more severe and that prescribed fires harder to control. This could harm Florida ziziphus populations. Sea level rise in coastal Florida is already a reality and may lead to an increase in development in interior Florida, thus increasing the vulnerability of Florida ziziphus habitats (Volk et al. 2017). The National Climate Assessment (Melillo et al., 2014) reports that the average precipitation has decreased in central Florida since 1900; however, heavy downpours are increasing in frequency

and intensity since 1970. Future projected precipitation changes in seasonality for central Florida indicate 0 to +10% in winter, 0 to -10% in spring, -10 to -20% in summer, and +10 to +20% in fall will occur. Statewide annual rainfall is projected to increase from 0 to +20% by 2100. In additional to changes in precipitation, Florida has undergone increases in average temperatures since the beginning of the 20th century (Runkle et al. 2022). Warming is expected to increase in the future and will result in declines in soil moisture loss. Consecutive dry days are expected to increase 10 to 20% for most of Florida. Predictions of increased drought frequency, intensity, and duration could result in plant losses due to prolonged drought conditions (Melillo et al., 2014). However, this plant and other xeric species are relatively drought-resistant, but seasonality changes may affect seedling recruitment and general phenology of the species. Although Florida's coastal areas will likely be influenced by sea level rise, based on our understanding of current sea level rise models and the species occurrences inland on well drained soils (e.g., ancient ridges mainly in central Florida), sea level rise does not currently pose a threat to this species. The Service has no direct evidence that climate changes observed to date have had any adverse impact on the species or its habitat (USFWS, 2024).

***Recovery***

**Reclassification Criteria:**
Not defined. (USFS, 1999)

Recovery Priority Number: 5

**Delisting Criteria:**
1. At least 40 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)

2. Populations (as defined in criterion 1) in sand hill habitat are distributed across the known range of the species. (USFWS, 2019)

3. Populations are protected and managed via a conservation mechanism to a degree that enough suitable habitat is present for the species to remain viable for the foreseeable future. (USFWS, 2019)

**Recovery Actions:**
- Determine current distribution of Z. celata. It is possible that populations of this species have yet to be discovered. Currently, three of the sites for Z. celata are in pastures and the other two are in restricted remnant areas. A complete survey has not been made of the Lake Wales Ridge for this species, making defining a distribution difficult. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties has been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases is isolated. Within the islands of xeric habitat, this species is found in only two remnant natural sites and three pastures sites, indicating how little habitat is left for Z. celata. For this reason, existing populations are in need of protection. (USFWS, 1999)
- Continue research on life history characteristics of Z. celata. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species more specific biological information is needed. (USFWS, 1999)

- Continue monitoring existing populations of Z. celata. (USFWS, 1999)
- Provide public information about Z. celata. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. Care is needed, though, to avoid revealing specific locality information about Z. celata. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of Z. celata and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)
- Habitat-level Recovery Actions: Prevent degradation of existing habitat. Restore areas to suitable habitat. Conduct habitat-level research projects. Monitor habitat/ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES Recovery actions outlined in the initial recovery plan (Service 1999) and the amendment to the recovery plan (Service 2019) are mostly ongoing or partially complete. Stakeholders (e.g., state agency, private conservation groups) are actively working toward the recovery of this plant, including maintaining ex situ collections, monitoring, and protecting existing populations. Recovery Activities • Continue to maintain captive populations to use for reintroductions and/or to increase genetic diversity at extant sites. • Maintain regular fire-return intervals across the inhabited landscape Monitoring and Research Activities • Continue regular census of extant populations, determine genetic makeup of populations. • Search appropriate habitat types in private lands (that have yet to be scouted) for potential additional populations. • Monitor sites post-fire to understand how long after fire FL ziziphus will recover/resprout. • Maintain collaboration and data sharing agreements with state agencies and the Archbold biological station to ensure that all data on monitoring of extant populations are collated and shared with appropriate parties (USFWS, 2024).
