**Narrative:** At the time of listing, the Vine Hill Preserve population of Clarkia imbricata was threatened by over-collection and damage associated with trespassing by recreational plant enthusiasts seeking not only the C. imbricata plants and seeds, but also Arctostaphylos densiflora and Ceanothus foliosus var. vineatus, ostensibly for the nursery trade. However at this time overcollecting is not thought to be a major threat, as no incidents have occurred within the last 10 years (P. Van Soelen, personal communication 2010). Therefore over collection remains a threat, but less so since 1997. (USFWS, 2011)

**Stressor:** Risk of extirpation due to small population sizes (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Risk of extinction through random events was listed as a threat in the 1997 listing rule. The small number of individuals in the single Clarkia imbricata population increases the threat of extinction of the species as a whole through stochastic demographic and environmental events. C. imbricata has been reduced to a single protected population with fluctuating numbers of individuals. Even with as many as 5,000-10,000 plants in an annual plant population, risk of extirpation due to small populations is a major threat because we do not know enough about population dynamics, and annual plant numbers can vary greatly between years. (USFWS, 2011)

**Stressor:** Climate change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Global climate change was not included in the 1997 listing rule, but is a potential threat to Clarkia imbricata. Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999; Cayan et al. 2005; IPCC 2007). C. imbricata may be at risk with global climate change if it cannot disperse to favorable climate and conditions. (USFWS, 2011)

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of the listing, regulatory mechanisms thought to provide protection to Clarkia imbricata included: 1) listing under the Endangered Species Act; 2) the National Environmental Policy Act (NEPA); 3) listing under the California Endangered Species Act (CESA); 4) the California Environmental Quality Act (CEQA); and 5) the California Native Plant Protection Act (NPPA). In summary, the Act is the primary Federal law that provides protection for Clarkia imbricata since its listing as endangered in 1997. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent its status under the Act. Therefore, we continue to believe other laws and regulations have limited ability to protect the species in absence of the Federal Endangered Species Act. (USFWS, 2011)

**Stressor:** Destruction of habitat (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing in 1997, the most significant threat to the two remaining populations of Vine Hill clarkia was land conversion to housing, vineyards, and/or orchards (Service 1997, p. 55799). The 2011 5-Year Review described the threat of land conversion of occupied habitat as a lesser threat given that the single extant occurrence of the species was protected on the Vine Hill Preserve, while all natural populations had been extirpated (Service 2011, p. 6). At the time of the 2016 Recovery Plan and 2019 5-Year Review (Service 2016, p. I-6; Service 2019, p. 3), land-use conversion remained a lesser threat to the known extant occurrence of Vine Hill clarkia. However, the few plants that are growing on the adjacent property to Vine Hill Preserve are not protected, and current land-use and management activities on the adjacent property may reduce available habitat for the species (USFWS, 2024)

**Stressor:** Competition and reduced fire regime (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Vine Hill clarkia is a shade intolerant species and is restricted to open areas as it is easily outcompeted for light and space by large shrubs and trees. The 2011 5-Year Review identified competition by overshading species and natural succession of the grassland habitat in the Vine Hill Preserve as a major threat (Service 2011, p. 7). Invasive non-native species were also documented as a threat; common velvet grass (Holcus lanatus) was present in the Vine Hill Preserve and continues to compete with the Vine Hill clarkia (Service 2011, p. 7; Laguna de Santa Rosa Foundation 2023, pp. 4, 5, 8). In the 2016 Recovery Plan and 2019 5-Year Review, the threat of competition was highlighted, particularly as it related to the state-endangered Vine Hill manzanita (Arctostaphylos densiflora) (Service 2016, p. I-9; Service 2019, pp. 3–4). While the Vine Hill manzanita and Vine Hill clarkia likely co-occurred naturally in various habitats, they are both now only found naturally in the Vine Hill Preserve (Service 2019, p. 4). Natural fire regimes keep succession in balance and maintain open areas; however, with reduced fire regimes due to fire suppression, artificial maintenance to control community succession is necessary to support Vine Hill clarkia (Service 2016, p. I-9). At the time of this review, the threat of competition remains at

the Vine Hill Preserve, though the immediate risks have been ameliorated due to the decline in Vine Hill manzanita from Phytophthora infection and managed seeding of Vine Hill clarkia throughout areas previously occupied by manzanita (Gordon pers. comm. 2023). Additionally, the Vine Hill Preserve Management Plan was created in 2023 to guide management of the Preserve for the perpetual success of the Vine Hill clarkia, Vine Hill manzanita, and state-rare Vine Hill ceanothus (Ceanothus foliosus var. vineatus) (Milo Baker Chapter 2023, entire). This Plan provides protocols and recommendations for removal of native and nonnative competitive species, through methods like hand pulling and controlled burns when feasible (USFWS, 2024)

**Stressor:** Pesticides (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Environmental Protection Agency (Agency) recently released final biological evaluations assessing the effects of labeled uses of three neonicotinoid pesticides on listed species (Agency 2022a, entire; Agency 2022b, entire; Agency 2022c, entire). The three pesticides (clothianidin, imidacloprid, and thiamethoxam) are registered for use on a variety of agricultural crops; there are also some non-agricultural applications. The three pesticides target insect species by acting on their neurotransmitters to cause excessive nervous stimulation, paralysis, and death. The pollinators of Clarkia species are diverse and include species of specialized and generalist bees, flies, and beetles (Anderson et. al. 2021, entire). The Agency's final biological evaluations determined that all three pesticides are highly toxic to bees and other invertebrate pollinators, have the potential to result in bee brood and colony reductions, and if affected pollinators decline near Vine Hill clarkia, there is a potential for the three pesticides to indirectly adversely affect the species (Agency 2022a, pp. 4, Appendix 4-1; Agency 2022b, pp. 2, Appendix 4-1; Agency 2022c, pp. 3, Appendix 4-1). The Agency anticipates releasing amended proposed interim decisions and a national consultation with the Agency is currently pending. (USFWS, 2024)

***Recovery***

**Reclassification Criteria:**
E/1. There are three separate locations with C. imbricata, each consisting of 2 acres or more, and each with a 10-year average of 4,000 plants or more. Due to the longterm persistence of the species at the Vine Hill Preserve (smaller than 2 acres) and the successful management of the site by CNPS, the Vine Hill Preserve may be counted as one of the three locations if it meets all other aspects of the downlisting criteria. For the purpose of meeting this criterion, a separate location is defined as a group of C. imbricata plants sufficiently separated from any other group of C. imbricata as to minimize the potential that a typical single stochastic event (e.g., fire or storm damage) would affect more than one location with C. imbricata. (USFWS, 2015)

E/2. Develop a management plan to control competing native and non-native vegetation. Competing native and non-native vegetation should be controlled at a level whereby years with less than 4,000 C. imbricata plants at each location counted towards recovery (as defined in delisting criterion E/1) cannot be attributable to competition with native and non-native vegetation. Also, there is a monetary commitment in place to continue control in perpetuity for all locations counted toward recovery (as defined in downlisting criterion E/1). (USFWS, 2015)

A/1. All populations of C. imbricata counted toward recovery, as defined in E/1, are protected from incompatible uses with a binding legal commitment from the landowner, and funding has been secured for the perpetual implementation of the management plans defined in E/2. (USFWS, 2015)

Recovery Priority Number: 5

**Delisting Criteria:**
A/1. All populations of C. imbricata counted toward recovery are protected from incompatible uses with a binding legal commitment from the landowner, and funding has been secured for the perpetual implementation of the management plans. (USFWS, 2015)

E/1. There are five separate locations with C. imbricata, each consisting of 2 acres or more, and each with a ten year average of 4,000 plants or more . Due to the longterm persistence of the species at the Vine Hill Preserve and the successful management of the site by CNPS, the Vine Hill Preserve (smaller than 2 acres) may be counted as one of the five locations if it meets all other aspects of the delisting criteria. For the purpose of meeting this criterion, a separate location is defined as a group of C. imbricata plants sufficiently separated from any other group of C. imbricata as to minimize the potential that a single stochastic event (e.g., fire or storm damage) would affect more than one location with C. imbricata. (USFWS, 2015)

E/2. Competing native and non-native vegetation are controlled to a level whereby years with less than 4,000 C. imbricata plants at each location counted towards recovery (as defined in delisting criterion E/1) cannot be attributable to competition with native and non-native vegetation. Also, there is a monetary commitment in place to continue control in perpetuity for all locations counted toward recovery (as defined in delisting criterion E/1). (USFWS, 2015)

**Recovery Actions:**
- Establish additional populations of Clarkia imbricata. (USFWS, 2015)
- Monitor and manage competing native and non-native vegetation affecting Clarkia imbricata. (USFWS, 2015)
- Conduct research for the development of a population viability analysis, determine levels of genetic diversity and interbreeding coefficients, and model the rate at which genetic diversity can be expected to be lost to genetic drift. (USFWS, 2015)
- Protect, manage, and increase the population where possible within its native range. If appropriate areas that are not within the native range are found, reintroduce C. imbricata. (USFWS, 2011)
- Establish at least two additional separate populations on protected land. (USFWS, 2011)
- Control of succession and nonnative plants where possible through hand removal of vegetation. (USFWS, 2011)
- Explore the use of a burn box to determine how fire affects C. imbricata seed bank and germination, in addition to nonnative species such as Holcus lanatus seed bank and germination. (USFWS, 2011)
- Gather information about life history and the ecosystem requirements of Clarkia imbricata. More specifically, gather information about how long the seed bank remains viable and how it responds to fire, germination requirements, and genetic diversity. (UFSWS, 2011)

- Create and implement a monitoring plan for Clarkia imbricata. Yearly plant counts are already conducted. Add estimation of percent cover of nonnative species and percent cover by shrubs and trees.
- Monitor land-use conversion in parcels adjacent to Vine Hill Preserve. If development occurs, attempt to rescue plants or seeds if possible. (USFWS, 2011)
- Control and monitor access to the Vine Hill Preserve to prevent and monitor trespassing. (USFWS, 2011)
- Pruning and managing the extent of Vine Hill Manzanita. Reports suggest the Vine Hill clarkia and Vine Hill manzanita coexisted naturally in the Sonoma Barrens prior to European settlement (USFWS 2016). Today, both plants only exist at the Vine Hill Preserve. In previous years, Vine Hill clarkia existed in the margins between individual Vine Hill manzanitas. Currently, the Vine Hill manzanita have grown to a point that they are shading and excluding the Vine Hill clarkia from these areas, limiting the number of individual clarkia which can grow at the site. We suggest pruning the Vine Hill manzanita to increase the amount of available habitat for the Vine Hill clarkia. This will require coordination with the California Department of Fish and Wildlife, as the Vine Hill manzanita is a state listed species. (USFWS, 2019)
- Continued seeding upslope. Vine Hill clarkia populations could be dispersal limited (S. Gordon, pers. comm. 2018). Upslope areas at the Vine Hill Preserve previously contained plants (S. Gordon, pers. comm. 2018); however, today the population has shifted spatially within the preserve to areas where its survival is threatened by competition with the Vine Hill manzanita (USFWS 2016). This threat would decrease if individual Vine Hill clarkia seeds were collected and distributed upslope habitat every few years. (USFWS, 2019)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of the Vine Hill clarkia. Some of these recommendations have already been discussed in the previous status reviews (Service 2011, pp. 10–11; Service 2019, p. 4) and remain valid. 1. Continue managing competing vegetation at Vine Hill Preserve. 2. Continue out-planting at different locations at Vine Hill Preserve to increase occupied habitat. 3. Build communication with the landowners of the properties neighboring Vine Hill Preserve and those with assumed extirpated localities in order to survey those sites, secure protection, and create management plans. 4. Monitor land-use conversion in parcels adjacent to Vine Hill Preserve. If development occurs, attempt to rescue plants or seeds, if possible. 5. Identify and consider permanently protecting locations within the Vine Hill clarkia's historical range that contain suitable habitats for future out-plantings. 6. Attempt out-planting at protected locations on private and public land within the Vine Hill clarkia's historical range. (USFWS, 2024)

# SPECIES ACCOUNT: *Clarkia speciosa ssp. immaculata* (Pismo clarkia)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 1/17/1995; California/Nevada (Region 8)

**Physical Description**

An annual herb, with branched stems, in the four o'clock family (Onagraceae). It is up to 50 cm (20 in) tall and has flowers 1.5 to 2.5 cm (0.5 to 1.0 in) wide that are white or cream colored at the base, streaking into pinkish or reddish-lavender at the tips. (USFWS, 2009)

**Taxonomy**

A member of the four o'clock family (Onagraceac), was first collected in Carpenter Canyon by Frank Harlan Lewis and Margaret Ensign Lewis in 1947. Their monograph on the genus Clarkia (Lewis and Lewis 1955) described the plant for the first time (USFWS, 1998). Clarkia speciosa ssp. immaculata differs from the more abundant ssp. speciosa in having somewhat larger flowers with a different petal-color pattern (lacking a red spot); genetic studies (Lewis and Lewis, Univ. Calif. Publ. Bot., 1955) showed "considerable" genetic differentiation between these two subspecies. (NatureServe, 2015)

**Historical Range**

See Current Range.

**Current Range**

Western San Luis Obispo County, California, ranging from San Luis Obispo south to the Nipomo Mesa area, an area approximately 20 kilometers (km) (13 miles (mi)) long by 10 km (7 mi) wide. (USFWS, 2009). Pismo clarkia's range increased to an area approximately 35 km by 13 km or 22 mi by eight mi from what we estimated it to be in 2009 (22 km by 10 km or 14 mi by seven mi; Service 2009, pg. 5). When we simply trace the circumference around the outermost datapoints on Figure 1, the taxon's range occupies approximately 40,359 hectares or 99,730 acres (USFWS, 2023).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: 1 year (USFWS, 1998)

**Breeding Season**

Adult: May through July, occasionally extending into September (USFW, 1998)

**Reproduction Narrative**

Adult: Pismo clarkia is an annual herb that typically flowers from May through July, occasionally extending into September. (USFWS, 1998). The reproductive biology of Pismo clarkia is not well studied. All C. speciosa have relatively large, showy flowers with eight stamens arranged in two series of four and a stigma that is distinctively four-lobed. The mature style is longer than the stamens and situated above them. It reaches maturity after the stamens (called protandry), and this is believed to have evolved to encourage outcrossing and help ensure that self-fertilization does not occur. However, all species in the genus are self-compatible (Lewis and Lewis 1955, pg. 246, 249, 289). Selfing evolved independently from other outcrossing species within Clarkia at least 10 times but is likely not utilized for reproduction in C. speciosa because of its persistent protandrous floral morphology (Moeller and Geber 2005, pg. 787). While selfing may occasionally occur in C. speciosa, most successful reproductive events occur via outcrossing with insect pollinators. Based on studies from other Clarkia species, potential pollinators of C. speciosa may include both specialist and generalist bees, flies, butterflies and moths, beetles, and hummingbirds (Lewis and Lewis 1955, pg. 249; Moeller 2005, pg. 30–31; Miller et al 2014, pg. 320–321). However, evaluations of floral visitors and pollinators for taxa within C. speciosa have not occurred. We do not know how long Pismo clarkia seeds remain viable. Seeds likely persist in the soil as a seedbank based on observations by researchers that Pismo clarkia plants did not appear in the same locations in consecutive years (Service 1998, pg. 33). Other research showed that C. williamsonii seeds remained viable and ungerminated as a seed bank in any given year of monitoring (Price et al 1985, pgs. 154–155). C. springvillensis seeds stored at room temperature were not viable after eight years. However, they remained viable for at least two consecutive years of study (McCue and Holtsford 1998, pg. 33). Therefore, we presume Pismo clarkia is similar to many other California native annual plants that produce seeds with multiyear dormancy and make large, and potentially long-lasting soil seed banks (USFWS, 2023).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Forest Edge, Forest/Woodland, Old field, Shrubland/chaparral, Woodland - Hardwood (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs at elevations below 600 feet (USFWS, 1998)

**Spatial Arrangements of the Population**

Adult: Patches (USFWS, 2009)

**Environmental Specificity**

Adult: Narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Pismo clarkia typically occurs in fine, dry, sandysoils, derived from ancient marine terraces, in grasslands or openings in chaparral and oak woodlands at elevations below 600 feet. Due to the patchy distribution of these openings, C. speciosa subsp. immaculata populations (and polygons within each population) are fragmented by nature. (USFWS, 1998; USFWS, 2009)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

26 populations. Of these, two are extirpated, six are likely extirpated, four are at least partially extant, four are extant, and 14 are presumed extant. We also know of two other occurrences where development projects are proposed, and these are presumed extant (USFWS, 2023)

**Population Narrative:**

Currently, there are 14 populations listed within CNDDB that are extant or presumed to be extant. While more populations have been found in recent years, the overall status of this species is not improving. Development has adversely affected or threatens to adversely affect nine of the remaining 14 known populations and fragmentation due to development is a serious concern for the survival of the species as a whole. (USFWS, 2009). Pismo clarkia currently consists of 26 known CNDDB occurrences. Of these, two are extirpated, six are likely extirpated, four are at least partially extant, four are extant, and 14 are presumed extant. We also know of two other occurrences where development projects are proposed, and these are presumed extant. Lastly, we know of 17 georeferenced Pismo clarkia herbarium specimens, although we do not know the status of the taxon at these locations. We have little current information about Pismo clarkia abundance throughout the range and are unable to assess any trends about the status of the taxon, even at the scale of individual occurrences. At this time, we have met none of the downlisting criteria established for the taxon and therefore delisting criteria are not considered (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Development and secondary impacts from development (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Residential development and other secondary impacts associated with urban development continue to be the greatest threat to the continued existence of Clarkia speciosa subsp. immaculata. Development has caused the loss of all or part of five known populations of this species since listing. Development has affected or continues to threaten nine additional populations in part or in whole (Roalman 2000, CNPS 2006, CNDDB 2009). In addition to direct loss of plants and occupied sites, development eliminates adjacent suitable habitat that otherwise would allow for natural population expansion and movement as suitable microhabitats shift in the landscape. Furthermore, it may eliminate habitat that supports populations of pollinators and seed dispersal vectors and habitat that contains a seedbank, in cases where there is no germination in a given year when surveys are conducted. (USFWS, 2009)

**Stressor:** Urban sprawl and development (USFWS, 2009)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** Urban sprawl and development leads to habitat loss and increased fragmentation and is the number one cause of imperilment to listed species, including Clarkia speciosa subsp. immaculata, in California (Doyle et al. 2001). Likewise, urban sprawl and development are directly linked to introduction of and competition from non-native species and outdoor recreation, the second and third leading cause in the decline of listed species, including C. speciosa subsp. immaculata (Alberts et al. 1993, Doyle et al. 2001). The fragmentation of habitat and populations due to development projects may pose the greatest threat to the recovery of the species. Commercial and residential development is rapidly increasing within areas in close proximity to existing and potential C. speciosa subsp. immaculata habitat (Draeger 2002), leading to a substantial increase in fragmentation of populations since listing. A large increase in the amount of development (e.g., residential, recreational, infrastructure) within this area has occurred between populations, which may have increased their isolation from each other (CNDDB 2005; AirPhotoUSA Inc. 2000, 2003; USDA National Agricultural Image Program 2005; M. Elvin, Service Biologist, pers. obs. 2006). Additionally, numerous development projects have further fragmented individual populations by extirpating portions of them (CNDDB 2005; AirPhotoUSA Inc. 2000, 2003; USDA National Agricultural Image Program 2005; L. Althouse, pers. comm. 2006). (USFWS, 2009)

**Stressor:** Habitat fragmentation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat fragmentation affects persistence of populations or species within habitat fragments (Wilcove et al. 1986, Noss et al. 1997). Fragmentation also may lead to a decrease in pollination and reduced reproductive success, due to decreased visitation from pollinators to small and/or isolated populations (Kearns and Inouye 1997). While fragmentation does not necessarily lead to extinction of a species within a habitat patch, small populations in small habitat patches have an increased likelihood of extinction and are increasingly affected by their surroundings (i.e., edge effects such as physical effects differing at the boundaries of a patch and the interior of a patch) (Noss and Cooperrider 1994). At what point in the fragmentation process biological integrity of this species declines dramatically is not known. (USFWS, 2009)

**Stressor:** Habitat degradation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The CNDDB indicates that many of the properties containing Clarkia speciosa subsp. immaculata populations have been proposed for development since listing (CNDDB 2005), although many of these projects either have not occurred yet or have fallen through (L. Althouse pers. comm. 2009; Google Earth 2009). We know of two instances where the translocation of C. speciosa subsp. immaculata populations (soil and seedbank) was attempted in an effort to mitigate for impacts to portions of the original populations due to development (EO 16 and 17). Plants survived during the monitoring and management phases of these projects, but after the monitoring and management ended, the sites became so degraded and the vegetation/habitat was altered to the point that suitable habitat for C. speciosa subsp. immaculata no longer exists at any of the sites. Plants have not been seen at these locations since 1998 and all of these sites (original donor populations and the recipient translocated populations) are now presumed to be

extirpated (J. Dart, pers. comm. 2006; L. Althouse, pers. comm. 2006; M. Elvin, pers. obs. 2006; CNDDB 2009). Therefore, all of the known translocation efforts for C. speciosa subsp. immaculata have failed and the translocation of populations of this species may not be a sufficient mitigation or conservation strategy. (USFWS, 2009)

**Stressor:** Non-native plants (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Cortaderia jubata (pampas grass) and Ehrharta calycina (veldt grass) are nonnative plants adversely affecting many populations (CNDDB 2005, 2009; L. Althouse pers. comm. 2009), and their invasions are most likely an indirect effect from nearby development and plants that escaped from landscaping. (USFWS, 2009)

**Stressor:** Roadside threats (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Threats and adverse effects from road grading, roadside traffic, and roadside maintenance (including mowing and herbicide spraying) have not caused the extirpation of any entire occurrence, but they continue to threaten the species as a whole. At least three occurrences are threatened by road maintenance activities (CNDDB 2005, CNPS 2006, CNDDB 2009). (USFWS, 2009)

**Stressor:** Cattle grazing (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** We noted that two of the four known extant occurrences (at that time) had been subject to grazing by livestock (Service 1994), but that C. speciosa subsp. immaculata might be able to sustain a certain amount of grazing by livestock (Dunn 1987). Although cattle grazing may adversely affect Clarkia speciosa subsp. immaculata, it may not necessarily be a threat to its survival under all conditions. If controlled and timed correctly, cattle grazing may provide some benefits to C. speciosa subsp. immaculata by reducing competition from other vegetation. Over-grazing, on the other hand, can be extremely detrimental to the species, particularly through trampling and alterations to the hydrology (Service 1997, 1998). While this plant may be able to withstand a small amount of grazing, grazing still appears to adversely affect it through the reduction of reproductive success due to loss of flowers and a correlated reduction in the production of seeds (Service 1998). Grazing has been reported as a potential threat at four occurrences (CNDDB 2009). (USFWS, 2009)

**Stressor:** Stochastic events (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Clarkia speciosa subsp. immaculata may be threatened with stochastic extinction due to the small number of individuals within populations and isolation of the remaining populations (Airphoto USA Inc. 2000, 2003; CNDDB 2009). It is generally accepted that small populations

have higher probabilities of extinction than larger populations because their low numbers make them susceptible to inbreeding, loss of genetic variation, high variability in age and sex ratios, demographic stochasticity, and random naturally occurring events such as wildfires, floods, droughts, or disease epidemics (Soulé 1987, Shaffer 1981, 1987; Meffe and Carroll 1997, Primack 1998). (USFWS, 2009)

**Stressor:** Isolation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Another factor commonly understood to make populations vulnerable to stochastic events is isolation. Isolation often acts in concert with small population size to increase the probability of extinction. Isolated populations are more susceptible to long-term/permanent extirpation by accidental or natural catastrophes because the likelihood of recolonization following such events is negatively correlated with the extent of isolation (i.e., colonization is less likely as isolation increases) (Wilcox and Murphy 1985, Meffe and Carroll 1997). (USFWS, 2009)

**Stressor:** Isolation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In addition, wide fluctuations in numbers from year to year in annual plants, such as Clarkia speciosa subsp. immaculata, may reduce population viability if there is a series of poor seed production years (Menges 1991). The limited gene pool may depress reproductive vigor or a single human-caused or natural environmental disturbance (e.g., wildfire) could extirpate one or more populations of this species. Additionally, small populations are threatened by inbreeding depression and can have significantly lower germination rates than larger populations of the same species due to high levels of homozygosity (Menges 1991). (USFWS, 2009)

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since the time of listing, we have identified climate change as a potential threat to the species. Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects. While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to particular species at this time. Clarkia speciosa subsp. immaculata may be particularly threatened by climate change because its geographic distribution is so narrow and its current range is unlikely to overlap with regions that would be climatically suitable in the future (Levine et al. 2008). (USFWS, 2009)

***Recovery***

**Reclassification Criteria:**

1. Eight populations are on lands secured from human-induced threats with adequate surrounding habitat to permit natural population expansion and movement as suitable microhabitats shift in the landscape. (USFWS, 1998)

2. The eight protected populations represent the plant's entire range. (USFWS, 1998)

3. These populations must be large, stable or increasing (a minimum of 10 years of monitoring is needed because the population sizes fluctuate due to precipitation). (USFWS, 1998)

4. Management of these populations and associated lands in the future must be reasonably assured for the long term, and must be effective, as demonstrated by stable or increasing populations. (USFWS, 1998)

Recovery Priority Number: 6C

**Delisting Criteria:**
When the downlisting criteria have been met for a species, the species can be considered for delisting if:

(1) Threats are reduced or eliminated so that occurrences are capable of persisting without significant human intervention or perpetual endowments are secured for management necessary to maintain the continued existence of the species; (USFWS, 2019)

(2) An ex situ seedbank is established in a Center for Plant Conservation-affiliated botanic garden. While sufficient seedbank in the soil would typically provide a strategy for the taxon to persist through several years of short- or medium-term drought, it may not be sufficient to persist through long-term drought. Therefore, an ex situ seedbank would provide assurance that an occurrences could be reseeded, should long-term drought – or other stochastic events – make it necessary; (USFWS, 2019)

(3) All existing occurrences are stable or increasing in the wild for at least 10 years. We expect above-ground occurrence size to fluctuate annually, based on response to amount and timing of rainfall. Therefore, a period of 10 years should be long enough to include most of the variability in rainfall that occurs in this region. Monitoring of occurrences should be undertaken and access to private properties that support the species should be pursued, which will provide a baseline for the status of these occurrences; these data should provide a basis for monitoring occurrence attributes and trends to determine the species trajectory over time. (USFWS, 2019)

**Recovery Actions:**
- Secure populations and habitat on unprotected lands. Methods for securing lands include in-fee purchase, gifts ofeasement orfee interest by the property owner, deed restrictions (provided restrictions cannot be changed privately without the knowledge of Federal, State and County agencies), acquisition of property rights (e.g., development rights) or permanent conservation easements. (USFWS, 1998)
- Manage secured lands to control or eliminate other known threats. Although habitat alteration through development is currently the most substantial and irreversible threat facing all of the species in this plan, the management of lands secured from development will remain a formidable task, made more so in those cases where the secured habitats are

adjacent to high density residential and urban development. (USFWS, 1998)

- Evaluate potential threats and conduct management-oriented research. Conduct habitat-oriented research for Morro Bay species. Conduct species-specific research. Evaluate research results and use in future management. (USFWS, 1998)
- Determine population dynamics and effects of recovery efforts. Studies should be conducted to learn the number and size of successful self sustaining populations for the species to establish criteria for its reclassification. (USFWS, 1998)
- Develop and implement an education/information program. The benefits of protecting native species and their habitats and maintaining native biological communities should be explained clearly to all concerned parties. (USFWS, 1998)
- Reevaluate recovery criteria and revise recovery plan based on expanded knowledge from research, monitoring, and management. The scientific validity ofthe recovery criteria and recovery plan should be reviewed and revised as more information becomes available. The criterion ofmaintaining sufficient numbers ofpopulations or conservation areas should be assessed, and the success or failure of management actionsshould be evaluated. (USFWS, 1998)
- Recommendations for Actions from 2009 5-Year Revview: Work with local partners to secure occupied sites that meet recovery criteria. Work with local partners (including the County of San Luis Obispo) to help development projects avoid impacts to Clarkia speciosa subsp. immaculata, considering the two attempted translocation projects for this species have failed, resulting in the presumed extirpation of both populations. Work with the County of San Luis Obispo to develop an improved system to track projects that might adversely affect listed and other sensitive species. Amend the recovery objectives and tasks to account for the increase in fragmentation and how it affects our ability to accomplish the recovery criteria. (USFWS, 2009)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Obtain access (if possible) to all mapped Pismo clarkia occurrences to conduct comprehensive surveys of abundance, assess the status of the taxon, and evaluate threats at these locations. Include estimates of numbers of individuals present, global positioning system (GPS) mapping of occupied spatial area, ecological setting, co-occurring and codominant vegetation, presence of natives versus nonnative species, timing of phenology, and observations of potential insect pollinators. Update information in resource agency databases (CNDDB) to ensure that these data remain accurate and current. 2. Pursue grants and other funding to purchase properties that support the taxon and other plausible mechanisms to secure occurrences from development threats. Acquisitions should also include endowments to manage Pismo clarkia and its habitat in perpetuity. 3. Conduct experimental research on strategic, applied grazing as a management tool for Pismo clarkia recovery and nonnative, invasive weed controls. 4. Conduct experimental research across the species' range to improve and refine our understanding of techniques for population reintroduction, augmentation, and establishment. 5. Continue making accessions for conservation seed banking throughout the species; range so that all populations are represented in the collections. Conduct seed bulking of accessions that may serve as a source for recovery efforts and a backup in the event of stochastic loss and local extirpation (USFWS, 2023).

# SPECIES ACCOUNT: *Clarkia springvillensis* (Springville clarkia)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 10/14/1998; California/Nevada (Region 8) (USFWS, 2015)

**Physical Description**

An erect annual herb, up to about 1 m tall. Flowers (May-July) have lavender petals with a long narrow base and an expanded, diamond-shaped tip that has a darker, purplish basal spot. (NatureServe, 2015)

**Historical Range**

See current range/distribution.

**Current Range**

Endemic to the foothills of the Sierra Nevada in a small area of Tulare County, California along the Tule River drainage. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: 1 year (USFWS, 2009)

**Breeding Season**

Adult: May to July (NatureServe, 2015)

**Reproduction Narrative**

Adult: Clarkia springvillensis is a narrowly distributed annual in the evening primrose family (Onagraeae) and blooms from May to July. (USFWS, 2009)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Forest Edge, Forest/Woodland, Woodland - Hardwood (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Prefers sunny open sites (USFWS, 2009)

**Geographic or Habitat Restraints or Barriers**

Adult: Found at elevations between 330 and 1,220 m (1,080 to 4,000 feet) (USFWS, 2009)

**Spatial Arrangements of the Population**

Adult: Colonies (USFWS, 2009)

**Environmental Specificity**
Adult: Narrow (inferred from USFWS, 2009)

**Habitat Narrative**
Adult: Clarkia springvillensis grows mostly on the uphill slope of roadbanks, on small decomposing granitic domes, and in sunny openings from elevations between 330 and 1,220 meters (1,080 to 4,000 feet) within the blue oak woodland community. Clarkia springvillensis is found on granitic soils at sunny sites. Population surveys revealed 18 colonies in 2002 and 23 colonies in 2003. (USFWS, 2009)

***Dispersal/Migration***

**Dispersal/Migration Narrative**
Adult: Not available

***Population Information and Trends***

**Population Trends:**
Declining (USFWS, 2009)

**Number of Populations:**
27 Presumed Extant (USFWS, 2022)

**Population Size:**
1,016 (USFWS, 2022)

**Population Narrative:**
The California Department of Fish and Game (2001) characterized the species as a whole as declining in 1999. There are about 10 populations known extant (NatureServe, 2015). The population size of Clarkia springvillensis can vary enormously from one year to the next due to interactions between the soil seed bank and seasonal weather conditions. (USFWS, 2009). At the time of listing, there were 15 occurrences of Springville clarkia occupying 61 hectares (150 acres), which are now considered historical occurrences (Service 1998, p. 49023; Forest Service 2012, p. 10). At the time of our 2009 5-year review, there were 17 presumed extant occurrences (Service 2009, p. 3). New occurrences of Springville clarkia have been added to the Diversity Database since the previous status review (Diversity Database 2021). These occurrences are likely due to increased survey efforts and do not change the overall distribution of the species. According to the Diversity Database (2021), there are currently 28 occurrences. The type locality is possibly extirpated, while the other 27 occurrences are presumed extant (Diversity Database 2021). Of the extant occurrences, nine occurrences have not been surveyed since before 2000 (Diversity Database 2021). Collected specimen from Diversity Database occurrences #29 and #30 are thought to be an atypical outcrossing form of Kern River clarkia (Clarkia exilis) (U.S. Army Corps of Engineers 2021, p. 45). However, further field work is needed to confirm (Diversity Database 2021). See Appendix Table 1 for further details on Diversity Database occurrences (note: table includes all occurrences recorded as Springville clarkia in the Diversity Database, including occurrences that need further expert verification on species identity) USFWS, 2011).

Abundance: Abundance of Springville clarkia varies across colonies and across years (Diversity Database 2021). Recorded abundance data includes extremes of single plants to hundreds of thousands of plants (Diversity Database 2021). As is common in annual plants, the aboveground population size of Springville clarkia drastically fluctuates from year to year (Service 2009, p. 5). The number of plants depends on interactions between the soil seed bank and weather (Forest Service 2012, p. 12). Rainfall patterns may be the most important factor for determining abundance in the following year (Forest Service 2012, p. 12). For example, as discussed in the previous status review, a comprehensive multiyear study of Springville clarkia as part of Southern California Edison's Lower Tule River Hydroelectric Project documented this drastic change in abundance in the project area (Service 2005, p. 4). The project area overlaps with the Siphon Canyon–Coffee Canyon area in the Middle Fork of the Tule River watershed. Survey data from 2002 to 2005 revealed that the area's abundance fluctuated between 2,500, 4,880, 1,800, and 10,000 individuals, with high and low numbers corresponding to wetter and drier years, respectively (Service 2005, pp. 8–9). Surveys estimate 3,055–3,315 individuals within the area in 2016 (Cardno, Inc. & Stebbins 2016, p. 3-2–3-3. The most recently available survey data estimates 1,016 individuals within the area in 2021, representing the low in the 2017–2021 reporting period (Cardno, Inc. & Colgate 2021, p. 3-4). The highest abundance surveyed during this period was 7,590 individuals in 2019 (Cardno, Inc. & Colgate 2021, p. 3-4). While abundance continues to fluctuate in this area, the changes do not as closely correspond with annual precipitation as previously reported (Cardno, Inc. & Colgate 2021, pp. 3-4–4-1). Botanists hypothesized that the Pier Fire in 2017 created unsuitable microhabitat conditions and/or precipitation patterns were unfavorable for the species (Cardno, Inc. & Colgate 2021, p. 3-4) (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Residential development (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Prior to listing, residential development affected Clarkia springvillensis at two sites. Element Occurrence 5 was damaged, but not destroyed, when an access road, building pad, and well were constructed in the midst of the C. springvillensis population (Ashford 1989) for a home that was never built. Mobile home development contributed to the extirpation of Element Occurrence 1. No mobile homes are currently located at that site, but road construction, maintenance and improvement associated with the former residences are believed to be responsible for its disappearance (J. Stebbins, pers. comm. 2001, J. Stebbins in litt. 2002; CNDDB 2009). (USFWS, 2009)

**Stressor:** Road maintenance (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Road maintenance and improvements have affected Clarkia springvillensis on steep banks near roadways to some extent (Stebbins 1991, J. Stebbins, in litt. 2002; CNDDB 2009). Road maintenance is still a threat at five occurrences in Clarkia springvillensis habitat. The dirt along which it grows are maintained either by Tulare County, Pacific Gas and Electric, or Souther California Edison. Road maintenance includes activities such as mowing, grading, spraying

herbicide, mechanically removing brush, and clearing culverts (USFS 1996), whereas road improvements are activities such as widening or straightening roads, or installing culverts (USFWS, 2009)

**Stressor:** Livestock grazing (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The apparent decline of Clarkia springvillensis is likely due to a complex combination of inappropriate livestock (J. Shevock, USFS, in litt. 1985; Stebbins 1991; Hansen 1992; USFS; 1996), competition from nonnative plants (McCue et al. 1996), and altered fire regimes (McCue et al. 1996; S. Carter, pers. comm. 2001, J. Stebbins, in litt. 2002). Inappropriate grazing practices that apparently contributed to the decline of C. springvillensis included (1) repeated consumption of the same plants in a single growing season; (2) grazing late in the season (May or later) so C. springvillensis plants did not have time to send up new shoots or set seed before dying back (McCue 1997; J. Stebbins, pers. comm. 2001); and (3) livestock spending long periods in one area, which caused direct trampling of plants, soil compaction, and surface disturbance (Hansen 1992). Concern over grazing peaked in the 1980s, and several occurrences were then fenced to exclude livestock (Stebbins 1991). (USFWS, 2009)

**Stressor:** Random demographic, environmental or genetic events (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The combination of small range and restricted habitat still renders Clarkia springvillensis susceptible to extirpation due to random events such as flood, drought, disease, or other factors (Shaffer 1981, 1987; Groom et al. 2006). Demographic events that may put small populations at risk involve random fluctuations in survival and reproduction of individuals (Shaffer 1981, 1987; Lande 1998; Groom et al. 2006). Small populations may also be subject to increased genetic drift and inbreeding (Menges 1991, Ellstrand and Elam 1993). Populations that are continually small in size are particulary susceptible to genetic changes due to drift. However, drift may also cause genetic changes with populations that occasionally fluctuate to small sizes. Increased homozygosity resulting from genetic drift and inbreeding in small populations may lead to a loss of fitness. In addition, reduced genetic variation in small populations may make any species less able to successfully adapt to future environmental changes (Ellstrand and Elam 1993). Clarkia springvillensis has small population size for at least five occurrences, therefore, it also is susceptible to extirpation due to demographic events, genetic drift, and inbreeding. (USFWS, 2009)

**Stressor:** Competition with nonnative plants (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Nonnative plants, especially Bromus grass species (brome), may have contributed to the decline of Clarkia springvillensis by competing directly for moisture and nutrients (J. Stebbins in litt. 2002). Dead stems of nonnative grasses create a build-up thatch that may have prevented C. springvillensis from becoming established in openings, thereby isolating populations (McCure et al. 1996; J. Stebbins, pers. comm. 2001). Prolonged grazing may have exacerbated these

problems because soil disturbance favors some nonnative plants over native species (Hansen 1992). A related problem is that the stems and thatch of nonnative plants contribute to an increased fire frequency. Conversely, fire suppression activities may have inadvertently contributed to the decline of Clarkia springvillensis by allowing encroachment of shrubs and trees into the openings where it grows (McCue et al. 1996; S. Carter, pers. comm. 2001, J. Stebbins in litt. 2002). (USFWS, 2009)

**Stressor:** Global climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Impacts to Clarkia springvillensis under predicted future climate change are unclear. A trend of warming in the mountains of western North America is expected to decrease the snowpack, hasten spring runoff, and reduce summer stream flows, and increased summer heat may increase the frequency and intensity of wildfires (IPCC 2007). While it appears reasonable to assume that the species may be affected, we lack sufficient certainty on knowing how and how soon climate change will affect the species, the extent of average temperature increases in California, or potential changes to the level of threat posed by drought and fire. (USFWS, 2009)

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

Recovery Priority Number: 8

**Delisting Criteria:**
Delisting criteria are not available.

**Recovery Actions:**
- Recovery actions are not available.
- Complete and published the draft recovery plan, and approve a final recovery plan (USFWS, 2009)
- Establish reliable baseline data for monitoring plant occurrences. Monitor the status and trend of Clarkia springvillensis in order to estimate current population sizes, the number and distribution of populations, the threats to each occurrence, and whether the species is stable, increasing, or declining. (USFWS, 2009)
- Work with the Forest Service, Bureau of Land Management, and California Department of Fish and Game to conduct research on a) the value of prescribed burning and mechanical brush removal; and b) study the effects of livestock grazing on Clarkia springvillensis. (USFWS, 2009)

***Conservation Measures and Best Management Practices:***
- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of Springville clarkia. Some of these recommendations have already been discussed in the previous status review (Service 2009, pp. 13–14) and remain valid. 1. Verify Springville clarkia occurrences recorded in the California Natural Diversity Database, especially occurrences with a currently unknown status

and/or that have not been surveyed in the previous ten years. 2. Conduct further research on Springville clarkia’s reproduction parameters (e.g., seed production rate, germination rate) and their relationship to environmental conditions to better understand population dynamics and effective population size. 3. Establish reliable baseline data for monitoring Springville clarkia occurrences, including both aboveground presence and soil seed bank. Work with the U.S. Forest Service and other landowners/managers to monitor the status and trend of occurrences to (a) track any threats, (b) estimate current colony/population sizes and the number and distribution of colonies/populations, and (c) determine whether the species is stable, increasing, or declining. Annual precipitation and monitoring data should be compared to assess the impact of drought on population changes, as this may be the most significant threat to the species. 4. Conduct genetic and ecological studies to gain a better understanding of the potential for hybridization between Springville clarkia and other clarkia species, such as elegant clarkia (Clarkia unguiculata). Create a species identification key based on genetic and morphological relationships. This information can then be used to help determine the status of California Natural Diversity Database occurrences with an uncertain identification. 5. Conduct further research on the effect of disturbance on Springville clarkia. Work with the U.S. Forest Service, Bureau of Land Management, and California Department of Fish and Wildlife to conduct research on (a) the value of prescribed burning and mechanical brush removal and (b) the effects of livestock grazing on Springville clarkia. 6. Provide support to the Tule River Indian Tribe of California to implement conservation actions for Springville clarkia on the Tule River Reservation. The Tribe plans to implement several conservation measures to protect occurrences on the Reservation and intends to survey for new colonies should any activities occur in suitable habitat. 7. Complete a recovery plan for Springville clarkia. The plan would establish a framework for agencies and landowners to coordinate conservation efforts. The plan would set recovery priorities and estimate costs of various tasks necessary to accomplish them. It also would describe site-specific management actions necessary to achieve conservation and survival of the Springville clarkia (USFWS, 2022).

# SPECIES ACCOUNT: *Clematis socialis* (Alabama leather flower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/27/1986; Southeast Region (R4)

**Physical Description**

A member of the family Ranunculaceae. The most distinctive features are its rhizomatous habit and formation of dense clones with erect stems reaching 0.2-0.3 meters(in) or 7-12 inches (in.) in height. The leaves are variable from the base to the apex of the stem. The lowermost leaves are scalelike, oblong or triangular in shape and mostly under 1 centimeter (cm) (0.39 in.) long; median leaves are simple, mostly elliptic-linear in shape, 4-12 cm (1.6-4.7 in.) long, and 0.5-1.0 cm (0.20-0.39 in.) wide; upper leaves are 3 to 5 foliolate and shaped as in median leaves. The flowers are solitary at the tips of slender stems, urn to bell-shaped, 2-3 cm (0.79-1.18 in.) long, and blue-violet in color. The fruits are aggregates of achenes which are densely pubescent and 2.5-3.0 cm (0.98-1.18 in.) in length (Figure 1). Clematis socialis, a member of the Viorna section of Clematis, superficially resembles the more widespread C. crisna but is distinguished by its erect stems, rhizomatous nature, solitary flowers and lack of tendrils (Kral 1982, 1983). (USFWS, 1989)

**Taxonomy**

Described as a new species in 1982 by Dr. Robert Kral. (USFWS, 1989)

**Historical Range**

The Alabama leather flower was known from only two sites, one each in St. Clair and Cherokee counties, Alabama, at the time of listing in 1986. (USFWS, 2010)

**Current Range**

St. Clair County (3 populations) , Cherokee County (two populations), and Etowah County (1 population), Alabama.  Floyd County, Georgia (two populations). (USFWS, 2017)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Clonal, sexual (USFWS, 2010)

**Dependency on Other Individuals or Species**

Adult: Bombus pennsylvanicus and Anthophora ursina (USFWS, 2010)

**Breeding Season**

Adult: March - June (USFWS, 2010)

**Other Reproductive Information**

Adult: Genetic sampling of populations in Alabama by Goertzen et al. (2011) revealed that individual genets (genetically distinct individuals) of Alabama leather flower can be quite large, spreading to at least 36 feet (ft.) (11 meters [m]) via underground rhizomes. The authors note that these genets may span greater distances than their sampling scheme detected. These data, coupled with earlier estimates that Alabama leather flower's rhizomes grow approximately 4 inches (10 centimeters [cm]) per year (Goertzen and Boyd 2007), indicate that the species is relatively long-lived and capable of living for at least 55 years. (USFWS, 2017)

**Reproduction Narrative**

Adult: Flowering occurs March to June. Fruit development begins in June; seeds mature by late July through early August and seeds have senesced by late August. Pollinators include queen bumblebee (Bombus pennsylvanicus), bee (Anthophora ursina); pollination not required for production of seeds, but seed production increases with pollination. Anthophora is a more productive pollinator than Bombus (EPA, 2016). Plants are believed to reproduce primarily by forking and spreading rhizomes which form dense clones (Kral 1982, Garrett 2004). Timmerman-Erskine and Boyd (1999) suggested that sexual reproduction in this species was limited by a combination of pollinator frequency, herbivory, low light levels, and post-maturation achene predation by mice. The level of genetic diversity in the Alabama leather flower is higher than average for rare species and surprising given that it is a narrow endemic with a clonal nature, thus suggesting that considerable sexual reproduction has likely occurred in these populations despite low observed seedling recruitment (Boyd et al. 1998, Goertzen and Boyd 2007) (USFWS, 2010).

**Habitat Type**

Adult: Terrestrial, palustrine (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Herbaceous wetland, riparian, forest, grassland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Periodic fires (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped, scattered (USFWS, 2010)

**Environmental Specificity**

Adult: Moderate (NatureServe, 2015)

**Habitat Narrative**

Adult: Silt and clay of alluvial, grass-sedge openings along a highway right-of-way, extending into the adjacent hardwood edge. Associated members of the grass-sedge community prior to logging included: Scarpus lineatus, S. atrovireus, Fimbristylis puberula, and Rhynchospora caduca; several andropogons, such as A. gerardi and A. scoparius; patches of Allium and Sysyrinchium were noted, in addition to violets and composites. The woodland overstory prior to logging (Kral, 1982) was composed of lowland oaks, hickories, white and green ash, sweet gum, black gum, persimmon, and red maple. The understory included flowering dogwood, swamp cornel, sassafras, buckthorn, elderberry, viburnums, honeysuckle, and blackberry. Many of these species have been documented as components of the climax vegetation usually associated with southeastern loblolly pine forests. These forests experience natural fires approximately every ten years (Wright and Bailey, 1982). It has a moderate environmental specificity (NatureServe, 2015). Open grass-seed-rush prairie areas and adjoining hardwood swamp forests. Soil types are Conawauga and Firestone formations (developed from weather shale, are acidic, low fertility, and poor in organic material); Tupelo series with Dowellton series inclusions (calcareous flatwood communities growing on circum-neutral soils) (EPA, 2016). The Alabama leather flower is found occurring in tight patches or sparsely scattered (Goertzen and Boyd 2007). Though plants are found in sunny and shaded conditions, they are more vigorous in full or partial sunlight where plant competition is low (Emanuel 2000, 2002; Garrett 2004, 2005; Garrett and Schotz 2005; Sherbundy and Martin 2007) (USFWS, 2010).

***Dispersal/Migration***

**Dependency on Other Individuals or Species for Dispersal**

Adult: Unknown

**Dispersal/Migration Narrative**

Adult: Dispersal mechanisms are unknown.

***Population Information and Trends***

**Population Trends:**

Not available

**Species Trends:**

Stable (USFWS, 2017)

**Number of Populations:**

6 extant natural pops in Alabama. 2 populations in Georgia, 1 Natural with transplants augmented and 1 transplanted (USFWS, 2022)

**Population Size:**

Approximately 13,000 - 18,000 stems across extant populations (USFWS, 2017)

**Additional Population-level Information:**

Because of the clonal nature of Alabama leather flower, individual populations can be thought of in terms of both genetically distinct individuals (genets) and clones (ramets). Genets are often composed of numerous ramets (clonal stems). As such, population assessments using numbers of stems alone can easily overestimate the actual population in terms of genets (Tepedino 2012). With respect to Alabama leather flower clonality, as noted above, genets have been documented to be at least 36 ft. (11 m) long (Goertzen et al. 2011). It is unknown how large individual Alabama leather flower genets can grow or how many ramets a given genet may produce. Similarly, no known study has attempted to characterize the number of genets found in an entire population of Alabama leather flower, let alone all populations of the species. In addition, ramets from individual genets grow intermixed with each other (Service 1989), further complicating population estimates using aboveground stem counts. Given these challenges, stem counts/estimates can be considered to represent maximum ramet population sizes, but are likely to overestimate the actual genet population size. (USFWS, 2017)

**Population Narrative:**

Alabama leather flower's known range has expanded from two Alabama counties (St. Clair and Etowah) at the time of listing (see Service 1986) and completion of the recovery plan (see Service 1989). Currently, the species is known from eight natural populations—six extant, one extirpated, and one uncertain (likely extirpated)—in northeastern Alabama's Cherokee, Etowah, and St. Clair Counties and northwestern Georgia's Floyd County . The species' entire known range spans less than 90 miles (145 kilometers [km]), with individual populations typically separated by 30 or more miles (48 km) from their nearest neighbors. All known populations occur within the Valley and Ridge physiographic province. (USFWS, 2017). Limited new information on Alabama leather flower populations is available. Of note, two of Alabama's populations, both in Cherokee County, are extirpated (Service 2017, Byrd 2020) and three of the species' six extant populations are considered large (≥1,000 plants). No new information is available for either of Georgia's populations (including one natural population and one transplanted population) (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat for this species has been reduced through development and conversion to agriculture and pine plantations. Logging operations have degraded the habitat at two sites in Alabama (ANHP data, Byrd 2016c). The use of heavy equipment has adversely impacted these sites by creating ruts and promoting erosion, and has destroyed several plants. In addition, soil disturbance has fostered invasion by exotic and weedy species, further reducing habitat integrity and species viability. One population, in Cherokee County, Alabama, has been repeatedly impacted by disking for row-crop agriculture and has recently been extirpated by conversion to a soybean field (Schotz pers. comm. 2014, Byrd 2016c). One subpopulation in St. Clair County, Alabama was damaged by silt fencing installation for road improvement work (Byrd 2016c). Road improvements (e.g., widening, repaving) could jeopardize the continued viability of plants in adjacent rights-of-way if such activities are not conducted in an appropriate manner and coordinated with the Service. Rutting by ATVs and mowing equipment also pose threats to plants in rights-of-way (Emanuel 2000, Byrd 2016c). Development, particularly for residential purposes, has been identified as a significant threat to at-risk species associated with privately owned forested lands (Stein et al. 2010), such as Alabama leather flower. Within the southeastern United States, the urban footprint has been projected to more than double by 2060 compared with 2009 (Terando et al. 2014), thus putting further development pressure on Alabama leather flower and its habitats. Development and associated land use changes on unprotected sites could negatively impact or destroy populations if precautions are not taken. (USFWS, 2017)

**Stressor:** Small, isolated populations (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A number of the populations remain vulnerable due to the small number of plants and the limited area they occupy. Three of the populations occupy no more than an acre in area and

one of these consists of only 2 plants occupying a 15 m2 area (Martin 2008, 2009).

**Stressor:** Disease or predation (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Disease and predation are not known to threaten Alabama leather flower. Herbivore browsing damage has been observed in Georgia and fencing has been erected to deter herbivores around some plants (von Schmeling pers. comm. 2016). Accounts of such herbivore damage to Alabama leather flower are rare, indicating that this may be a localized rather than widespread phenomenon. One study identified a species of carpenter bee, Xylocopa virginiana, exhibiting nectar-robbing behavior on Alabama leather flower (Boyd and Wall 1998, Wall et al. 2003); however, the authors noted that given the apparently low visitation rates of this nectar-robbing bee, its effects on Alabama leather flower reproduction is likely small. It has also been suggested that deer mice (Peromyscus sp.) may be seed predators of Alabama leather flower (Timmerman-Erskine and Boyd 1999), which may potentially limit seedling recruitment. However, given the species' clonal nature (i.e., its ability to spread locally without seedling recruitment), it is unlikely that seed predation by deer mice alone presents a substantial threat to Alabama leather flower. Furthermore, as noted by Goertzen et al. (2011), Alabama leather flower's relatively high genetic diversity indicates that sufficient sexual reproduction is occurring within the species, despite low apparent seedling recruitment. (USFWS, 2017)

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** No State laws in Alabama protect Alabama leather flower and its habitat. In Georgia, the species is State protected as endangered under the Wildflower Preservation Act of 1973, O.C.G.A. 12-6-170. This law authorizes rules for the collection, transport, sale, and listing of protected plants within the State. In addition, no protected plants may be collected without landowner approval and no transport within the state is allowed without a State-issued permit (Patrick et al. 1995). Otherwise, protections are afforded to this species under sections 7 and 9 of the ESA. Two populations are considered protected from outright habitat destruction or adverse habitat modification due to their protection on a TNC preserve (in Alabama) and on lands set aside as a state Natural Area by the State of Georgia (in Georgia). In Georgia, state-designated Natural Areas are managed by GDNR to conserve natural communities and rare species (GDNR 2017). In addition, part of one population has received some habitat protection and management by the City of Gadsden, Alabama.(USFWS, 2017)

**Stressor:** Inadequate/Incompatible Habitat Management (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Inadequate management—e.g., lack of mowing, prescribed fire, and/or hand clearing—remains a persistent concern for Alabama leather flower populations. At least one subpopulation in St. Clair County, Alabama has not been relocated, in part, due to growth of encroaching plants (Byrd 2016c), which has obscured plants and/or suppressed their growth. Plants at this site have not been observed since 2009 and it is unknown if they still exist. Three

other subpopulations in St. Clair and Cherokee Counties are in need of management activities to reduce competing understory and woody vegetation (Wiggers 2014, Byrd 2016c). (USFWS, 2017)

**Stressor:** Competition from Encroaching Species (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Alabama leather flower is an apparently poor competitor, as it is most vigorous in open areas with little competing vegetation and open canopies. Indeed, low light levels have been associated with increased flower abortion (Timmerman-Erskine and Boyd 1999). The species also benefits from occasional, limited disturbance (such as periodic mowing or prescribed fire) which reduces encroachment of competing vegetation. However, Alabama leather flower can apparently remain dormant for some time as evidenced by its appearance in openings created in woods that were selectively logged (Service 1989). Even though the increased light initially benefited Alabama leather flower, it also stimulated more aggressive competing vegetation including the exotic Japanese honeysuckle (Lonicera japonica). All populations of Alabama leather flower need active management (e.g., thinning overstory trees, mowing, prescribed fire) due to shading and competition from more aggressive vegetation. (USFWS, 2017)

**Stressor:** Small Population Size and Small Number of Populations (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Attempts to locate additional Alabama leather flower populations since completion of the species' original Recovery Plan in 1989 (e.g., Boyd 1991, Boyd and Hilton 1992, Govus 1999, Ware 1999, Garrett and Schotz 2005) have had some success thus far, with eight natural populations now known for the species. Of these populations six are extant (ANHP data, GNHP data, Byrd 2016c, Byrd pers. comm. 2016a, b, Thompson 2016), one may have been extirpated (Schotz pers. comm. 2014, Byrd 2016c), and one has been extirpated (Schotz pers. comm. 2014). Only three populations are considered to be large (1,000+ stems), while two are of moderate size (400–500 stems) (GNHP data, Wiggers 2014, Byrd 2016c). Alabama leather flower's limited number of extant populations and relatively small local population sizes increase the species' vulnerability to anthropogenic and environmental perturbations. In addition, small population sizes increase the risks posed by inbreeding and genetic drift, which may limit the species' adaptive capacity and ability to cope with future stressors (Ellstrand and Elam 1993). However, the unexpectedly high level of genetic diversity maintained within Alabama leather flower populations studied thus far (Boyd et al. 1998, Goertzen and Boyd 2007, Goertzen et al. 2011), may limit some of the genetic threats posed by the species small number of populations and overall small population size. Attempts to augment existing and establish new populations have been made in Georgia, but these efforts have had limited success (GNHP data, CNC 2010, Hodges pers. comm. 2013, 2014, von Schmeling pers. comm. 2016). As such, the one known established population is not yet considered a viable population for recovery. (USFWS, 2017)

**Stressor:** Climate Change (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** The precise magnitude and impacts of climate change on the southeastern United States are uncertain, but models have projected that climate change in the region may include increased temperatures of 2 to 4°C (3.6 to 7.2°F) and reduced average annual precipitation by the end of the century (Joyce et al. 2011, Ingram et al. 2013). Specific effects of climate change on populations of Alabama leather flower are poorly understood; however, a variety of effects are possible. Climate change has the potential to affect distribution and abundance of plants by influencing seasonal weather patterns, frequency and timing of severe weather events, and myriad plant physiological responses (Hawkins et al. 2008). Davenport (2007) suggested that Alabama leather flower may be negatively impacted by climate change within Alabama if available habitat becomes constricted under drier conditions. In addition, climate change may disrupt plantpollinator interactions via phenological shifts in flowering and/or pollinator activity (Memmott et al. 2007, Hawkins et al. 2008), which may thereby reduce sexual reproduction of Alabama leather flower. Given that only two primary pollinators have been identified for Alabama leather flower, Wall et al. (2003) suggested that such asynchrony between flowering and pollinator activity may be particularly severe for this species. Given the variety and complexity of climate change's potential effects (cf. Hawkins et al. 2008, Walther 2010), more research is needed to assess its potential long-term impacts on Alabama leather flower populations and habitats. (USFWS, 2017)

***Recovery***

**Reclassification Criteria:**
When 10 geographically distinct, self-sustaining populations, occupying a minimum of one acre of habitat each, are known and protected from any foreseeable threats. (USFWS, 1989)

Recovery Priority Number: 5

**Delisting Criteria:**
When 20 geographically distinct, self-sustaining populations, occupying a minimum of one acre of habitat each, are known and protected from any foreseeable threats. (USFWS, 1989)

**Recovery Actions:**

- 1. Protect and manage populations and habitat. The first step in the recovery process is to protect the populations and their habitat. Protection efforts, excluding Section 7 obligations, may include land donations, conservation easements, long-term conservation agreements, land acquisition or other methods. (USFWS, 1989)
- 2. Establish a monitoring program for protected sites. A monitoring program should be established on protected sites in order to track population trends and evaluate effectiveness of recovery efforts. (USFWS, 1989)
- 3. Study ecology and species' biology. An understanding of the ecology and species' biology of the Alabama leather flower is necessary in order to appropriately manage and protect this species. (USFWS, 1989)
- 4. Determine effective management for maintaining or increasing populations. Management needs of the Alabama leather flower are largely unknown; however, this species appears more vigorous in areas of partial or full sunlight with little competition. In order to maintain or expand populations, active management of its habitat, targeted at controlling competing vegetation, will probably be necessary. Management is further necessitated due to the disturbed nature of the present sites. (USFWS, 1989)

- 5. Preserve genetic stock. This species is extremely vulnerable due to such few populations. Protection of the gene pool should be accomplished through seed bank storage and by maintaining material in cultivation. Additionally, this will provide material for research, propagation, and horticultural interests to reduce pressure on wild populations and other recovery activities. Such activities should be conducted under the guidance of the Center for Plant Conservation which sponsors the establishment of garden populations of endangered plants at member botanical gardens. (USFWS, 1989)
- 6. Establish experimental population(s) within historic range. if deemed necessary. Clematis socialis is only known from two sites and only one is protected. If after extensive surveys, no new populations are located and secured, it may be necessary to establish additional ones in the wild to decrease this species vulnerability. (USFWS, 1989)
- Recommendations for Future Actions from 2017 5-Year Review: - Work with federal and state entities, non-governmental organizations, and private individuals to permanently protect and manage existing habitats and populations,including the development and implementation of management plans. - Conduct surveys to locate additional populations. - Conduct studies to determine the number and distribution of populations required to maintain the species’ genetic diversity. - Conduct studies into the species’ life history, biology, habitat, and ecology to inform future population searches, management, and potential population augmentation and (re)establishment efforts. - Investigate efficacy of habitat management techniques (e.g., fire). Update and improve monitoring and habitat management methods. - Develop and implement long-term demographic monitoring to track population trends and evaluate management efforts. - Expand ex situ conservation efforts to include plants from all known extant populations. - Update the species’ recovery plan to reflect current knowledge (e.g., distribution, habitats) and needs (e.g., data/knowledge deficiencies, management).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIVITIES The following actions are recommended to support and promote recovery of Alabama leather flower. Use of a numbered list for these recommendations is for convenient reference and does not necessarily imply prioritization of any activity over others. 1. Work with federal and state entities, non-governmental organizations, and private individuals to permanently protect and manage existing habitats and populations, including the development and implementation of management plans. 2. Conduct surveys to locate additional populations. 3. Conduct studies to determine the number and distribution of populations required to maintain the species’ genetic diversity. 4. Conduct studies into the species’ life history, biology, habitat, and ecology to inform future population searches, management, and potential population augmentation and (re)establishment efforts. 5. Investigate efficacy of habitat management techniques (e.g., fire). Update and improve monitoring and habitat management methods. 6. Expand ex situ (off-site) conservation efforts to include plants from all known extant populations. 7. Update the species’ recovery plan to reflect current knowledge (e.g., distribution, habitats) and needs (e.g., data/knowledge deficiencies, management) (USFWS, 2022).

# SPECIES ACCOUNT: *Clitoria fragrans* (Pigeon wings)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 5/27/1993; Southeast Region (R4)

**Physical Description**

Pigeon wings is a 15 to 100 cm tall herbaceous plant. Plants have a thick horizontal root, which may grow to more than 2 m long, and bear one to several erect, purplish, wiry, very straight stems. The somewhat leathery leaves consist of three leaflets. Leaflets of the upper leaves are obtuse at the tip and narrower than those of lower leaves. (Fantz 1977).Pigeon wings produce flowers aboveground (chasmogamous flowers) and underground (cleistogamous flowers). Aboveground flowers usually occur in pairs, each corolla consisting of one 3.5 to 5 cm-long standard petal and a small white keel. The common name of this species refers to the petals of the aboveground flowers, which resemble wings. The seed pod (legume) is 5 to 8 cm long and extends from the calyx (Fantz 1979). (USFWS, 1999)

**Taxonomy**

Clitoria fragrans was described and named from a Highlands County specimen in 1926 (Small 1926). The name C. pinetorum was recognized but never published (Fantz 1977). The North American Clitoria species were moved to the genus Martiusia by Small (1933), but were later transferred back to the genus Clitoria by Fantz (1977). This herb?s common name, pigeon wings, was derived because of its flowers? bird-like appearance (Fantz 1979). It is one of three species of the genus occurring in the southeastern United States. The others are the native butterfly pea (C. mariana) and a butterfly pea escaped from cultivation (C. ternata). (USFWS, 1999) The Integrated Taxonomic Information System (2024) uses the common names sweetscented pigeonwings and pigeon wings (Clitoria fragrans) and indicates that the taxonomy for the species is still valid. We are not aware of any changes to the taxonomy of this entity, and it is still considered valid by the Service. (USFWS, 2025)

**Historical Range**

In Florida, along the Lake Wales Ridge, primarily in Highlands, Orange, and Polk counties; in central Osceola County; near Leesburg IN Lake County. (USFWS, 1999)

**Current Range**

In Florida, along the Lake Wales Ridge, primarily in Highlands, Orange, and Polk counties (USFWS, 1999)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollinated

**Lifespan**

Adult: > 5 years

**Breeding Season**

Adult: Chasmogamous flowers bloom from May to June.

**Reproduction Narrative**

Adult: Pigeon wings are long-lived (> 5 years) perennials. Flowers are pollinated by insects, while cleistogamous flowers are self-pollinating. Cross-fertilization of cleistogamous flowers is prevented, since the flowers do not open. Chasmogamous flowers bloom from May to June. Cleistogamous flowers occur later in the summer through late September. No information is available on the pollination vector, fertilization rate, seed production, or germination rates for this species.

**Habitat Type**

Adult: Xeric upland/sandhill and oak hickory scrub

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: SUMMARY: Widely scattered in undisturbed clearings of xeric sandhill and scrub communities on well-drained upland soils. END SUMMARY. Suzanne Cooper of the Florida Natural Areas Inventory (unpublished FNAI data) reports that C. fragrans is more commonly found in the sandhill or sandhill/scrub ecotones than in the scrub proper, which is contrary to published reports. Sandhill typically occurs on rolling hills of yellowish sand with a longleaf pine/turkey oak overstory (bluejack and/or sand live oak may also be dominant) and a ground cover of numerous herbs dominated by wiregrass. The white sand scrub is generally found with an overstory of scattered pines (sand, slash or longleaf), a middle layer of scrub oaks, several ericaceous shrub species and saw palmetto, and a thin layer of many herbaceous or dwarf shrub species (Duever 1983). Clitoria is typically found in undisturbed clearings in the scrub but also occurs in very open scrub as well (Kral 1983). (NatureServe, 2015). Pigeon wings occurs in a range of xeric upland habitats on the Lake Wales, Winter Haven, and Bombing Range Ridges and on xeric upland sites west of Bombing Range Ridge within APAFR. On the southern third of the LWR (i.e., the part within Highlands County), it occurs primarily in sandhill and oak-hickory scrub (Menges et al. 2007b). On APAFR, it occurs primarily in sandhill and oak scrub (S. Orzell, APAFR, pers. comm. 2008). Pigeon wings is a soil generalist, occurring on a yellow, white, and gray sands (Menges et al. 2007b; S. Orzell, pers. comm. 2008). Pigeon wings is a soil generalist, occurring on a yellow, white, and gray sands (Menges et al. 2007b; Orzell 2008, pers. comm.; Stout 2008a, pers. comm.), although mainly on yellow sands (Menges et al. 2019). It occurs in a range of xeric upland habitats on the Lake Wales, Winter Haven, and Bombing Range Ridges and on xeric upland sites west of Bombing Range Ridge within Avon Park Air Force Range. Generally, its habitats are sandhill, turkey oak barrens, and scrub (Menges et al. 2019). On the southern third of the Lake Wales Ridge (i.e., the part within Highlands County), it occurs primarily on yellow sands (e.g., Astatula, Paola, and Tavares) in sandhill and oak-hickory scrub, but also on moderately well-drained white sands (Archbold) and on gray sands (Satellite) (Menges et al. 2007a). On the Lake Wales Ridge in Polk and Lake Counties, it is also known from yellow, white, and gray sands. On Avon Park Air Force Range, it is recorded from four gray sand types

(Daytona, Narcoossee, Zolfo, and Duette), primarily in sandhill and oak scrub (Orzell 2008, pers. comm.; Stout 2008a, pers. comm.). Orzell reported a small population at Avon Park Air Force Range on Satellite soil (Stout 2008b, pers. comm.). (USFWS, 2025)

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

63 extant populations (USFWS, 2025)

**Population Size:**

1000 - 2500 individuals (NatureServe, 2015)

**Population Narrative:**

Requires undisturbed soils and fire. Doesn't seem to return quickly to abandoned farmland or neglected orange groves. Never abundant at a given site Fifty nine Element Occurrences recorded by FNAI as per July 1995 (Gary Knight, pers. comm., July 17, 1995) (NatureServe, 2015). Data on population trends are not available for pigeon wings because monitoring programs at most sites do not involve repeated censuses of populations within well defined areas. However, the evidence that is available, usually based on short-term surveys of relatively few individuals, suggests substantial year to year fluctuations in aboveground population sizes. For example, annual monitoring of a small pigeon wings population (< 70 plants in all years surveyed) at ABS from 1992 to 2000 found annual survival rates ranging from 72 to 98 percent (C. Weekley, pers. comm. 2008). Over the nine years of the study, sexual reproduction was negligible and few seedlings were found (C. Weekley, pers. comm. 2008). The study also documented the presence of belowground dormancy in pigeon wings, with 14 percent of tagged plants re-appearing aboveground following a year or more in which they were absent. Stout et al. (2003) recorded an annual survival rate of 68% (28 of 43 plants) in one APAFR population tagged in 2002 and re-surveyed one year later. Weekley and Menges (2003) characterized pigeon wings as a moderate resprouter based on the percentage of tagged aboveground individuals present two years after a prescribed burn (48.4 percent). However, aboveground pigeon wings populations may fluctuate annually due to belowground dormancy (C. Weekley, pers. comm. 2008). Anecdotal evidence also indicates that dramatic increases in post-burn aboveground population sizes may be short lived (C. Weekley, pers. obs. 2008). Thus, population densities may increase post-fire and decline with time-since-fire. High percent flowering by postburn plants also suggests that they are more likely resprouts than seedling recruits (C. Weekley, pers. obs. 2008). The FNAI identifies 77 occurrences of pigeon wings. Fifty-four (70.1 percent) of the occurrences are on protected sites on the Lake Wales (45) or Winter Haven Ridges (1), or on the APAFR (8). Of the 24 occurrences outside protected areas, all but two are on the LWR (one each on the Winter Haven and Mount Dora Ridges). Since most of these occurrence records are more than 20 years old, it is not known how many of the unprotected sites remain. Pigeon wings is currently known from 18 managed areas on the LWR: A. D. Broussard Catfish Creek Preserve State Park, ABS, Crooked Lake Sandhill, Jack Creek, LWRSF (Arbuckle, Hesperides, and Walk-in-Water Tracts), Lake Wales Ridge National Wildlife Refuge (Carter Creek South, Flamingo Villas), LWRWEA (Carter Creek North, Holmes Avenue, Lake Placid Scrub, Mountain Lake Cutoff, Royce Ranch, Silver Lake, and Sunray/Hickory Lake Tracts), Seminole State Forest (Warea Tract), and Tiger Creek Preserve. It is also protected at Lake Griffin State Park on the Sumter Upland, LWRWEA

(Lake Blue) on the Winter Haven Ridge, and at APAFR. EORs compiled by FNAI often have abundance estimates, although these are not standardized. Among the reports with pigeon wings abundance estimates, populations are rarely estimated as having 100–999 plants (4 EORs), while smaller populations of 10–99 plants (23) and less than 10 plants (18) are more typical (FNAI 2019). Abundance data based on counts or estimates are also available for three of the largest protected sites. At APAFR, Stout (pers. comm. 2008b) reported 2,951 plants, based on complete surveys of 59 soil polygons conducted between 2002 and 2006. Plants there were individually tagged and mapped with a GPS (Stout pers. comm. 2008c). At LWRSF, Malatesta (pers. comm. 2008) reported >1,800 plants in total throughout the Arbuckle, Walk-in-Water, and Hesperides tracts; however, the surveys were conducted over a period of three years and some populations may have been counted twice, thereby potentially inflating the final estimate. Finally, at the Tiger Creek Preserve, Pace-Aldana (pers. comm. 2008) estimated the pigeon wings population at >1,000 plants. These numbers, collected over large areas, generally provide estimates of the lower limits of population sizes at each of these three sites. Minimum abundance estimates are also available for several of the smaller sites, including Crooked Lake Sandhill (n ≥ 49; Pace-Aldana, pers. comm. 2008), the Warea Tract of Seminole State Forest (n = 43; Cox 2006), and the Carter Creek North (n = 15), Silver Lake (n = 58), and Lake Blue (n = 19) tracts of the Lake Wales Ridge Wildlife and Environmental Area (LWRWEA) (Menges et al. 2007a; Weekley, pers. comm. 2008). Population trends - In a study of the postfire responses of 12 Florida scrub endemics, Weekley and Menges (2003) characterized pigeon wings as a moderate resprouter based on the percentage of tagged aboveground individuals present two years postburn (48.4 percent). However, aboveground pigeon wings populations may fluctuate annually due to belowground dormancy (Weekley, pers. comm. 2008). Populations tend to increase markedly and flower profusely following fire, but then decline with timesince-fire (Lewis 2007; Weekley, pers. obs. 2008; H. Rosner-Katz, Florida Department of Agriculture and Consumer Services [FDACS], pers. comm. 2019). High percent flowering by postburn plants also suggests that they are more likely resprouts than seedling recruits (Weekley, pers. obs. 2008). (USFWS, 2020). Florida Natural Areas Inventory (2024) reported 63 extant populations (this excludes 10 historical, 1 possibly extirpated, and 2 extirpated occurrences) of pigeon wings; however, 24 (38 percent) of these populations have not been observed in over two decades. Pigeon wings occurs on protected lands at 53 (84 percent) of the reported populations. In comparison, the previous 5- year review (Service 2020) reported 45 extant populations (excluding 2 extirpated and 17 historical occurrences) all on protected lands. Florida Natural Areas Inventory (2024) also ranked the estimated viability of the reported populations based on size and condition of the population and the condition of the surrounding landscape. Of the 46 populations that were assigned a viability ranking, 38 (83 percent) had an estimated viability from fair to excellent. (USFWS, 2025)

***Threats and Stressors***

**Stressor:** Predation
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Heavy vertebrate and invertebrate predation, including the destruction of entire seed crops or the complete removal of aboveground individuals, have been documented for pigeon wings (e.g., Stout and Lewis 2004; Lewis 2007; A. Faivre, pers. comm. 2008). Other likely invertebrate predators on pigeon wings include orthopterans and possibly seed predating

coleopterans. Vertebrate herbivores probably include white-tailed deer (Odocoileus virginianus) and eastern cottontail rabbits (Sylvilagus floridanus). Herbivory may threaten the persistence of local populations. The impact on pigeon wings plants of partial or complete defoliation is unknown.

**Stressor:** Inadequate fire frequency/management
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Human development has disrupted the natural disturbance regime for pigeon wings. Because pigeon wings occurs in pyrogenic communities with a range of natural fire return intervals, we can infer that it can tolerate a range of fire frequencies and intensities. Some data (Weekley and Menges 2003, Lewis 2007) and anecdotal evidence (C. Weekley, pers. obs. 2008) suggest that aboveground populations decline with time-since-fire. Thus, inadequacies in existing prescribed fire programs or the use of mechanical methods such as mowing or gyro-tracking as a substitute or pre-treatment for fire may be adversely affecting the persistence of populations.

**Stressor:** Habitat destruction or modification
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Pigeon wings is protected in 18 managed areas on LWR and in three managed areas off LWR. However, almost one-third (24 of 77) of the FNAI EORs are on unprotected sites. It is not known how many of these sites remain. Although unprotected populations at Avon Park Lakes were targeted for acquisition (Turner et al. 2006), the site is quickly being converted to residential development and the population will almost certainly be lost. Surveys of other unprotected FNAI EORs will be required to determine it they are still extant. (USFWS, 2008)

**Stressor:** Human development
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Human development has disrupted the natural disturbance regime for pigeon wings. Because pigeon wings occurs in fire dependent communities with a range of natural fire return intervals, we can infer that it can tolerate a range of fire frequencies and intensities. Some data (Weekley and Menges 2003, Lewis 2007) and anecdotal evidence (C. Weekley, pers. obs. 2008) suggest that aboveground populations decline as the time-since-fire interval increases. Thus, inadequacies in existing prescribed fire programs or the use of mechanical methods such as mowing or gyro-tracking as a substitute or pretreatment for fire may be adversely affecting the persistence of populations. Observations by B. Blihovde at Lake Wales Ridge NWR suggest pigeon wings thrive in and around mechanically treated fire breaks. Data being generated by ABS's PDEP project aims to provide answers to some of these questions. In the meantime, development of science-based guidelines for the management of pigeon wings is precluded for lack of data.

***Recovery***

**Reclassification Criteria:**

Not relevant. (USFWS, 1999)

Recovery Priority Number: 14

**Delisting Criteria:**
1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations and sites needed to ensure 95 percent probability of persistence for 100 years (USFWS, 1999)

2. When these sites, within the historic range of C. fragrans, are adequately protected from habitat loss, degradation, and fragmentation (USFWS, 1999)

3. When these sites are managed to maintain the ecotone between xeric oak scrub and high pine that supports C. fragrans (USFWS, 1999)

4. When monitoring programs demonstrate that populations of C. fragrans on these sites support the appropriate numbers of self-sustaining populations, and those populations are stable throughout the historic range of the species. (USFWS, 1999)

**Recovery Actions:**
- Determine current distribution of C. fragrans. Some portions of C. fragrans?s range have been well surveyed, yet a total distribution has not been ascertained for this species. A thorough survey is needed to determine the distribution for this species. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Conduct research on life history characteristics of C. fragrans. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species, more specific biological information is needed. (USFWS, 1999)
- Monitor populations of C. fragrans. Develop monitoring protocol to assess population trends for C. fragrans. Develop a quantitative description of the population structure of C. fragrans. (USFWS, 1999)
- Provide public information about C. fragrans. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. Care is needed, though, to avoid revealing specific locality information about where C. fragrans is found. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of C. fragrans and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)
- Habitat-level Recovery Actions. Prevent degradation of existing habitat. Restore areas to suitable habitat. Conduct habitat-level research projects. Monitor habitat/ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • Quantitative surveys (e.g., Weekley et al. 2001; Stout and Lewis 2006; Malatesta, pers. comm. 2008) of pigeon wings populations at several sites to establish the basis for level 2 monitoring (sensu Menges and Gordon 1996) to track changes in population size over time and in response to management treatments. These surveys should be repeated at defined intervals (e.g., annually, bi-annually, every five years; both before and after imposition of management treatments) and take place within well-defined areas (e.g., within plots small enough to be searched thoroughly and thereby reduce inconsistencies in sampling intensity). • Where monitoring is being conducted, data should be collected on fire and other management activities to aid in the interpretation of trends and to identify the most favorable treatments. • Conduct surveys to assess the status of the 19 FNAI EORs that occur on unprotected sites and to evaluate the feasibility of protecting additional pigeon wings populations. Any new populations discovered should be added to the FNAI database. • Demographic data need to be collected across the full geographic range of pigeon wings, from both scrub and high pine habitats, and from populations responding to contrasting management treatments (e.g., fire alone vs. various mechanical treatments being used as a substitute or pre-treatment to fire). Demography needs to be related to fire management parameters, including fire frequency, time-since-fire, fire intensity, and fire patchiness. • As we learn more about the fire requirements of pigeon wings, prescriptions should be adjusted to a frequency and intensity appropriate to avoid habitat degradation. • Study the seed production, seedling establishment, and seedling survival at various populations. • Study the floral biology, pollination ecology, and demography in detail throughout the species' range, including comparison of pollinator numbers to chasmogamous flowers at different populations. • Careful data collection is needed to further investigate plant dormancy, which may be an important trait allowing persistence at a site through unfavorable times. • The extent of invertebrate and vertebrate predation on pigeon wings needs to be quantified. • Genetic studies should be conducted to understand the genetic diversity of the species; this may aid in the identification of new acquisition needs. (USFWS, 2020)
- RECOMMENDED FUTURE ACTIVITIES • Quantitative surveys (e.g., Weekley et al. 2001; Stout and Lewis 2006; Malatesta 2008, pers. comm.) of pigeon wings populations at several sites to establish the basis for level 2 monitoring (sensu Menges and Gordon 1996) to track changes in population size over time and in response to management treatments. These surveys should be repeated at defined intervals (e.g., annually, bi-annually, every five years; both before and after imposition of management treatments) and take place within well-defined areas (e.g., within plots small enough to be searched thoroughly and thereby reduce inconsistencies in sampling intensity). • Where monitoring is being conducted, data should be collected on fire and other management activities to aid in the interpretation of trends and to identify the most favorable treatments. • Conduct surveys to assess the status of populations that occur on unprotected sites and to evaluate the feasibility of protecting additional pigeon wings populations. Any new populations discovered should be added to the Florida Natural Areas Inventory database. • Demographic data need to be collected across the full geographic range of pigeon wings, from both scrub and high pine habitats, and from populations responding to contrasting management treatments (e.g., fire alone vs. various mechanical treatments being used as a substitute or pre-treatment to fire). Demography needs to be related to fire management parameters, including fire frequency, time-since-fire, fire intensity, and fire patchiness. • As we learn more about the fire requirements of pigeon wings, prescriptions should be adjusted to a frequency and intensity appropriate to avoid habitat degradation. • Study the seed production, seedling establishment, and seedling survival at various populations. • Study the floral biology, pollination ecology, and demography in detail throughout the species' range, including

comparison of pollinator numbers to chasmogamous flowers at different populations. • Careful data collection is needed to further investigate plant dormancy, which may be an important trait allowing persistence at a site through unfavorable times. • The extent of invertebrate and vertebrate predation on pigeon wings needs to be quantified. • Genetic studies should be conducted to understand the genetic diversity of the species; this may aid in the identification of new acquisition needs. # SPECIES ACCOUNT: *Conradina brevifolia* (Short-leaved rosemary)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 8/11/1993; Southeast Region (R4)

**Physical Description**

The short-leaved rosemary (Conradina brevifolia) is a shortlived, erect, woody, perennial shrub that reaches about 1 m in height (Kral 1983). It is very similar to the relatively widespread, and quite variable C. canescens of the Florida panhandle, Alabama, and Mississippi, and it is similar to the endangered C. glabra of the Apalachicola bluffs (Gray 1965, FWS 1994). As its name implies, C. brevifolia's alternate leaves are shorter than C. canescens. The larger leaves on well-developed flowering branches are 6.0 to 8.2 mm long, and mostly shorter than the internodes, whereas C. canescens'leaves are 7 to 20 mm long and are mostly longer than the internodes. C. brevifolia also tends to have more flowers per axil than C. canescens: one to six per axil versus one to three in C. canescens. (USFWS, 1999)

**Taxonomy**

The short-leaved rosemary is one of five shrubby mints in the interior central Florida scrub. The others are Calamintha ashei, Dicerandra frutescens, D. christmanii, and a Dicerandra population whose taxonomic status is unresolved. C. brevifolia was described as a new species by Shinners (1962). Taxonomic reviews of Conradina have upheld C. brevifolia's treatment as a distinct species (Gray 1965, Wunderlin et al. 1980, Kral 1983, Kral and McCartney 1991). However, Wunderlin (1982) and DeLaney and Wunderlin (1989) included C. brevifolia in C. canescens, without noting C. brevifolia as a synonym. Gray (1965) showed that C. brevifolia, like C. glabra, is morphologically not strongly differentiated from, and is less variable than, C. canescens. (USFWS, 1999)

**Historical Range**

Not Available

**Current Range**

Lake Wales Ridge in Polk and Highlands counties, Florida (USFWS, 1999)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

<u>Adult:</u> Sexual

**Reproduction Narrative**

<u>Adult:</u> We have no species-specific data on the reproductive biology of C. brevifolia. In fire-dependent scrub habitat, most plants respond to fire by sprouting while a few recruit from seed that is stored in the sand (Johnson and Abrahamson 1990). Anecdotal information suggests that

C. brevifolia does not persist when burned, clipped, or defoliated (FWS 1996). If this is true, sprouting and other forms of asexual reproduction are unlikely. (USFWS, 2019)

**Habitat Type**

Adult: white sands/scrub

**Environmental Specificity**

Adult: Very narrow to narrow. (Natureserve, 2015)

**Habitat Narrative**

Adult: Conradina brevifolia inhabits white sand scrub with a scattered overstory of sand pine (Pinus clausa), interspersed with evergreen scrub oaks (Quercus spp.). C. brevifolia is usually found interspersed in clearings with other small shrubs and herbs (FWS 1992). Like all other xeric scrub communities, oak scrub is a fire-dependent vegetative complex that persists when burned at intervals of 10 to 20 years. In the slower-growing oak scrub of Florida's ridges, including Highlands and Polk counties, fire frequencies of 15 to 20 years are sufficient to maintain the vegetative diversity of the scrub habitats. (USFWS, 1999)

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

21 (USFWS, 2021)

**Population Size:**

1000 - 2500 individuals (NatureServe, 2015)

**Population Narrative:**

The FNAI 2015 Element Tracking Summary (FNAI 2015), identifies 28 occurrences, 15 of which are on 7 different managed areas that are presumed or known to be extant. The other 13 occurrences were located on private lands. This represents roughly a 20 percent decline from the last 5-year status review, which reported 35 known occurrences (Service 2008c). The current status of occurrences and trends of short-leaved rosemary on private lands is unknown. (USFWS, 2019) . Short-leaved rosemary is a perennial herb occurring in rosemary scrub and related scrub ecosystems in Highlands and Polk Counties on the central portion of the LWR. It is restricted to a small portion of this range and does not occupy all available habitat, possibly due to fire suppression and inherit limitation to dispersal (Weekley et al. 2008). FNAI data (2021) show that there are only 21 populations and that one-third are unprotected. Short-leaved rosemary usually responds favorably to fire, often with strong population growth, but the duration of that population growth may be limited. Lack of frequent fire in both managed and unmanaged sites is the main threat to this pyrogenic species, although invasive species could also be an important threat at some locations. There has been little intensive monitoring of short-leaved rosemary, and therefore, not enough data exist to evaluate species viability in a substantive manner or determine long-term population trends. In addition, compared to many LWR endemic plants, relatively little is known about the basic biology of short-leaved rosemary, making it difficult to target for land management and other conservation measures. Threats from habitat loss due to development and climate change factors are expected to continue. For these reasons, shortleaved rosemary continues to meet the definition of endangered under the ESA. (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species is restricted to xeric scrub habitats in one or more of the interior Central Florida counties of Polk, Highlands, Hendry, Osceola, and Lake, where habitat destruction from development continues to occur and development pressure remains high. Areal extent of post-Columbian xeric upland habitat loss on the Lake Wales Ridge is estimated to exceed 85 percent (Weekley et al. 2008a). Increasing pressure from population growth is likely to result in further loss of these habitats going forward. Carr and Zwick (2016) analyzed existing land use and landscape patterns to identify areas (including central Florida) most likely for development to accommodate a growing human population. They suggests that Florida's 2070 population will be early 15 millionpersons greater than in 2010, for an estimated total of 33,721,828. Using these figures, they estimated relative losses to agriculture, open space, and conservation to other land uses. If trends continue, they estimate 34 percent of land will be developed by 2070, up from 19 percent in 2010. At the same time, conservation lands will increase less than 1 percent (from 9,269,000 acres in 2010 to 9,525,000 acres by 2070). Overall, loss of habitat to development, primarily on private lands, will likely continue in Central Florida, eliminating populations and reducing the area of suitable habitat for these species. Therefore, habitat on protected lands are critical for the recovery of this scrub plants. (USFWS, 2019)

**Stressor:** Lack of adequate fire management
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire is necessary to maintain the scrub habitats upon which this species depends. Historically, lightning-induced fires were a vital component in maintaining native vegetation within the scrub community. Fire suppression started on a regional scale on the Central Florida ridges about 80 years ago. Due to the extent of residential and agricultural development throughout Central Florida, fire has all but disappeared from the region as a widespread, natural phenomenon. Prescribed fire is a crucial management component for maintenance of all scrub habitats. Because of the difficulties of applying prescribed fire on an ever-increasing urban landscape, imperiled species on unmanaged sites will almost certainly disappear over time (Turner et al. 2006). In managed areas, prescribed fire is essential to manage habitats and restore or maintain suitable conditions for scrub species. (USFWS, 2019)

**Stressor:** Limited geographic range
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species occurs occur within a relatively limited geographic range in Central Florida. The limited geographic range in combination with the loss of habitat has resulted in a highly fragmented landscape where the remaining scrub areas and their residing species have

become more and more isolated from each other, thereby making resiliency, redundancy, and representation more challenging to achieve. The effects of habitat fragmentation on species richness have been exhaustively studied (MacArthur and Wilson 1967, Diamond 1975, 1978; Simberloff and Abele 1976, 1982; Zimmerman and Bierregaard 1986). For most taxonomic groups, large habitat patches in close proximity to each other provide for the greatest species diversity and minimize extinction probabilities. On the contrary, small patches that are isolated are less likely to preserve species that would otherwise be common in the mosaic of communities that existed before isolation. Since at least the Pleistocene, Florida scrub has been characterized by an insular, discontinuous distribution, but the degree of habitat fragmentation seen today is unprecedented and certainly will contribute to increases in extinction rates among scrub-dependent plants and animals. (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**

1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations required to ensure 20 to 90 percent probability of persistence for 100 years (USFWS, 1999)

2. When these populations, within the historic range of C. brevifolia, are adequately protected from further habitat loss, degradation, and fire suppression (USFWS, 1999)

3. When these sites are managed to maintain sand pine scrub (USFWS, 1999)

4. When monitoring demonstrates that these sites support sufficient population sizes, are distributed throughout the historic range, and are sexually or vegetatively reproducing at sufficient rates to maintain the population (USFWS, 1999)

Recovery Priority Number: 8C

**Delisting Criteria:**

1. At least 20 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)

2. Populations (as defined in criterion 1) in rosemary and yellow sand scrub habitats are distributed across the known range of the species. (USFWS, 2019)

3. Populations are protected and managed via a conservation mechanism to a degree that enough suitable habitat is present for the species to remain viable for the foreseeable future. (USFWS, 2019)

**Recovery Actions:**

- Determine current distribution of C. brevifolia. Some portions of C. brevifolia's range have been well surveyed yet a total distribution has not been ascertained for this species. A thorough survey is needed to determine the distribution for this species. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases,

isolated. For this reason, existing populations are in need of protection. (USFWS, 1999)
- Conduct research on life history characteristics of C. brevifolia. Little is known of the basic biology and ecology of this species. To effectively recover this species more specific biological information is needed. (USFWS, 1999)
- Monitor populations of C. brevifolia. Develop monitoring protocol to assess population trends for C. brevifolia. Develop a quantitative description of the population structure of C. brevifolia. (USFWS, 1999)
- Conduct research on life history characteristics of C. brevifolia. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit, since the recovery of C. brevifolia and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)
- Habitat-Level Actions: Prevent degradation of existing habitat. Restore areas to suitable habitat. Conduct habitat-level research projects. Monitor habitat/ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS A detailed discussion of recovery actions and criteria are presented in the Recovery Plan and amendment (Service 1999 and 2019, respectively). During this status review new and/or targeted potential recovery activities were identified and are included below. Recovery Activities • Acquire private sites with existing populations and/or implement conservation actions on private sites with existing populations. • Work with State, Federal, and non-profit partners to ensure adequate fire management is achieved at sites that support short-leaved rosemary. Monitoring/Research Activities • Conduct field surveys of occurrences, including Level 2 (population sizes) (as recommended by Menges et al. 2019) and Level 3 monitoring, throughout short-leaved rosemary’s geographic range, including sites across a spectrum of time-since-fire and management regimes • Monitor this species’ responses to management actions on conservation lands. • Conduct basic and applied research on the biology and ecology of short-leaved rosemary, including responses to management, propagation techniques, and germplasm storage. • Strengthen ex situ conservation measures, including ensuring representation of shortleaved rosemary at the National Center for Genetic Resources Preservation in Fort Collins, Colorado. (USFWS, 2021)

USFWS. 2019. Amendment 1. Recovery Plan for Conradina brevifolia (short-leaved rosemary), Crotalaria avonensis (Avon Park harebells), Dicerandra christmanii (Garrett's mint), Dicerandra frutescens (scrub mint), Eryngium cuneifolium (snakeroot), Hypericum cumulicola (Highlands scrub hypericum), Liatris ohlingerae (scrub blazing star), Polygala lewtonii (Lewton's polygala), Polygonella basiramia (wireweed), Polygonella myriophylla (sandlace), Warea carteri (Carter's mustard), and Ziziphus celata (Florida ziziphus). U.S. Fish and Wildlife Service, Atlanta, Georgia. 23 pp. September 24, 2019.

USFWS. 2021. Short-leaved rosemary (Conradina brevifolia) 5-Year Review: Summary and Evaluation. U.S. Fish and Wildlife Service South Atlantic-Gulf Region Florida Ecological Services Field Office Vero Beach, Florida. 16 pp.

# SPECIES ACCOUNT: *Conradina etonia* (Etonia rosemary)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 8/11/1993; Southeast Region (R4)

**Physical Description**

A perennial, aromatic shrub, reaching 1.5 m tall, with slender, arching branches. Leaves are 1.5-3 centimeters long with rolled margins. Both sides of the leaves are hairy; mid-rib and veins are strongly raised on the lower surface. Flowers appear in clusters of 3-7 bent flowers, lavender in color, the lip marked with streaks and dots. (NatureServe, 2015)

**Taxonomy**

Conradina etonia could be the best marked species in a genus whose species differ mostly in very fine characters (Kral and McCartney, 1991). (NatureServe, 2015)

**Historical Range**

It is known from only two sites near Etonia Creek, northeast of Florahome, Putnam County, Florida (USFWS, 1994).

**Current Range**

Occurs at six sites near Etonia Creek, northeast of Florahome, Putnam County, northeastern Florida. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Spring - fall (USFWS, 1994)

**Reproduction Narrative**

Adult: Flowering occurs from early spring to late fall (USFWS, 1994).

**Habitat Type**

Adult: Terrestrial (USFWS, 1993)

**Habitat Vegetation or Surface Water Classification**

Adult: Forest, savanna, shrubland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Periodic fire (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Excessive shade (inferred from NatureServe, 2015)

**Environmental Specificity**

Adult: Very narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: It occurs in Florida scrub vegetation with sand pine and shrubby evergreen oaks. Scrub in this area is the northeastern range limit for several plant species of Florida scrub, including silk bay [Persea humilis), sand holly [Ilex cumulicola), Garberia heterophylla, and the scrub palmetto [Sabal etonia), which is named for this area but does not occur in the immediate vicinity of Conradina etonia (Krai and McCartney 1991; S. Christman, Florida Dept, of Natural Resources, pers. comm., 1991). (USFWS, 1993)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Dispersal mechanisms are unknown (EPA, 2016).

***Population Information and Trends***

**Population Trends:**

Increasing (USFWS, 2019)

**Number of Populations:**

3 (USFWS, 2024)

**Population Size:**

>3,000 (USFWS, 2024)

**Population Narrative:**

All presently known individuals occur within 6 km of each other with a contiguous landscape of xeric uplands (Figure 1). The known populations are approximately 1,500 m away from each other, meeting the definition of separate populations by NatureServe (2004), where occurrences greater than 1 km from each other are considered different populations. It is likely that increased survey efforts have led to the discovery a new population (i.e., the Florida Trail population) and additional plants. Increased management has also likely increased the number of plants within populations. These efforts have increased the number of plants from 1,475 in 2018 and peaked in 2021 at 3,232. Most of the increase in population is from the Big Scrub population, which has increased in population three-fold since 2018. The entire plant count has remained above 3,000 over the past three years (Figure 2). Management actions within Etoniah State Forest, such as prescribed fire, site preparation for planting trees, and herbicide treatments, have been effective in increasing the number of plants by recruiting seedlings. Additional details about each known population are described below (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Habitat loss and degradation (Factor A)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** Development has and continues to be the primary threat to C. etonia. In 1991, there were only two known populations; both on what were then private lands (USFWS 1994). These private lands were platted and planned for development. In 1993, the State of Florida purchased much of these lands as the Etoniah Creek State Forest (ECSF), and surveys found additional populations of C. etonia in areas that are now protected. Within ECSF, there is still a large population located mostly on privately owned lots (Garden Drive/Blossom Street population). ECSF has purchased several of these lots and plans to continue to acquire additional property as funds become available. (USFWS, 2019)

**Stressor:** Hurricanes (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In 2004, hurricanes impacted populations at ECSF and DCSP by blowing over sand pines and crushing plants in areas occupied by C. etonia. At DCSP, four of the historic sites of C. etonia could not be located since the area was covered with downed sand pines (Herring 2004). ECSF also had areas where the presence of downed sand pines made it difficult to access known sites of C. etonia. During the 2004 surveys at ECSF, it was determined that the number of plants did decrease after the hurricanes. However, since then surveys at ECSF and DCSP have shown an increase in the number of plants. The increase in plants is most likely due to more intensive surveys of additional areas at ECSF and DCSP. (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**
1. When five (5) wild populations are under protection and management (USFWS, 1994).

Recovery Priority Number: 8C

**Delisting Criteria:**
1. In addition to the five (5) populations identified in the downlisting criteria, at least five (5) additional populations are established or discovered that exhibit stable or increasing trends as evidenced by natural recruitment, and multiple age classes. (USFWS, 2019)

2. All ten (10) populations are located on lands protected via a conservation mechanism. (addresses Factors A and D). (USFWS, 2019)

3. Threats (e.g. inadequate management, invasive species) have been reduced and/or managed to a degree that Etonia rosemary will remain viable for the foreseeable future (addresses Factors A and D) (USFWS, 2019)

**Recovery Actions:**
- Protect and monitor natural populations (USFWS, 1994).
- Survey for additional populations along Etonia Creek, in Putnam County, and potential areas of scrub habitat (USFWS, 1994).
- Continue propagation at several locations to prevent extinction of the species due to disease or other disaster at any one propagation site (USFWS, 1994).

- Determine habitat requirements, life history characteristics, and requirements for reproduction (USFWS, 1994).
- Locate potential (re)introduction sites on protected lands, including public land, highway rights-of-way, and conservation easements on private land (USFWS, 1994).
- (Re)introduce plants to protected sites using plants under cultivation and/or plants from natural sites (USFWS, 1994).
- Revise the current recovery plan to include updated objective and measurable recovery criteria, as well as updated information on the species distribution and biology. (USFWS, 2019)
- Provide funding and technical support for further research on: (a) The effects of prescribed burning and other management tools (e.g., thinning sand pines or mechanical clearing to reduce the understory) on C. etonia. Continue working with public land managers to increase the management on their sites. (b) The role pollinators play in the life history of C. etonia. Additional life history information may also be needed. (c) The genetics of the different populations to determine how different they are based on geographic distribution. Genetics could also tell us if inbreeding depression is occurring in some of the smaller populations. This information will help us determine what constitutes a stable population. (USFWS, 2019)
- Acquire additional private lands within ECSF that currently contain C. etonia (USFWS, 2019).
- Work with the Service's partners for Fish and Wildlife program staff to encourage private landowners to protect this species on their lands (USFWS, 2019).
- Conduct additional surveys on public lands adjacent to ECSF and DCSP (such as along the Crescent City Ridge) to look for suitable habitat and new populations of C. etonia. Continue annual surveys of populations at ECSF and DCSP (USFWS, 2019).
- Consider reintroduction and monitoring on adjacent publicly owned lands with suitable habitat. Conduct research into whether C. etonia will hybridize with other more common Conradina species, which could equate to loss of genetic variability of C. etonia. Reintroduction of C. etonia could help to increase the number of geographically distinct, self-sustaining populations on protected sites and augment populations where needed (USFWS, 2019).

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES A detailed discussion of recovery actions and criteria are presented in the Recovery Plan (Service 1994). In the course of this status review new and/or targeted potential recovery activities were identified and are included below. Recovery Activities - Manage habitat with mowing, chopping, or burning as necessary to create the open habitats that are needed for this species to thrive. - Plant the species on managed conservation lands with adequate habitat to create new populations and meet downlisting and delisting population targets. - Conserve lands with suitable habitat adjacent to the Etoniah Creek State Forest. Monitoring and Research Activities - Annually monitor current populations. - Develop methods for propagation and outplanting to increase success. - Germination trials to determine what factors promote germination and how seeds can be successfully stored (USFWS, 2024).

# SPECIES ACCOUNT: *Conradina glabra* (Apalachicola rosemary)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 8/11/1993; Southeast Region (R4)

**Physical Description**

Conradina glabra is a much-branched shrub up to 2 meters tall. The branches of C. glabra are spreading or upright. The leaves are evergreen, opposite, with additional leaves in short shoots in the axils giving the appearance of fascicles. The leaves are needle-like, "very similar to the needles of fir" (Kral 1983, p. 949). The leaves are hairless on the upper surface—the only species of Conradina for which this is the case. Conradina glabra flowers from March to June and then intermittently until frost (Kral 1983). The flowers are usually in groups of two or three. The calyx and corolla are two-lipped. The corolla is 1.5 to 2.0 centimeters (0.5 to 0.75 inches) long from its base to the tip of its longest lobe, with a slender corolla tube that is straight for about 5 millimeters (mm) long, then bends sharply downward to form a funnel-shaped throat 5 mm long, then widens out into upper and lower lips. The outside of the tube and throat are white, with the lobes and lips lavender blue at the tips. The lower lip of the corolla is three-lobed, with a band of purple dots extending along its inner side. The four stamens are paired. Many flowers are male sterile. (USFWS, 1994)

**Taxonomy**

Conradina glabra was named as a distinct species by Shinners (1962), a treatment that was upheld by Gray (1965) and Kral and McCartney (1991). The plant had first been collected in 1931, and Small (1933, p. 1167) mentioned the specimen without assigning a name. (USFWS, 1994)

**Historical Range**

Historical extent and abundance of this species is unknown because the silviculture industry destroyed large areas of this species' sandhill habitat during the 1950's, and the species was not described until 1962. We can assume that the species was once more widespread within the sandhill habitat in Liberty County, Florida. (USFWS, 2017)

**Current Range**

Conradina glabra is restricted to approximately 1000 to 1470 ha in northern Liberty County, Florida, west of Tallahassee near the Apalachicola River. (USFWS, 2017)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

<u>Adult:</u> Sexual, asexual (NatureServe, 2015)

**Breeding Season**

Adult: March - first frost (NatureServe, 2015)

**Reproduction Narrative**

Adult: Reproduction for C. glabra occurs both rhizomatously/clonally and sexually via seed set, but in-situ attempts at seed germination have failed; seed viability is low. Currently, we cannot distinguish whether or not nearby stems are from the same genetic individual, so it is difficult to determine what constitutes a “plant.” For now, we will use ‘clumps’, which was also used by Pruner and Schmidt (2017) for C. glabra (USFWS, 2019).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Longleaf pine forest, field, steephead (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: 15 - 40 year fire intervals (USFWS, 2009)

**Geographic or Habitat Restraints or Barriers**

Adult: Heavy shade (USFWS, 1994))

**Environmental Specificity**

Adult: Very narrow to narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Florida rosemary (Ceratiola ericoides) requires longer fire cycles (15–40 year intervals) to maximize soil seed bank (Quintana-Ascencio et al. 2003) (USFWS, 2009). Conradina glabra occurs in an area of several square miles northeast of Bristol, Liberty County (Figure 2). The area is a gently undulating upland, originally with longleaf pinewiregrass vegetation, dissected by ravines of the Sweetwater Creek system, which drain westward to the Apalachicola River. Parts of the Apalachicola ravines are incorporated in public and private nature preserves that protect rich hardwood forests with the narrowly endemic Florida torreya (Torreya taxifolia, also federally listed as endangered) and Florida yew (Taxus floridana). Heads of ravines, called steepheads, have slopes that are undermined by groundwater seeping into the ravine bottom, causing the slopes to gradually slump, carrying the vegetation with it. At least one steephead shrub, Florida yew, appears to be adapted to slowly moving down the slopes (Redmond 1984, cited in Platt and Schwarz 1990), and C. glabra may sometimes be carried into ravines. “Many older Conradina shrubs occur at the edge of the ravine and even extend a short distance down into open areas of the ravine; younger Conradina plants have become established in the barren, exposed soil adjacent to the pines and often extend into the pine stand. This suggests that C. glabra is able to compete effectively in open, newly exposed areas but is unable to compete in closed stands of mixed hardwoods or pines. This species probably features significantly in secondary plant succession in the area, much of which is frequently subjected to burning” (Gray 1965). Wilson Baker (pers. comm. cited in Schultz 1987) suggested that Conradina spread from the ravine edges into newly planted pine plantations on the uplands during the 1950’s. Kral (1983) considered C. glabra to have inhabited the grassy understory of the upland longleaf pine-wiregrass vegetation before pine plantations were developed, as well as steephead edges. Kral thought that C. glabra was increasing in slash pine plantations, along with another woody mint, Calamintha dentata. However, Kral thought it “premature to state that this will be a stable system” because the planted slash pine had not thrived, the plantations were probably more open than had been intended, and that if the slash pines matured, they might provide “more shade and more competition than is good for the Conradina”. Most of the slash pine was cut in 1987 and replanted to sand pine (S. Gatewood, TNC, in litt., 1987). Conradina glabra currently “is found on road edges, in planted pine plantations and along their cleared edges, and along the edges of the ravines” (Baker, pers. comm., in Schultz 1987). A recent (1993) survey along the Florida Gas Transmission pipeline found an estimated 10,000 plants, artificially divided into six populations. The plants appeared to be thriving in the exposed soil along the pipeline (Biological Assessments, Florida Gas Transmission Company, Phase III Natural Gas Pipeline Expansion Project, 1993). Additionally, a new population was discovered east of State Highway 12 (R. Hilsenbeck, pers. comm.) (USFWS, 1994).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

30 - 50% decline (NatureServe, 2015)

**Species Trends:**

Stable (USFWS, 2017)

**Number of Populations:**

1 (USFWS, 2022)

**Population Size:**

>100,000 (USFWS, 2022)

**Additional Population-level Information:**

The only population on public land is found at the SCT, Torreya State Park. This area was prepared by a bulldozer scraping topsoil and remaining vegetation into linear berms called windrows, planted in slash pine (with 500-700 stems per acre of sand pine), and then logged in the late 1980s (Spector and Bente 2009). Despite this severe alteration of habitat, SCT contains the majority of C. glabra. The estimated number of plants (or ramets, see recovery action 2.1) in 2009 for 102 ha was about 89,815 (Spector 2009); current and projected counts are underway (R. Pruner, Florida State Parks, 8/4/2017, pers. comm.). At present, about 15-20% of the core known habitat within the park remains to be surveyed (R. Pruner, Florida State Parks, 8/4/2017, pers. comm.). Data are collected on an ongoing basis, allowing for trend analysis as well as assessing the effects of restoration, particularly the effects of aggressive fire. (USFWS, 2017)

**Population Narrative:**

The species is currently known from only one natural population on public land, from three introduced sites in 1991, rights-of-way, and private silvicultural lands. The population on public land, which contains most of the plants, is found at the SCT, Torreya State Park (TSP; Fig. 1). At SCT, C. glabra covers an area between 1,000 ha (2,471 acres, Spector and Bente 2014; Fig. 1) to 1,470 ha (3,632 acres, Pruner and Schmidt 2017). This area was prepared by a bulldozer scraping topsoil and remaining vegetation into linear berms called windrows, planted in slash pine (Pinus elliottii), with 500-700 stems per acre of sand pine (Pinus clausa), and then logged in the late 1980s (Spector and Bente 2009). Despite this severe alteration of habitat, SCT contains the majority of C. glabra. The estimated number of plants (or ramets) in 2009 for 102 ha was about 89,815 (Spector 2009); whereas the estimated number of plant clumps in 2017 was > 100,000. According to Pruner and Schmidt (2017), about 15-20% of the core known habitat within the park remains to be surveyed. They also provided preliminary trend analysis as well as some assessment of the effects of restoration, particularly the effects of aggressive fire (Appendix A). But current estimated counts are presently unknown due to the impact of Hurricane Michael on SCT habitat and C. glabra plants and subsequent site prepped (A. Schmidt, Wildland Resources LLC, pers. comm., 2021). (USFWS, 2022)

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat modification remains the main threat to date for this species as a result of silviculture practices. The entire range was altered by site preparation (e.g. bulldozing of topsoil into linear berms called windrows, and possible herbicide application) and conversion to pine plantations in the 1950s (Spector and Bente 2009). A large extent of Liberty County was logged mainly for longleaf pine, and many acres were converted to slash pine. The uplands on the SCT were managed for timber for several decades. The St. Joe Timberland Company harvested planted slash pine in1987, followed by sand pine plantation. Although C. glabra has been seen growing at the edges and sporadically within pine plantation, plant density is low compared to more open areas. Therefore, shading, due to increases in canopy cover from natural longleaf pine forests to managed pine plantations, is a threat to this species and should be evaluated. (USFWS, 2017)

**Stressor:** Inappropriate fire management (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Longleaf pine has not been introduced to the ongoing Florida Park Service forest management restoration treatments (restoration zone 2), at SCT. Introduction of longleaf pine may result in hotter fires due to needle accumulation. Also, ongoing conversations are considering a planting density of 400+ longleaf pine trees per acre to control woody species such as oak, potentially allowing for hotter fires (R. Pruner, Florida State Parks, 8/4/2017, pers. comm.). This should be closely monitored because C. glabra is also a woody species. Therefore, the use of a too frequent fire return interval and intensity could be a threat to the species. (USFWS, 2017)

**Stressor:** Herbicides (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Recovery Plan mentioned that the use of the herbicide (hexazinone, Velpar) is a threat when it is used in timber regeneration areas. According to M. Ludlow (Department of

Environmental Protection; 2009, pers. comm. to Negrón-Ortiz), spot application of Garlon 4 (a less toxic herbicide) is used to treat exotic shrubs or trees at TSP. In addition, there are almost no woody exotics in the area where C. glabra occurs. Therefore, herbicide use is currently considered a minor threat. (USFWS, 2017)

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Section 7(b)(4) and 7(b)(2) of the Act generally do not apply to listed plants species. However, limited protection of listed plants from take is provided to the extent that the Act prohibits the removal and reduction to possession of federally listed threatened and endangered plants or the malicious damage of such plants on areas under federal jurisdiction, or the destruction of endangered plants on nonfederal areas in violation of state law or regulations or in the course of any violation of a state criminal trespass law. Conradina glabra is protected under Florida State Law, chapter 85-426, which includes preventions of taking, transport, and the sale of the plants listed under the State Law. The rule Chap. 5B-40, Florida Administrative Code, contains the "Regulated Plant Index" (5B-40.0055) and lists endangered, threatened, and commercially exploited plant species for Florida; defines the categories; lists instances where permits may be issued; and describes penalties for violations (http://www.virtualherbarium.org/EPAC). Several sites containing C. glabra occur on private timberland and highway and utility right of way (ROWs). While the Act requires federal agencies to carry out programs for the conservation of endangered and threatened species, no such programs are stipulated for non-federal landowners. Neither section of the Act provides protection for plants on non-federal lands as long as the activity is permissible under state/local laws. The State requires permission of private landowners for collecting of state-listed plants from their property. At present, we have not been able to comment on state park management practices, and the Service doesn’t have a legal mechanism to regulate management on state lands. The next revision of the park management plan will likely start around 2020 and finalized in 2022, and the Service should be able to attend public meetings and request a copy of the draft plan for commenting (R. Pruner, Florida State Parks, 9/25/2017, pers. comm.). Right of way maintenance activities are not always reviewed for threatened and endangered species impact. However, if there is an activity (e.g., construction, mowing, or maintenance projects) affecting federally listed species on state highway ROWs, then the Service can recommend consultation to the Florida Department of Transportation (FDOT) under the Act because FDOT recently assumed NEPA authority and is considered a federal agency for consultation purposes. The FDOT routinely consults with the Service on all major road construction activities. Currently, these protections are inadequate for this plant and its habitat. (USFWS, 2017)

**Stressor:** Climate change (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** According to the Intergovernmental Panel on Climate Change Report (IPCC 2013), warming of the earth’s climate is “unequivocal,” as is evident from observations of increases in average global air and ocean temperatures, widespread melting of snow and ice, and rising sea level. Scientific evidence indicates a rapid and abrupt climate change, rather than the gradual changes that were previously forecasted (IPCC Report 2007), posing a significant challenge for

fish, wildlife, and plant conservation. Highly specialized or endemic species, such as C. glabra, are likely to be most susceptible to the stresses of changing climate. Species that are already rare may become rarer. This may be even more pronounced for those species with restricted ranges, with poor dispersal ability, requiring long generation times, possessing susceptibility to extreme conditions (such as flood or drought), exhibiting extreme habitat/niche specialization, or requiring symbiotic relationships (Hawkins et al. 2008). Using the NOAA Sea Level Rise (SLR) and Coastal Flooding Impacts Viewer (https://coast.noaa.gov/slr/), the projections indicated no potential impact to C. glabra population in Liberty County by intrusion of saltwater. Heatwave intensities and drought events, however, have strengthened in parts of the United States including the southeast (Mazdiyasni and AghaKouchak 2014) and Florida (Gao et al. 2012), and are becoming more likely to overlap. Heatwaves can make xeric areas such as sandhills even drier, and if these concurrently occur with drought events, represent a growing threat to C. glabra survival. Thus, it is recommended to avoid or postpone prescribed-fire during extreme drought and heatwave conditions. (USFWS, 2017)

**Stressor:** Forestry and Development (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Most of the remaining population of C. glabra is now protected under ownership by the State of Florida and managed by the Florida Park Service. The private land east of SCT where C. glabra likely occurred has been recently cut. In addition, herbicide was applied to the entire tract, limiting the likelihood of C. glabra persistence in the treated area (M. Maples, Florida State Parks, 9/12/2017, pers. comm.). There are other properties adjacent to SCT that have not been surveyed, but likely contain this species. Given the ownership of these surrounding properties, it is probable that they will continue to be utilized as pine plantations or converted to residential and/or commercial development in the near future. Therefore, conversion to pine plantations and residential or commercial developments are threats. (USFWS, 2017)

***Recovery***

**Reclassification Criteria:**
1. The Sweetwater Creek Tract population is assessed as resilient (addresses Factor A). Resilient: naturally reproducing, stable or increasing in number, and actively and appropriately managed. (USFWS, 2019)

2. Five additional populations are: 1) discovered or reintroduced within the historic range of the species, and 2) under long-term protection. These populations must be resilient (addresses Factors A and D). (USFWS, 2019)

**Delisting Criteria:**
1. Threat reduction and management activities (e.g., compatible silviculture practices, fire return interval and intensity, and restoration) have been implemented to a degree that the long-term resiliency of all six C. glabra populations and habitat is demonstrated over multiple prescribed burn cycles (addresses Factors A and D). (USFWS, 2019)

**Recovery Actions:**

- 1. Protect existing populations. Encourage conservation of existing populations on private lands. Conduct annual mapping and monitoring of all known populations of C glabra. Manage rights-of-way. Acquire habitat. (USFWS, 1994).
- 2. Conduct population biology studies. Study the effects of prescribed fire and forest management practices. Conduct life history studies. Survey for Conradina glabra outside its current range (USFWS, 1994).
- 3. Conduct genetic studies. Research is needed to determine genetic variability within reintroduced populations. This research will ensure that reintroduced populations have genetic variability similar to natural populations to withstand drought, diseases, etc. (USFWS, 1994)
- 4. Propagate Conradina glabra and reintroduce and/or augment populations within its historic range. Establishment of the artificial population on ABRP shows that C. glabra can be propagated and introduced rather easily. If necessary, additional reintroductions could take place on protected sites within the historic range of the plant. (USFWS, 1994)
- An in-depth C. glabra inventory across the species' historic sites and on new locations is conducted where appropriate habitat exists (addresses Factor A and redundancy). (USFWS, 2019)
- The effects of prescribed fire and forest management practices on long-term persistence of C. glabra (survival, growth and reproduction) in the sandhill community is assessed and a standardized monitoring technique is in place (addresses Factor D and resiliency). (USFWS, 2019)
- The contribution of sexual reproduction and clonal propagation to population maintenance is assessed via research related to (1) in-situ soil seed bank, seed viability, and seedling recruitment (in-situ seed germination, seedling survival and growth), and (2) genetic composition and clonality (addresses Factors A, D, and E, and resiliency; it will inform representation). (USFWS, 2019)
- A living collection of viable germplasm3is maintained at botanical gardens and other Service approved facilities for research, recovery, and public outreach (addresses Factor E, and representation). (USFWS, 2019)
- 1. Conduct population surveys using a consistent, statistically valid, repeatable survey method. Once population numbers are known and an inventory has been conducted to find new populations throughout appropriate sandhill habitat, consistent surveys would allow for the analysis of long-term trends for this species. This information would help to determine when the species is stable and may be considered for reclassification. This information would also help to inform conservation managers of appropriate management techniques, and whether restoration of the pine plantation back to sandhill is assisting in the recovery of the species. - Continue and complete ongoing surveys throughout the present distribution. - Continue regular monitoring of marked individuals (e.g., the total number of individuals, number of flowering vs. non-flowering plants, and whether seedling recruitment is occurring). (USFWS, 2017)
- 2. Conduct an inventory of sites where appropriate habitat exists. This action can include the use of aerials and species distribution modeling methods to initially determine potential sites, with subsequent field inventory of the site using a consistent, statistically valid, repeatable inventory method. If new populations are discovered, protection should be sought. (USFWS, 2017)
- 3. Identify appropriate soil types and other environmental conditions within the C. glabra range and adjacent areas as well as other sandhill areas within the Florida panhandle. This

action can include the use of aerials and species distribution modeling methods to initially determine potential habitat associations. (USFWS, 2017)

- 4. An ex-situ plant collection should be actively pursued and implemented. Studies on the viability of seeds, germination, and seedling establishment, in addition to whether the C. glabra spread by rhizomes and a persistent seed bank is present should be addressed. (USFWS, 2017)
- 5. Continue the restoration of and subsequent management of C. glabra's habitat. This is crucial for the long-term population stability (Park Service staff, 2017, pers. comm.) given that the global population of C. glabra is only found at the TSP. - Determine the fire regime (intensity) and monitor the effect of this event on C. glabra density, fecundity, and size structure. (USFWS, 2017)
- 6. Avoid or postpone prescribed-fire during extreme drought and heatwave conditions. (USFWS, 2017)
- 7. Evaluate the benefits and risks of translocation, augmentation, and reintroduction strategies under the combined pressures of habitat fragmentation and climate change. (USFWS, 2017)
- 8. Assess the occurrence of vegetative reproduction (i.e., clonality) using genetic markers and determine the conservation implications. (USFWS, 2017)
- 9. Develop a stand-alone plan for managing listed plants at the TSP and integrate it to the restoration protocol and the Torreya State Park Unit Management Plan. - Evaluate the reference (remnant) site and determine the relevance and utility in informing restoration. (USFWS, 2017)
- 10. Seek partnership with private landowners to help better understand the present distribution of C. glabra. (USFWS, 2017)
- 11. Acquire the following properties adjacent to SCT: Candence Bank (3 parcels), Holland Ware, and R Dell Phillips. (USFWS, 2017)
- 12. The recovery plan should be updated to define objective measurable recovery criteria. A few key points to consider when addressing this action are: current population resiliency, effects of management and restoration efforts (particularly the effects of aggressive fire), and seedling recruitment. (USFWS, 2017)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Continue and complete ongoing surveys throughout the present distribution. This will assess the effect of 2018 Hurricane Michael (HM) and subsequent site prepped post HM on C. glabra at SCT. Conduct population surveys using a consistent, statistically valid, repeatable survey method (Service 2013). Once population numbers are known and an inventory has been conducted to find new populations throughout appropriate sandhill habitat, consistent surveys would allow for the analysis of long-term trends for this species. This information would help to determine when the species is stable and may be considered for reclassification. This information would also help to inform conservation managers of appropriate management techniques, and whether restoration of the pine plantation back to sandhill is assisting in the recovery of the species 2. Continue regular monitoring of marked individuals (e.g., the total number of individuals, number of flowering vs. non-flowering plants, and whether seedling recruitment is occurring). 3. In-situ seed germination and seedling recruitment studies o Many plants in fire-prone environments produce seeds that need fire, directly or indirectly, to germinate. To address whether seeds of C. glabra germinate postfire, a seed burial and retrieval experiment is recommended. 4. Investigate the longevity of seeds (soil seed bank), viability, seed germination and seedling recruitment. Ongoing by the Atlanta Botanical Garden, 2019-2021: Grant No. F18AC00195: Studies to assess resiliency and status of endangered Apalachicola rosemary (Conradina glabra). ABG proposed to 1) collect seeds from wild SCT populations, 2) test for seed viability via staining and microscopy, and 3) perform seed germination trials. 5. Conduct an inventory of sites where appropriate habitat exists. This action can include the use of aerials and species distribution modeling methods to initially determine potential sites, with subsequent field inventory of the site using a consistent, statistically valid, repeatable inventory method. If new populations are discovered, protection should be sought. 6. Private land conservation Seek partnership with private landowners to assess adjacent properties to SCT [e.g., Candence Bank (3 parcels), Holland Ware, and R Dell Phillips] for the presence of C. glabra. Objectives are to: • conduct surveys and document previously unknown locations. • better understand the present distribution of C. glabra. • develop conservation goals and best management practices • secure populations via land acquisition, conservation easement, or by implementing permanent conservation measures. 7. Identify appropriate soil types and other environmental conditions within the C. glabra range and adjacent areas as well as other sandhill areas within the Florida panhandle. This action can include the use of aerials and species distribution modeling methods to initially determine potential habitat associations. 8. An ex-situ plant collection should be actively pursued and implemented. This action can be guided by the genetic study currently being carried out by the ABG (2021). 9. According to A. Stiles (DRP, pers. comm., 11/09/2021), observations suggest a decrease in the abundance C. glabra in high-density sand pine plantations, supporting restoring SCT to a Sandhill natural community. Therefore, restoration of and subsequent management of C. glabra's habitat should continue. This is crucial for the long-term population stability given that the global population of C. glabra is only found at the TSP. 10. Determine the fire regime (intensity) and monitor the effect of this event on C. glabra density, fecundity, and size structure. Ongoing. 11. Avoid or postpone prescribed fire during extreme drought and heatwave conditions. 12. Assess the occurrence of vegetative reproduction (i.e., clonality) using genetic markers and determine the conservation implications. Ongoing 13. Evaluate the benefits and risks of translocation, augmentation, and reintroduction strategies under the combined pressures of habitat fragmentation and climate change. Partially done (Bladow et al. 2017). 14. Evaluate the reference (remnant) site and determine the relevance and utility in informing restoration. Partially done. 15. Develop a stand-alone plan for managing listed plants at the TSP and integrate it to the main management plan and the restoration protocol. (USFWS, 2022)

# SPECIES ACCOUNT: *Conradina verticillata* (Cumberland rosemary)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 12/30/1991; Southeast Region (R4)

**Physical Description**

Cumberland rosemary, an evergreen perennial shrub in the mint family, is most noted for its aromatic leaves, which smell like the culinary herb rosemary, and for its abundant pink to purple flowers. A full technical description can be found in Gray (1965), but a few characteristics from Kral (1983), Patrick and Wofford (1981), and Roulston (1994) are presented and will aid in field identification. Inflorescence: Flowers on short-stalked, linear-bracted, axillary cymes from most or all upper nodes; the cyme stalks hispidulous; the bracts covered with long-spreading gland-tipped hairs. Flowers: They are 1 to 2 centimeters (cm) long; lavender, purple, or rarely white, usually with dark spots leading down the throat; two-lipped, the upper lip with two lobes, the lower with three; floral tube strongly bent, giving the flower an s-shape in profile; borne in small clusters in the axils of the present year's leaves from early May until early June. Calyx: Bilabiate, five-toothed, persistent, 7 to 9 millimeters (mm) long, glandular-pubescent and/or sparsely puberulent to appressed pubescent. Stems: Four-sided; woody but lax, often decumbent; seldom growing more than 1 foot tall before falling over, rooting at the nodes, and putting up more stems. Leaves: Entire, needlelike, opposite with additional pairs clustered in the axils appearing whorled, somewhat fleshy, with strongly revolute margins, 1 to 3 cm long, resin dotted, aromatic. Seeds: Up to four per calyx, dry, dark brown, spherical, 1 mm in diameter; loose in calyx but usually not falling out before calyx falls off plant. No other plants are likely to be mistaken for it when it is in flower. Without flowers, however, it resembles Aster linari~folius, Hypericum densforum, and Pycnanthemum tenuforum, which also have needlelike leaves and grow in the same habitat but do not have the distinctive rosemary aroma. (USFWS, 1996)

**Taxonomy**

Conradina is a genus of six allopatric species confined to the Southeastern United States (Shiners 1962, Gray 1965, Kral and McCartney 1991) (USFWS, 1996).

**Historical Range**

This species is known from five counties in north-central Tennessee and one county in southeastern Kentucky (USFWS, 1996).

**Current Range**

Tennessee: Cumberland, Fentress, Morgan, Scott, and White Counties; Kentucky: McCreary County. These occurrence are along nine major streams of the Cumberland Plateau--Big South Fork River, New River, Clear Fork River, White Oak Creek, Caney Fork River, Obed River, Daddys Creek, Clear Creek, and Emory River. (USFWS, 2018)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**
Adult: Asexual, sexual (NatureServe, 2015)

**Dependency on Other Individuals or Species**
Adult: Bumblebees and honeybees (USFWS, 1996)

**Breeding Season**
Adult: May - June (USFWS, 1996)

**Key Resources Needed for Breeding**
Adult: Insect pollinators (USFWS, 2018)

**Reproduction Narrative**
Adult: Flowering occurs from May to June, with fruiting in mid June. Pollination is primarily by bees, especially bumblebees and honeybees, although it attracts many different types of insects (USFWS, 1996). Less than 10 percent of the seeds are fully developed and fertile. Germination takes about 2 weeks (USFWS, 1996). C. verticillata reproduces sexually and asexually. Due to low seed viability, a majority of reproduction is the result of asexual reproduction via fragmentation (NatureServe, 2015).

**Habitat Type**
Adult: Wetland (USFWS, 1996)

**Habitat Vegetation or Surface Water Classification**
Adult: Riparian, flood plain, sand bar (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**
Adult: Seasonal flooding (NatureServe, 2015); full to moderate sunlight (USFWS, 1996)

**Geographic or Habitat Restraints or Barriers**
Adult: Excessive vegetation/shading ; saturated soil (USFWS, 1996)

**Spatial Arrangements of the Population**
Adult: Clumped (USFWS, 1996); colonial (NatureServe, 2015)

**Environmental Specificity**
Adult: Very Narrow (USFWS, 2018)

**Habitat Narrative**
Adult: Cumberland rosemary is found on rocky river bars composed of unsorted boulders, cobbles, gravel and sand, with the largest populations occurring in open, 8 washed-out areas near the centers of these bars. The essential habitat requirements of this species are: open to barely shaded sites; moderately deep, sandy, well-drained soils with no visible organic matter; periodic forceful flooding to maintain openness; topographic features to enhance sand deposition; and, perhaps, periods of inundation of at least two weeks to induce rooting at the lower nodes (Patrick and Wofford 1981). (USFWS, 2018)

### *Dispersal/Migration*

**Dispersal/Migration Narrative**

Adult: Dispersal seems to be mainly through fragmentation during winter storms (USFWS, 1996).

### *Population Information and Trends*

**Population Trends:**

Not available

**Species Trends:**

Unknown (USFWS, 2011)

**Number of Populations:**

3 (USFWS, 2023)

**Population Size:**

Unknown (USFWS, 2018); < 4,000 (NatureServe, 2015)

**Population Narrative:**

There currently are 66 extant occurrences; though, it is likely many others also are extant but lack current observation data to verify their persistence. While most extant sites are located on conservation lands, few are actively managed to improve habitat conditions and promote population growth of Cumberland rosemary occurrences. Data are lacking from most sites for generating reliable estimates of the species abundance, either in terms of individual clumps or genetically distinct plants. However, viability ranks assigned by Kentucky and Tennessee NHPs indicate that fewer than 100 clumps are present at 90 percent of extant occurrences. Available monitoring data suggest general trends in each of the major watersheds where the species occurs, at least among monitored sites, including declines at a majority of occurrences in the Big South Fork and Caney Fork watersheds and increases or stability at a majority of sites monitored in the Obed-Emory. (USFWS, 2018). Cumberland rosemary is represented by three populations in Tennessee and Kentucky in the Big South Fork, Emory, and Caney Fork watersheds. The species is monitored at 25 sites at varying frequency by the National Park Service's Appalachian Highlands Inventory and Monitoring Network (NPS-APHIN), Tennessee Department of Environment and Conservation (TDEC), and the Office of Kentucky Nature Preserves (OKNP) (USFWS, 2023).

### *Threats and Stressors*

**Stressor:** Habitat destruction and modification (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The potential exists that small ponds and reservoirs constructed in upper reaches of watersheds have altered hydrologic and geomorphologic processes necessary to maintain suitable conditions for the species on the cobble bars where it occurs. White (pers. comm. 2010)

reported that encroachment of woody species, both native and exotic, onto cobble bar habitats led to the decline of at least three Cumberland rosemary occurrences in Kentucky, and suggested that either drought or altered hydrology could be factors contributing to these declines. Impacts associated with hiking and equestrian trails at Big Island in BSFNRRA and impacts from vehicular and camping activity at the Lilly Bridge site in ONWSR may be a threat (USFWS, 2011).

**Stressor:** Recreational activities (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Recreational activities have been identified as a potential threat to Cumberland rosemary due to trampling in areas near trails used for horseback riding and hiking, camping, off-road vehicle traffic, and whitewater boating. There is no updated information on this threat, but riparian recreation on Big South Fork NRRA, Obed WSR, and Catoosa Wildlife Management Area is still popular, and trampling remains a potential threat (USFWS, 2023).

**Stressor:** small, fragmented range (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The best available information continues to indicate that the small, fragmented range that Cumberland rosemary occupies increases the species vulnerability to localized extinction due to random events, such as natural disasters and loss of genetic diversity and adaptive potential through genetic drift (Service 2018). Low seed viability and low recruitment also reduce the species' ability to recover from habitat-related threats. These factors persist, but we are not aware of any additional studies addressing them. Research into the need for and requirements of a captive propagation program would lay the groundwork for future efforts to increase numbers of individuals and boost population size at wild sites (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
Not applicable.

Recovery Priority Number: 8

**Delisting Criteria:**
There are 25 protected and managed colonies with 50 genetically distinct individuals per colony on the five major rivers (five colonies on each river) where it occurs (USFWS, 1996).

**Recovery Actions:**
- Protect existing colonies and habitat. Only three populations with 91 colonies are known to exist, with the majority in north-central Tennessee and a few in adjacent Kentucky. The largest colonies in each population need immediate protection. A total of76 colonies are located on land managed by the National Park Service, and 15 sites are located on privately owned land. Only five colonies are known to have more than 100 clumps of plants. Protection of five colonies in each of the five major rivers in which Cumberland rosemary occurs is considered to be essential to the recovery of the species and to prevent its

irreversible decline. (USFWS, 1996)

- Search for new populations within the known range and in other watersheds. The search for new populations is necessary within both the known range and other watersheds. This information will be useful in making management decisions and for determining the genetic variability of the species. The most intensive searches for Cumberland rosemary in Tennessee were conducted in 1979 and 1980 (Patrick and Wofford 1981, Patrick 1979, Schmalzer and DeSelm 1982). These searches were restricted to the five major rivers within the known range of the species. Only a few new colonies have been found since 1980 (see Appendix). Suitable habitat north of and between the known Kentucky population has been thoroughly searched; no new colonies were located (White 1994). Searches should be conducted in other watersheds in Tennessee's northern Cumberland Plateau. Because of the restricted riparian habitat, access by canoe is the most efficient method of surveying for new colonies. Searches in the BSFNRRA and the 16 ONWSR should continue in order to ensure that all federally owned colonies are adequately managed and protected. (USFWS, 1996)
- Conduct studies of the species' biology. Additional information on the biology of C. verticillata is important and necessary for developing and implementing management guidelines. (USFWS, 1996).
- Maintain and expand cultivated sources for the species. Vegetative material should be preserved for the purpose of establishing new populations if natural populations were to be eliminated. (USFWS, 1996).
- Develop materials to inform the public about the status of the species and the recovery plan objectives. Public support for the conservation o fCumberland rosemary could play an important part in encouraging conservation efforts. In order to ensure that the taking threat is not increased, information materials should not identify specific plant locations. (USFWS, 1996).
- Annually assess the success of recovery efforts for the species. The review of new information, evaluation of ongoing actions, and redirection of recovery efforts, if necessary, are essential for assuring that full recovery is achieved as quickly and efficiently as possible. (USFWS, 1996)
- Work with NPS, TDEC, and KSNPC to reconcile data concerning extant and historic locations, abundance at extant locations, and threats (USFWS, 2011).
- Continue efforts to control invasive, exotic plants at occurrences on NPS lands at BSFNRRA and expand these efforts, as needed, to ONWSR (USFWS, 2011).
- Continue long-term monitoring begun by TDEC. Expand monitoring effort to occurrences in Kentucky. Review monitoring protocols and revise, if warranted, to provide a more repeatable system for tracking changes in distribution and abundance. Incorporate threats assessment into monitoring program (USFWS, 2011).
- Use data from NPS Cobble Bar Monitoring program to track threats to Cumberland rosemary at BSFNRRA and ONWSR (USFWS, 2011).
- Continue implementation of Recovery Plan for Cumberland rosemary (USFWS, 2011).
- · Conduct a population genetics study to assess the level of genetic variation found in the species and how that variation is distributed among watersheds and sites within watersheds; assess inbreeding risk for watersheds and occurrences; and evaluate the relationship between number of clumps/plants (ramets) 30 observed at sites and the number of genetically distinct individuals (genets) they represent. This information should be used to evaluate abundance at site and watershed levels and determine whether

population augmentation should occur in some watersheds/sites to facilitate gene flow and increase the number of compatible mates. (USFWS, 2018)

- · Coordinate monitoring efforts between KSNPC, TDEC, and NPS-APHN to avoid duplication and ensure monitoring is conducted at standardized times of year, using consistent methodology. Monitoring programs should also be designed to document threats observed at Cumberland rosemary sites, including assessing impacts of recreational activities in sites with known threats, and should attempt to document seedling recruitment into populations. (USFWS, 2018)
- · The Service's (2016) programmatic BO for streams crossings on trails at BISO included a nondiscretionary requirement that NPS coordinate with the Service to devise a monitoring plan for Cumberland rosemary that includes formally designated trail crossings and other significant sites where this plant occurs in proximity to trails in BISO. While NPS conducts monitoring at 18 sites in BISO and OBRI, there has been little coordination with the Service on the monitoring program. Some NPS monitoring sites for Cumberland rosemary are located along trails, but we do not currently know which sites, nor do we know if data are collected regarding evidence of impacts related to recreational use of trails or nearby areas. The NPS staff at BISO, OBRI, and APHN, should coordinate with the Service to evaluate whether the current NPS monitoring program includes a representative set of sites for assessing effects of recreational uses on and near trails and to establish routine coordination and reporting procedures. (USFWS, 2018)
- · Evaluate data and reports from the NPS-APHN (Murdock et al. 2013) long-term cobble bar monitoring program, to increase understanding of cobble bar geomorphology and dynamics in relation to vegetation structure and composition, as well as responses of Cumberland rosemary to changes in these habitats over time. We are not currently aware of any publicly available data or reports that have been produced from this monitoring program. (USFWS, 2018)
- · There is a need to reconcile NPS data on observations of Cumberland rosemary at OBRI and BISO with data in NHP databases. Nearly one-third (~30 percent) of all known EOs are considered historical, because there are no observations recorded for them in NHP databases since prior to 1998. The greatest number of these historical occurrences are located in the Big South Fork watershed, where NPS-APHN conduct cobble bar monitoring and other biological surveys and potentially have collected data on Cumberland rosemary occurrences (both previously known and not yet documented). While some data have been provided to Tennessee's NHP program, there is a need to ensure that NPS observation data for Cumberland rosemary and other listed species are routinely shared with NHP programs. (USFWS, 2018)
- · Once NPS and NHP data are reconciled, data should be reviewed and sites prioritized for surveys where recent observation data are lacking. Current data are needed to verify persistence of many EOs and to estimate abundance for evaluating the species' status with respect to recovery criteria. (USFWS, 2018)
- · Surveys for new occurrences should be conducted and negative data stored in a collective database. (USFWS, 2018)
- · Prioritize and increase efforts to control invasive species and assess whether additional management is needed on highest priority sites. Document areas where invasive species control and other habitat management occurs. (USFWS, 2018)
- · Additional seed banking and testing of seed viability are needed to provide adequate ex situ resources for conservation of the species. (USFWS, 2018)

# SPECIES ACCOUNT: *Cordylanthus maritimus ssp. maritimus* (Salt marsh bird's-beak)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/29/1978; California/Nevada (Region 8) (USFWS, 2015)

**Physical Description**

A hemiparsitic annual herb, 1-3 dm tall, with grayish-green, herbage, often tinged with purple. Specimens are branched and may be up to 16 inches (40 centimeters) tall with numerous flowers arranged on flower stalks termed spikes. The flowers of some C. maritimum taxa have showy pale pink pouches with darker purple lips on purplish-green plants. The hairiness of the foliage and stems is variable, and most plants have visible salt-encrusted glandular hairs. Chloropyron maritimum ssp. maritimum may occur as short, erect, scarcely branched plants, or as plants with a profusion of spreading or ascending branches. (USFWS, 2013; NatureServe, 2015)

**Taxonomy**

At the time Chloropyron maritimum ssp. maritimum was listed (as Cordylanthus maritimus ssp. maritimus), the genus Cordylanthus was placed in the Scrophulariaceae (figwort family). However, based on molecular systematic studies using DNA sequences of three plastid genes, Olmstead et al. (2001) transferred the hemiparasitic group Castillejiinae, including Cordylanthus, to the Orobanchaceae. Though the taxon continues to be called Cordylanthus maritimus ssp. maritimus on the Federal List of Threatened and Endangered Wildlife and Plants (List) pursuant to the Endangered Species Act (Act) (16 U.S.C. 1531 et seq.), here we use the currently accepted name, Chloropyron maritimum ssp. maritimum. The species is divided into northern and southern coastal subspecies, and an inland subspecies. Chloropyron maritimum ssp. maritimum, the southern California coastal subspecies, is distinguished from the northern ssp. palustris, mainly by geographic distribution in that it occurs from Morro Bay south through southern California. It is also distinguished by branching patterns, growth habit, narrower and more acute leaves, and variations in seed size and floral traits (Chuang and Heckard 1973, 1993). The three intergrading subspecies have distinct ecological and geographical distributions. Chloropyron maritimus ssp. canescens (hoary salt marsh bird’s-beak) is a widely distributed, but uncommon, plant of inland saline/alkaline wetlands of the Great Basin; Chloropyron maritimum ssp. maritimum (salt marsh bird’s-beak), an endangered tidal marsh plant limited to few populations in southern California and Baja California, Mexico; and Chloropyron maritimum ssp. palustre (Point Reyes bird’s-beak), a similar rare tidal marsh plant from San Francisco Bay to Oregon. (USFWS, 2013)

**Historical Range**

Historically, C. maritimum ssp. maritimum was widespread near the upper edges of coastal tidal marshes from Morro Bay in San Luis Obispo County to San Diego County and northern Baja California. (USFWS, 2013)

**Current Range**

Chloropyron maritimum subsp. maritimum is currently known to persist in seven coastal salt marshes: San Diego County at Tijuana Estuary (separated into Border Field State Park and

Tijuana Slough NWR), Naval Radar Receiving Facility (NRRF), and Sweetwater Marsh Unit of San Diego Bay NWR; Orange County at Upper Newport Bay (State) Ecological Reserve; Ventura County at Naval Base Ventura County, Point Mugu; Santa Barbara County at Carpinteria Salt Marsh; San Luis Obispo County at Morro Bay. (USFWS, 2009)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (NatureServe, 2015)

**Dependency on Other Individuals or Species**

Adult: Bees are thought to be the principal pollinators of ssp. maritimum at other locations (Parsons and Zedler 1997).

**Breeding Season**

Adult: May to October (USFWS, 2009)

**Reproduction Narrative**

Adult: Chloropyron maritimum subsp. maritimum is a taxon of annual plants in the Orobanchaceae (broom rape family). The flowering period is between May and October (Munz 1974, p. 801; Naval Base Ventura County Point Mugu 2003, p. 1). Each flower may produce 10-40 seeds with an average of 15 to 20 seeds per capsule (Chuang and Heckard 1993, p. 1029). (USFWS, 2009)

**Habitat Type**

Adult: Estuarine (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Herbaceous wetland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Requires water salinities between 5 to 33 parts per thousand and less than 12 parts per thousand for germination (USFWS, 2013)

**Geographic or Habitat Restraints or Barriers**

Adult: Requires periodic tidal inundation; prefers brackish to tidal marsh with low vegetative cover (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Patchy (USFWS, 2009)

**Environmental Specificity**

Adult: Narrow/specialist

**Habitat Narrative**

Adult: Plants have naturally patchy distributions in sites subject to only higher tidal influxes in coastal salt marshes. (USFWS, 2009). The range of salinity associated with growth of ssp. maritimum is 5 to 33 parts per thousand, but pulses of freshwater from flooding or rainfall are probably necessary for germination (Parsons and Zedler 1997). Salinity at the time of germination usually cannot exceed 12 parts per thousand (Newman 1981). Populations generally occur in areas with low salinity in the spring and low vegetative cover (Newman 1981, Dunn 1981). Cordylanthus maritimus spp. maritimus roots form haustoria to obtain water and nutrients through the roots of other host plants. Chloropyron maritimum ssp. maritimum can grow without host plants (Chuang and Heckard 1971), but hemiparasitism may permit them to flourish in the hot, dry, higher soil-salinity conditions of summer (Vanderwier and Newman 1984). (USFWS, 2013; USFWS, 2009)

***Dispersal/Migration***

**Dispersal**

Adult: High (USFWS, 2013)

**Dependency on Other Individuals or Species for Dispersal**

Adult: Animals, especially birds (USFWS, 2013)

**Dispersal/Migration Narrative**

Adult: Physical factors such as currents, tides, wave action, and sheet erosion are among the ways seeds are moved around within and between marshes. The seeds of C. maritimum ssp. maritimum have a honeycombed surface that traps air bubbles and makes them highly buoyant. They have been shown to float for up to 50 days and floatation may be the primary local dispersal mechanism for C. maritimum ssp. maritimum (Newman 1981). Animals, especially birds, may carry the seeds on their feet, or in their fur, feathers, or digestive systems (U.S. Fish and Wildlife Service 1985a). (USFWS, 2013)

***Population Information and Trends***

**Population Trends:**

Decline of >30% (NatureServe, 2015)

**Number of Populations:**

9 (USFWS, 2020)

**Population Size:**

30,000 (highly variable) (NatureServe, 2015)

**Population Narrative:**

CHMAMA is currently extant at nine coastal marsh complexes across the species' range, including seven marsh complexes in the United States [Morro Bay, Carpinteria Salt Marsh, Ormond Beach/Mugu Lagoon, Upper Newport Bay, San Diego River Mouth, San Diego Bay (including Sweetwater Marsh) and Tijuana Estuary], and two marsh complexes in Baja California, Mexico (Estero Punta Banda, and Bahía de San Quintín). One new population has been established since the last 5-year review, at the San Diego River Mouth. Conservation efforts have occurred and are ongoing throughout the subspecies' range, including work to introduce CHMAMA at Magnolia Marsh, within the Huntington Beach Wetlands. (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Habitat loss (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Historically, Chloropyron maritimum subsp. maritimum occurred in many more salt marshes than it did at the time of listing. Many of these salt marsh areas were either filled in for development (e.g. Artesia and Long Beach in Los Angeles County) or cleared for marinas (e.g. Mesmer near Santa Monica in Los Angeles County). Diversion of fresh water from the salt marsh areas may also have led to the habitat becoming unsuitable to sustain C. maritimum subsp. maritimum populations. (USFWS, 2009)

**Stressor:** Off-highway vehicles (OHVs) (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Impacts from off-highway vehicles have been reported for some occurrences of Chloropyron maritimum subsp. maritimum (CNDDB 2008). These occurrences are in San Diego County in an area of the Tijuana Slough NWR in the Tijuana Estuary where OHV activity is controlled by the Refuge managers; in Orange County at Upper Newport Bay where OHV activity is controlled by managers of the Upper Newport Bay State Ecological Reserve; in Ventura County at Ormond Beach where OHV activity is controlled to a degree by the Coastal Conservancy and The Nature Conservancy's Conservation Easement, and at the Ventura County Naval Base Point Mugu (CNDDB 2008). Potential impacts from OHVs are currently minimal and management measures are in place to minimize these impacts. (USFWS, 2009)

**Stressor:** Hydrological changes (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Modification for natural tidal flow in Point Mugu Lagoon in Ventura County, noted as a threat in the listing rule, was completed in about 1980. As a result, a portion of the populations at the occurrence were destroyed, but most remained. Since listing, increased tidal flow at one site in the Carpinteria Marsh in 1984 reportedly created wetter conditions (CNDDB 2008, EO 17). However, there are no subsequent reports on the precise location of the site or condition of plants in the area and occurrences in the area are presumed to be extant (CNDDB 2008). Hydrological alterations to promote populations of endangered birds (e.g., light-footed clapper rail) have taken place at historical occurrence sites of Chloropyron maritimum subsp. maritimum, though the impact on plant populations is unknown. (USFWS, 2009)

**Stressor:** Global climate change (USFWS, 2009)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** According to the Intergovernmental Panel on Climate Change (IPCC) there has been a general but measured increase in global average temperatures since the turn of the century (IPCC WG I 2007, p. 6). This translates to the fact that the average temperature of the ocean has also risen. The same is true for global average sea level (IPCC WG I 2007, p. 6). The total rise in sea level during the 20th century is estimated to be about 0.56 feet (0.17 meters). This means that the tidal flows will encroach further into all coastal marshes including those that support C. m. subsp. maritimum. The impact on distribution of associated vegetation and host plants is unknown. Although the degree of sensitivity Chloropyron maritimum subsp. maritimum to incremental changes in sea level is unknown, ultimately, it is likely that the full extent and distribution of populations will be affected and likely move inland or up the elevational gradient. The populations could potentially migrate inland in step with changes in the estuarine hydrology as long as the physiography of the site allowed. The physiography of each occurrence differs, which in turn dictates whether or not C. maritimum subsp. maritimum can naturally migrate to other suitable sites. The potential for adjacent habitats to become suitable for C. maritimum subsp. maritimum as the inundation regime changes also likely varies from occurrence to occurrence. Habitat for C. maritimum subsp. maritimum at generally broad open estuaries such as Tijuana Estuary in San Diego County and Point Mugu in Ventura County would persist more readily than that at Newport Bay in Orange County where the adjacent bluffs could preclude inland migration of the habitat. Sea level rise poses a significant rangewide threat to all extant occurrences of C. maritimum subsp. maritimum and coastal marsh areas under consideration for restoration and/or enhancement. (USFWS, 2009)

**Stressor:** Storm drain runoff (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since listing, erosion from storm drain runoff is listed as a threat to occurrences in Upper Newport Bay in Orange County (CNBBB 2008). This runoff is generated by neighborhoods on the bluffs above the bay. Projections of precipitation as less snow and more rain (CEC 2006, p. 31) mean that there would likely be more runoff than is currently experienced. The amount and timing of runoff impacts coastal salt marsh habitat and any changes due to climate change likely result in changes to the condition and distribution of suitable habitat for Chloropyron maritimum subsp. maritimum. (USFWS, 2009)

**Stressor:** Herbivory (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since listing, herbivory by the microlepidopteran, salt marsh snout moth (Lipographis fenestrella) has been documented (Parsons and Zedler 1997, p. 259). This is listed in CNDDB as insect damage for a few of the occurrences (Appendix 1). The larvae of the moth consume capsules and even unfertilized ovaries, however, a large number of capsules escape attack (Parsons and Zedler 1997, p. 259). These authors report that although there was more damage between mid-May and mid-June there was no correlation with environmental variables. The extent and impact of herbivory to populations of Chloropyron maritimum subsp. maritimum is unknown. (USFWS, 2009)

**Stressor:** Trampling (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since listing, new threats from trampling have been reported for occurrences at the Naval Radar Receiving Station (NRRF), San Diego County, Upper Newport Bay Ecological Reserve, Orange County, and at the south end of Morro Bay, San Luis Obispo County (Appendix 1). The extent and persistence of the threats from trampling is unknown. (USFWS, 2009)

**Stressor:** Nonnative plants (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since listing nonnative plants (e.g. Limonium spp. (sea-lavender) and Carpobrotus spp. (sea-fig)) have been noted as a new threat to Chloropyron maritimum subsp. maritimum at occurrences in Santa Barbara County (e.g., Carpinteria ) (CNDDB 2008) and San Luis Obispo County (e.g., Morro Bay) (CNDDB 2008). No specific impacts were provided, thus the nature and magnitude of this threat cannot be assessed at this time. These invasive plants may alter movement and availability of fresh water or otherwise preclude germination and growth of the Chloropyron maritimum subsp. maritimum and/or its hosts. (USFWS, 2009)

***Recovery***

**Reclassification Criteria:**
1. Fifteen acres [6 hectares] of secured and protected high marsh habitat at appropriate elevations is required at a minimum of eight marshes for a period of at least five consecutive years. (USFWS, 2009)

**Delisting Criteria:**
1. Twenty acres [8 hectares] of secured, protected, and managed high marsh habitat at appropriate elevations is required at each of the 12 major marshes within the historical range of the plant for a period of ten consecutive years. (USFWS, 2009)

**Recovery Actions:**
- Conservation easements or fee-title purchase from willing sellers should be sought to place remaining undeveloped shoreline under protective ownership. (USFWS, 2013)
- Many of the threats facing the subspecies are aggravated by its small population size and limited range-wide distribution; therefore, population augmentation and initiation of new subpopulations in suitable unoccupied habitat at Morro Bay should be planned and implemented to reduce the risk of regional extinction. (USFWS, 2013)
- Morro Bay populations of Chloropyron maritimum ssp. maritimum are sensitive to trampling and disturbance and should be protected, by use of fencing, against recreational pressures from nearby residential areas and from park visitors. Access and trails should be routed away from sensitive habitat. Boat haulouts near populations of C. maritimum ssp. maritimum must be curtailed. Dredge disposal should be managed to minimize the risk of sand movement burying subpopulations of the species. (USFWS, 2013)
- Shoreline stands of Carpobrotus edulis (iceplant) should be eradicated and replaced with native marsh-upland ecotone vegetation. Other non-native plants should be controlled to

prevent crowding, shading, or other impacts to the salt marsh bird's-beak and its habitat. (USFWS, 2013)

- Populations of Chloropyron maritimum ssp. maritimum should be monitored annually for distribution, abundance, and reproductive output. (USFWS, 2013)
- Continuing and new threats should be identified and reported. Disturbances and sand dune movement should be monitored, and measures to address impacts—as well as to evaluate the success of these measures—should be developed. (USFWS, 2013)
- Management plans that address protective and population augmentation actions for Chloropyron maritimum ssp. maritimum should be developed and implemented for lands in public or conservation ownership. (USFWS, 2013)
- Resurvey historical and extant occurrences, especially inland salt marsh habitats, to detect presence and local distribution of plants. There is some potential for the inland occurrences to have persisted. (USFWS, 2009)
- Develop a threats-based recovery plan to guide conservation actions for the species. Incorporate SLAMM assessments of sea level change. (USFWS, 2009)
- Determine the distribution of genetic diversity at extant occurrences. This will assist us in identifying pollinators and pollen sources should pollen transfer among occurrences prove necessary. As part of this effort, verify the subspecific relationships of the occurrences in Morro Bay. (USFWS, 2009)
- Prepare site specific monitoring protocols to determine, if possible, fine-scale habitat requirements and species fidelity to those habitat requirements. This will allow us to discriminate between lack of seed dispersal and unsuitable habitat as explanations for discontinuities in plant distributions. (USFWS, 2009)
- Establish site and species monitoring protocols, based on those developed by VFWO at Point Mugu, to identify potential impacts of sea level changes associated with climate change. This will help detection of species responses to long term changes in sea level and associated vegetation. (USFWS, 2009)
- Work with partners to help conserve Chloropyron maritimum subsp. maritimum. Identify opportunities through the Service's Partners for Fish and Wildlife and Coastal Programs to seek habitat restoration and enhancement opportunities. (USFWS, 2009)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Continue to work with partners to expand the current distribution of CHMAMA, including planning, site selection, and augmentation and reintroduction efforts. 2. Collect voucher specimens and conduct genetic work to resolve taxonomic questions about the distribution of the listed entity, especially at Morro Bay. 3. Continue to support partners in removing nonnative Limonium from occupied marshes. Conduct additional research into CHMAMA seed tolerance to solarization when treating Limonium. 4. Engage stakeholders and species experts in CHMAMA sea-level rise planning. 5. Conduct additional research into environmental covariates important for CHMAMA abundance at marshes, using existing monitoring data where available. (USFWS, 2020)

# SPECIES ACCOUNT: *Cordylanthus mollis ssp. mollis* (Soft bird's-beak)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 11/20/1997; California/Nevada (Region 8) (USFWS, 2015)

**Physical Description**

Chloropyron molle ssp. molle is an erect annual herb in the Orobanchaceae (broomrape) family. Mature plants range from approximately 10 to 40 cm (4 to 16 in) tall. Stems and leaves are gray-green, often purple-tinged, and covered with very fine hairs bearing glands as well as longer soft non-glandular hairs. Leaves and stems are sparsely to heavily covered with crystals of salt exuded from leaf glands. Leaves are typically 1.0 to 2.5 cm (less than 0.5 to 1.5 in long, oblong, and may be entire or pinnately lobed 3 to 7 lobes). The tubular flowers are pale cream to yellowish at the tip, and crowded together in spikes 5.0 to 15.0 cm (2 to 6 in long). The fruit is a capsule, approximately 8 mm (0.3 inch) long (Ruygt 1994). (USFWS, 2013)

**Taxonomy**

At the time Chloropyron molle ssp. molle was listed (as Cordylanthus mollis ssp. mollis), the genus Cordylanthus was placed in the Scrophulariaceae (figwort family). However, based on molecular systematic studies using DNA sequences of three plastid genes, Olmstead et al. (2001) transferred the hemiparasitic group Castillejiinae, including Cordylanthus, to the Orobanchaceae, thereby placing it in the genus Chloropyron. The species Cordylanthus mollis was split into two subspecies by Chuang and Heckard (1973), based on geographic variation in spike length, branching pattern, corolla hair density, seed size, and hair stiffness. Chloropyron mollis ssp. hispidus is distinguished from ssp. molle by its pronounced bristly stem and leaf hairs, and its growth habit of branching strongly from the base of the plant. The flowers of ssp. hispidus are sparsely hairy, not densely tomentose (woolly) as in ssp. mollis. Within its range, Chloropyron molle ssp. molle can be distinguished from two other taxa in the Scrophulariaceae that occur in brackish tidal marshes: Chloropyron maritimum ssp. palustre and Castilleja ambigua. When in flower, C. maritimum ssp. palustre is readily distinguished from C. molle by its rose-purple and pinkish-white flowers, and the presence of four fully developed stamens (not two plus two vestigial stamens, as in C. molle). The inner bracts of C. maritimum ssp. palustre are notched, not lobed, while the bracts of C. mollis are pinnately lobed. C. ambigua flowers in spring (variably late March to May) before C. molle. The bracts and leaves of C. ambigua are palmately cleft, not pinnately lobed as in C. molle. Although, typical C. ambigua ssp. ambigua has white and yellow flowers like C. molle, the Point Pinole population of ssp. ambigua and other historical San Francisco Bay populations have flowers that mature and senesce with a purplish tinge (P. Baye unpubl. data 1997-2000), as do the white-tipped bracts (Chuang and Heckard 1993). In contrast, the bracts of C. molle are gray-green or a blend of gray-green and dull dark purplish highlights, and its flowers are creamy yellow or yellowish-green and lack an open beak tip that allows the stigma to protrude (Chuang and Heckard 1993). (USFWS, 2013)

**Historical Range**

Endemic to California, reported from Contra Costa, Marin, Napa, Solano, Sonoma, Sacramento, and Del Norte counties. (NatureServe, 2015)

**Current Range**

The species is currently restricted to widely scattered populations in Napa, Solano, and Contra Costa Counties, from Point Pinole and Fagan Slough marsh through the Carquinez Strait to Suisun Bay. (USFWS, 2009)

**Critical Habitat Designated**

Yes; 4/12/2007.

**Legal Description**

On April 12, 2007, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Cordylanthus mollis ssp. mollis (Soft bird's-beak) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes five critical habitat units (CHUs), in California (72 FR 18518-18553).

**Critical Habitat Designation**

The critical habitat designation for Cordylanthus mollis ssp. mollis includes five CHUs in Contra Costa, Napa, and Solano Counties, California. This species critical habitat encompasses approximately 2,276 acres (ac) (921 hectares (ha)) (72 FR 18518-18553).

Unit 1: Fagan Slough Marsh (Napa County): Unit 1 consists of approximately 384 ac (156 ha) located adjacent to the Napa River to the west, Napa County Airport to the east, Fagan Slough to the south, and Steamboat Slough to the north. This unit consists of 297 ac (120 ha) of Stateowned land (Fagan Slough Ecological Reserve), which is managed by the CDFG, 6 ac (2 ha) of county-owned land, 9 ac (4 ha) of land owned by the City of Napa, and 72 ac (29 ha) of privately owned land. Cordylanthus mollis ssp. mollis occupied the unit at the time of listing as identified in the final listing rule (62 FR 61916; November 20, 1997) and contains the features essential to the conservation of C. mollis ssp. mollis. The unit receives tidal inundations regularly (NWI 2005) from the abovementioned tidal sloughs and the Napa River.

Unit 2: Hill Slough Marsh (Solano County): Unit 2 for Cordylanthus mollis ssp. mollis consists of approximately 525 ac (213 ha) located north of Potrero Hills between Grizzly Island Road and Highway 12. The unit consists of approximately 440 ac (178 ha) of Stateowned land (Hill Slough Wildlife Area), which is managed by the CDFG, and 85 ac (35 ha) of privately owned land. Cordylanthus mollis ssp. mollis occupied the unit at the time of listing as identified in the final listing rule (62 FR 61916; November 20, 1997) and contains the features essential to the conservation of C. mollis ssp. mollis. The unit receives tidal inundations irregularly (not daily) (NWI 2005) from Hill Slough and a flood control channel along the western unit boundary.

Unit 3: Point Pinole Shoreline (Contra Costa County): Unit 3 consists of approximately 22 ac (9 ha) located along the Contra Costa shoreline in San Pablo Bay just east of Point Pinole. This unit consists of 13 ac (5 ha) of County-owned land (Point Pinole Regional Shoreline Park), which is managed by the East Bay Regional Park District, and 9 ac (4 ha) of Stateowned land. Cordylanthus mollis ssp. mollis occupied the unit at the time of listing as identified in the final listing rule (62 FR 61916; November 20, 1997) and contains the features essential to the conservation of C. mollis ssp. mollis. The unit receives tidal inundations on a regular basis (NWI 2005) from natural and artificial (dredged) tidal channels within the unit. Additional special management considerations or protections beyond those discussed above may be required to minimize the impact of industrial or commercial encroachment from the south that could increase stormwater and wastewater runoff into the unit.

Unit 4: Rush Ranch/Grizzly Island Wildlife Area (Solano County): Unit 4 for Cordylanthus mollis ssp. mollis consists of approximately 1,181 ac (477 ha) located adjacent to Suisun Slough to the west, Cutoff and Montezuma Sloughs to the south, and Potrero Hills to the North. This unit consists of 231 ac (93 ha) of State-owned land (Joice Island portion of the Grizzly Island Wildlife Area), which is managed by the CDFG, and 950 ac (384 ha) of land owned and managed by the Solano Land Trust (local non-profit public land trust). Cordylanthus mollis ssp. mollis occupied the unit at the time of listing as identified in the final listing rule (62 FR 61916; November 20, 1997) and contains the features essential to the conservation of C. mollis ssp. mollis. The unit receives tidal inundations regularly (at least once daily) (NWI 2005) from the above-mentioned tidal sloughs).

Unit 5: Southampton Marsh (Solano County): Unit 5 consists of approximately 164 ac (66 ha) of State-owned land managed by the California Department of Parks and Recreation (CDPR) as a wetland natural preserve (CDPR 1991, p. 44). The unit is located in the Benicia State Recreational Area along Interstate Highway 780 and just northwest of the City of Benicia. Cordylanthus mollis ssp. mollis occupied the unit at the time of listing as identified in the final listing rule (62 FR 61916; November 20, 1997) and contains the features essential to the conservation of C. mollis ssp. mollis. The unit receives tidal inundations on a regular-to-irregular basis (NWI 2005) from natural and artificial (dredged) tidal channels within the unit. Additional special management considerations or protection of the PCEs beyond those discussed above may be required to minimize the impact of residential encroachment from the north that could increase stormwater and wastewater runoff into the unit.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Cordylanthus mollis ssp. mollis critical habitat consists of three components (72 FR 18518-18553):

(i) Persistent emergent, intertidal, estuarine wetland at or above the mean high-water line (as extended directly across any intersecting channels);

(ii) Open channels that periodically contain moving water with oceanderived salts in excess of 0.5 percent; and

(iii) Gaps in surrounding vegetation to allow for seed germination and growth.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the areas determined to be occupied at the time of listing and that contain the PCEs may require special management considerations or protection. Most of the PCEs and the known occurrences of Cirsium hydrophilum var. hydrophilum and Cordylanthus mollis ssp. mollis are threatened by: (1) tidal wetland conversions to diked, managed, or muted tidal marshes; (2) changes to channel water salinity and tidal regimes; (3) mosquito abatement activities; (4) marsh invasions by nonnative plants; (5) plant-eating insects; (6) urban, industrial, and agricultural encroachment; (7) impacts from livestock overgrazing; (8) feral pigs (Sus scrofa); and (9) impacts from unauthorized foot and off-road vehicle traffic. These combined threats result in the loss and fragmentation of suitable habitat for C. hydrophilum var. hydrophilum and C. mollis ssp. mollis, which could significantly affect their long-term survival. Individually, these threats may require special management considerations or protection as addressed under the critical habitat unit descriptions below.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (NatureServe, 2015)

**Lifespan**

Adult: 1 year (USFWS, 2009)

**Breeding Season**

Adult: July to September (NatureServe, 2015)

**Reproduction Narrative**

Adult: Cordylanthus mollis ssp. mollis is a hemiparasitic annual herb in the Orobanchaceae (broomrape) family with flowers that bloom from July to September. The number of seeds produced per plant ranged from 91 to 790, depending on year and microhabitat (Futrell in litt. 2013). C. mollis ssp. mollis can hybridize with C. mollis ssp. hispidus indicating sexual reproduction (USFWS, 2009; USFWS, 2013)

**Habitat Type**

Adult: Estuarine (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Tidal flat/shore (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Prefers higher soil salinity and hydroperiods (USFWS, 2013)

**Geographic or Habitat Restraints or Barriers**

Adult: Found in high marsh near limits of tidal action (USFWS, 2009)

**Spatial Arrangements of the Population**

Adult: Colonies (USFWS, 2013)

**Environmental Specificity**

Adult: Very Narrow (inferred from USFWS, 2009)

**Dependency on Other Individuals or Species for Habitat**

Adult: As a hemiparasitic plant, seedling survival in Cordylanthus mollis ssp. mollis is critically dependent on establishing an early connection with a suitable host plant. (USFWS, 2009)

**Habitat Narrative**

Adult: Cordylanthus mollis ssp. mollis is found predominantly in the high marsh (upper reaches) of salt grass-pickleweed marshes at or near the limits of tidal action (Stromberg and Villasenor

1986) and is associated with Salicornia virginica (pickleweed), Distichlis spicata (salt grass), Jaumea carnosa (fleshy jaumea), Frankenia salina (alkali heath), and Troglochin maritima (arrow-grass) (Stromberg and Villasenor 1986). Seedling survival in Cordylanthus mollis ssp. mollis is critically dependent on establishing a connection with a suitable host plant. Typical host plants include Distichlis spicata (salt grass) and Salicornia virginica (pickleweed) (Grewell et. al. 2003, Grewell 2004). Most known Cordylanthus mollis ssp. mollis occurrences are found in regularly flooded and permanently saturated habitats within mixed halophytic plant communities, that is, communities where plants are adapted to live and reproduce in salt or brackish water (NWI 2005) with extended tidal hydroperiods and somewhat higher soil salinity (Grewell 2004). (USFWS, 2009; USFWS, 2013)

***Dispersal/Migration***

**Dispersal**

Adult: Moderate (USFWS, 2009)

**Dispersal/Migration Narrative**

Adult: Seeds may disperse short distances from parent plants by tidal inundations or animals (Grewell et al. 2003), but successful long-distance dispersal by these or other means has not been documented. Repeated surveys indicate that most dispersal occurs over short distances (Ruygt 1994) on the order of 10 meters [11 yds] or less (Grewell et al. 2003). (USFWS, 2009)

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

11 (USFWS, 2009)

**Population Narrative:**

Although no recent comprehensive status surveys have been conducted, the latest information indicates that 11 extant populations of Cordylanthus mollis ssp. mollis are currently distributed within 50 percent of the historical range and that a large percentage of the remaining plants are in Solano County (Grewell et. al. 2003). In the final listing rule, it was reported that the number of individuals within the populations varied from 1 to 150,000 plants and that most sites varied between 1,000 and 6,000 plants (CNDDB 1996). (USFWS, 2009)

***Threats and Stressors***

**Stressor:** Altered tidal regimes (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since listing, continuation of altered tidal regimes still occurs in much of the potential habitat and represents both the most significant historical and current threat to Cordylanthus mollis ssp. mollis and its habitat. With respect to effects to C. mollis ssp. mollis, alteration of tidal regime includes muting of tidal flows, increases in freshwater runoff, or decreases in freshwater

inflows such as diversion of freshwater for agricultural and municipal uses, that increase salinity. (USFWS, 2009)

**Stressor:** Habitat loss (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Cordylanthus mollis ssp. mollis habitat in the San Francisco estuary has dwindled over the last 200 years, San Pablo Bay and Suisun Bay having experienced 70 and 79 percent reductions in tidal marsh, respectively (Goals Project 1999). Historically, a large portion of tidal marshes in San Pablo Bay were diked and managed for agricultural production and livestock grazing (discussed further under Factor E), whereas, in Suisun Bay, most historical tidal marshes were diked and managed for waterfowl, though cattle grazing also occurred. These historical reductions of habitat have affected the extent and composition of tidal marsh communities. As a result, many native halophytic (salt-tolerant) plants are exceedingly rare in tidal marshes within the estuary (Goals Project 1999). (USFWS, 2009)

**Stressor:** Muting tidal flows (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Some Cordylanthus mollis ssp. mollis occurrences exist in muted tidal marshes around the perimeter of high tidal areas near Hill Slough and Fagan Slough marshes, where they were once completely diked and managed. The occurrences of C. mollis ssp. mollis populations in muted marshes, though, may likely be a result of dormant seed banks and associated marsh conditions that still promote their establishment. These populations face the risk of extirpation if the levee fails or is unmaintained in the future. Also, future land use and management activities that further mute tidal flows in these marshes may rapidly alter marsh conditions to further restrict or exclude the subspecies from the local plant community (Goals Project 1999). Muting of tidal flows is known to have extirpated Cordylanthus mollis ssp. mollis in at least one instance. Mitigation for the expansion of the Potrero Hills Landfill, initiated in 2002, involved extending tidal flows into a mitigation area to support vernal pool species, thereby reducing, and in some cases eliminating, tidal flows from the Hill Slough area which supported C. mollis ssp. mollis. Continuous hydrologic recorders in place at the site since 2001 to support local restoration research documented the change in hydrology that resulted in negative impacts to C. mollis ssp. mollis. (USFWS, 2009)

**Stressor:** Freshwater inflow (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Changes to freshwater inflow have also modified the habitat for this species. For example, at BSRA, increased freshwater runoff from nearby urban development has replaced halophytic communities (including species such as Salicornia virginica (pickleweed) with freshwater emergent marsh communities not appropriate as host plants (Grewell, pers comm. 2007). (USFWS, 2009)

**Stressor:** Agriculture and municipal uses (USFWS, 2009)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Agricultural and municipal uses have diverted much historical annual inflow of freshwater from the Suisun Marsh and Delta, creating a more saline environment. In addition, artificially variable soil salinities may threaten Cordylanthus mollis ssp. mollis by reducing the distribution and abundance of its host plants. (USFWS, 2009)

**Stressor:** Sea level rise (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Sea level rise, such as that potentially associated with global climate change, and anticipated associated flood control responses, though not discussed in the listing rule, may impose significant long-term threats to conservation of Cordylanthus mollis ssp. mollis. Conservation of high marsh zones in the face of sea level rise requires landward migration of the marsh profile on broad, sloping plains (Field et al. 1999, Baye 2006). Many alluvial terraces and valleys adjacent to the estuary are bordered by steep levees or are already converted to intensive agriculture, residential, or commercial development. In Suisun and northern San Pablo Bay, however, some undeveloped grazing land remains. Conflicting needs for flood protection, agriculture, and marsh transgression could effectively compress tidal marsh zones to a point at which they could cease to support C. mollis ssp. mollis habitat (Grewell 2006). Land use planning and economic pressures that favor conversion of “underdeveloped” grazing lands contribute to the loss of potential transgressive high marsh habitat for long-term viability of the species (Baye 2006). (USFWS, 2009)

**Stressor:** Mosquito abatement (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Mosquito abatement activities noted in the final listing rule continue to threaten Cordylanthus mollis ssp. mollis populations, though to a lesser degree than the above threats. Specifically, ditch cleaning and dredging along first order channels for mosquito abatement purposes alter the natural hydrology of the habitat and chemical spraying of vegetation threatens the species as well. Off-road vehicle traffic associated with mosquito control (discussed under Factor A) continues to threaten Cordylanthus mollis ssp. mollis populations in most known locations (Grewell 2005; CNDDB 2006). Foot traffic in Suisun Marsh at the time of listing was believed to contribute to habitat degradation via trampling. Foot traffic remains a threat today, specifically via excessive recreational and research access (Grewell, pers. comm. 2007). (USFWS, 2009)

**Stressor:** Seed predation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Intense seed predation by insects was reportedly observed at Joice Island and Hill Slough within the Suisun Marsh in Solano County (U.S. Fish and Wildlife Service 1997). Insect predation reportedly was responsible for decline in one of the largest populations of

Cordylanthus mollis ssp. mollis. Since the time of listing, much light has been shed on the specifics of C. mollis ssp. mollis seed predation which still poses a threat to populations in Suisun Marsh. Cordylanthus mollis ssp. mollis seed production can be significantly influenced by pre-dispersal seed predation from moth larvae (Saphenista spp., Tortricidae and salt marsh snout moth, Lipographis fenestrella, Pyralidae) (Ruygt 1994; Grewell et al. 2003). Areas with muted tidal regimes can support the subspecies (CDWR 1999), but increased tidal muting can constitute a threat to C. mollis ssp. mollis by increasing the prevalence of unsuitable host plants, and by changing the balance of seed production to seed predation maintained between the plant and seed-eating moths, such as various Saphenista species (Grewell 2004; Grewell 2006). The moth larvae burrow in the sediment during part of their life cycle, so reduced tidal flooding may improve their survivorship. Under full tidal regimes, the interaction between the rare Lepidopteran moth (Cordylanthus mollis specialist) and its rare plant host appears to be in balance (Grewell et al. 2003;Grewell 2004). (USFWS, 2009)

**Stressor:** Non-native plants (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Aside from the alteration of natural tidal cycles, the most significant threat to the species is that from invasion of non-native plants, especially winter annuals, which are inappropriate host plants. Since the time of listing, the threat posed by nonnative plant competitors and winter annuals as inappropriate host plants has become more defined. Lepidium latifoium (perennial pepperweed) and Spartina patens (salt-meadow cord grass) are two non-native species endangering native tidal marsh ecosystems in the range of Cordylanthus mollis ssp. mollis (Grewell 2005). Both plants are highly invasive, however L. latifolium is thought to be a more significant threat due to its proximity to C. mollis ssp. mollis occurrences, especially in Suisun Marsh. Lepidium latifolium is also of particular concern because it forms large monospecific patches that displace native marsh vegetation. L.C. Lee and Associates (2003) observed that one of the five most dominant associates of C. mollis ssp. mollis at Rush Ranch, based on canopy coverage in sample plots, was L. latifolium. Lepidium latifolium is a highly invasive non-native plant that forms monospecific stands that are very difficult to remove. Spartina patens also exists in the general vicinity of Cordylanthus mollis ssp. mollis habitat. It presents a more minor threat to C. mollis ssp. mollis because it is not known to exist along the high marsh edge. However, it does present a threat to the high marsh plant community in general in that the species displaces native habitat essential for a fully functioning ecosystem. (USFWS, 2009)

**Stressor:** Inappropriate hots plants (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** High levels of premature mortality were found to be correlated with the presence of non-native winter annual grasses in the immediate vicinity of C. mollis ssp. mollis seedlings (Grewell et al. 2003). Non-native winter annuals such as Hainardia cylindrica (bargrass) and Polypogon monspeliensis (annual rabbitsfoot grass) or native winter annuals such as Juncus bufonius (toad rush) are not suitable hosts since they typically die before C. mollis ssp. mollis can flower and produce seeds (Grewell et al. 2003, 2004). The prevalence of inappropriate plant hosts is correlated with muted tidal regimes (Grewell et al. 2003, 2004). (USFWS, 2009)

**Stressor:** Chronic pollution (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Oil spills and chronic pollution from point and non-point sources are unavoidable occurrences that continue to occur in or near habitat for Cordylanthus mollis ssp. mollis (U.S. Fish and Wildlife Service 2007). In particular, because of their location, Point Pinole and BSRA populations are the most threatened by oil spills and pollution (U.S. Fish and Wildlife Service 2006). (USFWS, 2009)

**Stressor:** Cattle grazing and feral hogs (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Cattle grazing still occurs and introduced feral hogs (Sus scrofa) roam Cordylanthus mollis ssp. mollis habitat in some locations (Grewell et al. 2003). Cattle and feral hogs can degrade habitat for the species by trampling and can also damage the plant itself by crushing fragile underground connections (haustoria) to host plants. These connections are critical to the hemiparasitic life history of C. mollis ssp. mollis. In fact, the Rush Ranch population described in the final listing rule was extirpated due to trampling by cattle around 1999 (Grewell, in litt. 2008). Populations at Hill Slough and Rush Ranch (the reintroduced population) are currently subject to rooting, wallowing, trampling, and grazing impacts from livestock and feral hogs that could result in damage or loss to C. mollis ssp. mollis populations or soil disturbance and compaction leading to a disruption in natural marsh ecosystem processes (U.S. Fish and Wildlife Service 2006). (USFWS, 2009)

**Stressor:** Random events (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since the time of listing, the distribution of the species within its range has not increased and the habitat of the species remains restricted due to fragmentation and historic conversion to other uses. The resulting small populations are still highly susceptible to extinction due to random natural and human-made events, such as pest outbreaks, extended drought, fire, oil spills, genetic or demographic problems or a combination of these events. (USFWS, 2009)

**Stressor:** Hybridization (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** No new information exists regarding the threat of hybridization with Cordylanthus mollis ssp. hispidus, so we must assume the threat is still present. Also, though a permitted reintroduction effort involving seed harvesting and planting has been conducted (Grewell et. al. 2003), no new information exists regarding the threat of unpermitted seed harvesting and planting. We must also assume this threat still persists. (USFWS, 2009)

***Recovery***

**Reclassification Criteria:**
1. The minimum area inhabited annually by the species in the Suisun Bay Area Recovery Unit must be 3,000 acres and the minimum area inhabited annually by the species around San Pablo Bay Recovery Unit must be 1,000 acres, over a period of five years. (USFWS, 2013)

2. A minimum of 5,000 acres of suitable habitat in the Suisun Bay Area and San Pablo Bay Recovery Units must be permanently preserved and under protective management. (USFWS, 2013)

3. Reduction in extant Lepidium latifolium populations in tidal areas (in and downgradient of the high marsh-upland ecotone) to less than ten percent cover for five years. (USFWS, 2013)

4. There must be less than ten percent total cover of other non-native, invasive perennial or non-native winter annual grass species (other than Lepidium latifolium), including, but not limited to, Apium graveolens (celery), Cotula coronipfolia (brass-buttons), Juncus gerardi (black-grass rush), Spartina patens (salt-meadow cordgrass), Polypogon monspeliensis (annual beard grass), Hainardia cylindrical (barbgrass), Parapholis incurva (sicklegrass), Crypsis schoenoides (swamp grass), and Lepidium latifolium within 50 feet of extant C. molle ssp. molle populations. (USFWS, 2013)

5. Natural tidal range must be restored at Hill Slough and the ponded area at Rush Ranch to return periodic tidal flooding. (USFWS, 2013)

6. At least nine populations must occur in the Suisun Bay Area Recovery Unit and at least four populations must occur around San Pablo Bay Recovery Unit. (USFWS, 2013)

7. Over five years of monitoring, each population must have a mean of at least 3,000 individuals. (USFWS, 2013)

8. The entire species must not fall below 500 individuals for two consecutive years over a period of five years. (USFWS, 2013)

9. There must be an average of more than 10 seed capsules produced per plant, resulting in an average of more than 15 mature seeds per plant. (USFWS, 2013)

Recovery Priority Number: 9C

**Delisting Criteria:**
1. The minimum area inhabited annually by the species in the Suisun Bay Area Recovery Unit must be 6,000 acres and the minimum area inhabited annually by the species around San Pablo Bay Recovery Unit must be 2,500 acres over a period of eight years. (USFWS, 2013)

2. A minimum of 9,000 acres in the Suisun Bay Area Recovery Unit or around San Pablo Bay Recovery Unit must be permanently preserved and under protective management. (USFWS, 2013)

3. All conditions under downlisting criterion A/3 have been met. In addition, a plan must be developed and implemented for early detection and control of Lepidium latifolium following any future increase beyond ten percent cover in tidal areas (in and down-gradient of the high marsh-upland ecotone). Also, a funding source must be secured to fund such actions in perpetuity. (USFWS, 2013)

4. All conditions under downlisting criterion number 4 must have been met. (USFWS, 2013)

5. All conditions under downlisting criterion number 5 must have been met. (USFWS, 2013)

6. Trampling damage by grazed cattle and feral pigs to C. molle ssp. molle and its haustorial connections to host plants must have been eliminated at all populations for eight years. (USFWS, 2013)

7. Reliable propagation and reintroduction methods must be developed and available. (USFWS, 2013)

8. Pre-dispersal seed predation on C. molle ssp. molle from moth larvae (Saphenista spp., Tortricidae and salt marsh snout moth, Lipographis fenestrella, Pyralidae) must, on average, fall below 15 percent. (USFWS, 2013)

9. At least ten separate populations must occur in the Suisun Bay Area Recovery Unit and at least eight separate populations must occur around San Pablo Bay Recovery Unit. (USFWS, 2013)

10. Over eight years of monitoring, each population must have a mean of at least 3,000 individuals; or if the species is widespread and abundant and is not divisible into separate populations, there must be a mean of at least 300,000 individuals in the Suisun Bay Area Recovery Unit and at least 300,000 individuals around San Pablo Bay Recovery Unit over a period of eight years. (USFWS, 2013)

11. The entire species must not fall below 1,000 individuals for two consecutive years over a period of eight years. (USFWS, 2013)

12. There must be an average of more than 10 seed capsules produced per plant, resulting in an average of more than 15 mature seeds per plant. (USFWS, 2013)

13. Seed banking of all extant populations and representative genetic diversity (per commonly accepted seed banking protocols) must be complete. (USFWS, 2013)

14. To minimize impacts sustained after oil spills occurring at or near populations, the San Francisco Bay and Delta Area section of the Sector San Francisco-Area Contingency Plan must be revised to place high priority on the emergency protection of C. molle ssp. molle. (USFWS, 2013)

15. High marsh/upland transition lands must be preserved or created as part of new marsh restoration efforts and managed to provide opportunity for landward migration of species in response to sea level rise. (USFWS, 2013)

**Recovery Actions:**

- Non-native plant control should target Lepidium latifolium at Hill Slough, Rush Ranch, BSRA, and other population locations. (USFWS, 2013)
- Adaptive management for and monitoring of ground-nesting and other native bees, particularly near C. molle ssp. molle populations, is needed. Protection of predatory wasps that feed on moth larvae infesting C. molle ssp. molle inflorescences should reduce losses of reproductive output to seed-eaters. (USFWS, 2013)
- Management of grazing should aim to reduce trampling and breaking of haustorial connections to host plants due to disturbance. (USFWS, 2013)
- Controls should be erected and maintained to prevent illicit off-road vehicle use in habitat of C. molle ssp. molle. (USFWS, 2013)
- Where urban runoff has displaced former tidal marsh habitat at BSRA with freshwater emergent marsh, solutions should be identified to direct the runoff away from sensitive habitat. (USFWS, 2013)
- Natural tidal range should be maintained or restored, since their resulting effects on vegetation and soil chemistry are important to the persistence of C. molle ssp. molle. (USFWS, 2013)
- Seed banking is recommended for C. molle ssp. molle, including banking from different population areas. (USFWS, 2013)
- In addition to monitoring needed for appropriate management and tracking of progress toward recovery, it is recommended that field surveys be conducted for additional, as-yet undiscovered populations of C. molle ssp. molle. (USFWS, 2013)
- Given the importance of a host plant community comprised of a matrix of native perennials, information on host plants within C. molle ssp. molle population patches should also be gathered. (USFWS, 2013)
- Research is needed on many aspects of life history and conservation of C. molle ssp. molle. (USFWS, 2013)
- Over the longer term, restoration of suitable tidal marsh habitat and introduction/ reintroduction of C. molle ssp. molle within its historic range will advance recovery of the species. (USFWS, 2013)
- A recovery plan for Cordylanthus mollis ssp. mollis should be developed which describes recovery strategies and specific tasks necessary for recovery of the species. A draft recovery plan for this species and five other listed tidal marsh species is currently in development at SFWO. (USFWS, 2009)
- Control of non-native competitor species and non-native winter annual species should be conducted at all appropriate sites. Lepidium latifolium should be targeted at Hill Slough Wildlife Area, Rush Ranch, BSRA, and other population locations where it presents a threat and Spartina patens (salt-meadow cord grass) should be targeted at BSRA. Nonnative winter annuals that invade upper tidal marsh habitats at the known locations should be controlled to increase survival of Cordylanthus mollis ssp. mollis seedlings (Grewell et al. 2003). Initially, surveys for these invasive plants should occur at each site in order to document the extent of spread and prioritize treatment efforts. (USFWS, 2009)
- Natural tidal cycles of San Pablo and Suisun Bays should be maintained or restored to the extent possible because middle to high marsh areas with periodic tidal flooding provide appropriate hydrology and help retain the healthy extent and composition of tidal marsh communities, including Cordylanthus mollis ssp. mollis. Additionally, natural tidal regimes encourage low abundance of damaging non-native winter annuals and seed predators. (USFWS, 2009)

- Surveys should be conducted within potential Cordylanthus mollis ssp. mollis habitat as well as at known population centers to identify potential new occurrences as well as to provide an updated species status with which to make management decisions. (USFWS, 2009)
- Management of Cordylanthus mollis ssp. mollis habitat should involve reducing trampling and breaking of haustorial connections to host plants by grazed cattle and feral hogs. Removal of cattle and feral hogs or other protection of the populations from grazing should occur at Hill Slough and Rush Ranch populations, as well as other locations where trampling presents a threat to C. mollis ssp. mollis. A regional-scale feral hog eradication effort should be coordinated with CDFG to decrease that species' impact on habitat for sensitive plants. (USFWS, 2009)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The following recommendations for future actions are based on the Service's Recovery Plan (2013) and incorporation of recent research and findings, such as the USGS' 2021 range wide survey and genomics study in Chloropyron molle ssp. molle. Surveying and Monitoring: • Recovery Actions A/1, A/2. Develop and implement an annual, range wide survey and monitoring plan for Chloropyron molle ssp. molle. As population sizes of C. molle ssp. molle can fluctuate dramatically between years, surveys that attempt near-exact counts rather than abundance estimates of populations should be the primary focus. Special attention should be given to acquire exact counts, annually, of the populations at regularly inhabited sites. Surveys should also include: the number and location of populations; estimates of area inhabited by each population. • Recovery Actions A/3, A/4. Work with partners to develop and implement a survey and monitoring plan for invasive species in areas inhabited by Chloropyron molle ssp. molle. Surveys should be focused on populations of Chloropyron molle ssp. molle and areas within 50 ft. of each population and they should be conducted based on the development and phenology of the identified invasive plants. These surveys should include: the location of the areas surveyed; survey frequency; invasive plants of interest at each site; abundance estimates of invasive plants found; and proximity to nearest population of C. molle ssp. molle. Known invasive plant threats currently include but might not be limited to: Lepidium latifolium, Hainardia cylindrica, Polypogon mospeliensis, Cotula coronopifolia. Cuscuta salina is native to the Bay-Delta, however, it should be included in such surveys based on the predicted inappropriate plant-host relationship it can form with C. molle ssp. molle. Survey follow-up and monitoring records should include information on historical, ongoing, and/or planned invasive mitigation and eradication techniques in collaboration with partners. • Recovery Action A/6. Develop and implement a survey and monitoring plan to focus on trampling and rooting damage by livestock and feral pigs to Chloropyron molle ssp. molle populations. This plan should cover how to monitor damage, the partners and groups responsible for organizing and conducting surveys and monitoring, the locations to be surveyed and monitored, and the frequency at which surveys/monitoring are needed. Restoration Activities: • Recovery Action A5. Develop a plan to restore tidal marsh, including restoration of periodic tidal flooding at Hill Slough and Rush Ranch pond areas. Complete the actions that are achievable within 5 years. Follow-up with a monitoring plan of tidal flooding at Hill Slough and Rush Ranch pond areas. • Recovery Action A/7. Renew efforts and advance methods for propagation, including a plan to scale-up propagation, of C. molle ssp. molle to be used in restoration and reintroduction / mitigation efforts. • Recovery Actions E/1d, E2. Develop and implement a seed banking plan for C. molle ssp. molle including development of seed storage protocol with estimates of storage effects on seed viability/longevity. Seed collection and banking efforts should be developed based in-part on current knowledge of the range wide distribution of genetic diversity. • Develop a plan to reintroduce 1-2 populations of C. molle ssp. molle that might serve as connector populations to promote gene flow between Fagan Marsh and Point Pinole populations in the west and all other populations of C molle ssp. molle in the eastern portion of the range. This plan should incorporate information from the USGS' 2021 range wide survey of sites with potentially suitable habitat, as well as in-depth surveys of all existing public lands in the area for currently unknown sites of potentially suitable habitat. Source material for reintroductions should also rely on genotypic information and diversity estimates from the 2021 USGS study. Additional Future Actions for Consideration: • Genetic monitoring of populations, particularly those that appear to be at-risk of intraspecific hybridization with Chloropyron molle ssp. hispidum, and the western-most isolated populations at Fagan Marsh and Point Pinole that appear to be experiencing restricted gene flow. • Breeding trials between Chloropyron molle ssp. molle and C. molle ssp. hispidum to determine what level of threat intraspecific hybridization poses in the northeastern portion of C. molle ssp. molle's range. • Investigation(s) into seed ecology of C. molle ssp. molle to support seed banking efforts and to inform on the potential use of direct-seeding in restorations. • Investigation(s) into plant-pollinator relationships to inform on reproductive biology of C. molle ssp. molle and to aid in making predictions regarding current and future gene flow across the species range. • Quantitative genetics studies to estimate species' phenotypic plasticity (i.e., the capacity to respond to changing environmental conditions) especially to variation in hydrological factors. • Studies focused on the C. molle ssp. molle's plant-host relationships to better determine potential risk from inappropriate host relationships. • Conduct public outreach and education to develop potential partnerships with private landowners with property where C. molle ssp. molle might be present (USFWS, 2023).

# SPECIES ACCOUNT: *Cordylanthus palmatus* (Palmate-bracted bird's beak)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 07/01/1986; California/Nevada (Region 8) (USFWS, 2015)

**Physical Description**

An annual herb in the broomrape family (Orobanchaceae) (Olmstead et al. 2001). The plants are 4-12 inches tall and highly branched. The stems and leaves are grayish green and sometimes are covered with salt crystals excreted by glandular hairs. Small pale whitish flowers, up to 1-inch long, are arranged in dense clusters (spikes) and are densely surrounded by herbaceous leaf-like bracts. The petals are divided into two lips. The upper one is shaped like a bird's-beak, leading to the common name of the genus. (USFWS, 2009)

**Taxonomy**

Tank et al. (2009) moved four species of Cordylanthus (maritimus, mollis, palmatus, and tecopensis) to Chloropyron. (NatureServe, 2015)

**Historical Range**

Historically, the species is known from scattered locations in the Sacramento and San Joaquin Valleys (Bittman 1985, 1986; Center for Conservation Biology 1991, 1992, 1993, 1994) (USFWS, 2009)

**Current Range**

The species ranges from the northern Sacramento Valley south to the San Joaquin Valley. (USFWS, 2009)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: 1 year (USFWS, 2009)

**Dependency on Other Individuals or Species**

Adult: Bumblebees (Bombus californicus, B. occidentalis, and B. vosnesenskii) were the primary pollinators of palmate-bracted bird’s-beak at the Springtown Alkali Sink in 1993. (USFWS, 1998)

**Breeding Season**

Adult: May to October (USFWS, 1998

**Key Resources Needed for Breeding**

Adult: Seasonal overland flooding may disperse seeds and promote seed germination by diluting the saline soils (Coats et al. 1993).

**Reproduction Narrative**

Adult: Palmate-bracted bird's-beak is an annual herb in the broomrape family (Orobanchaceae) (Olmstead et al. 2001). This species flowers from May until October (Skinner and Pavlik 1994). Both self- and cross-pollination can contribute to seed-set (Center for Conservation Biology 1993j, and individual plants can produce up to 1.000 seeds in a single growing season (Center for Conservation Biology 1991). Seasonal overland flooding may disperse seeds and promote seed germination by diluting the saline soils (Coats et al. 1993). Bumblebees (Bombus californicus, B. occidentalis, and B. vosnesenskii) were the primary pollinators of palmate-bracted bird's-beak at the Springtown Alkali Sink in 1993. (USFWS, 1998; USFWS, 2009)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Grassland/herbaceous, Shrubland/chaparral (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Seasonal flooding (USFWS, 1998)

**Geographic or Habitat Restraints or Barriers**

Adult: Restricted to elevations of less than 155 m (500 feet) (USFWS, 1998)

**Spatial Arrangements of the Population**

Adult: Small and isolated patches (USFWS, 2009)

**Environmental Specificity**

Adult: Very Narrow (USFWS, 2009)

**Habitat Narrative**

Adult: Palmate-bracted bird's-beak is restricted to seasonally-flooded, saline-alkali soils in lowland plains and basins at elevations of less than 155 meters (500 feet). It occurs in a mosaic pattern of small and isolated patches. Within these areas, palmate-bracted bird's-beak grows primarily along the edges of channels and drainages, with a few individuals scattered in seasonally-wet depressions, alkali scalds (barren areas with a surface crust of salts), and grassy areas. Suitability of microhabitats for palmate—bracted bird's beak depends primarily on soiI pH and to a lesser extent on soil layering, salinity, and moisture. This species occurs on neutral to alkaline soils pH 7.2 to 9.5) under natural conditions (Coats et al. 1993, Center for Conservation Biology 1993, 1994). (USFWS, 1998; USFWS, 2009)

***Dispersal/Migration***

**Dispersal**

Adult: Moderate (inferred from USFWS, 2009)

**Dispersal/Migration Narrative**

Adult: The pattern of genetic variation within palmate-bracted bird's-beak populations support the hypothesis that the historical frequency and extent of seed dispersal by overland flooding has influenced population genetic structure. In brief: (1) sites that are more-frequently flooded or that have more extensive floods (leading to enhanced seed dispersal). (USFWS, 2009)

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2009)

**Number of Populations:**

7 (USFWS, 2023)

**Additional Population-level Information:**

Historically, palmate-bracted bird's-beak was documented at nine sites between 1916 and 1982 (in Alameda, Colusa, Fresno, Madera, San Joaquin, and Yolo Counties), but only three were known to be extant at the time the species was listed in 1986: two natural populations (Springtown Alkali Sink and southeast of Woodland, which is now known as Alkali Grasslands Preserve) and one transplanted population (Mendota Wildlife Area) (Service 1986, p. 23767). As of our 2009 status review, the species was known to occurr as a mosaic of small, isolated patches on approximately 1,500 acres of occupied habitat at eight sites ranging from the northern Sacramento Valley south to the San Joaquin Valley (Sacramento, Colusa, and Delevan National Wildlife Refuges (collectively referred to as the Refuges); Alkali Grasslands Preserve; Springtown Alkali Sink; Western Madera County; Alkali Sink Ecological Reserve; and Mendota Wildlife Area) (Service 2009, p. 20). The Sacramento Refuge population was introduced in 1990 (Service 1998, p. 35); additional sites were located through intensive survey efforts. There have been few changes in the distribution of palmate-bracted bird's-beak since our 2009 status review. The population in Western Madera County is likely extirpated based on recent vernal pool mapping showing that the four occurrences were disked and later converted to agriculture (Witham 2021, unpaginated geodatabase). In addition, no new information is available for the Mendota Wildlife Area population, which may have been extirpated by changing conditions prior to the 2009 status review (USFWS, 2023).

**Population Narrative:**

The palmate-bracted bird's-beak has declined significantly over the past century. Several palmate-bracted bird's-beak species experts have suggested that (a) except, perhaps, for Sacramento National Wildlife Refuge Complex there are fewer palmate-bracted bird's-beak today than when the species was originally listed and (b) population trends are down. Of the eight known occurrences (up to 10 populations reported historically), five are located on public lands and are protected from development. The constrained dispersal abilities of C. palmatus can limit its ability to withstand changes in climate. (USFWS, 2009)

***Threats and Stressors***

**Stressor:** Urban sprawl (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Urban sprawl and associated human activities have also been identified as the leading cause of species imperilment – including the palmate bracted bird's-beak -- in the State (National Wildlife Federation 2001). Sprawl (low density, automobile dependent development into natural areas outside of cities and towns) results in habitat loss, habitat degradation (including the disruption of natural processes, wildfire suppression, noise pollution, and high-impact outdoor recreation), habitat fragmentation (including blocking wildlife movement and edge effect), and loss of species diversity (including an increase in exotic species and changing ecosystem dynamics). (USFWS, 2009)

**Stressor:** Habitat loss (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** These widespread and ongoing threats include: the conversion of native habitat into irrigated agricultural fields (e.g., palmate-bracted bird's-beak sites at Woodland, Sacramento Valley, San Joaquin Valley); installation of pipelines and transmissions lines (Woodland); drainage facilities (Springtown residential development); gas and water pipelines (Springtown); and off-road vehicle use (Springtown). (USFWS, 2009)

**Stressor:** Cattle grazing (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, cattle grazing was identified as a major factor (Service 1986:23767). Cattle grazing has undoubtedly altered the plant species composition of the areas occupied by the palmate-bracted bird's-beak, but the specific effects and mechanisms were not indicated. Existing grazing levels, at that time, did not appear to threaten those areas still supporting the palmate-bracted bird's-beak. Cattle grazing as a management tool, it now appears, can be beneficial as well as harmful to the palmate-bracted bird's-beak. Grazing can enhance the conservation status of the palmate-bracted bird's-beak through the removal of invasive non-native plants that compete with the palmate-bracted bird's-beak for resources or displace host plants (Wingo-Tussing et al., 2005; Wingo-Tussing 2006). (USFWS, 2009)

**Stressor:** Invasive non-native plants (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasive non-native plant species are a potential threat to palmate-bracted bird's-beak and associated native host plants at Colusa NWR and Delevan NWR (Wight 2000; Wingo-Tussing et al. 2005; WingoTussing 2006). Populations of the annual ryegrass (Lolium multiflorum), tall wheatgrass (Elytrigia pontica ssp. pontica), broad-leaved pepperweed (Lepidium latifolium), and fleshy-leaved Russian-thistle (Salsola soda) have been increasing in habitat occupied by palmate-bracted bird's-beak, and associated (host) plants such as Great Valley gum plant (Grindelia camporum var. camporum), pappose spikeweed (Hemizonia parryi spp. rudis), alkali heath (Frankenia salina), and saltgrass (Distichlis spicata; host plant). These plants compete with the palmate bracted bird's-beak for resources (e.g., space, water, and nutrients) and can displace host plants. (USFWS, 2009)

**Stressor:** Accidental flooding (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Accidental flooding of palmate-bracted bird's-beak during the dry period (June to September) from rice field run-off has also impacted one palmate bracted bird's beak patch at Colusa NWR (J. Silveira, in litt., 2006). Extensive and unseasonal flooding can kill palmate-bracted bird's-beak plants, as well as allow other plants to invade after the waters recede. Deep flooding that persists over several weeks can kill individual plants. (USFWS, 2009)

**Stressor:** Decline of pollinators (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Another widespread threat to palmate-bracted bird's-beak is the loss of pollinators through the spraying of malathion and other pesticides. Bees are important pollinators of the palmate-bracted bird's-beak in California (SaulGershenz et al., 2004). Malathion application to bees and the vegetation where they occur may be a specific threat to the genetic diversity of palmate-bracted bird's-beak by reducing pollination. The effects of malathion application are extremely local given that bees typically range only about 300-400 meters (about 980-1300 feet) from the nest to a flower (Kroodsma 1975; Keasar et al., 1996; Capaldi et al., 2000; Kwak 2002). (USFWS, 2009)

**Stressor:** Pesticides (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Sacramento/Yolo Mosquito Vector Control District (Undated) also has an ongoing program to control the West Nile virus through the aerial application of pyrethroids and other insecticides that may affect palmate-bracted bird's-beak pollinators. It is not clear if sites with palmate-bracted bird's-beak are being sprayed or if palmate-bracted bird's-beak pollinators are being affected.

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Due to the highly restricted range of palmate-bracted bird's beak, climate change in the Central Valley could have a particularly negative effect on the species. As stated previously, the palmate-bracted bird's-beak is restricted to the Sacramento Valley and the San Joaquin Valley under a unique set of geographic (flat) and climatic (hot and dry) conditions (Figures 1-3). The range of palmate-bracted bird's-beak is restricted by soil type (alkaline-saline). Some climate change models predict for California an overall warming of 1.7 degrees Centigrade – 5.8 degrees by 2100 (Cayan et al. 2006), but they vary in their predictions for precipitation. VanRheenen et al. (2004) predict a decrease in precipitation in the San Joaquin Valley. Changes in annual precipitation have a large effect on the abundance of palmate-bracted bird's-beak, as typical of desert annuals (Germano et al. 2005; Warrick 2006). (USFWS, 2009)

**Stressor:** Ozone (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Another potential threat to palmate-bracted bird's-beak is ozone due to photochemical smog. Numerous studies have documented the negative effects of ozone on plants, such as pronounced foliar injury and growth reduction (e.g., Miller 1992; Grantz and Yang 1996; Bytnerowicz 2002), but no studies have been performed specifically on palmate-bracted bird's-beak. The California Air Resources Board (2006) reported for southern portions of the San Joaquin Valley as many as 26 days per year above the national 1-hour ozone standard and as many as 116 days per year above the national 8-hour ozone standard during the period 2002 - 2005. (USFWS, 2009)

**Stressor:** Excessive dust (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** An additional potential threat to the palmate-bracted bird's-beak is excessive dust. Dust may affect photosynthesis, respiration, and transpiration, as well as allow the penetration of phytotoxic gaseous pollutants (Farmer 1993). No research, however, has analyzed the effects of dust specifically on palmate-bracted bird's-beak. From 1996 – 2005, Bakersfield – in the southern portion of the San Joaquin Valley – on average surpassed the State of California 24-hour PM10 (particulate matter with an aerodynamic diameter of 10 microns or less) standard 170 days per year and surpassed the national 24-hour PM2.5 (particulate matter with an aerodynamic diameter of 2.5 microns or less) standard 16 days per year (California Air Resources Board 2006). In 2005, the primary sources of particulate matter (PM10 and PM2.5) in Kern County, for example, were farming operations, road dust, and fugitive windblown dust (California Air Resources Board 2006). (USFWS, 2009)

***Recovery***

**Reclassification Criteria:**
1. Protection of occupied habitat A) 95 percent of occupied habitat on public lands is secured and protected, and B) 75 percent or more of the population at Springtown Alkali Sink and 75 percent or more of the occupied area and upland habitat for pollinators within 300 meters (984 feet) of the population margins is secured and protected, and C) Two or more populations are secured and protected in the San Joaquin Valley. (USFWS, 2009)

2. A management plan that includes the survival of palmate-bracted bird's-beak as an objective has been approved and implemented for all protected areas identified as important to continued survival. (USFWS, 2009)

3. The populations are stable or increasing through a precipitation cycle. (USFWS, 2009)

**Delisting Criteria:**
1. Eight or more distinct populations, including two or more in the San Joaquin Valley are secured and protected. (USFWS, 2009)

2. 95 percent or more of the occupied habitat [under Service ownership] of Colusa National Wildlife Refuge, Delevan National Wildlife Refuge, and Sacramento National Wildlife Refuge is secured and protected. (USFWS, 2009)

3. 95 percent or more of the occupied habitat [under CDFG ownership] of the Alkali Sink Ecological Reserve-Mendota Wildlife Area (San Joaquin Valley) is secured and protected. (USFWS, 2009)

4. 260 hectares (640 acres) or more of any occupied habitat [under any ownership] elsewhere in the San Joaquin Valley, including western Madera County, is secured and protected. (USFWS, 2009)

5. 90 percent or more of the plants and occupied habitat [under ownership by City of Livermore, Federal Communications Commission, or private] of the Springtown Alkali Sink is secured and protected. (USFWS, 2009)

6. Two or more distinct populations each about 260 hectares (640 acres) [under any ownership] in the Sacramento Valley are protected. (USFWS, 2009)

7. A management plan has been approved and implemented for all protected areas identified as important to the continued survival of the species. (USFWS, 2009)

8. There is no decline after downlisting.  If the population is declining, then the Service should determine the cause and reverse the trend. (USFWS, 2009)

**Recovery Actions:**
- Recovery actions are not available.
- Protection of palmate-bracted bird’s-beak habitat on private lands. One of the most important goals for the conservation of this species is the protection of occupied palmate-bracted bird’s-beak habitat primarily at three sites. (USFWS, 2009)
- General and applied ecological research of palmate-bracted bird’s-beak. Little is known about the basic biology of this species or how it responds to management practices (C. Feldheim, in litt., 2007). (USFWS, 2009)
- Over the next 5 years, genetic variation at the remaining sites should be characterized and synthesized with existing knowledge.  The genetic variation at all sites should then be compared leading to a ranking of sites to guide conservation efforts according to the nature and extent of differences, as well as the importance of rare or unique alleles.  A seed collection, based on the site rankings, should also be completed. (USFWS, 2009)
- Natural resource managers should consider the negative impacts of invasive nonnative species in order to enhance conservation and restoration programs for the palmate-bracted bird’s-beak. Controlled grazing (see Wingo-Tussing et al. 2005; Wingo-Tussing 2006) and controlled burns (see Wight 2000) may enhance the conservation status of the palmate-bracted bird’s-beak. (USFWS, 2009)
- The continued survival of the palmate-bracted bird’s-beak depends on many demographic factors.  The natural variation of these factors, though, is poorly understood (Fleishman et al., 1994, 1996).  An outline for future actions that incorporates demographic monitoring of the several populations and minimum levels of demographic parameters maintained should

be established. (USFWS, 2009)
- The scientific name should formally be changed in the Code of Federal Regulations from Cordylanthus palmatus to Chloropyron palmatum.

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations that will aid in the recovery and conservation of the palmate-bracted bird's-beak. Some of these recommendations have already been discussed in our previous status review (Service 2009, pp. 37–39) and remain valid. 1. Conduct surveys at known occurrences to monitor population trends and habitat changes, including occurrences that are likely extirpated in Madera County and Mendota Wildlife Area to confirm status. 2. Pursue protection of the Springtown Alkali Sink and Woodland Regional Park occurrences through conservation easements and map the net occupied area of these populations. 3. Review existing management plans and revise them to include an objective for survival of palmate-bracted bird's-beak if this objective is missing. 4. Determine the most effective methods for controlling invasive non-native species at sites where palmate-bracted bird's-beak occurs and ensure the results are shared with land managers. 5. Consider historical hydrologic connection within populations to maintain genetic variation when collecting and distributing seed. Genetic isolation of populations occurring in vernal pools in the same locality should be maintained. However, seed should be collected and distributed from throughout the population where historical overland flow has been impeded by manmade barriers. 6. Evaluate the need for additional re-introductions and the effectiveness of seeding methods currently employed at the Alkali Grasslands Preserve. 7. Change the scientific name in the Code of Federal Regulations from Cordylanthus palmatus to Chloropyron palmatum (USFWS, 2023).

# SPECIES ACCOUNT: *Cordylanthus tenuis ssp. capillaris* (Pennell's bird's-beak)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 03/06/1995; California/Nevada (Region 8)

**Physical Description**

A branching herbaceous annual of the broomrape family (Orobanchaceae). The plant grows 30 to 60 centimeters (12 to 24 inches) tall, with yellow-green hairless herbage that becomes purplish with age. The leaves are entire (with smooth edges), or those of the primary stem three-parted, and threadlike. The floral bracts are three-parted up to two-thirds of their length, with fine marginal hairs on bracts and calyx (collective term for the sepals or outermost whorl of flower parts). The tubular corolla (collective term for all the petals) is 1.5 centimeters (0.6 inch) long (Chuang and Heckard 1986), and gamet-brown laterally, paler dorsally (Pennell 1950). Each capsule contains 10 to 16 seeds (Chuang and Heckard 1986). (USFWS, 1998; USFWS, 2019b)

**Taxonomy**

Cordylanthus capillaris (Pennell’s bird’s-beak) was first described by Pennell (1950). Chuang and Heckard (1986) reclassified the Cordylanthus genus and considered Pennell’s bird’s-beak to be a subspecies: C. tenuis ssp. capillaris. At the time of listing, the genus was considered within the snapdragon family (Scrophulariaceae). Presently, the genus Cordylanthus is considered within the broomrape family (Orobanchaceae) (Olmstead et al. 2001). (USFWS, 2011)

**Historical Range**

Known only from the Outer North Coast Ranges floristic province of Sonoma County, California, a range of a few square miles (vicinity of unincorporated Camp Meeker area). (USFWS, 2019b)

**Current Range**

Known only from the Outer North Coast Ranges floristic province of Sonoma County, California, a range of a few square miles (vicinity of unincorporated Camp Meeker area). (USFWS, 2019b)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (self-incompatible) (USFWS, 2011)

**Lifespan**

Adult: 1 year (USFWS, 2011)

**Dependency on Other Individuals or Species**

Adult: Members of the Cordylanthus genus require bees for effective pollination (Chuang and Heckard 1986).

**Breeding Season**

Adult: June to July (USFWS, 2011)

**Reproduction Narrative**

Adult: Pennell's bird's-beak is an herbaceous annual of the broomrape family (Orobanchaceae) (Olmstead et al. 2001) and it flowers from June through July (Chuang and Heckard 1986). Members of the Cordylanthus genus require bees for effective pollination (Chuang and Heckard 1986). The fruit are capsules containing 10 to 16 seeds (Chuang and Heckard 1986). C. tenuis ssp. capillaris were found to be self-incompatible (Chuang and Heckard 1986). Members of the bird's-beak group require bees for effective pollination (Chuang and Heckard 1986). (USFWS, 2019b)

**Habitat Type**

Adult: Terrestrial (USFWS, 2011)

**Habitat Vegetation or Surface Water Classification**

Adult: Chaparral communities (USFWS, 2011)

**Geographic or Habitat Restraints or Barriers**

Adult: Restricted to elevations from 45 to 245 meters (148 to 804 feet) (USFWS, 2011)

**Spatial Arrangements of the Population**

Adult: Colonies (USFWS, 2011)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2011)

**Habitat Narrative**

Adult: Cordylanthus tenuis ssp. capillaris grows only on serpentine soils among chaparral and closed pine forests (Chuang and Heckard 1986) and are found in colonies. Occurrences range in elevation above mean sea level from 45 to 245 meters (148 to 804 feet) (Calflora 2011, CNPS 2011). Cordylanthus tenuis ssp. capillaris is associated with Sargent's cypress (Cupressus sargentii), Baker's manzanita, and coffeeberry (Rhamnus californica) (Chuang and Heckard 1986). (USFWS, 2011)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2019a)

**Number of Populations:**

4 (USFWS, 2024)

**Population Size:**

Unknown; fluctuates from well over 10,000 to a few individuals at each location (USFWS, 2024)

**Population Narrative:**

In 2011, Pennell’s bird’s-beak was recognized to occur in five separate locations (USFWS 2011). Currently, Pennell’s bird’s-beak is known from four locations (CNDDB 2018). California Natural Diversity Database lists occurrence #1 as mainly within the Harrison Grade Ecological Reserve, owned and managed by CDFW. The fifth occurrence is combined with occurrence #4. Two occurrences (#2 and #4) are within what is now the Bohemia Ecological Preserve. This property is protected under a conservation easement, which is owned and managed by Land Paths since 2012 (E. Mullen, pers. comm. 2018). Occurrence #3 is located on the privately owned Twin Valley Ranch near Porter Creek, about 11 kilometers (6.8 miles) northeast of occurrence #2. However, this site has not been surveyed in the past 20 years. While the status of this population remains unknown, it is assumed to be extant. Anecdotal reports suggest many Pennell’s bird’s-beak populations exist on private property outside of the before mentioned occurrences in areas where botanical surveys have not been done (G. Cooley, pers. comm. 2018). Biologists with CDFW have observed Pennell’s bird’s-beak on private properties outside of the reserve boundaries at the Harrison Grade Ecological Reserve (J. Bjerke, in litt. 2018b). The full extent of the population remains unknown. (USFWS, 2019a). At the time of listing in 1995, Pennell’s bird’s-beak was documented at two locations near one another (Service 1995, p. 6673): one on Bohemian Highway and the other partially within the Harrison Grade Ecological Reserve. Little has changed since our 2019 status review where the species was known from four locations (Service 2019a, p. 2). There are two occurrences within the Bohemia Ecological Preserve, which is still managed by LandPaths; one on Harrison Grade Ecological Reserve, owned and managed by the Department; and one assumed to be extant on privately owned lands near Porter Creek that has not been surveyed since it was identified in 1997 (Diversity Database, entire). In addition, there are some plants at the Regional Parks Botanic Garden located in Berkeley, California (California Plant Rescue 2023, entire). Seed was also collected in 2005 and is stored in Claremont, California (California Botanic Garden 2024, entire; Service 2011, p. 15). Abundance: Pennell’s bird’s-beak is an annual plant with population sizes that can vary greatly (Service 1995, p. 6673; Service 2011, p. 5; Service 2019, p. 2). A small population size one year can be followed by a much larger one the following year when conditions are optimal. This makes population trends difficult to detect. Moreover, population sizes are not consistently estimated, and it is rare that they are estimated in consecutive years. Numeric estimates of individual populations exist for only nine years between 1981 and 2018. These have occurred most often at Harrison Grade Ecological Reserve, which was counted six years in that time period. It also has the highest number of plants recorded with more than 10,000 in 1981 (Diversity Database p. 3); more recently, the highest population estimate there was in 2009 with thousands observed (Diversity Database, p. 3). (USFWS, 2024)

***Threats and Stressors***

**Stressor:** Development (USFWS, 2011)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** At the time of listing, development and associated road construction on the private lands containing occurrence 1, which would result in loss, modification, and destruction of Cordylanthus tenuis ssp. capillaris habitat, were considered potential threats. Development plans had included the donation of 87 hectares (including C. tenuis ssp. capillaris habitat) to the county for use as a park (Service 1998). However, although some roads were constructed, the development never took place, and the land was subsequently sold. Habitat for Cordylanthus tenuis ssp. capillaris along Bohemian Highway has been significantly reduced within the past 23 years (Herrick, in litt. 2011). Parts of the talus and bank have been removed and a windrow has been planted in areas known to be previously colonized by C. tenuis ssp. capillaris (Herrick, in litt. 2011). (USFWS, 2011)

**Stressor:** Vineyards (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Presently, within the past 5 to 10 years along Stoetz Lane parcels of land have been converted vineyards. The conversion to vineyards of potential C. tenuis ssp. capillaris habitat continues to threaten populations at CNDDB occurrence 2 (Herrick, in litt. 2011). (USFWS, 2011)

**Stressor:** Timber harvest (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** CNDDB Occurrence 1 is located on property where timber harvesting has occurred since the time of listing (G. Hale, Sonoma Land Trust, in litt. 2011). Similarly, timber harvesting has occurred on the property where Occurrence 6 is located, and may continue in the future (Robertson 2011, Zito 2011). Timber harvesting can cause significant changes in the species richness and diversity in the herbaceous plant layer (Battles et al. 2001, Macdonald and Fenniak 2007). Although some effects of canopy removal can be short-lived, many other effects persist over a much longer timeframe (e.g., disturbance-mediated limitations to dispersal) (Gilliam 2007). Such effects could be detrimental to populations of C. tenuis ssp. capillaris. Roadside maintenance such as mowing has been reported at occurrence 4, and cattle grazing was reported at occurrence 5 (CNDDB 2011). (USFWS, 2011)

**Stressor:** Mowing and grazing (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Mowing and grazing before the plants flower, typically June through July (Chuang and Heckard 1986) would prevent the generation of seeds. As an annual herbaceous plant species, C. tenuis ssp. capillaris relies on seed banks to maintain population levels. Horses and deer were reported to browse on Cordylanthus tenuis ssp. capillaris. The site of occurrence 5 has been used for cattle grazing (CNDDB 2011). In general, however, the number of plants damaged by grazing continues to be unknown. (USFWS, 2011)

**Stressor:** Diseases (USFWS, 2011)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Due to the hemiparasitic nature of Cordylanthus tenuis ssp. capillaris, diseases to potential host species may threaten C. tenuis ssp. capillaris populations. Phytophthora cinnamomi is a pathogen causing mortality in a number of native forests and chaparral communities in northern California (Swiecki, in litt. 2008, p. 2). Phytophthora ramorum is another pathogen known to cause sudden oak death in at least four coastal California oak species (Garbelotto et al., 2001; Rizzo and Garbelotto 2003). The Service lacks adequate information to determine the potential effects of these pathogens on Cordylanthus tenuis ssp. capillaris. (USFWS, 2011)

**Stressor:** Increasing human populations (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Increasing human populations in central California coastal counties were reported to place a great strain on undeveloped wild-lands, such as those found on the serpentine soils (Service 1995). Listed factors include pedestrian and off-road vehicle traffic, hiking and bicycle trails, and unauthorized garbage dumping. These factors can lead to increased erosion, the establishment of non-native, invasive plants, and the fragmentation of the native plant populations (Service 1995). In turn the native plant populations are increasingly susceptible to natural factors that can negatively affect viability, such as fire and disease (Brigham and Schwartz 2010). The limited number and isolated conditions of the Cordylanthus tenuis ssp. capillaris populations, resulting from these natural and manmade factors, can render the species susceptible to stochastic extinction (Brigham and Schwartz 2010). (USFWS, 2011)

**Stressor:** Roadside maintenance (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Roadside maintenance, such as mowing and spraying, and vehicular traffic were mentioned as threats to Cordylanthus tenuis ssp. capillaris in the 1995 listing (Service 1995). Unauthorized dumping of articles ranging from appliances to bottles also was mentioned as factors affecting C. tenuis ssp. capillaris (Service 1995). Whereas light road grading was thought to facilitate establishment of C. tenuis ssp. capillaris, heavy road disturbance may increase the invasion of non-native plant species (Service 1995). (USFWS, 2011)

**Stressor:** Habitat fragmentation (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Leimu et al. (2006), in meta-analyses of plant studies published between 1987 and 2005, determined that the negative effects of habitat fragmentation (e.g., reduced genetic variation, increased demographic stochasticity) are more common among self-incompatible and rare plant species. Cordylanthus tenuis ssp. capillaris is not only rare, but also self-incompatible (Chuang and Heckard 1986). Although natural selection pressures have acted over time to create a niche for C. tenuis ssp. capillaris on serpentine soils, the fragmented nature of serpentine habitats can leave rare plants dependent upon them susceptible to vagaries of stochastic events

Indeed, populations of C. tenuis ssp. capillaris vary among years (CNDDB 2011), and the causes for annual variations are not readily apparent. (USFWS, 2011)

**Stressor:** Climate change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). However, predictions of climatic conditions for smaller sub-regions such as California remain uncertain. It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects. While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to particular species at this time. (USFWS, 2011)

**Stressor:** Ozone (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Ozone due to photochemical smog is another potential threat to Cordylanthus tenuis ssp. capillaris. Several studies have documented harmful effects of increased nitrogen deposition, such as increased foliar injury and growth reduction (e.g., Miller 1992; Grantz and Yang 1996; Bytnerowicz 2002), yet no information exists specifically for C. tenuis ssp. capillaris. (USFWS, 2011)

**Stressor:** Pesticide Use (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Research analyzing the potential effects of pesticide use is becomingly increasingly important, particularly in areas where agriculture is prevalent such as the wine-growing region of Sonoma County, California. The Environmental Protection Agency (Agency) recently released the final biological evaluations assessing the effects of labeled use of three neonicotinoid pesticides on listed species (Agency 2022a, entire; Agency 2022b, entire; Agency 2022c, entire). The three pesticides (clothianidin, imidacloprid, and thiamethoxam) are registered for use on a variety of agricultural crops; there are also some non-agricultural applications. The three pesticides target insect species by acting on their neurotransmitters to cause excessive nervous stimulation, paralysis, and death. Members of the bird's-beak group require bees for effective pollination (Chuang and Heckard 1986, p. 24). The Agency's final biological evaluations determined that all three pesticides are highly toxic to bees, have the potential to result in bee brood and colony reductions, and if affected bee colonies decline near Pennell's bird's-beak, there is a potential for the three pesticides to indirectly adversely affect the species (Agency 2022a, pp. 4, Appendix 4-1; Agency 2022b, pp. 2, Appendix 4-1; Agency 2022c, pp. 3, Appendix 4-1). The Agency anticipates releasing amended proposed interim decisions and the Service is working on a national Section 7 consultation with the Agency (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
A minimum of five populations of Pennell's bird's-beak are fully protected and managed with the primary intention of preserving the populations in perpetuity. Each protected area should include occupied habitat with adjacent unoccupied habitat and a 150-meter (500-foot) buffer. Occupied habitat is secured and voluntarily protected in at least five sites (or populations).

All known populations, and any occupied or unoccupied habitat identified as essential to survival, are voluntarily protected in perpetuity on parcels large enough to incorporate the spread and establishment of new colonies.

Management plan(s), approved by the Service, are implemented for all populations described in A/1 and any occupied or unoccupied habitat identified as essential to survival. The plans include provisions for standardized annual monitoring of populations.

Recovery Priority Number: 6

The spread of pathogenic species that might be harmful to Pennell's bird's-beak habitat is controlled at or below a level at which a population viability analysis indicates it does not pose a threat to the persistence of the species.

Until research shows otherwise, recovery efforts will target securing protected populations containing a minimum of 2,000 individual plants each, but preferably many more.

Population trends at all sites are stable or increasing over 20 years that include two normal precipitation cycles (or longer if suggested by the results of demographic monitoring).

Impacts from plants that are non-native to serpentine habitats have been managed at levels that do not pose a threat to the persistence of Pennell's bird's-beak

Seeds representative of the breadth of the species' genetic diversity are stored in at least two Center for Plant Conservation certified facilities; seed germination, propagation, and out-p

**Delisting Criteria:**
A/1: Areas of occupied habitat are secured or established and voluntarily protected in perpetuity for at least ten known sites large enough to incorporate the seasonal and spatial variation of new colonies. Protected areas are at least 12 hectares (30 acres), unless future research indicates otherwise. (USFWS, 2019b)

A/2: The breadth of current genetic variation is represented at protected sites. (USFWS, 2019b)

A/3: No damage is recorded over the course of 20 years due to trampling or vandalism. (USFWS, 2019b)

E/1: Plants that are nonnative to serpentine habitats are monitored and controlled at a level that allows for the increase, establishment, and persistence of Pennell's bird's-beak in protected areas on suitable habitat. (USFWS, 2019b)

**Recovery Actions:**

- 1. Establish or protect additional populations of Pennell's bird's-beak. 1.1 Conduct botanical field surveys to discover additional populations. (Priority 1). 1.2 Protect additional populations through voluntary conservation agreements or land acquisitions. (Priority 1). 1.3 Collect and introduce Pennell's bird's-beak seeds in areas of appropriate habitat on protected lands. (Priority 1). 1.4 Survey reintroduction sites annually to determine abundance and extent. (Priority 2). (USFWS, 2019b)
- 2. Conduct research to increase understanding of Pennell's bird's-beak life history and annual establishment. 2.1 Conduct research to determine the full range (area and extent). of the species. (Priority 3). 2.2 Conduct demographic surveys and long-term monitoring that includes, but is not limited to, habitat surveys, genetic research, host-parasite dynamics, and annual establishment. (Priority 1). 2.3 Investigate and monitor potential management methods to maximize population success. Adapt and modify management as necessary. (Priority 2). (USFWS, 2019b)
- 3. Conduct genetic research to determine if genetically distinct populations exist outside of protected areas. (Priority 3). (USFWS, 2019b)
- 4. Monitor and manage Pennell's bird's-beak populations on protected lands. 4.1 At locations where the plant is protected, establish management plans to ensure the quality of existing habitat is maintained and/or degraded habitat is restored. (Priority 2). 4.2 Conduct regular patrols to deter illegal dumping in habitat. If needed, mitigate the 51 effects of illegal dumping on habitat. (Priority 3). 4.3 Store seeds in at least two Center for Plant Conservation certified facilities. Unless storage techniques and/or research show otherwise, replenish seed stock every 10 years to ensure seed viability. (Priority 2). 4.4 Establish a Service-approved monitoring plan to cover a minimum of 5 years post-delisting. The plan will be ready for implementation at the time of delisting to ensure the ongoing conservation of the species and the continued effectiveness of management actions. Adequate funding must be dedicated in order to implement the delisting management plan. (Priority 3). (USFWS, 2019b)
- Until research shows otherwise, recovery should target securing populations containing a minimum of 2,000 plants each (but preferably more). The probability of population persistence over the long-term is expected to be higher for larger populations because large size decreases the likelihood of reduced viability or population extirpations due to random demographic or genetic events (Barrett and Kohn 1991, Ellstrand and Elam 1993). (USFWS, 1998)
- Protecting and managing populations at the two remaining locations by working with the California Department of Fish and Game and private landowners to ensure long-term survival of the species. Populations on private land should be protected by land acquisition, conservation easements, or other means. In general, the largest possible block of serpentine habitat should be protected at each site. Protection should, at least, involve securing the populations themselves as well as a 150- meter (500-foot) buffer around each population, where possible, to reduce external influences and allow expansion of populations. In addition, other unoccupied habitat at the sites that might provide space for expansion of the populations and habitat for pollinators and seed dispersers must be protected. Management plans emphasizing Cordylanthus tenuis ssp. capillaris and other special status species in these locations must be developed and implemented. The plans should include provisions for standardized annual monitoring of Cordylanthus tenuisssp. capillaris populations to determine demographic trends. The plans should also include strategies to

minimize known threats at the sites as well as to identify new threats as they may appear. In particular, threats from off road vehicle use, dumping, and roadside maintenance must be eliminated. If new threats (e.g. invasion of non-natives) are identified or other new information becomes available, management plans need to be reevaluated and revised. (USFWS, 1998)

- Collection and banking of seed in Center for Plant Conservation certified botanic gardens is also a high priority recovery action for Cordylanthus tenuis ssp. capillaris. Seed banking is prudent to guard against extinction of the species from chance catastrophic events and to provide potential material for enhancement efforts in existing populations, repatriations, andlor introductions to new sites. In the absence of genetic data for Cordylanthus tenuis ssp. capillaris, seed banking should include collections from all known populations. Care should be taken to ensure that seed collection does not adversely affect the donor populations. (USFWS, 1998)
- Other suitable serpentine habitat should be surveyed to determine whether undiscovered populations exist. If new populations are discovered, they should be protected and managed as discussed above. During these surveys, potential introduction sites might also be identified. (USFWS, 1998)
- Research on seed germination and propagation techniques that take into account the hemiparasitic nature of the plant, the use of burning as a management strategy, and basic research on demography (including soil seed bank) and reproduction (including mating system and pollination). Demographic research would be valuable to identify limiting life history stages. (USFWS, 1998)
- Recommended Future Action from 2011 5-Year Review: Protect known occurrences from threats by acquiring the private lands from willing sellers where Cordylanthus tenuis ssp. capillaris is known to occur. (USFWS, 2011)
- Recommended Future Action from 2011 5-Year Review: Design and implement a comprehensive survey method for Cordylanthus tenuis ssp. capillaris. Survey designs should incorporate geographic information systems (G.I.S.) technology to identify additional suitable sites for C. tenuis ssp. capillaris. (USFWS, 2011)
- Recommended Future Action from 2011 5-Year Review: Work with land owners and land managers to gain access to known and potential suitable sites for Cordylanthus tenuis ssp. capillaris populations. Annual population surveys of known occurrences should be reported to the CNDDB. (USFWS, 2011)
- Recommended Future Action from 2011 5-Year Review: Scientific studies should be conducted to identify ideal host species. Chuang and Heckard (1971) have inferred suitable host species for Cordylanthus tenuis ssp. capillaris, yet individual plant fitness varies with host plant relationships. Studies remain to identify decisively the optimal host species. (USFWS, 2011)
- Recommended Future Action from 2011 5-Year Review: Ascertain the importance of habitat disturbance to Cordylanthus tenuis ssp. capillaris. Current occurrences are openings among chaparral and conifer woodlands. Management strategies should evaluate the effectiveness of timber removal and fire ecology for the propagation of the species. (USFWS, 2011)
- Recommended Future Action from 2019 5-Year Review: Survey to identify potential habitat. A comprehensive and systematic survey of serpentine habitats for the presence of Pennell's bird's-beak has yet to be conducted. A new occurrence was discovered in 1997 during surveys for a different serpentine plant (CNDDB 2018). Anecdotal reports suggest additional populations might exist on private property. By identifying these areas and working with

local landowners, additional occurrences might be protected inperpetuity. (USFWS, 2019a)
- Recommended Future Action from 2019 5-Year Review: Conduct research to better understand Pennell's bird's-beak life history, demographics, annual establishment, etc. Very little is known about the demographics and life history of Pennell's bird's-beak. Future research should be focused on informing conservation and management decisions. Current occurrences indicate that site disturbance might promote colonization, yet the role of disturbance mechanisms such as fire and flooding is unknown. Conducting long-term 4 demographic surveys and monitoring that include habitat surveys, genetic research, host-parasite dynamics and annual establishment would further recovery goals. (USFWS, 2019a)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Survey to identify potential habitat. A comprehensive and systematic survey of serpentine habitats for the presence of Pennell's bird's-beak has yet to be conducted. A new occurrence was discovered in 1997 during surveys for a different serpentine plant (CNDDB 2018). Anecdotal reports suggest additional populations might exist on private property. By identifying these areas and working with local landowners, additional occurrences might be protected in perpetuity. Conduct research to better understand Pennell's bird's-beak life history, demographics, annual establishment, etc. Very little is known about the demographics and life history of Pennell's bird's-beak. Future research should be focused on informing conservation and management decisions. Current occurrences indicate that site disturbance might promote colonization, yet the role of disturbance mechanisms such as fire and flooding is unknown. Conducting long-term demographic surveys and monitoring that include habitat surveys, genetic research, host-parasite dynamics and annual establishment would further recovery goals. (USFWS, 2019a)
- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations that will aid in the recovery and conservation of Pennell's bird's-beak. Some of these recommendations have already been discussed in our previous status review (Service 2019a, pp. 3–4) and remain valid. 1. Conduct surveys at known occurrences to monitor population trends and habitat changes. 2. Conduct a comprehensive and systematic survey of serpentine habitats to locate additional occurrences of Pennell's bird's-beak. Anecdotal reports suggest additional occurrences exist on private property. By identifying these areas and working with local landowners, these might be protected in perpetuity and contribute towards species recovery. 3. Conduct studies to evaluate and monitor potential management methods to maximize population success such as introducing disturbance through vegetation clearing or burning. Disturbance has been suggested to promote colonization yet the role of disturbance mechanisms such as fire and flooding is unknown. Understanding these mechanisms would aid in management and recovery of the species. 4. Conduct long-term demographic surveys and monitoring that include habitat surveys, genetic research, host-parasite dynamics, and evaluation of seed germination and propagation techniques to improve annual establishment and further recovery goals. 5. Review existing management plans and revise them to include an objective for standardized monitoring of Pennell's bird's-beak if this objective is missing. Assess the need for annual and quantitative monitoring to achieve recovery objectives (USFWS, 2023).
- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations that will aid in the recovery and conservation of Pennell's bird's-beak. Some of these recommendations have already been discussed in our previous status review (Service 2019a, pp. 3–4) and remain valid. 1. Conduct surveys at known occurrences to monitor population trends and habitat changes. 2. Conduct a comprehensive and systematic survey of serpentine habitats to locate additional occurrences of Pennell's bird's-beak. Anecdotal reports

suggest additional occurrences exist on private property. By identifying these areas and working with local landowners, these might be protected in perpetuity and contribute towards species recovery. 3. # SPECIES ACCOUNT: *Coryphantha robbinsiorum* (Cochise pincushion cactus)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 01/09/1986; Southwest Region (R2) (USFWS, 2016)

**Physical Description**

A spiny succulent with a solitary round stem, 3-5 cm tall. Pale green-yellow flowers appear in March-April, followed in July and August by orange-red fruits (NatureServe, 2015).

**Taxonomy**

The Cochise pincushion cactus was originally named Cochiseia robbinsorum by W.H. Earle (1976). The genus Cochiseia was rejected almost immediately. Dr. A.D. Zimmerman (1978) assigned the species to the genus Coryphantha, which is currently the most frequently accepted placement. The only other synonym for the species is Escobaria robbinsorum, which is subject to an unresolved controversy (USFWS, 1993).

**Historical Range**

The Cochise pincushion cactus is known from the San Bernardino Valley, southwestern Cochise County, Arizona, and northern Sonora, Mexico (Lopresti 1984) (USFWS, 1993).

**Current Range**

It occurs in Cochise Co., Arizona and Sonora, Mexico (NatureServe, 2015). It is restricted to three small limestone hills in Cochise County, Arizona, along the U.S./Mexico border (USFWS, 2007). The Cochise pincushion cactus is known from among several Permian limestone hills in southeastern Cochise County, Arizona. Once thought to have occurred in northern Sonora, Mexico, the species has never been found in that country (USFWS,2020).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (inferred from NatureServe, 2015)

**Breeding Season**

Adult: March - April (USFWS, 2016)

**Key Resources Needed for Breeding**

Adult: Bee pollinators (USFWS, 1993)

**Reproduction Narrative**

Adult: Lower reproduction rate than most cacti - estimated average annual production is 3 fruits with 20 seeds per plant (NatureServe, 2015). Flowering begins in mid-March extending to mid-April (USFWS, 2016). Zimmerman (1985) noted the small bees Perdita opuntiae, Ashmeadiella opuntiae, and (rarely) Dialictus sp. visiting the flowers of Coryphantha robbinsorum (USFWS, 1993). At least 100 species of bees are using the Cochise pincushion cactus habitat; the rare cactus specialist bee, Macrotera parkeri, is the primary (but not the only) pollinator of Cochise pincushion cactus (USFWS, 2020).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Semidesert grassland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Full sunlight (USFWS, 2007)

**Geographic or Habitat Restraints or Barriers**

Adult: 1,280 - 1,544 m elevation (USFWS, 2016); dense vegetation (inferred from USFWS, 2016)

**Spatial Arrangements of the Population**

Adult: Scattered with a few dense clumps (USFWS, 2007)

**Environmental Specificity**

Adult: The Cochise pincushion cactus is known from among several Permian limestone hills in southeastern Cochise County, Arizona (USFWS, 2020).

**Dependency on Other Individuals or Species for Habitat**

Adult: The primary pollinator, Macrotera parkeri, is a widespread, but rare bee species and is on the Texas list of species of greatest conservation need (USFWS, 2020).

**Habitat Narrative**

Adult: Inhabits grey limestone hills within a semidesert grassland, with small shrubs, other succulents, and grama grasses (NatureServe, 2015). Found only on one type of high-calcium limestone outcrop in the Mexican Highland vegetation community at elevations of 1,280-1,433 meters (4,200 feet). Soils are thin with a soil crust of lichens, mosses, and algae, and bedrock is very near the surface at occupied sites. Plants tend to be in the open, not underneath other plants. Overall vegetation at occupied sites is sparse (USFWS, 2016). The soils are low in nutrients, with a pH of 7.9 to 8.0. Plants require well-drained substrates and grow in full sunlight. Within their limited habitat (10-16 sq. km), the plants are found scattered, with a few dense clumps ranging from 100-1,000 individuals (Zimmerman 1985) (USFWS, 2007).

***Dispersal/Migration***

**Dispersal**

Adult: Moderate (inferred from USFWS, 1993)

**Dispersal/Migration Narrative**

Adult: Zimmerman (1985) speculates that seeds are disseminated by rock wrens (Salpinctes obsoletus), cactus wrens (Campylorhynchus brunneicapillus), mockingbirds (Mimus polyglottos), black-throated sparrows (Amphispiza bilineata), thrashers (Toxostoma sp.), and house finches (Carpodacus mexicanus). The bright red, fleshy fruits probably attract the birds. He notes that his unpublished study of rock wrens in a population of Coryphantha robbinsorum showed that these birds fly from one Coryphantha population to another during their daily activities (USFWS, 1993).

***Population Information and Trends***

**Population Trends:**

Not available

**Species Trends:**

Declining (USFWS, 2007); Between 1989 and 2006, Cochise pincushion cactus individuals in 3 circular plots were monitored 14 times and all 3 plots had an overall declining trend (USFWS, 2020). The work since 2009 paints a different picture than the plots of 1989-2006. The population is thought to be stable (USFWS, 2020).

**Population Growth Rate:**

There appears to be a good distribution of Cochise pincushion cactus size classes, including some smaller and larger individuals, though most were intermediate sized individuals (USFWS, 2020).

**Number of Populations:**

2 (NatureServe, 2015)

**Population Narrative:**

It occupies 8.8 acres of rangeland (in U.S.?). This species is known only from 1 population in southeastern Arizona and 1 in adjacent Sonora, Mexico (NatureServe, 2015). The known range is very small and limited (USFWS, 2016). Population numbers appear to be declining based on current data (USFWS, 2007). The Cochise pincushion cactus is known from among several Permian limestone hills in southeastern Cochise County, Arizona. Once thought to have occurred in northern Sonora, Mexico, the species has never been found in that country (USFWS, 2020).

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Threats include grazing by livestock and wildlife, and oil/mineral exploration activities. Changes in grazing patterns by the local landowner have minimized the potential effects from livestock grazing. Impacts to populations from mining activities have not been a significant factor. However, each of these activities continues to be a potential threat to populations of Cochise pincushion cacti. Impacts from these threats could increase if land ownership changes or incentives for oil and mineral exploration increase. A new threat that has been escalating over

the past 10 years is related to illegal immigration and drug smuggling, and associated law enforcement activities. Plants can be trampled or otherwise damaged or injured. Cochise pincushion cactus habitat is destroyed or altered by foot and vehicle traffic, and there is the potential for the increased incidence of fire. Impacts from border activities have been documented within areas occupied by the Cochise pincushion cactus, but increased law enforcement efforts have, at least temporarily, reduced illegal traffic in the area (USFWS, 2007). In 2006, Cochise pincushion cactus plots were reported vandalized with many nails and tags removed; trash and other evidence of human visitation was also present (USFWS, 2020). Cochise pincushion cactus habitat continues to be used by cross-border violators, as evidenced by trails and litter in some areas (USFWS, 2020).

**Stressor:** Invasive plants (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** An additional threat comes in the form of invasive plant species, especially grasses. Of particular note is the spreading threat to Sonoran and Chihuahuan desert ecosystems resulting from the invasion of buffelgrass (Pennisetum ciliare). Buffelgrass can compete for resources with Cochise pincushion cactus, and it also increases the frequency and intensity of fire on the landscape as compared to natural conditions. Such a change in the fire regime could increase Cochise pincushion cactus mortality and alter important habitat microclimates. The recent development of a cold-tolerant strain of buffelgrass by the Agricultural Research Service (2005) increases the potential for this species to invade areas occupied by the Cochise pincushion cactus. Lehmann's lovegrass (Eragrostis lehmanniana) is another invasive grass species in southeastern Arizona (USFWS, 2007).

**Stressor:** Collection (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The desirability of this species, coupled with its limited distribution, increases the potential for significant impacts to populations if illegal collection were to occur. No evidence of illegal collection within known populations has been observed. However, collection remains a real threat to this species due to its limited numbers and distribution. Cochise pincushion cacti are available commercially on a limited basis, but if interest in this species increases or commercial availability decreases, pressure to collect plants from the wild may increase. The unique, rare nature of this species increases its desirability among collectors (USFWS, 2007). In 2019, a Cochise County Sheriff's Deputy provided a tip to U.S. Fish and Wildlife Service refuge law enforcement that a German national would be in the area to see and photograph Cochise pincushion cactus. Further investigation ultimately led to the man's arrest at the Denver Airport as he was attempting to smuggle Cochise pincushion cactus seeds out of the country. The man was found with 111 bags of cactus seed, including a purposefully mislabeled collection of Cochise pincushion cactus. The suspect admitted to collecting the seed from public lands and was arrested, released on $5,000 bond, and returned to Germany (USFWS, 2020).

**Stressor:** Insect depredation (USFWS, 2007)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** Depredation by insects was documented in the Cochise pincushion cactus long-term monitoring plots in 1994. As a result, mortality of individual plants during that year nearly doubled from the highest mortality previously recorded (see Figure 2). The documentation of this significant depredation event points to the potential for the distribution of this species to be driven by density-dependent insect depredation. As the density of Cochise pincushion cacti increases in a local population, it becomes more vulnerable to insect depredation. At some point, densities may become high enough that conditions favor a significant insect depredation event. Density of cacti is reduced, as is the subsequent depredation by insects. This cycle may repeat itself over time within each of the local populations of Cochise pincushion cactus. As a result, there may be a number of high-density populations within the landscape; however, the density of these populations would eventually be reduced by insect depredation. Low-density populations will gradually increase in density during favorable environmental conditions until they reach a point that favors insect depredation events. In order to determine if this cycle of depredation is indeed a natural component of the population dynamics of the Cochise pincushion cactus, monitoring techniques must be modified to sample the population across its range. Depredation may be a significant driver of the distribution and density of this species. Depredation effects would be amplified in populations suffering from others stressors such as drought (USFWS, 2007).

**Stressor:** Drought (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Ongoing, long-term drought is occurring within the range of the Cochise pincushion cactus. Drought increases mortality of adults and juveniles and reduces reproduction in populations of this species. Because of the limited number of individual plants and the limited distribution of this species, drought effects may significantly affect its ability to persist on the landscape. A return to normal winter and monsoon precipitation patterns is needed to decrease this threat. The declining trend in numbers of cacti within monitoring plots is likely evidence of the effects of drought on known populations (USFWS, 2007). Not only does climate affect plants directly, it has been shown that climate coupled with other stressors, can have a cumulative impact resulting in greater than anticipated decline in rare species (USFWS, 2020).

**Stressor:** Pesticides (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Application of pesticides within or adjacent to the range of the Cochise pincushion cactus could adversely affect these insects and associated ecosystem functions. The potential application of pesticides is most likely associated with rangeland grasshopper control. The application of pesticides remains a potential threat to insects that benefit the Cochise pincushion cactus (USFWS, 2007).

**Stressor:** Small mammal herbivory (USFWS, 2020)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Researchers noted that between 2016 and 2019, small mammal herbivory was much increased and associated flowering forbs were much decreased ; this is believed to be associated with ongoing drought in the region (USFWS, 2020). Recently documented extensive herbivory by small mammals has led to the removal of many adult plants, for example in 2019, 25 of 31 individuals monitored over time were removed by recent herbivory (USFWS, 2020). Despite this, small plants have appeared around the perimeter of missing plants (USFWS, 2020).

***Recovery***

**Reclassification Criteria:**
Not available

Recovery Priority Number: 8

**Delisting Criteria:**
Recovery of this species will require permanent protection and management of the habitat, trade protection through retention of the species on the Highly Safeguarded List of the Arizona Native Plant Law and CITES list following delisting, and demonstration through ten years of monitoring that viable populations are being maintained (USFWS, 1993).

**Recovery Actions:**

- Conduct biological studies necessary for effective management of the species (USFWS, 1993).
- Develop and implement a habitat management plan in cooperation with the private landowner and Arizona State Land Department (USFWS, 1993).
- Study the population biology of Cochise pincushion cactus to determine the effects of management (USFWS, 1993).
- Protect Cochise pincushion cactus from loss of individuals and habitat (USFWS, 1993).
- Establish an ex situ conservation and research program (USFWS, 1993).
- Define the range and distribution of Cochise pincushion cactus (USFWS, 1993).
- Modify the current monitoring protocol to expand the area monitored within the known range of the species. Design the protocol to more effectively evaluate the status of the species across the landscape. Monitoring should be designed to investigate possible density-dependent depredation issues and identify the distribution of both high-density and low-density populations (USFWS, 2007).
- Update the recovery plan with quantifiable criteria for delisting. For example, a goal of establishing 15,000 plants in 50 populations (Recovery Criteria #2) may not be realistic based on current information of the density and distribution of this species (USFWS, 2007).
- In conjunction with #2, evaluate the existing recovery actions outlined in the existing recovery plan and decide which are still appropriate for the species' recovery, based on current information (USFWS, 2007).
- Evaluate the results of Dr. Tom Van Devender's 2007 work on this species in Mexico and increase monitoring efforts in Mexico, if appropriate (USFWS, 2007).
- Continue to coordinate with and involve the landowners/lessees and SBNWR in recovery actions related to the Cochise pincushion cactus (USFWS, 2007).
- Evaluate the genetics of this species to determine variation within and among populations. This information is useful in determining if population augmentation or establishment of

new populations is warranted (USFWS, 2007).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The following are recommendations for future actions to conserve Cochise pincushion cactus and its habitat: 1) Work toward the purchase of some portion of Cochise pincushion cactus populations by a Federal entity (such as the expansion of the Buenos Aires National Wildlife Refuge). This would enable land management to benefit the species, and enable easy access to populations for monitoring, scientific study, and augmentation efforts. 2) Work toward building relationships with current landowners that would enable ease of access by researchers and land managers to survey, monitor, manage, and protect Cochise pincushion cactus. 3) Survey for additional Cochise pincushion cactus populations in appropriate limestone habitats in Arizona, New Mexico, and Mexico. 4) Continue annual monitoring of all accessible Cochise pincushion cactus populations, including attempting to relocate historical plots for re-measurement. 5) Work toward an understanding of stressor, threats, and conservation measures needed to help protect Cochise pincushion cactus. 6) Continue work at botanical gardens both developing plants for potential outplanting and periodically collecting seeds from a genetically diverse group of individuals for longterm storage. 7) Work toward public and partner education of the rarity and importance of Cochise pincushion cactus and the need for teamwork to conserve the species. (USFWS, 2020)
- Continue work at botanical gardens both developing plants for potential outplanting and periodically collecting seeds from a genetically diverse group of individuals for long-term storage

# SPECIES ACCOUNT: *Coryphantha scheeri var. robustispina* (Pima pineapple cactus)

***Species Taxonomic and Listing Information***

**Commonly-used Acronym:** PPC

**Listing Status:** Endangered; 10/25/1993; Southwest Region (R2)

**Physical Description**

Individuals of C. scheeri var. robustispina are small, hemispheric to cylindrical, stem succulent perennials of the Cactaceae (cactus family). Individual stems reach 5 to 46 centimeters (cm) (1.9 to 18.1 inches (in)) in height and 5 to 21 cm (1.9 to 8.3 in) in diameter, are comprised primarily of tough, fleshy pulp, and are protected by a leathery outer skin. Stems may be singular or form clumps. The surface of the stems is covered in 2 to 3 cm (0.8 to 1.2 in) long rounded projections called tubercles, each of which is grooved along the upper surface and contains one to several extra- floral nectaries (place that secretes nectar to attract pollinators) along the groove.. At the tip of each tubercle, arising from small bumps called areoles, are groupings of 7 to 20 straw-colored spines that darken with age (Roller 1996a, p. 9; Parfitt and Gibson 2004, p. 226). There is an average of two thick central spines, one of which is generally hooked and averages 1.7 millimeters (mm) (0.07 in) thick and 3 cm (1.2 in) long (Baker and Butterworth 2013, p. 996). There are 6 to 16 thinner radial spines about 1.1 to 3.5 cm (1.43 to 1.38 in). The young areoles are densely covered with deciduous wool. The stems of C. scheeri ssp. robustispina arise from taproots that are deeper than most Sonoran Desert cacti at about 15 cm deep. Lateral roots are found between 2 and 5 cm below the soil surface and extend approximately 1 m (3.28 ft) in length. The flowers of C. scheeri ssp. robustispina average 6.5 cm (2.6 in) long with pale yellow tepals (petals and sepals) that are variously tinged with red pigments. Flowers generally open early to mid-July following summer rains; fruit matures a few weeks later. The pale green fruits are narrowly ellipsoid, 3.2 to 5.7 cm (1.25 to 2.25 in) long and 1.3 to 1.9 cm (0.5 to 0.75 in) wide, with a soft rind and juicy sweet pulp surrounding a mass of brown to black seeds. (USFWS, 2018a)

**Taxonomy**

Arthur Schott originally described the taxon as Mammillaria robustispina from a collection he made from near El Sásabe, Sonora, Mexico (holotype MO 2017438) and the name was published by George Engelmann in 1856 (M. robustispina Schott ex Engelmann). Britton and Rose (1923, pp. 33-34) transferred the species to Coryphantha (C. robustispina). The name of the taxon was recombined by Benson (1982, p. 820) to C. scheeri var. robustispina and then again to C. robustispina (Schott ex Engelm.) Britton & Rose ssp. robustispina by Taylor (1998, pp. 17-18). According to Taylor, the species name C. robustispina has priority over the epithet C. scheeri. This view is accepted by Anderson (2001, p. 196). Within the 2018 Recovery Plan, however, we refer to the taxon as C. scheeri var. robustispina, the name in use when the taxon was listed as endangered under the Act in 1993 and how the taxon has been referred to in Service documents since that time. A morphometric study in 2004 suggested that a taxonomic cline exists between all C. robustispina occurring between Arizona and Texas and therefore no varieties are valid (Schmalzel et al. 2004, p. 553). Three varieties; robustispina, uncinata and scheeri, have been investigated recently and were shown to be geographically isolated (Baker 2005, p. 6), significantly different morphologically (Baker 2003, p. 17), and significantly different genetically (Butterworth 2010, p. 14; Baker and Butterworth 2013, p. 996), warranting subspecific division. We accept this varietal differentiation in this document. (USFWS, 2018a)

**Historical Range**

See Current Range. There is no indication that the historical range of the taxon differs widely from the current known distribution. (USFWS, 2018a)

**Current Range**

Found across roughly 152,920 ha (377,873 ac) of land within the Altar and Santa Cruz Valleys in Pima and Santa Cruz Counties, Arizona, including some lands that connect the two valleys. (USFES, 2018a)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Obligate outcrosser

**Lifespan**

Adult: Variable, can be 30 or more years (USFWS, 2018a)

**Dependency on Other Individuals or Species**

Adult: Pollinators

**Breeding Season**

Adult: Early to mid-July or five to seven days after the first summer rains of at least 3 mm and continues through the monsoon season. (USFWS, 2018a)

**Other Reproductive Information**

Adult: Flower buds begin to appear in mid-May and the timing is related to photoperiod and rainfall (Roller 1996a, p. 58). Flowering usually occurs in early to mid-July or five to seven days after the first summer rains of at least 3 mm and continues through the monsoon season (Kearney and Peebles 1951, p. 577; Roller 1996a, p. 58; Kidder 2014, entire). Flowers persist for a single day, yet the timing of flowering may assist with pollination, as there are few cactus species which bloom at this same time, resulting in a greater potential for pollination success (McDonald and McPherson 2005, p. 531). Schmalzel (2014, p. 4) suggests that plants do not reach maturity and begin to flower until they are more than 12 years of age and likely between 20 and 25 years of age. (USFWS, 2018a)

**Reproduction Narrative**

Adult: Pollinators of C. scheeri var. robustispina are fairly well known. Flowers of the taxon are morphology typical for the subgenus Cactoideae and exhibit characteristics considered generalized with respect to pollination, that is, the pollen being easily accessible to many different types of pollinators. Known pollinators include both native insects and the nonnative European honeybees (Apis mellifera) (Roller 1996a, p. 63). Coryphantha scheeri var. robustispina become isolated from potential pollination after 600 m (1,968.5 ft) and since the taxon is not able to self-pollinate (Service 2000a, p. 4), they are likely to be genetically isolated or inbred after 900 m (2,953 ft; McDonald 2005, p. 30). Pups (offsets of the parent cactus that are genetically identical) produced vegetatively will not increase genetic diversity of the population. (USFWS, 2018a)

**Habitat Type**

Adult: Semi-desert grasslands, desert scrub and the transition area between the two vegetation types.

**Dependencies on Specific Environmental Elements**

Adult: Open and transitional areas; deep, silty and gravely, alluvial soils (USFWS, 2018a)

**Environmental Specificity**

Adult: Moderate (inferred from USFWS, 2018a)

**Tolerance Ranges/Thresholds**

Adult: Found at elevations between 728 and 1,280 m (2,388 and 4,200 ft) (USFWS, 2018a)

**Habitat Narrative**

Adult: Coryphantha scheeri var. robustispina is typically found in open areas within the Sonoran Desert-scrub and desert-grassland vegetation types and in areas transitional between these vegetation communities. Routson (2003, p. 3) found that individuals of C. scheeri var. robustispina within the Altar Valley occurred most frequently in disclimax (displaced climax due to disturbance) desert-grassland among woody vegetation on well-drained soils. Many studies describe the subshrubs Zinnia species (desert zinnia), Gutierrezia sarothrae (snakeweed), Isocoma tenuisectus (burroweed), and Eriogonum spp. (buckwheat) as common associates. Schmalzel (2000c, p. 2) noted greater rates of mortality among C. scheeri var. robustispina occurring under the canopies of Prosopis velutina (velvet mesquite). Similarly, Kidder (2014, entire) found occupied sites were characterized by overall high incoming solar radiation (Kidder 2015, p. 110). McPherson (2002, p. 3), however, found individuals occur more frequently under the canopy of perennial plants than at a distance of at least 1 m (3.28 ft) from the canopy edge. (USFWS, 2018a). Coryphantha scheeri var. robustispina is a taxon of lower Sonoran desert-scrubland, desert-grassland, and the ecotone (transition area) between desert-scrubland and desert-grassland in southeastern Arizona and adjacent Sonora, Mexico. The primary habitats of Coryphantha scheeri var. robustispina are open areas on flat ridge tops or areas with less than 10 percent slope, which are also areas very well suited for human development (USFWS, 2024)

***Dispersal/Migration***

**Motility/Mobility**

Adult: Low

**Dispersal**

Adult: Rabbits and rodents act as seed disperses.

**Dependency on Other Individuals or Species for Dispersal**

Adult: Rabbits and rodents for seed dispersal (USFWS, 2018a)

**Dispersal/Migration Narrative**

Adult: Fruit and seed dispersal for the taxon is probably facilitated, for the most part, by rodents and, perhaps less so, by ants. It has also been hypothesized that jack rabbits (Lepus spp.) may play a key role in fruit and seed dispersal (Westland 2005, p. 33; Schmalzel and McGibbon 2010, p. 11). In 2001, Westland (2005, p. 33) examined jackrabbit dung and discovered intact C. scheeri var. robustispina seeds within. They noted that dung increased around plants at the time fruits are maturing. A study conducted by Baker and Routson beginning in 2002 documented that ants were mostly associated with extrafloral nectaries, however there were multiple cases of ants eating the fruits and transporting seeds (Baker 2013, p. 21). This study also documented the presence of a single seed in jackrabbit feces, which supports the jackrabbit dispersal hypothesis (Baker 2013, p. 33). In a study of antelope jackrabbit (Lepus alleni ) habitat structure and vegetation characteristics, Altemus (2016, p. 10) did not detect a spatial association between the jackrabbits and the presence of C. scheeri var. robustispina, but suggested further study was warranted, as this was a habitat selection study for the herbivore and did not emphasize the distribution of fruits. Additionally, Harris' antelope squirrels (Ammospermophilus harrisii), (USFWS, 2018a)

**Additional Life History Information**

Adult: Ample seed production, however, does not necessarily equate to persistant seedbanks or recruitment (e.g. see Godinez-Alvarez et al. 2003, p. 183; Aragon and Lasso 2018, p. 1). One field study reported the results of two trials where 200 or more C. scheeri var. robustispina seeds were planted in close proximity to in situ C. scheeri var. robustispina adult plants and germination was followed (Schmalzel 2002, p. 7). In the first trial, 16 of 220 seeds germinated in the first year and none in the second. In the second trial, 35 of 200 seeds germinated; 30 in the first year and 5 in the second year of study (Schmalzel 2002, p. 7). In another study, field germination testing from 5 study sites found that C. scheeri var. robustispina seeds had high germination rates of 88 percent (Roller 1996a, p. 75). Observations from laboratory and shadehouse over a 22-month period showed continuous germination indicating that there is no set dormancy period for the seeds (Roller 1996a, p. 72). (USFWS, 2018a)

***Population Information and Trends***

**Population Size:**

Roughly 8000 individuals and 152,920 ha (377,873 ac) of habitat (USFWS, 2018b)

**Additional Population-level Information:**

Between 1995 and 2007, 45 individual C. scheeri var. robustispina were monitored in an exclosure on Coronado National Forest land in the Santa Cruz Valley. In 2010, no living plants were found (Coronado National Forest 2010, entire), however, in a partial survey of this area in 2015, some C. scheeri var. robustispina were found both within and outside of this exclosure (Service 2015b, entire). Similarly, plants are monitored regularly on the Pima County and Palo Alto Pima Pineapple Cactus Conservation Bank properties. On one portion of the County-owned Conservation Bank property in 2006, 67 plants were mapped; when last counted in 2014, 13 of the original 67 plants remained alive and 11 new plants had been found (Pima County 2015, p. 1). Within or adjacent to the Palo Alto Conservation Bank property, 49 plants were found in

2001; as of September, 2015, 9 of the original individuals remained alive and 11 new plants were discovered, for a total of 24 known C. scheeri var. robustispina (Westland 2015, p. 2). (USFWS, 2018a)

**Population Narrative:**

We are aware of roughly 8,000 individuals and 152,920 ha (377,873 ac) of habitat within the Altar and Santa Cruz Valleys in Pima and Santa Cruz Counties, Arizona, including acreage of some lands that connect the two valleys. Maintaining linkages for pollinators and lands dominated by native plants are important for the survival of the taxon. Long-term monitoring plots of Coryphantha scheeri var. robustispina indicate overall decreases in the number of individuals monitored over time. Attempts at transplanting individuals out of the path of development has resulted in a mix of successes and failures. We are aware of at least 1,837 individuals and tens of thousands of acres of habitat that have been lost, primarily due to development. (USFWS, 2018b)

***Threats and Stressors***

**Stressor:** Habitat loss due to commercial development (2018a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The primary habitats of C. scheeri var. robustispina are open areas on flat ridge tops or areas with less than 10 percent slope, which are also areas very well suited for human development. Urban and suburban development in the areas south and west of Tucson, Green Valley, and Nogales, Arizona, and mining in the Sierrita Mountains and Green Valley, threats first recognized in the 1980s (Phillips et al. 1981, p. 11; Mills 1991, p. 7; Reichenbacher 1985, p. 21; Service 2000a, p. 7), are responsible for complete and permanent modification of lands that previously supported C. scheeri var. robustispina and its pollinators. By 2000, the Service estimated that 43 percent of the total habitat surveyed to date had been modified or destroyed due to urbanization (Service 2001a, p. 6). For example, 143 ha (353 ac) of habitat and 47 individual plants were lost to a single housing development project in 1998 (Service 1998c, p. 16). In 2014, 197 ha (487 ac) of suitable C. scheeri var. robustispina habitat and 99 individual plants were lost to a single infrastructure development project (Service 2014a, p. 33). (USFWS, 2018a)

**Stressor:** Habitat loss due to nonnative plant invasion and altered fire regimes (USFWS, 2018a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Coryphantha scheeri var. robustispina occur in both the desert-grassland and desert-scrubland plant communities, especially in the ecotone of the two (Roller 1996a, p. 9). Invasive nonnative grasses in both communities compete with native plants for water and nutrients, reduce community composition and structure, and alter fire frequency and intensity. Historically, low severity fires that occured every 10 to 20 years in grasslands, or every 250 years in deserts, likely posed no threat to the long-term survival of C. scheeri var. robustispina individuals. When invaded by invasive nonnative grasses, fire frequency and intensity increase, leading to the deterioration of both natural grassland and desert communities. Invasive nonnative grasses produce more fine fuels than native vegetation, allowing for a more uniform and higher intensity burn compared with the discontinuous fuels of some native grasslands and deserts, thus

reducing the number of microsite refuges safe from fire. Coryphantha scheeri var. robustispina is not fire adapted, but may survive fires through refugia (e.g. older soils or spaces between native plants), chance, shrinking into the ground, reproducing through basal resprouting, or possibly recolonization from a surviving seedbank, barring adequate rainfall to allow for survival. Further research into the relationship of fire, drought, nonnative species, soil types, and C. scheeri var. robustispina and their seedbanks would help to better understand the tolerance of this taxon to wildland and prescription fires. Research into desert-scrubland and desert-grassland restoration (e.g. removal of nonnative grasses and the establishment of native plants) is also essential, as this is a large-scale problem currently without large-scale solutions. (USFWS, 2018a)

**Stressor:** Effects of Livestock Grazing (USFWS, 2018a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Some livestock grazing practices that occurred in the past have resulted in enduring landscape-level impacts, because recovery in dryland ecosystems is slow or stagnant. Historically overgrazed lands have altered microclimate and hydrology, increased soil compaction and erosion, reduced structural complexity and abundance of the vegetation community, and species composition; all of which may impact the current suitability of habitat for C. scheeri var. robustispina in certain areas of its range. In general, poorly managed livestock grazing may negatively impact C. scheeri var. robustispina seedlings and adult plants through soil erosion, soil compaction, hydrologic and micro-climatic changes, and invasion or expansion of invasive nonnative grasses. Low to moderate intensity grazing however, may also aid C. scheeri var. robustispina through the creation of open areas temporarily free of competition and with reduced fuels (Service 2000a, p. 9). Additional research into the relationships between livestock use and C. scheeri var. robustispina is needed to determine both the benefits of grazing and the threshold at which disturbance no longer benefits the taxon. In addition, research is needed into restoration of native species and fire regimes on desert grasslands and desertscrub. (USFWS, 2018a)

**Stressor:** Recreation and Border Activity (USFWS, 2018a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Off-road vehicle use and illegal border activity contribute to the overall degradation of C. scheeri var. robustispina habitat. In addition, individual C. scheeri var. robustispina have been run over by off-road vehicles. Although these activities could impact individual C. scheeri var. robustispina, off-road vehicles and illegal border activity are not likely significant sources of mortality for the taxon as a whole. (USFWS, 2018a)

**Stressor:** Overutilization for commercial, recreational, scientific, or educational purposes (USFWS, 2018a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Illegal collection of C. scheeri var. robustispina is difficult to detect and only one incident has been reported in recent years. Although illegal collection could impact C. scheeri var. robustispina, it is not as significant a threat for the taxon as previously thought. The

determination to not designate critical habitat for the species has helped reduce this threat by not making maps publically available, and continued outreach and education related to the issue of illegal collection remain important tools in the conservation of this taxon. (USFWS, 2018a)

**Stressor:** Disease or Predation (USFWS, 2018a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In general, cacti are susceptible to attacks from numerous types of insects, and C. scheeri var. robustispina is no exception. The interior flesh of cacti provides both a nesting area and food source for beetles, weevils, and other insects. Once an infestation has occurred, cacti can die from the feeding and tunneling activities of insects or from the introduction of fungus or disease. Plants already stressed from prolonged drought are more susceptible to insect attack and disease, as drought may cause physiological stress responses in plants, such as limiting their photosynthesis and cell. Predation by mammals and insects occurs on both adult C. scheeri var. robustispina and seedlings. Primary insect predators of C. scheeri var. robustispina are the native Gerstaeckeria sp. (cactus weevil), the native Moneilema sp. (cactus beetle), and the native Cactobrosis sp. (pyralid moth). Ants have been documented on C. scheeri var. robustispina and will consume seed, however they are not specialists of C. scheeri var. robustispina. O'Dowd and Hay (1980, p. 539) suggest that ants may also aid in reducing the seedbank of competing plant species. Predation of Coryphantha scheeri var. robustispina by mammals is well-documented. Harris' antelope squirrel), antelope jackrabbits and desert cottontails are known to eat stem material of C. scheeri var. robustispina, especially when other food sources are scarce, such as in times of drought. Researchers have documented C. scheeri var. robustispina mortality caused by javelina (Pecari tajacu). These and other animals can also impact cacti by digging under stems, or, at least for larger animals, knocking over or trampling stems. In summary, there are many insect and mammalian predators to C. scheeri var. robustispina adults and seedlings. Predation increases during times of drought and following damage to a cacti's protective spines, such as post-fire. Many individual C. scheeri var. robustispina die or become disposed to death annually from predation which has been recorded on numerous occasions over the past decade. (USFWS, 2018a)

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2018a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Because most C. scheeri var. robustispina occur on private and State Trust lands, they and their habitats are not subject to Federal protection unless there is a Federal nexus to a proposed action. Habitat loss due to urbanization remains a substantial threat to C. scheeri var. robustispina on these lands. Although best management practices may be implemented with regard to development, nonnative plant invasion and associated alteration of fire regimes, recreation, border issues, and the presence of livestock, management is not continuous across the range of the species and C. scheeri var. robustispina remain vulnerable to these threats and stressors. There are no regulations in place that address stressors to C. scheeri var. robustispina and its habitat from predation, drought and climate change, or small population size. (USFWS, 2018a)

**Stressor:** Drought and Climate Change (USFWS, 2018a)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Cacti are vulnerable to disturbance because they grow slowly, their germination and establishment occurs with low frequency, and they have little capability to recover from disturbance (Portilla 2011, p. 509). Disturbance can reduce recruitment, survival, fecundity, and population growth; disturbance coupled with drought, however, can exacerbate negative impacts on cacti. In summary, since the late 1990s, the southwestern United States has been experiencing drought conditions and increasing high temperatures. Climatic predictions suggest continued less frequent, but perhaps more intense, summer precipitation, reduced winter precipitation, and increasing temperatures in this region. Drought and increased temperatures increase C. scheeri var. robustispina stress, reduce defenses to predation and disease, and reduce reproduction, among other impacts. These impacts will continue to affect C. scheeri var. robustispina and its habitat throughout its range into the foreseeable future. (USFWS, 2018a)

**Stressor:** Small Population Size and Isolation (USFWS, 2018a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** High species diversity within the vegetative community is important to the survival of C. scheeri var. robustispina, as this cactus is not abundant enough to sustain its main pollinators. A key pollinator for C. scheeri var. robustispina is Diadasia rinconis, a cactus specialist bee which requires species of Cylindropuntia, Opuntia, and Ferocactus to survive. C. scheeri var. robustispina is a sparsely distributed plant that requires habitat connectivity and proximity to other plants for effective pollination. Large scale threats and stressors such as habitat degradation and regional drought increase the potential for isolation and genetic loss. Current information indicates that roughly 98 percent of all known C. scheeri var. robustispina occur within 900 m (2,952.8 ft) of one another. Should development or other threats or stressors remove or cause the deterioration of corridors and connectivity, this could result in genetic isolation and inbreeding. (USFWS, 2018a)

***Recovery***

**Reclassification Criteria:**
1. Threats and Habitat Criterion: At least 8,094 hectares (ha) (20,000 acres [ac]) of C. scheeri var. robustispina habitat per recovery unit are documented to be of optimal quality and remain that way through successful resource management, land conservation, and restoration techniques such as in situ germination. At least 24,281 ha (60,000 ac) of C. scheeri var. robustispina habitat per recovery unit are documented to be of good quality and remain that way in perpetuity. Habitat is considered optimal quality when it: is protected for conservation purposes; is managed in a manner that promotes the long-term survival of C. scheeri var. robustispina; has less than 20 percent cover of C. ciliaris, E. lehmanniana, or other invasive nonnative plant species that alter ecosystem function; contains contiguous habitat and corridors for pollinators; and the C. scheeri var. robustispina population is observed to be stable or increasing. Habitat is considered good quality when the cover of C. ciliaris, E. lehmanniana, or other nonnative plants that alter ecosystem function remains between 20 and 35 percent; the land is managed in such a way that promotes the continued existence or expansion of long-term survival of C. scheeri var. robustispina. Collectively, this represents approximately 42 percent of the known range of

C. scheeri var. robustispina. Additional acres of lesser quality C.scheeri var. robustispina also exist throughout the range of the species; some of whichoccurs on lands where ongoing efforts may continue to improve habitat quality. (USFWS, 2018a)

2. Conserve, protect, and restore mature C. scheeri var. robustispina individuals, theirseedbanks (approximately 10 meters), and habitat for pollinators (approximately 900 meterradius) in each recovery unit through resource management, land conservation, andrestoration techniques such as in situ germination. Quantitative monitoring, using a standardized monitoring protocol, of established plots across a variety of land ownerships and land management scenarios, with landowner support, is conducted within each of the two recovery units every 3 to 5 years. Plots demonstrate that the population is stable or increasing a minimum of 10 years over a 15-year period. (USFWS, 2018a)

Recovery Priority Number: 3

**Delisting Criteria:**
The first two criteria for downlisting must be met or surpassed, and monitoring must demonstrate that the population is increasing for a minimum of 20 years over a 30-year period. The additional time necessary to achieve delisting ensures continued population viability. Additionally, it will allow land managers to continue to reduce threats to C. scheeri var. robustispina from nonnative species invasion achieved during downlisting and track the long-term effectiveness of management. The additional time will also allow land managers to develop methods to reduce anticipated cost and effort needed to maintain habitat and population viability absent the protections of the Act. (USFWS, 2018a)

**Recovery Actions:**
- Conserve existing and newly discovered C. scheeri var. robustispina and associated habitat, including unoccupied areas that provide habitat and connectivity for pollinators. Promote urban planning for compact urban development, increase open space preservation and management (e.g. restrictions on trash dumping, off road vehicle use, placement of pedestrian trails, etc.), and connective habitat corridors. Engage in land acquisition to reduce habitat fragmentation and increase connectivity. Develop conservation easements for the protection of C. scheeri var. robustispina on private lands. Develop and monitor conservation mitigation banking to promote the protection of C. scheeri var. robustispina habitat. (USFWS, 2018a)
- Restore quality C. scheeri var. robustispina habitat in the U.S. and Mexico. Develop and implement land management plans that support and promote the taxon, including through the reduction of nonnative plant species and unnatural fire regimes, soil erosion, soil compaction, and headcutting. Work toward a better understanding of transplanting and seeding requirements for C. scheeri var. robustispina which could be implemented in appropriate habitat. (USFWS, 2018a)
- Develop range-wide standardized long-term monitoring of individuals in established plots, as well as their habitats, threats, and stressors. Monitor individuals in established plots across the range of the taxon using a tested standard protocol to enable an understanding of the long-term trend of the species, its habitat, threats, and stressors. Check the effectiveness of management actions by monitoring individuals subjected to natural and prescribed fire, mechanical site disturbance, various grazing regimes, various restoration techniques, and other management considerations. Monitor in situ grown and transplanted

individuals for effectiveness of sowing, planting, and transplanting protocols. (USFWS, 2018a)

- Encourage scientific study to improve our understanding of C. scheeri var. robustispina biology, ecology, abundance, status, threats, stressors, viability, propagation, restoration of individuals and of habitats, distribution, and genetics in the United States and Mexico. Identify information gaps, compatible land uses, threats, stressors, and appropriate management actions that lead to the conservation of the taxon. Conduct surveys in appropriate habitat, using a tested standard protocol, to better understand the geographic range and habitat requirements of the taxon. Investigate the feasibility of alternative survey methodologies, such as the use of detection dogs, drones, and distance sampling. Conduct research related to the biology, ecology, abundance, status, threats, stressors, viability, propagation, restoration of individuals and of habitat, and genetics of the taxon. (USFWS, 2018a)
- Maintain plants in captivity at botanic gardens and seeds at seed storage facilities; encourage research into propagation, in situ seed planting, and transplanting methods. Promote the propagation and planting of individuals ex situ at botanic gardens for conservation and public education purposes. Maintain seed from plants across the geographic range of the taxon for conservation purposes. Develop effective approaches to in situ conservation. (USFWS, 2018a)
- Develop public outreach, collaborative partnerships, and agreements with private landowners in the United States and Mexico that encourage C. scheeri var. robustispina conservation. Increase public outreach regarding threats, stressors, and conservation measures relating to C. scheeri var. robustispina in both the United States and Mexico. Develop collaborative partnerships and agreements with private landowners that result in management plans or that otherwise encourage C. scheeri var. robustispina conservation in the United States and Mexico. Develop a recovery implementation team comprised of species experts, agency and non-government agency partners, landowners, and stakeholders to meet regularly, review progress, discuss problems, and revise this plan as needed. (USFWS, 2018a)

***Conservation Measures and Best Management Practices:***

- The principle recovery strategy is to conserve the habitat of Coryphantha scheeri var. robustispina by protecting habitat, restoring habitat, and protecting Coryphantha scheeri var. robustispina individuals, their seedbanks, and habitat for their pollinators. Providing conservation and restoration of the taxon and its habitat will allow a stable, self-sustaining population to persist with some level of connectivity and opportunities for expansion and dispersal. Additional actions needed include monitoring, surveying, scientific study, outreach and partnership development, augmentation and introduction, and reduction or removal of stressors. Several recovery actions listed in the Recovery Plan are already under way, including protection of land from development (USFWS, 2018)..
- RECOMMENDATIONS FOR FUTURE ACTIONS The principal recovery strategy is to conserve the habitat of Coryphantha scheeri var. robustispina by protecting habitat, restoring habitat, and protecting Coryphantha scheeri var. robustispina individuals, their seedbanks, and habitat for their pollinators. Providing conservation and restoration of the taxon and its habitat will allow a stable, self-sustaining population to persist with some level of connectivity and opportunities for expansion and dispersal. Additional actions needed include monitoring, surveying, scientific study, outreach and partnership development, augmentation and introduction, and reduction or removal of stressors. Several recovery actions listed in the Recovery Plan (U.S. Fish and Wildlife Service 2018)

are already under way, including protection of land from development. If in the future the Recovery Plan becomes necessary to revise, the U.S. Fish and Wildlife Service will follow the protocol for a Recovery Implementation Strategy and include interested parties and cooperatives (USFWS, 2024).

# SPECIES ACCOUNT: *Coryphantha sneedii var. leei* (Lee pincushion cactus)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 11/26/1979; Southwest Region (R2)

**Physical Description**

Both the Sneed and Lee pincushion cacti are many branched, forming tight clumps of up to 100 or more stems. Individual stems are cylindroid or spherical to club-shaped, 2.5-7.5 cm long (1.0-2.9 inches) and 1-3 cm in diameter (0.4- 1.2 inches) with tubercles up to 3mm long (0.12 inches). The tubercles are persistent and hard after fall of the spines. The spines hide the stem. The central spines are acicular, white, tipped with pink and brown, 3-14 cm long (1.2-5.5 inches) and about 6-17 per areole. The radial spines are white, 3-12 mm long (0.2-0.47 inches) and 35-90 per areole. The flowers are about 1.2 cm tall (0.5 inches) and of equal diameter, not opening widely; they are brownish-pink to pale rose with pink filaments and bright orange anthers. The fruits are greyish-green, or greenish tinged with brown, or rarely pinkish when ripe. They are clavate up to 1.5 cm long (0.6 inches) and 6 mm in diameter (0.24 inches). The seeds are reddish-brown, 0.7-1 mm long (.027-.039 inches), and 1.25-1.5 mm broad (.049-.059 inches) (Benson, 1982). In the Lee pincushion cactus, the spines are deflexed on medium and small stems, slanting from the top of the tubercle toward the main portion of the stem; the flowers are dull medium brownish-pink; the seeds are 1 mm long (.039 inches) and 1.5 mm broad (.059 inches) (Benson, 1982).(USFWS, 1986)

**Taxonomy**

In the recent taxonomic publications (Kartesz 1999; Baker and Johnson 2000; Anderson 2001), both varieties of Coryphantha sneedii are placed in the genus Escobaria Britton and Rose. Baker and Johnson (2000) note that this genus is sometimes considered a subgenus of Coryphantha. Anderson (200 1) uses the genus Escobaria in his book "The Cactus Family," stating that the International Cactaceae Systematics Group has accepted this genus. (USFWS, 2015)

**Historical Range**

Coryphantha sneedii var. leei is known only from the Guadalupe Mountains in New Mexico (Eddy County), within, and immediately adjacent to, Carlsbad Caverns National Park. At the time of listing, it was known to only occur in "several canyons" (Weniger 1969). (USFWS, 2015)

**Current Range**

Occurs in the Guadalupe Mountains (Eddy County) of New Mexico (NatureServe, 2015). This subspecies includes individuals from six canyons scattered in populations of low abundance over approximately 22 kilometers (14 miles) of the Guadalupe Mountains including BLM lands (Carlsbad District). (USFWS, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Asexual: vegetative (USFWS, 1986; see dispersal narrative); sexual (inferred from USFWS, 1986)

**Breeding Season**

Adult: March - April (USFWS, 1986)

**Key Resources Needed for Breeding**

Adult: Winter and spring moisture, soils seed bank (USFWS, 1986)

**Reproduction Narrative**

Adult: Most Lee pincushion cacti bloom after 3 - 4 years. Plants bud in late March or early April; fruit formation is from August to November. Winter and spring moisture is important for bud set. Each fruit produces about 26 seeds and a flowering stem produces about 6 fruits. A typical plant may produce over 1,000 seeds per year. Since seeds can remain viable for up to 10 years, the soil probably contains a sizeable seed bank (USFWS, 1986).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Chaparral (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 1,220-1,800 m elevation (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: It is restricted to the Tansil Limestone Formation and grows only on north-facing limestone ledges, slopes and ridgetops, at 1,220-1,800 m elevation; precipitation averages 30 cm/year, in interior chaparral communities. The limestones are generally hard, resistant to erosion, and support a sparse vegetation of low shrubs, some rosette-forming perennials, many cacti, and both annual and perennial herbs (USFWS, 1986; NatureServe, 2015). Lee's occupies steep, rugged, remote terrain, so there has been limited survey effort relative to the extent of potential habitat for this species. Therefore, habitat and ecosystem conditions are largely unknown. Zimmerman (1985, p. 360) and Baker (2001e, 14119) observed that Lee's and Sneed's-form plants appeared to be stressed by the more arid conditions in lower elevation areas; plant appeared unhealthy, patches were confined to moister microhabitats, and/or recruitment of seedlings appeared to be limited. Therefore, habitat suitability and availability may be decreasing with increasing temperatures (USFWS, 2023)

***Dispersal/Migration***

**Dispersal**

Adult: Low (inferred from USFWS, 1986)

**Dispersal/Migration Narrative**

Adult: Only about 10% of all stems are of the non-flowering type, and these are broken off by animals or shifting rocks and may root, establishing new plants. Most fruits are eaten by insects or rodents who probably scatter a few seeds in the process. Birds have also been observed to feed on the fruits and should at least occasionally serve as dispersal agents. If a fruit is not eaten, weathering breaks down the fruit wall causing the seeds to be dispersed by wind or rain (USFWS, 1986).

***Population Information and Trends***

**Population Trends:**

Not available

**Resiliency:**

Initial species abundance estimates were made in 1984–1985, so the current abundance of Lee's populations are unknown. Trend data last collected in 1992–1995 documented that monitored recreation effects plots were stable to increasing. This historic information is unlikely to be a reliable estimate of current abundance and/or trends given the extended droughts of 2002–2004, 2011–2014, and 2020–2022 (National Integrated Drought Information System n.d., unpaginated). Trend data last collected in 2018 from fire effects monitoring plots documented that both monitored burned and unburned fire effects plots were declining. However, these were targeted plots, which are known to be biased toward detecting declining trends that may not represent actual population-level trends. Trends for most occurrence areas have never been monitored. Habitat suitability and availability may be decreasing with increasing temperatures (Zimmerman 1985, p. 360; Baker 2001e, 14119). (USFWS, 2023)

**Representation:**

Lee's currently occupies 2–3, geographically isolated and genetically distinct representation areas, depending on phylogenetic analysis results: one core Lee's population (consisting of the Serpentine Bends/Dark Canyon/CrookedCreek, Walnut Canyon, Rattlesnake Canyon, North Slaughter Canyon/Middle Slaughter Canyon, Bear Canyon, Midnight Canyon, Putnam Canyon, West Slaughter Canyon, and Yucca Canyon occurrences) and one core Sneed's-form population (consisting of the Lefthook Canyon, Double Canyon, Cottonwood Canyon, Gunsight Canyon, and Big Canyon occurrences), as well as a third, isolated, Lee's individual (Sargent Canyon). Genetic diversity within and between occurrence areas and/or populations is unknown, but there's evidence of gene flow between West Slaughter Canyon and Yucca Canyon, between Big Canyon and Cottonwood Canyon, and between these sets of canyons. However, based on small population size(s), we suspect that Sneed's is experiencing a loss of evolutionary potential from loss of diversity through genetic drift, except, potentially, under Zimmerman's (1985, p. 359) rough range-wide abundance estimate, which includes Sneed's-form occurrences. Therefore, while evolutionary processes appear functional, Lee's may have a compromised capacity to adapt to changing environmental conditions. (USFWS, 2023)

**Redundancy:**

Lee's relatively continuous known range (excluding the Sargent Canyon occurrence) extends approximately 30 km (19 mi) southwest to northeast (including Sneed's-form individuals within putative Guadalupensis occurrences) or approximately 15 km (9 mi) southwest to northeast (excluding that core population). This range is not extensive enough to ensure geographic independence of the two core population areas that constitute this range given the potential extent of regional extended droughts (National Integrated Drought Information System n.d., unpaginated) and other destructive, broad-scale severe weather events, which can span several states. However, this range is extensive enough to ensure that wildfires and vegetation treatments wouldn't affect all occurrences simultaneously (Bureau of Land Management 2023, unpaginated), given that recent fires in comparable habitats (such as the Dog, Cottonwood, Potrillo, Brushy, Foster, and San Luis fires of 2021– 2023) ranged from 3–11 km (2–7 mi) in extent (National Interagency Fire Center 2023, unpaginated). (USFWS, 2023)

**Number of Populations:**
10-15 (USFWS, 2023)

**Population Size:**
1,000 - 2,000 (USFWS, 1986)

**Population Narrative:**
Presently, Coryphantha sneedii var. leei is known from very limited portions of six canyons in the Guadalupe Mountains (USFWS, 2015). There are an estimated 1,000 - 2,000 plants (Heil and Brack, 1985a) (USFWS, 1986). In 2015, we understood Lee's to include individuals from six canyons (Service 2015, p. 7). We now understand Lee's to occur within 10–15 canyons or canyon complexes, depending on the taxonomic identity of Sneed's-form plants within Guadalupensis occurrence areas (Table 1; see, also, section 2.2.1.5). Sneed'sform plants in the five southmost canyons (Big Canyon to Lefthook Canyon) aren't known to co-occur with plants exhibiting classic Lee's traits. Given our 2015 Lee's range extent estimate of 22 km (Service 2015, p. 7), we likely did not consider plants within these canyons in our last analysis of Lee's status. Except for the addition of Sargent Canyon, which was discovered in 2022, this increase in occurrence areas doesn't represent new detections or range expansion because the remaining occurrence areas have been documented since at least 2001.

***Threats and Stressors***

**Stressor:** Fire (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Presently, the threat of wild and prescribed fires in or around occupied Coryphantha sneedii var. leei habitat could prove problematic to its survival. Most of the park has burned since 1941 (NPS 2005, map, p. 6). While lightning ignitions probably took place frequently in the Guadalupe Mountains, most fires were likely quite localized and less intense prior to fire suppression (NPS 2005). Fire suppression in many ecosystems creates more uniform fuel loads that support more landscape-scale high intensity fires (NPS 2005). Specific impacts of wild and prescribed fire on Coryphantha sneedii var. leei are inconclusive (USFWS, 2015).

**Stressor:** Longhorn cactus beetle (USFWS, 2015)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** There has been one observation of adult Moneilema armatum (longhorn cactus beetle) on C. sneedii var. leei, eating portions of this cactus. It is unknown what impact, if any, longhorn beetles have on this species (USFWS, 2015).

**Stressor:** Climate change (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Growing seasons are becoming longer and warmer in many regions (Parmesan 2007) including the southwest (Cayan et al. 2001; Easterling 2002; Lenart et al. 2007; Enquist and Gory 2008). Earlier soil moisture stress would result in decreased flowering and reproduction, and because this cactus has a limited distribution, we would predict a substantial population reduction with a long-term warming trend. Munson et al. (20 14) predicts declines in vegetative cover including cacti in Chihuahuan Desert habitats due to climate change. Coryphantha spp. are likely to have experienced and rebounded from periods of drought in the past. However, should substantial climate change materialize with increased severity and frequency of drought, it would likely reduce the long-term survivorship of this species (USFWS, 2015).

***Recovery***

**Reclassification Criteria:**
Not applicable. (USFWS, 1986)

Recovery Priority Number: 3

**Delisting Criteria:**
TheLee pincushion cactus will be considered for delisting when:

1. All core populations demonstrate stable or increasing trends in abundance over a 20-year period. This will be based on periodic demographic trend monitoring and analysis implemented under the recovery actions. (USFWS, 2019)

2a. Maintain a minimum of three geographically separated core populations for each species over a 20-year period. (USFWS, 2019)

2b. A minimum of one new core population will be discovered (use Criterion 1) or established outside the current range and wholly separated geographically from the other core populations, and remain occupied for 10 years out of the 20-year survey period. (USFWS, 2019)

3a. Maintain genetic diversity within all core populations as measured by the fixation indices inbreeding coefficient (FIS) at or within one standard deviation of the FIS of a closely related species with similar reproductive strategies and demonstrated acceptable viability. (USFWS, 2019)

3b. Maintain presence in 80 percent of subpopulations over 20-year monitoring period and outside of the core populations, with any subpopulation extirpations compensated by a newly identified or colonized subpopulation. (USFWS, 2019)

4. Develop and implement a Habitat Management Plan (HMP) for Sneed and Lee pincushion cacti conservation. (USFWS, 2019)

5. A Service approved post-delisting monitoring plan will be implemented. (USFWS, 2019)

**Recovery Actions:**

- Remove threats of collecting by enforcement of existing regulations. Because of the rarity of the Lee pincushion cactus, the populations must be protected by enforcement of existing international, Federal, and State regulations. Determine the extent and impacts of collecting. Develop and implement a law enforcement strategy. Publicize successful law enforcement actions. (USFWS, 1986)
- Manage existing habitat for protection of the cactus. Habitat management for the Lee pincushion cactus should be done through existing agency management procedures and through cooperation with private landowners. The following should be accomplished. Agencies should remain informed of the location and status of Lee pincushion cactus populations. Develop and implement habitat management plans for all populations on public lands. Seek cooperation of landowners to protect and maintain populations on private lands. (USFWS, 1986)
- Gather information for use in management. In-depth knowledge of the plant's growth, distribution, population biology and ecology is needed to understand habitat requirements. The knowledge gained can be used to help sustain and manage healthy natural populations. Study population biology and ecology. Develop techniques to artificially propagate and transplant the Lee pincushion cactus. Inventory known populations and search for new populations in the Franklin and Guadalupe Mountains. (USFWS, 1986)
- Develop a comprehensive trade management plan for all cacti. Studies are needed to determine what species are in trade, the overall trend of trade in listed cacti, and the feasibility of reducing collecting pressure on wild populations by promoting a commercial, artificial propagation program. Strategies for effective implementation of law enforcement responsibilities under ESA, CITES, Lacey Act, and State laws need to be developed. These studies should be national in scope and address all cacti. The results will be used to develop policy and a comprehensive trade management plan for all cacti. (USFWS, 1986)
- Develop public awareness, appreciation and support for preservation of the Lee pincushion cactus. Education of the public is a vital part of the recovery process. The cooperation of the public is essential to the ultimate success of the foregoing recovery measures. (USFWS, 1986)
- Recommendations for Future Actions from 2015 5-Year Review: • Determine if the genus associated with this species needs to be changed from Coryphantha to Escobaria on all future Service documents. • Revise the recovery plan for these species to incorporate new information on taxonomy, biology, ecology, and threats with management recommendations. Objective and measurable recovery criteria for down and de listing of the species should be developed which address all listing factors relevant to this species. • Develop a Coryphantha sneedii var leei and C. sneedii var. sneedii multi-agency working group to share and disseminate information regarding this listed species to promote education, protection, and recovery. • Develop standardized survey and monitoring protocols for these species to be conducted annually by well trained personnel. Continue monitoring of known sites as well as adding new sites to provide a robust dataset for long-

term trend analysis. Incorporate fire and climate change factors into long-term monitoring data collection. • Develop a mitigation banking requirement (a system whereby project proponents pay for plants to be preserved in an area suitable for their preservation as mitigation for losses incurred during projects). • Implement and monitor new transplant projects with experimental manipulations (watering, shading, planting depth, etc.) and controls to determine required establishment needs. • Provide legally grown seeds and plants of Coryphantha sneedii var. leei and C. sneedii var. sneedii, as the known populations allow, to the commercial succulent trade, but law enforcement must remain vigilant against the theft of cacti thr.oughout its range. • Provide viable Coryphantha sneedii var. leei and C. sneedii var. sneedii seeds to a seed bank operating under the Center for Plant Conservation guidelines. • Collect data on seed dispersal and growth past the germination stage, timing of seed set, and seedling establishment to more clearly define the vulnerable life history stages of these species. • Determine microhabitat needs of these species ("nurse" plants, pollinators, precipitation needs- amount and timing, slope and aspect requirements, disturbance patterns, etc.) to further quantify potential habitat for a transplant and mitigation site. (USFWS, 2015)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • Resolve the taxonomic identity of Sneed's-form plants range-wide and in the Sneed'sform core population area. • Survey suitable habitats as predicted by probabilistic models for the presence/absence and extent of Lee's occurrences, starting with the Sargent Canyon occurrence area. Consider evaluating the feasibility of using aerially assisted remote sensing and artificial intelligence assisted object detection techniques to identify potentially occupied areas for on-the-ground presence/absence survey efforts. • Map the bounds of Lee's occurrences within occupied areas, using standardized and repeatable methods. • Install randomly or systematically located demographic and density monitoring plots throughout the species' range. Determine the plot specifications and sample sizes needed to achieve the desired statistical power experimentally. • Assess the probability of wildfire exposure in occurrence areas. • Assess microclimate refugia in and adjacent to occurrence areas. • Assess Lee's resiliency to, and capacity to adapt to, projected future climate changes. If resiliency and adaptive capacity are low, identify future suitable habitat areas using probabilistic models that incorporate the range of available future climate scenarios and time periods. • Collect seeds along >50 maternal lines per occurrence area for ex-situ, long-term conservation storage. Consider what germplasm may be needed for successful reintroductions when planning collections (Maschinski et al. 2012, entire). • Finalize protections for Lee's occupied and adjacent and intervening habitats, including future habitats, via special designations and associated mineral withdrawals and management prescriptions for the purpose of conserving Lee's. (USFWS, 2023)

# SPECIES ACCOUNT: *Coryphantha sneedii var. sneedii* (Sneed pincushion cactus)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 12/07/1979; Southwest Region (R2)

**Physical Description**

Both the Sneed and Lee pincushion cacti are many branched, forming tight clumps of up to 100 or more stems. Individual stems are cylindroid or spherical to club-shaped, 2.5-7.5 cm long (1.0-2.9 inches) and 1-3 cm in diameter (0.4- 1.2 inches) with tubercles up to 3mm long (0.12 inches). The tubercles are persistent and hard after fall of the spines. The spines hide the stem. The central spines are acicular, white, tipped with pink and brown, 3-14 cm long (1.2-5.5 inches) and about 6-17 per areole. The radial spines are white, 3-12 mm long (0.2-0.47 inches) and 35-90 per areole. The flowers are about 1.2 cm tall (0.5 inches) and of equal diameter, not opening widely; they are brownish-pink to pale rose with pink filaments and bright orange anthers. The fruits are greyish-green, or greenish tinged with brown, or rarely pinkish when ripe. They are clavate up to 1.5 cm long (0.6 inches) and 6 mm in diameter (0.24 inches). The seeds are reddish-brown, 0.7-1 mm long (.027-.039 inches), and 1.25-1.5 mm broad (.049-.059 inches) (Benson, 1982). In the Sneed pincushion cactus, the stems have spines that are not deflexed but spread parallel to the stem surface; the flowers are pale, or medium to rose, magenta; the seeds are 0.75 mm long (.03 inches), and 1.25 mm broad (.049 inches) (Benson, 1982). (USFWS, 1986)

**Taxonomy**

In the recent taxonomic publications (Kartesz 1999; Baker and Johnson 2000; Anderson 2001), both varieties of Coryphantha sneedii are placed in the genus Escobaria Britton and Rose. Baker and Johnson (2000) note that this genus is sometimes considered a subgenus of Coryphantha. Anderson (2001) uses the genus Escobaria in his book "The Cactus Family," stating that the International Cactaceae Systematics Group has accepted this genus. Further elucidation of the taxonomic relationships of the C. sneedii complex, including Escobaria guadalupensis, is needed in order to understand the distribution and abundance of C. sneedii var. sneedii (USFWS, 2015).

**Historical Range**

Coryphantha sneedii var. sneedii is a regional endemic along the Texas/New Mexico border (USFWS, 2015). It was historically known only from the Anthony Gap area of the Franklin mountains in Dona Ana County, New Mexico. (USFWS, 1986)

**Current Range**

It occurs in western Texas and nearby southern New Mexico (between El Paso and Las Cruces) (NatureServe, 2015). It possibly occurs in the Guadalupe Mountains; in Dona Ana and Eddy Counties, New Mexico, and El Paso County in Texas (USFWS, 2015).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Asexual: vegetative (USFWS, 1986); sexual (inferred from USFWS, 1986)

**Breeding Season**

Adult: March - April, sometimes July - August (USFWS, 1986)

**Key Resources Needed for Breeding**

Adult: Rocks (USFWS, 1986; NatureServe, 2015)

**Reproduction Narrative**

Adult: A second blooming season has rarely been observed in July and August usually following summer rains. The best seedling survival is under rocks or deep in the cracks of rocks where seedlings are protected (USFWS, 1986; NatureServe, 2015). One type of stem remains small and probably serves to start new plants when they break off. Most Sneed pincushion cacti bloom after 3 - 4 years. Plants bud from March to April with the principal blooming period in April and fruit formation from august to November. Fruits from slaughter Canyon averaged about 18 seeds per fruit. With about 11 flowering stems per plant, about 140 seeds per plant are produced each year (USFWS, 1986).

**Habitat Type**

Adult: Terrestrial (USFWS, 1986; NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Desert and desert grassland (USFWS, 1986; NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 1,220-1,800 m elevation (USFWS, 1986; NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 1986; NatureServe, 2015)

**Habitat Narrative**

Adult: It is restricted to limestone ledges and the rocky slopes of limestone mountains in desert and desert grassland habitats; 1,22 0- 1,800 m elevation; precipitation 19.7 - 40.0 cm/year; and grows in cracks on vertical cliffs or ledges. The limestones are generally hard, resistant to erosion, and support a sparse vegetation of low shrubs, some rosette-forming perennials, many cacti, and both annual and perennial herbs (USFWS, 1986; NatureServe, 2015).

***Dispersal/Migration***

**Dispersal**

Adult: Low to moderate (inferred from USFWS, 1986)

**Dispersal/Migration Narrative**

Adult: The fruits have a prune-like odor when ripe and attract rodents which are likely dispersal agents. Birds have been noted to feed on the fruits and should serve as dispersal agents. Some fruits crumble with age, and water disperses the seeds (USFWS, 1986).

***Population Information and Trends***

**Population Trends:**
Not available

**Number of Populations:**
20 (USFWS, 1986)

**Population Size:**
Possibly > 100,000 (USFWS, 1986)

**Population Narrative:**
There are 20 documented localities for this taxon. Heil and Brack (1985a) have estimated the total number of sneed pincushion cacti in Carlsbad Caverns National Park to exceed 100,000. This figure needs verification through quantitative sampling (USFWS, 1986).

***Threats and Stressors***

**Stressor:** Fire (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Most of the park has burned since 1941 (NPS 2005, map, p. 6). While lightning ignitions probably took place frequently in the Guadalupe Mountains, most fires were likely quite localized and less intense prior to fire suppression (NPS 2005). Fire suppression in many ecosystems creates more uniform fuel loads that support more landscape-scale high intensity fires (NPS 2005). However, specific impacts of wild and prescribed fire on C. sneedii var. sneedii are still inconclusive (USFWS, 2015).

**Stressor:** Climate change (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Growing seasons are becoming longer and warmer in many regions (Parmesan 2007) including the southwest (Cayan et al. 2001; Easterling 2002; Lenart et al. 2007; Enquist and Gory 2008). Earlier soil moisture stress would result in decreased flowering and reproduction, and because this cactus has a limited distribution, we would predict a substantial population reduction with a long-term warming trend. Munson et al. (20 14) predicts declines in vegetative cover including cacti in Chihuahuan Desert habitats due to climate change. Coryphantha spp. are likely to have experienced and rebounded from periods of drought in the past. However, should substantial climate change materialize with increased severity and frequency of drought, it would likely reduce the long-term survivorship of this species (USFWS, 2015).

***Recovery***

**Reclassification Criteria:**

Downlisting of the Sneed pincushion cactus to threatened can be initiated when:

1. Six or more secure populations are established with at least three each near the eastern (Guadalupe Mountains) and western (Franklin Mountains and southern Organ Mountains) limits of the plant's known range. Populations will be considered secure when land managing agencies, organizations or individuals have developed and implemented habitat management plans for the Sneed pincushion cactus. At a minimum, the plans should contain methods for securing populations against present and future potential threats, methods for accurately quantifying population sizes, and methods for monitoring populations to determine their stability, growth, or decline. (USFWS, 1986)

2. When the known number of plants in these six secure populations totals 20,000. (USFWS, 1986)

**Delisting Criteria:**
The Sneed pincushion cactus will be considered for delisting when:

1. All core populations demonstrate stable or increasing trends in abundance over a 20-year period. This will be based on periodic demographic trend monitoring and analysis implemented under the recovery actions. (USFWS, 2019)

2. Maintain a minimum of three geographically separated core populations for each species over a 20-year period. (USFWS, 2019)

3a. Maintain genetic diversity within all core populations as measured by the fixation indices inbreeding coefficient (FIS) at or within one standard deviation of the FIS of a closely related species with similar reproductive strategies and demonstrated acceptable viability. (USFWS, 2019)

3b. Maintain presence in 80 percent of subpopulations over 20-year monitoring period and outside of the core populations, with any subpopulation extirpations compensated by a newly identified or colonized subpopulation. (USFWS, 2019)

4. Develop and implement a Habitat Management Plan (HMP) for Sneed pincushion cacti conservation. (USFWS, 2019)

5. A Service approved post-delisting monitoring plan will be implemented. (USFWS, 2019)

**Recovery Actions:**
- Remove threats of collecting by enforcement of existing regulations. Because of the rarity of the Sneed pincushion cactus, the populations must be protected by enforcement of existing international, Federal, and State regulations. Determine the extent and impacts of collecting. Develop and implement a law enforcement strategy. Publicize successful law enforcement actions. (USFWS, 1986)
- Manage existing habitat for protection of the cactus. Habitat management for the Sneed pincushion cactus should be done through existing agency management procedures and through cooperation with private landowners. The following should be accomplished. Agencies should remain informed of the location and status of Sneed pincushion cactus

populations. Develop and implement habitat management plans for all populations on public lands. Seek cooperation of landowners to protect and maintain populations on private lands. (USFWS, 1986)

- Gather information for use in management. In-depth knowledge of the plant's growth, distribution, population biology and ecology is needed to understand habitat requirements. The knowledge gained can be used to help sustain and manage healthy natural populations. Study population biology and ecology. Inventory known populations and search for new populations in the Franklin and Guadalupe Mountains. (USFWS, 1986)
- Develop a comprehensive trade management plan for all cacti. Studies are needed to determine what species are in trade, the overall trend of trade in listed cacti, and the feasibility of reducing collecting pressure on wild populations by promoting a commercial, artificial propagation program. Strategies for effective implementation of law enforcement responsibilities under ESA, CITES, Lacey Act, and State laws need to be developed. These studies should be national in scope and address all cacti. The results will be used to develop policy and a comprehensive trade management plan for all cacti. (USFWS, 1986)
- Develop public awareness, appreciation and support for preservation of the Sneed pincushion cactus. Education of the public is a vital part of the recovery process. The cooperation of the public is essential to the ultimate success of the foregoing recovery measures. (USFWS, 1986)
- Recommendations for Future Actions from 2015 5-Year Review: • Determine if the genus associated with this species needs to be changed from Coryphantha to Escobaria on all future Service documents. • Revise the recovery plan for these species to incorporate new information on taxonomy, biology, ecology, and threats with management recommendations. Objective and measurable recovery criteria for down and de listing of the species should be developed which address all listing factors relevant to this species. • Develop a Coryphantha sneedii var leei and C. sneedii var. sneedii multi-agency working group to share and disseminate information regarding this listed species to promote education, protection, and recovery. • Develop standardized survey and monitoring protocols for these species to be conducted annually by well trained personnel. Continue monitoring of known sites as well as adding new sites to provide a robust dataset for long-term trend analysis. Incorporate fire and climate change factors into long-term monitoring data collection. • Develop a mitigation banking requirement (a system whereby project proponents pay for plants to be preserved in an area suitable for their preservation as mitigation for losses incurred during projects). • Implement and monitor new transplant projects with experimental manipulations (watering, shading, planting depth, etc.) and controls to determine required establishment needs. • Provide legally grown seeds and plants of Coryphantha sneedii var. leei and C. sneedii var. sneedii, as the known populations allow, to the commercial succulent trade, but law enforcement must remain vigilant against the theft of cacti thr.oughout its range. • Provide viable Coryphantha sneedii var. leei and C. sneedii var. sneedii seeds to a seed bank operating under the Center for Plant Conservation guidelines. • Collect data on seed dispersal and growth past the germination stage, timing of seed set, and seedling establishment to more clearly define the vulnerable life history stages of these species. • Determine microhabitat needs of these species ("nurse" plants, pollinators, precipitation needs- amount and timing, slope and aspect requirements, disturbance patterns, etc.) to further quantify potential habitat for a transplant and mitigation site. (USFWS, 2015)

# SPECIES ACCOUNT: *Crotalaria avonensis* (Avon Park harebells)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 5/27/1993; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

Avon Park harebells (Crotalaria avonensis) is a spreading, perennial herb with one to three moderately hairy, flowering stems that may grow 2 to 10 cm above the surface. It has a large taproot, up to 14 mm thick and 40 cm long. The leaves of this plant are 8 to 19 mm long, broadly elliptic or round, somewhat succulent, and coated with white or yellowish-white hairs. The stems terminate in flowering racemes. Flowering is from March until June. The flower, shaped like a typical pea flower, has a yellow corolla 8 to 9 mm long. The seed pods are inflated and 14 to 25 mm long. These pods are tan to grey or maroon, and can be nearly as long as the upright stems that hold them in place. The pods contain up to 18 seeds, chestnut to maroon in color and 3.4 to 3.8 mm long by 2.4 to 2.6 mm wide. The plant generally appears to resemble clusters of fuzzy grayish leaves hugging the ground and sometimes appears bushy (DeLaney and Wunderlin 1989). (USFWS, 1999)

**Taxonomy**

C. avonensis is a member of the pea family (Fabaceae/Leguminosae). This small herb with large seed pods was not named until 1989, evidently because very few specimens had ever been collected and they had not been examined by taxonomists. This species is most closely related to C. rotundifolia, a variable species that ranges from Virginia to Panama (DeLaney and Wunderlin 1989). Crotalaria is a very large, mostly tropical genus that includes a number of robust annual weeds, all with inflated “rattlebox” seed pods. It has been suggested that this endemic is a relic of the Miocene on the southern Lake Wales Ridge (DeLaney and Wunderlin 1989). (USFWS, 1999)

**Historical Range**

See Current Range.

**Current Range**

Avon Park harebells is one of the most narrowly distributed of the Lake Wales Ridge endemics, having only been identified at three sites in Polk and Highlands counties. Its distribution includes the Avon Park Lakes acquisition area and the Saddleblanket Lakes State Preserve in Polk County, and the Carter Creek acquisition area in Highlands County. (USFWS, 1999)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollinated

**Breeding Season**

Adult: Flowering begins in mid-March and continues until June. (USFWS, 1999)

**Other Reproductive Information**

Adult: Flowering begins in mid-March and continues profusely until June. After flowering, this deciduous plant enters a vegetative phase, forming clusters of stems that give a clumped or rosette appearance. They are then dormant from late fall or early winter until March (DeLaney and Wunderlin 1989). Demographic information on pollinators, seed dispersers, and seed viability is lacking for this species. (USFWS, 1999)

**Reproduction Narrative**

Adult: Avon Park harebells are pollinated by insects, but visitation rates are very low. The plant is reproductively challenged, with less than 10 percent of flowers producing fruits. Seeds contribute to a persistent seed bank lasting at least three years. Seedlings have moderate survival and commonly begin flowering after 6-8 years (Menges et al. 2016). (USFWS, 2019)

**Habitat Type**

Adult: Scrub flatwoods rosemary scrub and pine scrub

**Environmental Specificity**

Adult: Very Narrow (USFWS, 1999)

**Habitat Narrative**

Adult: This species inhabits scrub communities found on the Lake Wales Ridge where it typically grows in full sun, on bare white sand, or in association with clumps of Cladonia lichens. However, it may also occur in the partial shade of other plants (DeLaney and Wunderlin 1989). It may also grow along trails, open edges, or previously disturbed roadbeds. The soils associated with this species have been classified as Archbold and Satellite sands (The Nature Conservancy 1991). Like other small scrub endemics, it appears to depend on bare patches of sand to become established. (USFWS, 1999)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: No information available (USFWS, 1999)

***Population Information and Trends***

**Number of Populations:**

4 (USFWS, 2023)

**Additional Population-level Information:**

The Avon Park harebells has a very narrow known historical distribution (Service 2007 and references therein). There are currently only four populations of Avon Park harebells, one of which is an introduced population. In 2012, 400 seeds and 84 transplants of C. avonensis were introduced to a site within management unit SL8 of the Silver Lake Tract of the Lake Wales Ridge Wildlife and Environmental Area (LWRWEA) (Smith et al. 2013, pp. 22, 25) ( Figure1). The site included both scrubby flatwoods and rosemary scrub, both being vegetation types with which the presence of Avon Park harebells is most often associated (Smith et al. 2013, p. 20) (USFWS, 2023).

**Population Narrative:**

Historically and currently, the species is known from just two populations. One population occurs partially in the unprotected Avon Park Lakes subdivision and continues to decline as vacant lots supporting the plant are developed (Menges et al. 2016). Part of this population is protected at a second site, The Nature Conservancy's Saddle Blanket Scrub Preserve. The second population is at the Florida Fish and Wildlife Conservation Commission's (FWC) Carter Creek unit of the Lake Wales Ridge Wildlife Management Area (LWRWEA). The unprotected Avon Park Lakes site hosts the largest number of plants, likely consisting of thousands. The Saddle Blanket site supported 531 plants in 2006 (Service 2007). The size of the Carter Creek population is unknown, but likely is in the thousands, based on Menges et al. (2016). Avon Park harebells has been reintroduced at two conservation sites which have to date been successful in establishing plants that have flowered and produced seed. The FNAI 2015 Element Tracking Summary (FNAI 2015) identifies 6 occurrences, 2 of these are protected at Saddle Blanket Preserve, and represent portions of the larger Avon Park Lakes population. Two others are FWC protected areas that represent the Carter Creek population. The final two occurrences represent unprotected portions of the Avon Park Lakes population. (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species is restricted to xeric scrub habitats in one or more of the interior Central Florida counties of Polk, Highlands, Hendry, Osceola, and Lake, where habitat destruction from development continues to occur and development pressure remains high. Areal extent of post-Columbian xeric upland habitat loss on the Lake Wales Ridge is estimated to exceed 85 percent (Weekley et al. 2008a). Increasing pressure from population growth is likely to result in further loss of these habitats going forward. Carr and Zwick (2016) analyzed existing land use and landscape patterns to identify areas (including central Florida) most likely for development to accommodate a growing human population. They suggests that Florida's 2070 population will be early 15 millionpersons greater than in 2010, for an estimated total of 33,721,828. Using these figures, they estimated relative losses to agriculture, open space, and conservation to other land uses. If trends continue, they estimate 34 percent of land will be developed by 2070, up from 19 percent in 2010. At the same time, conservation lands will increase less than 1 percent (from 9,269,000 acres in 2010 to 9,525,000 acres by 2070). Overall, loss of habitat to development, primarily on private lands, will likely continue in Central Florida, eliminating populations and reducing the area of suitable habitat for these species. Therefore, habitat on protected lands are critical for the recovery of this scrub plants. (USFWS, 2019)

**Stressor:** Lack of adequate fire management
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Fire is necessary to maintain the scrub habitats upon which this species depends. Historically, lightning-induced fires were a vital component in maintaining native vegetation within the scrub community. Fire suppression started on a regional scale on the Central Florida ridges about 80 years ago. Due to the extent of residential and agricultural development throughout Central Florida, fire has all but disappeared from the region as a widespread, natural phenomenon. Prescribed fire is a crucial management component for maintenance of all scrub habitats. Because of the difficulties of applying prescribed fire on an ever-increasing urban landscape, imperiled species on unmanaged sites will almost certainly disappear over time (Turner et al. 2006). In managed areas, prescribed fire is essential to manage habitats and restore or maintain suitable conditions for scrub species. (USFWS, 2019)

**Stressor:** Limited geographic range
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species occurs occur within a relatively limited geographic range in Central Florida. The limited geographic range in combination with the loss of habitat has resulted in a highly fragmented landscape where the remaining scrub areas and their residing species have become more and more isolated from each other, thereby making resiliency, redundancy, and representation more challenging to achieve. The effects of habitat fragmentation on species richness have been exhaustively studied (MacArthur and Wilson 1967, Diamond 1975, 1978; Simberloff and Abele 1976, 1982; Zimmerman and Bierregaard 1986). For most taxonomic groups, large habitat patches in close proximity to each other provide for the greatest species diversity and minimize extinction probabilities. On the contrary, small patches that are isolated are less likely to preserve species that would otherwise be common in the mosaic of communities that existed before isolation. Since at least the Pleistocene, Florida scrub has been characterized by an insular, discontinuous distribution, but the degree of habitat fragmentation seen today is unprecedented and certainly will contribute to increases in extinction rates among scrub-dependent plants and animals. (USFWS, 2019)

**Stressor:** land development (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The primary threat to Avon Park harebells in regard to Factor A is still land development. Projections expect an increase of up to 23 percent in the amount of developed land in central Florida, bringing the total to almost half of the land in the region (Carr and Zwick 2016, p. 23). While development directly decreases the amount of available habitat, it can also decrease the ability of land managers to utilize prescribed fire as a tool for maintaining the types of habitats in which Avon Park harebells are most often found (Melvin and McIntyre 2017, entire; Service 2019, p. 3). Development is also often associated with an increase in the use of various types of pesticides. The components of these pesticides can have a range of effects on insect pollinators, from inhibition of neurological or immune function to lethal outcomes (Sponsler et al. 2019, pp. 1020-1021). The loss of pollinators could be potentially devastating for Avon Park harebells, as they are dependent on pollination for successful reproduction (USFWS, 2023).

**Stressor:** Herbivory (USFWS, 2023)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Herbivory (under Factor C) has been shown to affect around 16 percent of plants annually, but these rates are highly variable between years (Menges et al. 2016, p. 565). The reduction of herbivory using protective cages around plants was also found to provide significant positive effects on survival, growth rates, and flowering, indicating that herbivory is a significant threat to Avon Park harebells (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
Not developed. (USFWS, 1999)

**Delisting Criteria:**
1. At least 20 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)

2. Populations (as defined in criterion 1) in yellow sand scrub and scrubby flatwoods habitats are distributed across the known range of the species. (USFWS, 2019)

3. Populations are protected and managed via a conservation mechanism to a degree that enough suitable habitat is present for the species to remain viable for the foreseeable future. (USFWS, 2019)

**Recovery Actions:**
- Determine current distribution of C. avonensis. This species' known distribution is isolated to Polk and Highlands counties. Additional surveys of scrub habitat with appropriate soils should be conducted in these two counties. A geographic nformation systems database should be developed to map existing populations and to assess the species' status and trends over time. The database should contain information on locations, population sizes, and status. This information should also be used for project review and in land acquisition activities. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or residential development. The remaining habitat is fragmented into small parcels and in many cases, isolated. (USFWS, 1999)
- Conduct research on life history characteristics. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species, more specific biological information is needed. (USFWS, 1999)
- Develop standardized monitoring. Standardized monitoring needs to be developed for this and other listed scrub species to determine the effect of management actions. (USFWS, 1999)
- Provide public information about C. avonensis. It is important that governmental agencies, conservation organizations, and private land owners be appropriately informed about this species. (USFWS, 1999)
- Establish reclassification criteria. Once the population is stabilized, research and monitoring results may provide data necessary to develop reclassification criteria. (USFWS, 1999)

- Habitat-Level Recovery Actions: Prevent degradation of existing habitat. Provide public information about scrub and its unique biota. (USFWS, 1999)

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES Recovery Activities • Continue applying prescribed fire when possible to maintain scrub habitat for Avon Park harebells. • Conduct further augmentation and introduction projects to expand the range of the species and increase the number of populations. • Acquire land within the range of Avon Park harebells and restore scrub habitat to these areas. Monitoring / Research Activities • Develop a consistent monitoring protocol to occur at regular intervals in areas that are occupied by Avon Park harebells and are accessible for survey.

# SPECIES ACCOUNT: *Cucurbita okeechobeensis ssp. okeechobeensis* (Okeechobee gourd)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 8/11/1993; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

A vigorous annual vine. Stems are nearly smooth. Leaves are alternate and paired, and have with long helical tendrils. The leaf blades have 5-7 shallow lobes. Flowers are cream-colored to nearly white, 6-7 cm long, narrowly bell-shaped. (NatureServe, 2015)

**Taxonomy**

Small (1922, 1930) originally described the gourds he found in the pond apple forest surrounding Lake Okeechobee as Pepo okeechobeensis. Bailey (1930) transferred the Okeechobee gourd to the genus Cucurbita, which includes pumpkins and squashes. Bailey (1943) subsequently described two new gourd species, C. martinezii and C. lundelliana. These two gourds were proven to be closely related to the Okeechobee gourd. Closely related gourds with cream-colored corollas (all others in the genus Cucurbita are bright yellow) are found in Florida and in Mexico, near the Gulf Coast. The Florida plants were described as the Okeechobee gourd (Bailey 1930) and the Mexican plants were designated (Bailey 1943) as the Martinez gourd (C. martinezii). However, Robinson and Puchalski (1980) showed through isozyme analysis that there was only a single allelic difference between the two varieties. The (ESA) does not allow Federal listing of disjunct populations of widespread plant species. Since the Mexican gourds are moderately abundant, and considering the findings of Robinson, the FWS originally opposed listing of the Okeechobee gourd. A later study by Walters and Decker-Walters (1991), also using isozyme analysis, showed a difference of just one allele. However, they calculated an estimated time since divergence of about 450,000 years between the Martinez and Okeechobee gourds, and concluded that they should be considered distinct at the subspecies level. Walters and Decker-Walters (1993) rearranged the nomenclature, designating the Florida gourds as Cucurbita okeechobeensis (Small) Bailey ssp. okeechobeensis, and assigning the Mexican gourds to the subspecies C. okeechobeensis ssp. martinezii (Bailey) Andres and Nabhan ex T. Walters and Decker Walters. The FWS concurred with this finding, and because the ESA allows protection of distinct subspecies, the Okeechobee gourd was subsequently listed as endangered. (USFWS, 1999)

**Historical Range**

Historically found on the southern shore of Lake Okeechobee, in Palm Beach County, Florida, and formerly in the Everglades area of Florida. (USFWS, 1999)

**Current Range**

Overall, the current range of Okeechobee gourd is limited to the shoreline and islands around the northwestern and southern portions of Lake Okeechobee in Glades and Palm Beach Counties and both sides of the St. Johns River from Lake Beresford south to Lake Monroe and along the western side of Lake Jessup along the Volusia and Lake County line and into Seminole County. These two populations are separated by over 100 miles and do not exhibit much genetic variation. Because Okeechobee gourd plants are difficult to count, we are unable to estimate the abundance of this subspecies. Surveys in 2007 indicated that the subspecies was present on four of the islands in Lake Okeechobee and on 12 sites along the St. Johns River. (USFWS, 2021) Most of the known occurrences in the Lake Okeechobee population are on public land, but extent of management is not reported. Consistent data showing fruit production at least every other year on Kreamer, Torry, and Ritta Islands and the southern Rim Canal of Lake Okeechobee have not been obtained. There are no stable, self-sustaining populations known to exist within the South Florida Ecosystem outside of Lake Okeechobee, except for the introduced population on private land west of Lantana in Palm Beach County. Finally, additional research on the viability of seeds following prolonged submergence and the survival of plants under rising water stages is needed for evaluation with the water regulation schedule for Lake Okeechobee (USFWS, 2021)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Key Resources Needed for Breeding**

Adult: Insect pollinators (USFWS, 1999)

**Reproduction Narrative**

Adult: Pollination occurs via insects. Based on closely related gourds, a variety of insects are likely to be available, including bees, flies, and squash beetles. Typically, male flowers greatly outnumber female flowers and where pollinators are rare, decreased fruit set may be observed (M. Minno, Eco Cognizant, Inc., personal communication 1998) (USFWS, 1999).

**Habitat Vegetation or Surface Water Classification**

Adult: Forested wetland, temporary pool, field (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Low water levels (USFWS, 2009)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 1999)

**Habitat Narrative**

Adult: Originally found in swampy forests and hammocks on muck soils. Today, this species is restricted to disturbed areas that are not cultivated, such as ditch banks and wet road shoulders. It is sensitive to changes in hydrology and freezing. (NatureServe, 2015). Occurs at Lake Okeechobee and the other along the St. Johns River; limited to areas along the shoreline and a few islands in the lake and along the St. Johns River. Inhabits open organic soils exposed by low water levels (EPA, 2016). The gourd is ephemeral by nature, often only growing when habitat conditions are favorable, and its growth habit of climbing amongst the tree canopy precludes the ability to count individual plants. This subspecies employs a strategy of growing on open organic soils exposed by low water levels with little to no competition, producing numerous seeds with somewhat long viability, and experiencing vegetative decline when competition increases or water levels rise (Moyroud 2009b) (USFWS, 2009). The gourd readily climbs any plant that will provide a trellis; in both Lake Okeechobee and the St. Johns River, the Okeechobee gourd grows on elderberry (Sambucus canadensis) and buttonbush (Cephalanthus occidentalis). Around Lake Okeechobee, the gourd is frequently associated with alligator nests. These disturbed sites provide areas where competition is reduced and elevated areas that promote the growth of elderberry, button bush, and other erect bushes and shrubs. Around Lake Okeechobee, the gourd relies on pond apple trees to support its vines above rising water levels during the wet season.

***Dispersal/Migration***

**Dispersal**

Adult: Unknown (USFWS, 1999)

**Dependency on Other Individuals or Species for Dispersal**

Adult: Possibly march rabbits (USFWS, 1999)

**Dispersal/Migration Narrative**

Adult: High lake levels facilitate dispersal. Although the exact mechanism for seed dispersal of the Okeechobee gourd is unknown, Walters et al. (1992) suggest that Okeechobee gourds disperse by floating in water bodies (in canals and along the shore of islands in Lake Okeechobee); however, no information is available regarding the distances seeds may disperse. Walters et al. (1992) also indicate that marsh rabbits are the main terrestrial disperser of gourd seeds, but others suggest that rabbits are only a predator of these seeds and are unlikely to be significant seed dispersers (M. Minno, Eco-Cognizant, Inc., personal communication 1998) (USFWS, 1999).

***Population Information and Trends***

**Population Trends:**

> 95% decline (NatureServe, 2015)

**Species Trends:**

Declining (USFWS, 2009)

**Number of Populations:**

2 (USFWS, 2009)

**Population Size:**

1 - 1000 individuals (NatureServe, 2015)

**Population Narrative:**

At least 50 gourds were found at one site by Walters and Decker-Walters in 1990-1991. In winter and early spring of 1990-1991 Walters and Decker-Walters found the Okeechobee gourd at 11 sites along the lake shores (Martin, 1992). The estimated population size is up to 1,000 individuals. The species Has already lost 95% of its former range (J.K. Small, 1930) (NatureServe, 2015). The species status is declining; fires destroyed no plants were found on the spoil islands that once supported substantial populations. The Okeechobee gourd is only found in Florida in two natural populations, one on Lake Okeechobee and the other along the St. Johns River. Very little genetic variation was observed within any of the three populations evaluated, and differences between populations were minor with nothing to differentiate between the Lake Okeechobee and St. Johns River populations of the Okeechobee gourd (Decker-Walters 2002c) (USFWS, 2009).

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Continued habitat degradation and loss threaten the existence of Okeechobee gourd. Decker-Walters (2002c) stated that factors that reduce the availability of habitat (e.g., lack of fluctuation in water levels and aggressive weeds) pose a large threat to the subspecies. In addition, several factors related to human values (e.g., water storage, flood control, navigation) and ecological values (e.g., waterfowl, fisheries, littoral zone vegetation, water quality, snail kite recovery, and others) that affect management decisions can potentially conflict (Service 1999). At this time, the habitat seems stable along the St. Johns River; however, proposed water withdrawals for alternative public water supplies may affect suitability for the Okeechobee gourd (Minno 2009). Permanent inundation of suitable soils prevents germination of gourd seeds, and changes in water level management that would reduce the likelihood of low water can threaten the subspecies. Within the range of Okeechobee gourd in the Lake Okeechobee region, the human population is predicted to grow from nearly 11,000 to over 17,000 in Glades County between 2005 and 2060 and from approximately 1,270,000 to over 2,700,000 in Palm Beach County (Zwick and Carr 2006). Population growth is expected to increase water demands and recreational pressure on the lake. Within the range of the St. Johns River gourd population, the number of residents in Volusia County is projected to increase over the same time period from nearly 500,000 to over 940,000 and nearly triple in Lake County from just over 260,000 to more than 700,000 (Zwick and Carr 2006) (USFWS, 2009).

**Stressor:** Competition (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Okeechobee gourd plants are not strong competitors and are often outcompeted by more aggressive plant species (Decker-Walters 2002c). Weed competitors include moonflower, common reed (Phragmites australis), Virginia saltmarsh mallow (Kosteletzkya virginica), camphorweed (Pluchea sp.), melaleuca (Melaleuca quinquenervia), Sesbania sp., and Polygonum spp. (Decker-Walters 2002a; 2002c) (USFWS, 2009).

**Stressor:** Herbicide usage (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Although necessary for control of exotic plants, herbicide use also poses a threat to the Okeechobee gourd. The occurrences at one of the sites along the St. Johns River were destroyed in 2005 where herbicide was sprayed, and the site is no longer suitable (Minno and

Minno 2005). Herbicides are routinely sprayed around Lake Okeechobee to keep waterways free of aquatic vegetation (USFWS, 2009).

**Stressor:** Disease (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Minno and Minno (1998) reported finding powdery mildew fungus (Sphaerotheco fuliginea), a hyperparasitic fungus (Ampelomyces quisqualis), mites (e.g., Bevipalpus sp., Propvioseius meridionalis, and Galendromus mcgregori), melonworm (Diaphania hyalinata), pickleworm (Diaphania nitidalis), sowbugs, grasshoppers, leaf-footed bugs, and scales (Saissetia neglecta) on leaves of the Okeechobee gourd along the St. Johns River. Little damage to the plants was observed except as a result of the powdery mildew fungus, melonworm, and pickleworm in which older leaves were killed and infected fruit was aborted (Minno and Minno 1998). During the 2002 survey on Lake Okeechobee's Torry Island, Okeechobee gourd plants appeared productive but unhealthy, and plants tested positive for several viruses, including cucumber mosaic virus, squash mosaic virus, and watermelon mosaic virus (Decker-Walters 2002a). Signs of viral infection (leaf puckering) were also seen on one of the FWC spoil islands, but few vines from the St. Johns River population exhibited signs of viral infection (Decker-Walters 2002a). The author believed that the Lake Okeechobee population may be affected by more diseases and insects as a result of local agricultural activities in the area, such as the production of squash, but suggested that reproduction may not be substantially affected (Decker-Walters 2002a) (USFWS, 2009).

**Stressor:** Predation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Insect predation was observed on Okeechobee gourd plants on one of the FWC spoil islands on Lake Okeechobee in 2002 (e.g., striped cucumber beetle [Acalymma vittatum], pickleworm, and melonworm) (Decker-Walters 2002a). Extensive herbivory by marsh rabbits (Sylvilagus palustris) was observed on one of the FWC spoil islands on Lake Okeechobee and appeared to have devastated the plants on this island; the other spoil island seemed to be unaffected by herbivory (Decker-Walters 2002c). Decker-Walters (2002c) suggested that rabbits, as well as wild pigs (Sus scrofa), present a threat to the subspecies through predation of seeds. Plants in the St. Johns River population were healthier in 2002 and exhibited no signs of insect damage (Decker-Walters 2002a) (USFWS, 2009).

**Stressor:** Small population size (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Small populations are susceptible to inbreeding depression, which compounds the effects of other threats, such as reduced resistance to herbivore damage and viral infections (Stephenson et al. 2004). Because Okeechobee gourds are ephemeral in nature, they tend to appear and disappear from sites, depending upon growing conditions (Service 1999). No stable core population remains south of the lake to ensure survival as a result of poor growing conditions (e.g., the permanent inundation of suitable soils as a result of water-level regulation)

(Service 1999). Even during natural environmental fluctuations, the subspecies may be more vulnerable to localized extinction because of small population sizes (Nee 2009). The presence of the large core population in the pond-apple forest around the lake in the past may have maintained viability of the ephemeral populations on the islands by providing a source for seeds (Nee 2009). Fewer individuals occur along the St. Johns River, making this small population more susceptible to catastrophic events than the lake population (Decker-Walters 2002a). Growing near water and in swamps helps to buffer plants from winter freezes which can kill exposed stems and leaves (Minno 2009). Because plants of the St. Johns River population survive mostly from stems growing along the ground or through dense vegetation, they may be more susceptible to the effects of freezes (Minno 2009) (USFWS, 2009).

***Recovery***

**Reclassification Criteria:**
1. The Okeechobee gourd is protected at all known sites within Lake Okeechobee (USFWS, 1999).

2. Plants on Kreamer, Torry and Ritta Islands and the southern Rim Canal of Lake Okeechobee produce fruit at each of these locations at least every other year (their [i.e., fruit] absence for a period of two or more consecutive years will violate this requirement) (USFWS, 1999).

3. The distribution of fruiting plants is expanded within Lake Okeechobee either by the discovery of additional sites or by translocation (USFWS, 1999).

4. One or two sites are established outside of the southeastern quadrant of Lake Okeechobee (outside of Palm Beach County) (USFWS, 1999).

5. A stable, self-sustaining population of the Okeechobee gourd is established within the South Florida Ecosystem outside of Lake Okeechobee (USFWS, 1999).

6. Measures of vitality are developed and monitored at each of the sites described above (USFWS, 1999).

7. Based on the results of research on the viability of seeds following prolonged submergence and the survival of plants under rising water stages, the water regulation schedule for Lake Okeechobee is found not to jeopardize the continued existence of the Okeechobee gourd (USFWS, 1999).

Recovery Priority Number: 3

**Delisting Criteria:**
1. At least 20 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (addresses Factor A) (USFWS, 2019)

2. Populations (as defined in criterion 1) occur in marsh and swamp habitats and are distributed across the historical range of the species. (addresses Factors A and E) (USFWS, 2019)

3. Populations (as defined in criterion 1) must be protected via a conservation mechanism or managed such that enough suitable habitat is present for the species to remain viable for the foreseeable future. (addresses Factors A and E) (USFWS, 2019)

**Recovery Actions:**

- Maintain information on the distribution and status of the Okeechobee gourd. Conduct regularly scheduled surveys. Individuals should be encouraged to provide information on sightings of the Okeechobee gourd. (USFWS, 1999).
- Protect and enhance existing populations. Ensure that spraying for control of aquatic vegetation does not harm or kill Okeechobee gourd plants. Assess the effect of Melaleuca and Brazilian pepper control efforts (both cutand- squirt and aerial spraying methods); use techniques to avoid direct impact on Okeechobee gourd plants. Use provisions of section 7 of the ESA to protect the Okeechobee gourd. Augment natural populations of the Okeechobee gourd. (USFWS, 1999).
- Initiate research on the life history and genetics of the Okeechobee gourd. Test experimentally the viability of Okeechobee gourd seeds kept submerged for long periods (1 to 3 years). Characterize the range of soil conditions where the Okeechobee gourd currently grows and provide detailed mapping of soil types in southeastern Lake Okeechobee. Through field surveys, determine dates of germination under natural conditions. Test experimentally the effect of seasonally rising water level on the survival of young plants. After information is available from the research studies described above and the annual field surveys, conduct population viability and risk assessment studies particularly with respect to water regulation schedule alternatives for Lake Okeechobee. Investigate the role of animals in dispersing seeds of the Okeechobee gourd. Document the potential ecological relationship between the American alligator and the Okeechobee gourd. Investigate the genetic distance between the two known populations of the Okeechobee gourd. (USFWS, 1999)
- Monitor existing populations of the Okeechobee gourd. Determine the most effective approach to monitor the condition of the Okeechobee gourd. After determining the most effective methods and indices, onduct monitoring on an annual basis. (USFWS, 1999)
- Increase public awareness about the Okeechobee gourd. Public awareness can be addressed through a variety of strategies, including, but not limited to, classroom programs, newspaper and magazine articles, public information displays at boat ramps in Lake Okeechobee, and outreach to fishing and airboating clubs. (USFWS, 1999)
- Habitat-level Recovery Actions: Prevent degradation of existing Okeechobee gourd habitat. Restore areas to suitable habitat. Research the acute and long-term tolerance of the Okeechobee gourd and other wetland plants to herbicides commonly used to control nuisance species of aquatic vegetation. Monitor habitat/ecological processes. Increase public awareness of ecological relationships, environmental stressors, and restoration activities in the South Florida Ecosystem. (USFWS, 1999)
- Conduct regular surveys to monitor growth and reproduction, especially from late November through mid-February when many trees are leafless and fruit are easy to see (USFWS, 2009).
- Monitor the spoil islands of Lake Okeechobee to evaluate how the plants respond in a restricted environment with other competitive colonizers and observe the establishment of the seed bank (USFWS, 2009).
- Monitor future translocation sites (USFWS, 2009).

- Continue research to evaluate temporal changes in the prevalence of the three viruses found and to determine the extent to which the fitness of Okeechobee gourd populations is being negatively impacted (USFWS, 2009).
- Conduct experiments on dry fruits from plants grown under controlled conditions (e.g., in the greenhouse) to explore the buoyancy of dried-fruit seeds in greater detail (USFWS, 2009).
- Continue to assess dormancy mechanisms and test viability limits through longer immersion periods of seeds (USFWS, 2009).
- Conduct buried seed experiments in Lake Okeechobee or St. Johns River soils (USFWS, 2009).
- Directly evaluate each gourd population for viral loads, determine the percentage of progeny that may carry the squash mosaic virus, and conduct off-site viral-inoculation experiments of progeny to evaluate degree of tolerance and reproductive impacts (USFWS, 2009).
- Re-evaluate the relationships amongst subspecies of Cucurbita okeechobeensis using modern molecular techniques and new morphological characteristics (USFWS, 2009).
- Continue research on fluctuations in abundance of the gourd in response to water conditions, particularly extended periods of high water, to determine the level of risk to the long-term survival of the subspecies (USFWS, 2009).
- Research the acute and long-term tolerance of the Okeechobee gourd and other wetland plants to herbicides commonly used to control nuisance species of aquatic vegetation (USFWS, 2009).
- Conduct population viability and risk assessment studies, particularly with respect to water regulation schedule alternatives for Lake Okeechobee (USFWS, 2009).
- Eradicate exotic weeds (e.g., Ipomoea alba) in locations that support gourds and take care when planting native trees to prevent introduction of these weeds (USFWS, 2009).
- Use controlled burns to open up areas of overly dense herbaceous and/or shrubby vegetation in lake littoral zones and marshes (USFWS, 2009).
- Prevent cultural (i.e., human caused) eutrophication of lakes and marshes (USFWS, 2009).
- Avoid disruptive changes to the riparian habitat along the St. Johns River where the population occurs (USFWS, 2009).
- Ensure that water-level regulation is compatible with management needs of the Okeechobee gourd (USFWS, 2009).
- Ensure aquatic vegetation management practices are compatible with recovery of the subspecies (USFWS, 2009).
- Consider Okeechobee gourd and the creation of habitat in planning phases of Everglades restoration (USFWS, 2009).
- Restore habitat by planting pond apple and cypress where appropriate (USFWS, 2009).
- Establish a translocation protocol, locate potential sites, and translocate plants to identified sites (USFWS, 2009).
- Ensure that the St. Johns River and Lake Okeechobee populations are not grown together in collections to avoid hybridization. If hybridization is suspected, hybrid material should not be used for reintroduction (USFWS, 2009).
- Develop recovery criteria for the Okeechobee gourd population along the St. Johns River (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Surveys:  Conduct regular surveys to monitor growth and reproduction, especially from late November through mid-February when many trees are leafless and fruit are easy to see.  Monitor the spoil islands of Lake Okeechobee to evaluate how the plants do in a restricted environment with other competitive colonizers and observe the establishment of the seed bank.  Identify sites appropriate for future translocations. Conduct and monitor future translocation sites. These actions continue to be top priorities for the recovery of the Okeechobee gourd. Research:  Continue research to evaluate temporal changes in the prevalence of the three viruses found in association with the gourd, and determine the extent to which the fitness of Okeechobee gourd populations is being negatively impacted.  Conduct experiments on dry fruits from plants grown under controlled conditions (e.g., in the greenhouse) to explore the buoyancy of dried-fruit seeds in greater detail.  Continue to assess dormancy mechanisms and test viability limits through longer immersion periods of seeds.  Conduct buried seed experiments in Lake Okeechobee or St. Johns River soils.  Directly evaluate each gourd population for viral loads, determine the percentage of progeny that may carry the squash mosaic virus, and conduct off-site viral-inoculation experiments of progeny to evaluate degree of tolerance and reproductive impacts.  Re-evaluate the relationships amongst subspecies of Cucurbita okeechobeensis using modern molecular techniques and new morphological characteristics.  Continue research on fluctuations in abundance of the gourd in response to water conditions, particularly extended periods of high water, to determine the level of risk to the survival of the subspecies in the long term.  Research the acute and long-term tolerance of the Okeechobee gourd and other wetland plants to herbicides commonly used to control nuisance species of aquatic vegetation.  Conduct population viability and risk assessment studies, particularly with respect to water regulation schedule alternatives for Lake Okeechobee. These actions continue to be top priorities for the recovery of the Okeechobee gourd. Management:  Eradicate exotic weeds (e.g., Ipomoea alba) in locations that support gourds and take care when planting native trees to prevent introduction of these weeds.  Use controlled burns to open up areas of overly dense herbaceous and/or shrubby vegetation in lake littoral zones and marshes.  Prevent cultural eutrophication of lakes and marshes.  Avoid disruptive changes to the riparian habitat along the St. Johns River where the population occurs.  Ensure that water-level regulation is compatible with management needs of the Okeechobee gourd.  Ensure aquatic vegetation management practices are compatible with recovery of the subspecies.  Consider Okeechobee gourd and the creation of habitat in planning phases of Everglades restoration.  Restore habitat by planting pond apple and cypress where appropriate.  Establish a translocation protocol, locate potential sites, and translocate plants to identified sites.  Ensure that the St. Johns River and Lake Okeechobee populations are not kept together in collections to avoid hybridization. If hybridization is suspected, hybrid material should not be used for reintroduction. These actions continue to be top priorities for the recovery of the Okeechobee gourd. (USFWS, 2021)

# SPECIES ACCOUNT: *Dalea carthagenensis floridana* (Florida Prairie-clover)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 11/6/2017; Southeast Region (R4)

**Physical Description**

Dalea carthagenensis var. floridana is a short-lived (less than 8 years) perennial shrub that is 2.6 to 9.8 ft (0.8 to 3.0 m) tall with a light brown woody stem and non-woody, light brown or reddish branches. The leaves are composed of 9 to 15 oval, gland-tipped leaflets, and are gland-dotted on the underside. The flowers are in small loose heads at ends of hairy, glandular stalks, less than 0.4 in long. The flower color is white and maroon; each of the petals is different lengths and shapes. The fruit is a small one-seeded pod, mostly enclosed by the hairy, gland-dotted calyx (bracts at base of each flower). (USFWS, 2017)

**Taxonomy**

Chapman (1886, p.102) was the first to report this taxon in Florida, calling it the tropical Dalea domingensis, based on specimens collected on Key Biscayne. Small (1913, p. 89) accepted this epithet but included the taxon in the genus Parosela, making the plant P. domingensis. Rydberg (1920, p. 114) renamed the plant, calling it Parosela floridana, which was retained by Small (1933, pp. 694-695). Clausen (1946a, p. 85) reviewed the taxonomy of Florida and West Indian Dalea and considered them all to be the same species. Clausen (1946a, p. 85) also found that the name D. domingensis was a homonym of D. emphysodes, and published the name D. emphysodes ssp. domingensis. Clausen (1946b, p. 572) later discovered that his use of the name D. emphysodes was in error, and renamed the plants D. carthagenensis ssp. domingensis. Long and Lakela (1971, p. 478) accepted this usage. Barneby (1977), in a monograph of the genus, also found that Florida plants were distinct from West Indian plants, citing differences in leaf characters, naming the Florida species D. carthagenensis var. floridana. Wunderlin (1998) has followed this treatment.(USFWS, 2017)

**Historical Range**

The historical range of Dalea carthagenensis var. floridana includes Miami-Dade, Monroe, Collier, and Palm Beach Counties in Florida (USFWS, 2017).

**Current Range**

In Florida, the current range of Dalea carthagenensis var. floridana includes Big Cypress National Park (Monroe and Collier Counties), three Miami-Dade County conservation areas, and three additional unprotected lands within the Cutler Bay region of Miami-Dade County. (USFWS ,2017)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual, perennial (USFWS, 2017)

**Lifespan**

Adult: Less than 8 years (USFWS, 2017)

**Reproduction Narrative**

Adult: Dalea carthagenensis var. floridana appears to be a short-lived (less than 8 years) perennial with a persistent seed bank (Maschinski et al. 2014, p. 45; Lange et al. 2016, p.15). D. carthagenensis var. floridana produces flowers from October to March and fruit ripen from November to April. The seed maturation period is January to May, with a peak in February and March. Larger plants can produce over 500 seeds. Seedling recruitment varies widely from year to year, with lower recruitment in drier years. Seedlings and juveniles experience rapid growth in their first 2 years. (USFWS, 2017)

**Habitat Type**

Adult: Pine rockland, rockland hammock, marl prairie, and coastal berm, and in the ecotones between these habitats (USFWS, 2017)

**Habitat Vegetation or Surface Water Classification**

Adult: Forest/Woodland, Woodland-Conifer

**Dependencies on Specific Environmental Elements**

Adult: Periodic fire is extremely important to maintaining habitat for this species. (USFWS, 2017)

**Environmental Specificity**

Adult: Moderate (inferred from USFWS, 2017)

**Tolerance Ranges/Thresholds**

Adult: The plants can stand partial inundation with fresh water for a portion of the year, but do not tolerate salinity. (USFWS, 2017)

**Habitat Narrative**

Adult: Dalea carthagenensis var. floridana grows in pine rockland, rockland hammock, marl prairie, and coastal berm, and in the ecotones between these habitats. It occurs in sparsely vegetated, well-lit, open areas that are maintained by disturbance. The dynamic nature of the habitat means that areas not currently open may become open in the future as a result of canopy disruption from hurricanes or invasive plant management, while areas currently open may develop more dense canopy over time, eventually rendering that portion of the hammock unsuitable for D. carthagenensis var. floridana. The species may also occur along roadsides within these habitats. The climate of south Florida where Dalea carthagenensis var. floridana occurs is classified as tropical savanna. (USFWS, 2017)

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Declining; habitat loss continues to occur in the species' range. (USFWS, 2017)

**Species Trends:**
Declining (USFWS, 2017)

**Number of Populations:**
15 occurrences (USFWS, 2023)

**Population Size:**
Approximatly 1000 individuals in 15 populations, ranged from one to 372 plants per population (USFWS, 2023)

**Population Narrative:**
The extant populations occur in the Big Cypress National Park (Monroe and Collier Counties, Florida), in several conservation areas in Miami-Dade County (R. Hardy Matheson Preserve, Charles Deering Estate, Virginia Key, and Crandon Park) , and on three additional unprotected lands within the Cutler Bay region of Miami-Dade County (USFWS, 2017). Florida prairie-clover is a shrub in the pea family (Fabaceae) with a woody base that is endemic to the pine rockland, rockland hammock, marl prairie, and coastal berm habitats of southern Florida. The species is restricted to fifteen (15) populations found primarily in Miami-Dade County with some populations found in Monroe County. Although it has been extirpated from Palm Beach County, a population previously thought extirpated in Everglades National Park was rediscovered in 2018 (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Present or Threatened Destruction, Modification, or Curtailment of Its Habitat or Range (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat loss, fragmentation and degradation, and associated pressures from increased human population are major threats this species. These threats are expected to increase as remaining pine rocklands and other habitats are lost to development, placing these plants at greater risk. This species may be impacted when pine rocklands are converted to other uses or when lack of fire causes the conversion to hardwood hammocks or other unsuitable habitats. On public lands, including National Park Service lands and Miami-Dade County-owned lands, implementation of prescribed fire has not been sufficient because of legal constraints (permitting requirements) and inadequate funding. Any populations of this species found on private property could be destroyed due to development. Although efforts are being made to conserve natural areas and apply prescribed fire, most pine rocklands remain in poor fire condition, and the long-term effects of large-scale and wide-ranging habitat modification, destruction, and curtailment will last into the future, while ongoing habitat loss due to population growth, development, and agricultural conversion continues to pose a threat to this species outside of conservation lands. (USFWS, 2017)

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2017)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** This species is found on Federal, State and County lands. NPS regulations provide protection at Everglades National Park and Big Cypress National Preserve. These two sites continue to support the largest and best managed populations. State regulations provide protection against trade, but allow private landowners or their agents to clear or remove species on the Florida Regulated Plant Index. State Park regulations provide protection for plants within Florida State Parks. The Natural Forest Communities program in Miami is designed to protect rare and important upland (non-wetlands) habitats in south Florida; however, this regulatory strategy has several limitations that reduce its ability to protect this plant and its habitat. Although many populations of this species are afforded some level of protection because they are on public conservation lands, especially Federal lands, existing regulatory mechanisms vary in strength and scope, and do not provide substantive protection of habitat at this time. They have not led to a sufficient reduction of threats posed to these plants by a wide array of sources. (USFWS, 2017)

**Stressor:** Other Natural or Manmade Factors Affecting Its Continued Existence (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Threats from other natural or manmade factors to this species include nonnative, invasive plants; management practices (such as mowing); recreation (including off-road vehicle use), effects from small population size and isolation; limited geographic range; and stochastic events including hurricanes, storm surges, and wildfires. Additionally, this plant is particularly vulnerable to the effects of climate change, including sea level rise, as changes in the water table, increased soil salinity from partial inundation, and storm surge will likely result in vegetation shifts in the decades prior to the fully anticipated sea level rise. Some of these threats (e.g., nonnative species) may be reduced on public lands due to active programs by Federal, State, and County land managers. Many of the remaining populations of this plant are small and geographically isolated, and genetic variability is likely low, increasing the inherent risk due to overall low resilience of these plants. The threats act together to impact populations of this species. (USFWS, 2017)

**Stressor:** Disease or predation (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Scale insects (Coccoidea) and Cassytha filiformis (love vine, a parasitic plant) infestations have been noted as parasites for Dalea carthagenensis var. floridana (Maschinski et al. 2015, p. 39) and may also influence populations of other listed pine rockland plant species. However, the best available data do not indicate that disease or predation is a threat to Sideroxylon reclinatum ssp. austrofloridense, Digitaria pauciflora, Chamaesyce deltoidea ssp. pinetorum, or Dalea carthagenensis var. floridana. (USFWS, 2017)

***Recovery***

**Reclassification Criteria:**
Not defined.

**Delisting Criteria:**
Not defined.

**Recovery Actions:**
- Not defined.
- Conserve pine rocklands and suitable habitat through purchase or conservation easements.
- Restore understories by removing exotic plants or hardwoods.
- Provide regular prescribed burns to sites to maintain suitable habitat conditions.
- Monitor and manage the remaining small populations in Miami-Dade County.
- Consider and conduct augmentation and reintroduction, at suitable sites (Maschinski et al. 2005, p. 165).
- Conduct additional surveys in the Big Cypress region, including Florida Panther National Wildlife Refuge.
- Monitor known populations.
- Investigate ways to increase population viability.
- Study the introduced insect lobate lac scale to determine the extent of this threat and identify any necessary actions.
- Conduct studies to determine current level of genetic variation remaining in extant occurrences.
- Research presence and longevity of seed banks in different habitats.

***Conservation Measures and Best Management Practices:***
- RECOMMENDED FUTURE ACTIVITIES Recovery Activities This species does not have a final recovery plan. In the course of this status review, we have identified the following potential recovery activities which are included below. Ɣ Continue regular fire prescriptions (every 3-7 years) at R. Hardy Matheson Preserve. Ɣ Identify other occurrences which may be candidates for prescribed fire. Monitoring / Research Activities In addition to the continued monitoring of known occurrences, new occurrences ought to be sought out either through broadscale surveys or restoration. Ɣ Identify new occurrences through broadscale surveys for extant Florida prairie clover populations. This effort may be aided by education. By teaching the public to identify and report this species through widely available platforms like iNaturalist new occurrences may be identified. Restoration efforts should work to identify new mechanisms of management and areas of potentially suitable habitat. Ɣ Identify methods to mimic prescribed fire where the application of fire is impractical, like publicly owned conservation lands embedded within urban communities. Ɣ Identify open mesic to xeric shrub communities (pine rockland, marl prairie, coastal strand, and ecotones between each of these habitats and rockland hammocks) with a high probability of persistence given sea-level rise projections. Pursue the sustained restoration and preservation of these sites be they preserves, parks, or private property. ż One such location may be the Richmond Pine Rockland (USFWS, 2023).

# SPECIES ACCOUNT: *Dalea foliosa* (Leafy prairie-clover)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 5/1/1991; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

A stout perennial herb, 2-8 dm tall, with several stems arising from a hardened root crown. Dense spikes of small purple flowers appear most abundantly from late July to early August, but may continue to bloom sporadically into September. (NatureServe, 2015)

**Taxonomy**

Dalea foliosa, a member of the legume family or Fabaceae, was first described as Petalostemonfoliosus by Asa Gray in 1868 (Gray 1868). The generic name Petalostemum A. Michaux, first published in 1803, has been conserved over the earlier Kuhnistera Lamarck of 1789, with the spelling of Petalostemon also conserved over the original Petalostemum (Greuter et al. 1988, Farr et al. 1979). Because the gender of Petalostemon is neuter, the correct name of leafy prairie-clover under this genus is Petalostemonfoliosuin A. Gray (USFWS, 1996).

**Historical Range**

The distributional center for Dalea foliosa is the limestone cedar glades of central Tennessee and northern Alabama, where the species is considered nearly endemic (Baskin and Baskin 1973) (USFWS, 1996).

**Current Range**

Mesic dolomite river-terrace prairies of northeastern Illinois, Middle Tennessee Limestone Glades, northern Alabama Limestone Glades. In Tennessee, occurs on only 13 USGS 7.5' quads in seven counties of the Central Basin. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

<u>Adult:</u> Sexual, autogamy (USFWS, 2015)

**Lifespan**

<u>Adult:</u> 8 years (USFWS, 1996)

**Dependency on Other Individuals or Species**

<u>Adult:</u> Bombus spp. based on closely related species (USFWS, 1996)

**Breeding Season**

<u>Adult:</u> July - August (USFWS, 1996)

**Key Resources Needed for Breeding**

Adult: Insect pollinators; moist soil (USFWS, 1996)

**Reproduction Narrative**

Adult: Produces flowers July to August; seeds ripen by early October. Bumblebees, small bees, syrphrid flies have been observed visiting flowers. Bombus species are probably required for successful seed set (based on other species in the same genus). Emergence occurs in March for existing plants. Seeds germinate in April and have several leaves by May. Molano-Flores (2005) determined that Dalea foliosa is self-compatible and that self-pollination (i.e., autogamy) can occur in this species, despite that fact that it is protandrous (USFWS, 2015). Dalea foliosa is short-lived and has no capacity for vegetative spread (Baskin and Baskin 1973; Schwegman and Glass, unpublished data). Plants may take up to 3 years to flower under field conditions (Baskin and Baskin 1989). Adequate soil moisture is critical for seedling establishment. The oldest living plants monitored to date have reached 8 years (n=2) and 7 years (n=2) of age (Schwegman and Glass, unpublished data). Mature plants may not flower every year (USFWS, 1996).

**Habitat Type**

Adult: Terrestrial, riverine, palustrine (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Spring, herbaceous wetland, riparian, barrens, grassland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Full sun, periodic fire (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 550-700 ft. elevation (USFWS, 1996)

**Environmental Specificity**

Adult: Moderate (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Moderate (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Occurs in Tennessee and Alabama in open, thin-soiled limestone glades and limestone barrens. In Tennessee, the plants occur on wet calcareous barrens and moist prairies or cedar glades, usually near a stream or where some seepage from limestone provides seasonal moisture. Associates in these habitats are rose-pink (Sabatia angularis), and black-eyed Susan (Rudbeckia triloba). The species is disjunct in Illinois, where it is restricted to thin-soiled (< 4.5 dm), wet or moist, open dolomite prairies on river terraces in the northeastern part of the state. The plants require full sun and low competition for optimum growth and reproduction; periodic fire is needed to maintain these conditions. (NatureServe, 2015). Occurs in shallow silt to silty clay loams over flat, often fractured horizontally bedded limestone or dolomite at 550-700 ft. elevation.

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seeds are dispersed by wind, gravity, small mammals, and birds. Seeds are dispersed from late fall to early spring

***Population Information and Trends***

**Population Trends:**

> 45% decline (NatureServe, 2015)

**Species Trends:**

Stable to declining (USFWS, 2015)

**Number of Populations:**

63 total (USFWS, 2022)

**Population Size:**

Unknown (NatureServe, 2015)

**Adaptability:**

Low (inferred from NatureServe, 2015)

**Population Narrative:**

This species has declined by over 45% from historical occurrences due to the destruction of habitat, overgrazing, and habitat loss from encroachment by woody plants (Thompson et al. 2006). There are approximately 60 extant occurrences presently recorded, but about 25 occurrences are of poor or very poor quality. There are currently known extant occurrences in 3 states: 50 in Tennessee, 4 in Alabama, and 8 in Illinois. In Tennessee, only 10 occurrences are ranked as good or excellent (EO data in the NatureServe central database as of February 2012). The Tennessee records occur on only 13 USGS 7.5' quads in 7 counties of the Central Basin. Long-term survival is fair to poor unless more sites can be maintained with mowing or ecological burning (NatureServe, 2015). The species status is stable in IL and TN; monitoring data from these states display substantial interannual variability in total numbers of plants as well as for multiple life history stages. The species has declined in Alabama, where only two extant populations are known to exist. Low levels of genetic variation were documented in this species by Edwards et al. (2004) (USFWS 2015). Range wide Dalea foliosa occurs within 63 populations. Of those, 50 are located in central Tennessee, while 11 are disjunct in northeast Illinois and 2 in northwest Alabama (USFWS, 2022)

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Nonetheless, several of the threats to Dalea foliosa habitat identified in the recovery plan still have the potential to affect this species even in protected sites, namely, degradation due to invasive exotic or native species encroachment, illegal outdoor recreational vehicle (ORV) use, and incompatible management of utility rights-of-way. Despite its protected status a

relatively large population was essentially lost to habitat destruction at the Sneed Road Cedar Glade DSNA site in Tennessee, which at the time was a Registered Natural Area owned by The Nature Conservancy. This site was severely impacted in 2001, apparently by activities associated with development of adjacent property that resulted in placement of fill material on areas where Dalea foliosa occurred. This population contained an estimated 300 or more plants in 1980, but had declined to 53 plants in 2000, despite removal of the fill material, and only 6 plants were observed there in 2003 (TDEC 2005a). Barbers and Wilhelm (2005) noted that the population at the Dellwood Park West site is periodically inundated by floodwater from the adjacent Illinois and Michigan Canal, which poses a threat to this population and to habitat restoration efforts at this site (USFWS, 2015).

**Stressor:** Succession (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The main threat to protected sites comes from the potential for either exotic or native, invasive plant species to displace Dalea foliosa from otherwise suitable habitat. Through the process of vegetation succession in the absence of disturbance (e.g., fire), native herbaceous and woody species also can pose a threat. Prescribed fire is used to manage most of the sites where Illinois populations occur on public lands. Efforts to develop a fire management program for lands managed by TDEC have met limited success, owing to insufficient funding, staff turnover, and challenges associated with burning in the urban interface (USFWS, 2015).

**Stressor:** Herbivory (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The recovery plan (Service 1996) identified intense livestock grazing and selective browsing by eastern cotton-tail rabbits (Sylvilagus floridanus) and white-tailed deer (Odoicoileus virginianus) as threats to D. foliosa. Molano-Flores (2004) observed herbivory at the Midewin NTP in 2002, with little evidence of recovery of affected plants during that growing season. McNicoll and Sivicek (2005) recorded evidence of damage caused by browsing animals in approximately 21 percent of the adult plants they counted at Keepataw Forest Preserve in 2005, and 483 of the 607 plants at Romeoville Prairie Nature Preserve in 2005 were impacted by herbivory (Key 2005). Taft et al. (2010) reported herbivory affecting 31.3 percent of adult plants at Keepataw Forest Preserve in 2010, which had increased from 12.5 percent in 2009. Because of the threat of browsing to seedlings, cages were used to protect at least a portion of the seedlings at each site where plantings occurred in 2008 as part of a project to reintroduce or augment populations (Redmer and Lah 2008) (USFWS, 2015).

**Stressor:** Small, isolated populations (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Edwards et al. (2004) found populations of Dalea foliosa "…were quite genetically depauperate" and that the isolated populations in Alabama and Illinois contained only a subset of the variation found in Tennessee populations. Measures of both polymorphism and expected heterozygosity were lower than reported averages for other endemic plant species (Hamrick and

Godt 1989 in Edwards et al. 2004). Population sizes tend to be small throughout the range of D. foliosa, which combined with spatial isolation could result in genetic drift exerting a dominant influence on population genetic structure. Increased incidence of inbreeding also is a risk associated with small populations, which can lead to a loss of fitness (i.e., inbreeding depression). These factors combined place many D. foliosa populations at a potentially heightened risk of localized extinction (Barrett and Kohn 1991). The ability of populations to adapt to environmental change is dependent upon genetic variation, a property of populations that derives from its members possessing different forms (i.e., alleles) of the same gene (Primack 1998). Small populations occurring in isolation on the landscape can lose genetic variation due to the potentially strong influence of genetic drift, i.e., the random change in allele frequency from generation to generation (Barrett and Kohn 1991). Smaller populations experience greater changes in allele frequency due to drift than do larger populations (Allendorf and Luikart 2007). Loss of genetic variation due to genetic drift heightens susceptibility of small populations to adverse genetic effects, including inbreeding depression and loss of evolutionary flexibility (Primack 1998) (USFWS, 2015).

**Stressor:** Climate change (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Both the final rule listing Dalea foliosa as endangered (Service 1991) and the recovery plan (Service 1996) identify drought as a threat to populations of this species. The recovery plan points out that the species possesses some life history traits (e.g., formation of persistent banks, dormancy response to drought) that enhance its resilience to this threat. However, threats associated with small population sizes and diminished genetic variation could combine with increased drought severity to diminish the species’ resilience to this threat over time, leading to substantial declines through the cumulative loss of small, isolated populations. In the face of accelerated climate change, it is imperative that effective monitoring programs are instituted throughout the range of the species in order to track trends in the face of potentially more severe (i.e., frequent, intense, or prolonged) drought conditions. In a study using count data of seedlings/juveniles, non-flowering adults, and flowering adults from Midewin NTP, all stages and total annual census were positively correlated with snowfall. Flowering plants negatively correlated with fall days below 0 oC, seedlings negatively correlated with mean February temperature, and non-flowering adults positively correlated with September precipitation (Molano-Flores and Bell 2012). When the authors incorporated predicted effects of climate change, using projections for mean February temperature and September precipitation in September, into regression models, the majority of the climate models predicted that population size would decrease from the mean population size of 188 plants from 1997-2008 (Molano-Flores and Bell 2012). This provides further evidence to suggest that climate change presents an increased risk of extinction for Dalea foliosa, especially for smaller populations and those with reduced genetic variation, which could limit potential for adapting to changing conditions (USFWS, 2015).

**Stressor:** Herbivory (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Available data indicate that herbivory by eastern cottontail rabbit (Sylvilagus floridanus) and white-tailed deer (Odoicoileus virginianus) herbivory continue to threaten the species. The recovery plan (Service 1996) identified livestock grazing and selective browsing by eastern cottontail rabbits and white-tailed deer as threats to Dalea foliosa. We currently are not aware of any sites where livestock grazing poses a threat to the species (USFWS, 2022).

***Recovery***

**Reclassification Criteria:**
1. A minimum of three populations ranked as high viability are protected and managed in Alabama for a minimum of 5 years. (USFWS, 1996)

2. A minimum of three populations ranked as high viability are protected and managed in Illinois for a minimum of 5 years. (USFWS, 1996)

3. A minimum of twelve populations ranked as high viability are protected and managed in Tennessee. (USFWS, 1996)

4. Restored populations persist at high or moderate viability for a minimum of 10 consecutive years. (USFWS, 1996)

Recovery Priority Number: 5

**Delisting Criteria:**
1. A minimum of three populations ranked as high viability are protected and managed in Alabama for 10 years (USFWS, 1996).

2. A minimum of three populations ranked as high viability are protected and managed in Illinois for 10 years (USFWS, 1996).

3. A minimum of twelve populations ranked as high viability are protected and managed in Tennessee. (USFWS, 1996)

4. Restored populations persist at high or moderate viability for a minimum of 10 consecutive years (USFWS, 1996).

**Recovery Actions:**
- Identify and prioritize protection. management. and restoration needs for all high- and moderate-viability populations (and low-viability populations with recovery potential for each geographic region in order to achieve the recovery criteria. Of the21 known or presumed extant leafy prairie-clover populations only 2 (10 percent) rank as high viability, 7 (33 percent) rank as moderate viability, and 12 (57 percent) rank as low viability. To meet the recovery criteria established in this plan, recovery activities need to be implemented for at least 18 (86percent) populations. This includes all nine populations of high and moderate viability, at least five populations of low viability with recovery potential, and an estimated four new populations. One or more recovery actions can increase a population from a low or moderate viability to a high viability. Key management needs or threats are identified for all critical sites by geographic region below and are summarized in Table 10 of the Recovery

Plan. More detailed site recommendations are also provided. (USFWS, 1996)
- Initiate and complete preserve design and implement the protection and management required to meet recovery criteria. Develop preserve designs. Implement protection. Develop management plans. (USFWS, 1996)
- Develop and implement population monitoring programs. A monitoring program should be designed to gauge the status of naturally occurring populations over a period of time and to evaluate the status of population recovery and restoration actions. By relating the data to changing environmental or management conditions, the monitoring program will help determine if and what management or recovery actions are needed for population maintenance. Populations can be monitored by tracking the total census count and by using sampling or demographic dataand should at least include accurate mapping of locations (patches). Demographic monitoring is most important in the initial stages of population restoration. Tracking of individual survivorship, reproductive status, and recruitment will help determine ifand how these variables are related to changes in successional stage, management actions, or environmental stochasticity (sensu Shaffer 1981); e.g., drought. At a minimum, monitoring data for all populations should include growth stage (seedling,juvenile, mature, or dormant), flowering frequency, rate of herbivory, number offlowering and/or fruiting ramets per plant, and observations of general vigor. Reproductive potential and seed output can also be estimated. (USFWS, 1996)
- Conduct research needed to enhance recovery efforts. (USFWS, 1996)
- Develop materials to inform the public about the status of the species and the recovery plan objectives. Public support for the conservation of leafy prairie-clover could greatly encourage landowner assistance in conservation efforts. However, informational material should not identify the plant’s precise locations in order to discourage vandalism to, or collection of, wild populations. (USFWS, 1996)
- Recommendations for Future Actions from 2015 5-Year Review: A. The Service should coordinate with Drs. Brenda Molano-Flores (pers. comm. 2008) and Tim Bell on their efforts to develop a population viability analysis for D. foliosa across its entire range. If this effort were successful across the species range, it could be used in conjunction with the existing PVI to provide a better estimation of the extinction risk faced by individual populations and the species as a whole. (USFWS, 2015)
- Recommendations for Future Actions from 2015 5-Year Review: B. Increase frequency of monitoring in Tennessee and Alabama populations, and standardize methods throughout the species’ range, as feasible. Feasibility is a constraint in Tennessee, owing to the large number of populations and the fact that TDEC is the only agency currently monitoring this species at most sites in the state. The Service should work with TDEC to increase capacity by participating in monitoring activities. (USFWS, 2015)
- Recommendations for Future Actions from 2015 5-Year Review: C. Increase use of prescribed fire, or other techniques, for maintaining open conditions with limited competing vegetation in areas with sufficient soil depth to support D. foliosa. (USFWS, 2015)
- Recommendations for Future Actions from 2015 5-Year Review: D. Determine the number of populations that are represented by element occurrences throughout the range of D. foliosa. This is of highest priority in Tennessee, where multiple occurrences within a single protected area are often tracked as distinct entities. This is especially relevant when calculating PVI values for populations, as aggregating multiple occurrences into what are believed to be biological populations could have the effect of increasing the population size, and in turn the calculated PVI for those populations. It appears that the only circumstance in

Illinois where such a determination might be warranted is the case of the two “populations” at the Waterfall Glen Preserve in DuPage County (Appendix B), which might be more appropriately treated as a single population for recovery purposes. Most of the Alabama occurrences appear to be separated by sufficient distance to warrant treatment as separate populations. (USFWS, 2015)

- Recommendations for Future Actions from 2015 5-Year Review: E. Continue efforts to reintroduce/augment Illinois populations. (USFWS, 2015)
- Recommendations for Future Actions from 2015 5-Year Review: F. Collect data to calculate a current PVI for each protected population, in order to evaluate the species’ status with respect to recovery criteria. (USFWS, 2015)
- The Service should coordinate with Drs. Brenda Molano-Flores (pers. comm. 2008) and Tim Bell on their efforts to develop a population viability analysis for D. foliosa across its entire range. If this effort were successful across the species range, it could be used in conjunction with the existing PVI to provide a better estimation of the extinction risk faced by individual populations and the species as a whole (USFWS, 2015).
- Increase frequency of monitoring in Tennessee and Alabama populations, and standardize methods throughout the species’ range, as feasible. Feasibility is a constraint in Tennessee, owing to the large number of populations and the fact that TDEC is the only agency currently monitoring this species at most sites in the state. The Service should work with TDEC to increase capacity by participating in monitoring activities (USFWS, 2015).
- Increase use of prescribed fire, or other techniques, for maintaining open conditions with limited competing vegetation in areas with sufficient soil depth to support D. foliosa (USFWS, 2015).
- Determine the number of populations that are represented by element occurrences throughout the range of D. foliosa. This is of highest priority in Tennessee, where multiple occurrences within a single protected area are often tracked as distinct entities. This is especially relevant when calculating PVI values for populations, as aggregating multiple occurrences into what are believed to be biological populations could have the effect of increasing the population size, and in turn the calculated PVI for those populations. Most of the Alabama occurrences appear to be separated by sufficient distance to warrant treatment as separate populations (USFWS, 2015).
- Continue efforts to reintroduce/augment Illinois populations (USFWS, 2015).
- Collect data to calculate a current PVI for each protected population, in order to evaluate the species’ status with respect to recovery criteria (USFWS, 2015).

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES • Since preliminary genetic testing reveals that genetic diversity in all Dalea foliosa populations is limited, evaluate whether a genetic management plan for potential movement of individuals between populations, potentially between states, is needed. • Determine the number of populations that are represented by element occurrences throughout the range of Dalea foliosa. This is of highest priority in Tennessee, where multiple occurrences within a single protected area are often tracked as distinct populations. This is especially relevant when calculating PVI values for populations, as aggregating multiple occurrences into what are believed to be biological populations could have the effect of increasing the population size, and in turn the calculated PVI for those populations. The two Alabama occurrences appear to be separated by sufficient distance to warrant treatment as separate populations. All Illinois populations are distinct. • Across the species range, plan and implement strategies to increase resiliency of populations that are ranked as having low or moderate viability, prioritizing those on publicly protected lands or where landowners are willing to enter into conservation agreements for the species. • Standardize annual monitoring methods by applying the PVI framework from the recovery plan throughout the species' range (USFWS, 2022).

# SPECIES ACCOUNT: *Deeringothamnus pulchellus* (Beautiful pawpaw)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/27/1986; Southeast Region (R4)

**Physical Description**

The beautiful pawpaw is a low-growing, diminutive shrub of the Annonaceae family rarely exceeding 0.5 m in height. The stems may be annual or perennial and arise from a stout taproot that averages 32.5 cm long and is about 2.5 cm wide at its widest point. The leaves are alternate, leathery, deciduous, and 4.0-7.0 cm long with slightly revolute (curving under) margins. The leaf shape is oblong to oblong-ovate or spatulate, with a rounded or notched end. The base of the leaf is rounded or tapering to a 2.0-4.0 mm long petiole. Young leaves have sparse, short, red hairs on both sides. Maturing leaves become dark green to glossy green above and paler green below. The flowers of this species occur singly in leaf axils and have between 6 and 10 creamy-white petals that are about 2.0-3.0 cm long. The fruits are fleshy, smooth and yellow-green when ripe and are 4.0-7.0 cm long. The seeds are dark brown and from 1.0-1.5 cm long. (USFWS, 1999)

**Taxonomy**

The species was first named and described by John K. Small as the only species belonging to the genus Deeringothamnus and separated from the genus Asimina by its "dimorphous sterns, the flat or depressed receptacle, and the narrow nearly uniform unsculptured petals" (Small 1924). Rehder and Dayton (1944) discussed placing the species in the genus Asimina. Because the use of the combination Asimina pulchella did not meet nomenclatural rules, they retained the Deeringothamnus pulchellus name. A subsequent treatment of taxonomy is consistent with that of Small (Kral 1960). However, Ward (2001) suggested that, due to the presence of forms that appear to be intermediates between D. pulchellus and its congener D. rugelii, they should be treated as a single species and varieties should be used to distinguish the two forms. According to Ward's (2001) assessment, beautiful pawpaw should be named D. rugelii var. pulchellus. The scientific community has not fully embraced this taxonomic change, and Ward also now considers them as two separate species (Norman 2003, 2008). The Integrated Taxonomic Information System (2009) does not indicate any formal changes to the name D. pulchellus. (USFWS, 2009)

**Historical Range**

Historically occurred on poorly drained sands of slash and longleaf pine- saw palmetto flatwoods in Lee and Charlotte Counties in southwestern Florida and was also found in Orange County east of Orlando. (USFWS, 2009)

**Current Range**

In Florida, in Charlotte, Lee, and Orange Counties. (USFWS, 2009)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

Adult: Research on the beautiful pawpaw has been conducted in the areas of phenology, pollination, reproductive structures, breeding system, germination, and hybridization (Norman 2003). Available information suggests that this species has poor fertilization, seed-setting, germination, and recruitment rates. Pollinators for this species are few, but those noted are a tumbling beetle (Mordella atrata) and two species of thrips (Frankliniella bispinosa and Thrips hawaiiensis) (Norman 2003). The reproductive biology of the species is not thoroughly understood, but the plant is thought to reproduce entirely by seed. Gopher tortoises (Gopherus polyphemus) may be an important seed disperser. Although not investigated in detail, ingestion of the seeds by gopher tortoises or other herbivores may be important for seed germination. However, seeds have been germinated without this type of treatment. On Pine Island, Lee County, plants begin flowering by mid-March and are at the peak of flowering the last week of April. Likewise, flowering was observed in Orange County in mid-March and lasted for 6 weeks (Norman 2003). Fruit is likely produced and dispersed during the summer. Because the species is thought to be long-lived, reproductive success is not critical every year (Service 1999). Other than follow-up monitoring during the first year after transplant of three transplanted populations, no long-term estimates of survival have been obtained for the species (Service 1998; Preston et al. 2004). No follow-up data have been collected. Additionally, no information has been reported on survival of individuals in natural occurrences, and life history stage and population structure data have not been collected. Limited experiments with seed collected from Orange County reported very low seedling survival, suggesting that the species may rely on a mycorrhizal fungal association to promote seedling survival (Norman 2009).

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: The species occurs in two disjunct locations in central and southwest Florida. It grows in xeric, mesic, and hydric pine flatwoods in western Charlotte and Lee counties and eastern Orange County. Soils in these habitats are poorly drained, although slight elevations provide better drainage than surrounding soils that are wetter. In Lee County, the pawpaw exists on Pine Island, where it occurs in pristine and modified flatwoods, on road edges, and on mowed lots. In Charlotte County it is found in an area broadly known as the Charlotte Harbor flatwoods and includes sites along State Road 765 and FWC's Cecil M. Webb Wildlife Management Area.

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

35 (USFWS, 2021)

**Population Size:**

~5,000

**Population Narrative:**

Surveys have been conducted intermittently in the past, but trend data are difficult to assess because surveys have generally only assessed a few occurrences at any one time and new occurrences have been discovered. Based upon the most comprehensive data available, there are currently thought to be approximately 5,000 pawpaw plants (FNAI 2008). The number of plants ranges from 1 to 2 plants on some sites to over 1,000 individuals on 3 sites (FNAI 2008). Nearly one-third of the occurrences were comprised of 15 or fewer pawpaws (FNAI 2008). Beautiful pawpaw is a long-lived shrub that occurs in open mesic flatwoods habitat within a disjunct range, occurring in Orange, Charlotte, and Lee Counties, Florida. The populations are fragmented and isolated within the range. Currently, there are an estimated 35 populations, though it is difficult to determine the status of each given the lack of monitoring. Consistent annual surveys are needed to evaluate long-term population trends and additional studies need to be completed on long-term survival, reproductive patterns, and population structure. (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Continued habitat loss, fragmentation, and changes in land use threaten the existence of beautiful pawpaw. Where plants occur on private sites, development has led to both direct destruction of habitat as a result of land clearing and habitat degradation from lack of management. One of the occurrences in Orange County has been extirpated (FNAI 2008). The property where this occurrence was reported was located adjacent to houses, the site was overgrown with Brazilian pepper (Schinus terebinthifolius), and trash was deposited in the area (FNAI 2008). It is likely that the plants were either crushed by debris or the habitat degraded to the point of being unsuitable for the species. (USFWS, 2009)

**Stressor:** Inadequacy of existing regulatory mechanisms
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The ESA provides protection for this species and its habitat through section 7. The beautiful pawpaw is also listed by the Florida Department of Agriculture and Consumer Services (FDACS) as endangered (5B-40.0055 Regulated Plant Index), but this legislation does not provide any direct habitat protection. Existing Federal regulations prohibit the removal or destruction of listed plant species on Federal lands. State regulations require both written permission from the owner or legal representative and a permit issued by FDACS to collect or remove plants listed as endangered on the Florida Regulated Plant Index. However, these regulations afford no protection to listed plants on private lands. Lee County offers some protection for the beautiful pawpaw through a listed species ordinance which requires mitigation for adverse effects to State and federally listed species (Lee County 1998). However, this ordinance does not apply to agricultural lands or those being re-zoned for agriculture, and part of the threat of habitat loss where pawpaws occur is a result of clearing for agricultural purposes. In some situations, existing regulatory mechanisms do not appear to be adequate, as several private properties with pawpaws have been developed. Because this plant occurs in habitat which is desirable real estate for development along the southwestern coast and inland near Orlando, this species remains

vulnerable to development pressures where it occurs on private property. (USFWS, 2009)

**Stressor:** Inadequate fire or land management (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species occurs in pine flatwoods habitat, which is typically maintained by fire. This species is adapted to live in pine flatwoods habitat where frequent ground fires are not hot enough to kill mature pine trees but do remove or thin understory vegetation and reduce competition with larger grasses and shrubs. During the first growing season after fire, the beautiful pawpaw takes advantage of newly-created openings by flowering and setting fruit (Service 1999). Therefore, land management practices such as prescribed fire are very important to maintaining and working towards recovery of the beautiful pawpaw. - Lack of management is a concern on some protected sites. Vegetation restoration and management programs are costly, and the availability of resources is never assured; therefore, habitat degradation and modification from inadequate management even on protected lands remains an imminent, though moderate, threat. - On many privately owned sites, fire has historically been suppressed, and habitat has not received regular maintenance. Where this species occurs on fragmented landscapes interspersed with development, burning may be unlikely due to proximity to neighbors. In areas that cannot be readily burned, mowing is sometimes used as a management strategy. In mowed habitat, the growth habit of this species is more prostrate with woody stems lying on the ground, while in fire-maintained habitat, it grows more erect with arching sterns. (USFWS, 2009)

**Stressor:** Invasive plant species (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In the absence of site maintenance, a threat to pawpaws is the establishment of invasive plant species such as Brazilian pepper, meialeuea (Melaleuca quinquenervia), and earleaf acacia (Acacia auriculifbrinis). However, herbicides used to control overgrowth, if not properly applied, also may pose a threat to the beautiful pawpaw. (USFWS, 2009)

**Stressor:** Natural events (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The species' limited distribution and its limited reproductive capacity also renders it vulnerable to random natural events, such as hurricanes and drought. However, Hurricane Charley crossed the northwest portion of the species' range in Lee and Charlotte Counties in 2004, and no apparent damage occurred to the beautiful pawpaws (Woodmansee and Barry 2007). During this hurricane, storm surge did not impact the occurrences but could in cases where storm surge is greater. The possibility of future hurricanes and tropical storms striking Florida is likely; this threat is expected to continue. . (USFWS, 2009)

**Stressor:** All-terrain vehicls and feral hogs (USFWS, 2009)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** A threat identified when the species was listed was damage by allterrain vehicles in at least a portion of the species' range. It is presumed that this threat continues on occurrence sites where access is not restricted. Feral hogs (Sus scrofa) may also pose a threat to beautiful pawpaw plants. (USFWS, 2009)

*Recovery*

**Reclassification Criteria:**
1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations and sites needed to ensure 20 to 90 percent probability of persistence for 100 years (USFWS, 1999)

2. When these sites, within the historic range of D. pulchellus, are adequately protected from further habitat loss, degradation, and fragmentation (USFWS, 1999)

3. When these sites are managed to maintain pine flatwoods to support D. pulchellus (USFWS, 1999)

4. When monitoring programs demonstrate that these sites support the appropriate numbers of self-sustaining populations, and those populations are stable throughout the historic range of the species (USFWS, 1999)

Recovery Priority Number: 2

**Delisting Criteria:**
1. When at least 30 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (Factor A) (USFWS, 2019)

2. When populations (as defined in criterion 1) occur in pine flatwoods habitat distributed across the historical range of the species in order to maintain and enhance the species geographic patterns of genetic diversity. (Factor A) (USFWS, 2019)

3. When populations (as defined in criterion 1) must be protected via a conservation mechanism and managed such that enough suitable habitat is present for the species to remain viable for the foreseeable future. (Factors A, E) (USFWS, 2019)

**Recovery Actions:**
- 1. Determine current distribution of D. pulchellus. - Conduct surveys for D. pulchellus. - Maintain distribution of known populations and suitable habitat in GIS database. Use GIS to map existing populations and to assess the species' status and trends over time. The database should contain information on locations, population sizes, and status. This information should also be used for project review, in land acquisition activities, and to coordinate updates with the Florida Natural Areas Inventory database. (USFWS, 1999)
- 2. Protect and enhance existing populations. - Acquire or otherwise protect habitat through acquisition, conservation easements, or agreements with landowners. - Protect populations on public lands. Develop management guidelines that allow for a fire regime that includes a mosaic of successional stages. - Use local or regional planning to protect habitat. Utilize

available regional and county planning processes to encourage protection of suitable unoccupied and habitat occupied habitat of D. pulchellus. Protecting this species on private property in Lee County is possible due to county ordinances that require conservation of listed plants. - Enforce available protective measures. Use local, State and Federal regulations to protect this species from overcollecting and damage from off-road vehicle use. Regulations should also be used to protect xeric vegetative communities where D. pulchellus lives. - Develop an ex situ collection. Ex situ collections are important for preserving genetic diversity, preventing extirpation, and determining ecological characteristics and habitat management needs of species. These collections will be instrumental in the recovery of D. pulchellus. Since longterm seed storage seems impossible for this species, cultivated populations are very important. Although D. pulchellus is not easily grown from cuttings, young plants should be kept for study and reintroduction material. - Augment natural populations of D. pulchellus. (USFWS, 1999)

- 3. Conduct research on life history characteristics of D. pulchellus. - Conduct research to determine demographic information, such as numbers of sites and populations, numbers of individuals in a population, recruitment, dispersal, growth, survival, and mortality. Observations of the relation of flowering to fire, pollination, seed production, and seedling biology will help to guide reintroduction efforts. - Once demographic data are known, conduct population viability and risk assessment analysis to determine the numbers of plants, sites, subpopulations/populations, and spatial distribution needed to ensure persistence of the species. - Conduct research to assess management requirements of D. pulchellus. Determine which natural populations can be stabilized or increased by habitat management. Surveys, research, and monitoring information will provide factors contributing to any declines at each site. Monitoring of populations should be in reference to various habitat management practices. Site-specific management guidelines should be provided to land managers and close coordination among land managers is essential to develop adaptive management techniques. - Assess feasibility of relocating D. pulchellus. Removing plants threatened with destruction may be the only conservation strategy available in some situations. Information on transplant techniques and plant survival are needed to assess whether transplanting should be pursued. (USFWS, 1999)
- 4. Monitor existing populations of D. pulchellus. - Develop monitoring protocol to assess population trends for D. pulchellus. - Develop a quantitative description of the population structure of D. pulchellus. This description will provide a baseline for monitoring population dynamics in response to natural environmental changes and management treatments. Data recorded should include morphology, survivorship, mortality, and reproduction for individual plants. Data about each plant’s microsite (vegetation cover, litter depth, substrate, and closest neighbors) may prove helpful in future management. - Monitor reintroduced plants. Monitoring of reintroduced plants will be essential for assessing the status of new plants and their contribution to the population as a whole. Compare adult survival, seed production, germination rates, seed survival, seedling survival, and growth rates between transplanted plants and natural plants. Where monitoring indicates that the introduction has been unsuccessful, reevaluate protocol and methodology. (USFWS, 1999)
- 5. Provide public information about D. pulchellus. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and

horticultural uses of endangered species provide little benefit to species, since the recovery of D. pulchellus and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)

- 6. Establish delisting criteria. Once reclassification is achieved, research and monitoring results may provide data necessary to develop delisting criteria. (USFWS, 1999)
- Habitat-level Recovery Actions: Prevent degradation of existing habitat. Extensive habitat loss, degradation, and fragmentation have already occurred throughout the range of this species. Urbanization, fire suppression, and agricultural land uses have decreased the available habitat. - Restore areas to suitable habitat. Native habitats that have been disturbed or that have experienced a long history of fire suppression may be good candidates for future reserves. - Continue habitat-level research projects. Study the response of D. pulchellus to various land management practices, such as prescribed fire regimes, vegetative thinning, and control of exotic/invasive vegetation. - Monitor habitat/ecological processes. Monitor the effects of land management actions, such as prescribed fire, mechanical disturbance, etc., on the habitats where D. pulchellus occurs. - Provide public information about pine flatwood vegetative communities and their unique biota. Educational efforts, especially those conducted by private conservation organizations, have been successful in providing important information about pine flatwood plant communities to the public. The State’s system of biological preserves depends for its funding and future success on a broad base of public understanding and support. In addition to past and ongoing educational efforts by The Nature Conservancy, Bok Tower Gardens, and Archbold Biological Station, future efforts by these organizations, the Florida Park Service, the Florida Native Plant Society and local garden clubs will play crucial roles in increasing public appreciation of pine flatwood plant communities and D. pulchellus. (USFWS, 1999)
- Management: • Continue management actions to include removal of hogs, debris, and exotic plants. Depending upon site, management efforts may include: licensed hunting or trapping of hogs, careful application of herbicides, controlling public access, and reintroduction of prescribed fire into the ecosystem. • Restore habitat in potential areas where plants could occur but are not currently reported, and provide follow-up surveys post-disturbance to determine if natural occurrences are present. • Identify additional reintroduction sites and establish reintroduced populations; augmentations should also be implemented. • Focus conservation efforts on marginal and small occurrences to preserve the genetic diversity of the species. (USFWS, 2009)
- Research: • Conduct research on the response of beautiful pawpaw to fire and fire prescriptions necessary to benefit the species. • Monitor burned and mowed sites to assess which technique is most beneficial to pawpaw reproduction and survival. • Continue research on the biology, ecology, genetics, and management needs of the species. • Conduct demographic studies to determine the age class structure and long-term viability of the species, especially in areas with active recruitment, and determine critical life stages. • Conduct genetic characterizations on occurrences, and apply this knowledge to future introductions and augmentations. • Continue to evaluate insect pollinators associated with the species over the long-term, and evaluate impacts to pollinators from aerial mosquito spraying. • Conduct seed germination studies and make efforts to develop additional outplanting techniques. • Continue propagation efforts and establish techniques for long-term germplasm storage; make sure all occurrences are represented in the Center for Plant Conservation's National Collection of Endangered Plants. • Evaluate the effects of climate change on the species, including those that result from precipitation pattern changes and

temperature rise. (USFWS, 2009)

- Surveys: • Continue to survey potential habitat and pursue conservation agreements, implement management recommendations, and/or acquire land and investigate incentives to encourage land managers to manage pine flatwoods for ecosystem health and listed species. • Conduct additional surveys for beautiful pawpaw on all known (particularly Estero Bay Preserve State Park, Pine Island Flatwoods Preserve, and the newly acquired Babcock Ranch) and potentially suitable sites in the three counties of occurrence; provide updated information to FNAI for consistent tracking. • Continue monitoring both reintroduced and natural occurrences. (USFWS, 2009)
- Other: • Promote partnerships to share information, conduct collaborative research on pine flatwoods habitat conservation, and provide land managers and the interested public with information about the ecosystem, threats, recovery actions, and associated rare biota. (USFWS, 2009)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIVITIES A detailed discussion of recovery actions and criteria are presented in the Recovery Plan and amendment (Service 1999 and 2019, respectively). During this status review, new and/or targeted potential recovery activities were identified and are included below. Recovery Activities x Continue removal of hogs and invasive plants species around beautiful pawpaw populations. Depending upon site, management efforts may include licensed hunting or trapping of hogs and careful application of herbicides to invasive plants. x Continue applying prescribed fire and reintroduce fire to habitats where this species occurs. Use careful mowing with minimal ground disturbance where burning is not possible or in combination with burning as a mechanical treatment to open up habitat and make the vegetation structure more suitable for beautiful pawpaw growth. x Restore habitat in potential areas where plants could occur but are not currently reported and provide follow-up surveys post-disturbance to determine if natural populations are present. x Identify additional (re)introduction sites, donor sites, and if needed, rescue sites (private lands slated for development) and establish reintroduced populations; augmentations should also be implemented where small, non-viable populations occur. x Focus conservation efforts on marginal and small populations to preserve the genetic diversity of the species. Monitoring/Research Activities x Continue to survey potential habitat all counties of occurrence and in corridor counties. x Conduct surveys of previously documented populations on private lands with a focus on those that have not been visited in over 20 years, occur on larger tracts, and/or are adjacent to existing conservation lands. x Conduct research on the response of beautiful pawpaw to fire and fire prescriptions necessary to benefit the species. x Monitor burned and mowed sites more closely to assess which technique is most beneficial to pawpaw reproduction and survival. x Determine long-term effects of using careful roller-chopping as a mechanical treatment on population viability x Conduct demographic studies to determine the age class structure and long-term viability of populations, especially in areas with active recruitment, and determine critical life stages. x Develop and carry out a monitoring protocol for reintroduced/augmented populations to better characterize long-term survival of individuals and population viability. x Conduct further genetic research to determine the level of genetic diversity that remains and is protected and apply this knowledge to future introductions and augmentations. Also, conduct further research to determine the level of hybridization with D. rugelii (Rugel's pawpaw) and A. pygmaea (dwarf pawpaw) in populations not yet assessed and the level of hybridization with A. reticulata. Collect voucher specimens of known hybrids to document their morphological characters. x Continue to identify and evaluate insect pollinators associated with the species with a focus on conducting pollinator surveys at night when likely but undocumented insect visitors may be active. x Investigate potential seed dispersers and their effectiveness. x Conduct additional seed germination trials and make efforts to develop additional outplanting techniques. x Continue propagation efforts and make sure all populations are represented in the Center for Plant Conservation's National Collection of Endangered Plants. x Support continued work and research into ex situ cryopreservation methods to preserve cell lines of this species. x Evaluate the effects of climate change on the species, including those that result from precipitation pattern changes and temperature rise. Outreach Activities x Promote partnerships to share information, conduct collaborative research on pine flatwoods habitat conservation, and provide land managers and the interested public with information about the ecosystem, threats, recovery actions, and associated rare biota. x Actively engage and encourage private landowners to manage pine flatwoods for ecosystem health and listed species. x Seek opportunities to include the media in conservation efforts to provide information about this species to the public. (USFWS, 2021)

# SPECIES ACCOUNT: *Deeringothamnus rugelii* (Rugel's pawpaw)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/27/1986; Southeast Region (R4)

**Physical Description**

A low, sparingly branched, scented shrub that grows from a stout taproot, rarely to 0.5 m tall. Leaves are alternate, erect, 1-7 cm long, oblong to oval in shape. Stems are arching or occasionally erect, seldom branched. Flowers are solitary in leaf axils with 9 yellow petals (NatureServe, 2015).

**Taxonomy**

Kartesz (1999) treats Deeringothamnus pulchellus and D. rugelii as distinct taxa. Ward (2001) treats D. pulchellus as a variety of D. rugelii (Novon 11(3): 360-365) (NatureServe, 2015).

**Historical Range**

D. rugelii is endemic to a small area of Volusia county (USFWS, 2018).

**Current Range**

D. rugelii is known to occur at Deep Creek Preserve, Longleaf Pine Preserve, Tiger Bay State Forest, Port Orange City Forest, Wiregrass Prairie Preserve, and Lake Monroe Conservation Area, which are all in Volusia County, FL (USFWS, 2018).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: 1 - 2 years (above ground) (USFWS, 1988)

**Breeding Season**

Adult: Germinates in spring (USFWS, 2018)

**Key Resources Needed for Breeding**

Adult: Fire (USFWS, 1988)

**Reproduction Narrative**

Adult: Blooms in the spring (Small 1933) (NatureServe, 2015). The above-ground stems bear seed and fruit the first year after a fire, and appear to live for only one or two years (Wunderlin et al. 1981) (USFWS, 1988).

**Habitat Type**

Adult: Flatwoods with an open canopy of slash pine (P. elliottii var densa) or longleaf pine. This species also occurs in pastures and in road and utility rights-of-way (USFWS, 2018).

**Habitat Vegetation or Surface Water Classification**

Adult: Groundcover assemblages within the flatwood communities include wiregrass (Aristida stricta) and a diverse array of other herbaceous plants (USFWS, 2018).

**Dependencies on Specific Environmental Elements**

Adult: Periodic fire (NatureServe, 2015)

**Environmental Specificity**

Adult: High

**Habitat Narrative**

Adult: Rugel's pawpaw occurs in flatwoods with an open canopy of slash pine (P. elliottii var densa) or longleaf pine. This species also occurs in pastures and in road and utility rights-of-way. It is found in mesic and wet flatwood enviroments, though one occurrence is known to occur in disturbed conditions. Soils that support this species are often deep, fine textured, poorly drained sand or sandy peats (USFWS, 2018). Fires limit the growth of larger shrubs that would otherwise compete with this species (USFWS, 1998).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available.

***Population Information and Trends***

**Population Trends:**

Stable (USFWS, 2018)

**Species Trends:**

Stable (USFWS, 2018)

**Number of Populations:**

22 Extant (USFWS, 2023)

**Population Size:**

2,142-4,538 (USFWS, 2018)

**Population Narrative:**

Rugel's pawpaw has only occurred in a small area of Volusia County in northeastern peninsular Florida. From the time of its initial discovery through 1998, 25 occurrences of D. rugelii had been located within Volusia County. In 1998, the number of plants reported from previous surveys among the known populations ranged from 2,142 to 4,538 individuals with 9 of the 25 occurrences including more than 100 plants. Many additional surveys were conducted since 1998 and as of 2017, there are 36 occurrences documented in Volusia County with 33 being natural occurrences. Eighteen occur on protected conservation lands and 15 occurrences on unprotected private lands or highway and utility rights-of-way. The introduced populations occur on two protected sites. When a separation distance between occurrences is used, 9 separate potential populations are evident. The species status is stable but range-wide surveys are needed to confirm presence on all sites and proper management of existing sites will provide long-term benefits to this species (USFWS, 2018). While the number and configuration of populations is unknown, currently, there are 42 known occurrence records (Table 1; Appendix A, Table A.1) with distribution occurring primarily between the Deland and Atlantic Coastal ridges in Volusia County, Florida. Of these occurrences, 22 are extant, 8 are extirpated, and the status of 12 are unknown. These occurrence records include Florida Natural Areas Inventory (FNAI) Element of Occurrence (EO) records, transplant sites, and additional sites identified through the Florida Native Plant Society (FNPS) Pawpaw Chapter's annual survey efforts. In 2021, 20 plants from the Bok Tower Gardens rescue and tissue culture collection were transplanted into a pre-selected site on the Longleaf Pine Preserve. Eighteen of these plants were sourced from tissue culture propagated plantlets and two were individuals rescued from the Defrates property (Edwards et al. 2021). As of 2023, no survival of transplanted individuals was recorded in this site (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Habitat degradation and destruction (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The primary threat to this species is destruction and modification of habitat on private lands. Degradation of habitat resulting from a lack of adequate management on public and private lands remain a threat. Habitat loss and destruction from development is not a threat, degradation as a result of inadequate management is a concern. Additionally, elongated fire return frequencies and complete absence of periodic fire in some places has also led to habitat degradation (USFWS, 2018).

***Recovery***

**Reclassification Criteria:**
Ten (10) viable populations are established at secure sites (USFWS, 1988).

Recovery Priority Number: 2

**Delisting Criteria:**
Twenty (20) viable populations are established at secure sites (USFWS, 1988).

**Recovery Actions:**
- Conduct a range-wide survey of all existing populations and historic sites where populations formally existed that have not been developed. For all populations occurring on conservation lands; document current abundance, population trends, demographic trends, and habitat suitability. Conduct a Population Viability Analysis (PVA) to help determine a minimum viable population number (USFWS, 2018).
- When surveying plants note any associations with caterpillars and collect insects for proper identification in order to better understand the relationship between the organisms (USFWS, 2018)

- Support further research on the effects of prescribed burning and other management tools on D. rugelii, its life history needs, and microhabitat requirements (USFWS, 2018).
- Support further research into population genetics to better understand basic biology of the species, genetic variation within and among populations and across landscape, and whether hybridization is occurring with related and co-occurring species (USFWS, 2018).
- Support further research into microbiome and whether specific microorganisms area associated with this species, which may serve to inform future introduction sites (USFWS, 2018).
- Continue collaboration with conservation land managers to increase habitat management and suitability of occupied habitat (USFWS, 2018).
- Collect habitat management activity information from conservation land managers to increase habitat management and suitability of occupied habitat (USFWS, 2018).
- Actively engage private landowners and public non-conservation land owners (e.g. roadside rights-of-way) to protect and increase management efforts to benefit occupied habitat (USFWS, 2018).
- Continue transplantings from threatened sites (USFWS, 2018).
- Conduct reintroductions and possibly augmentations on publically owned conservation lands with suitable habitat and develop best approaches for conducting introductions to assist in meeting recovery goals (USFWS, 2018).
- Develop a monitoring protocol that indicates frequency and timing for future consistency and long-term trend analysis (USFWS, 2018).
- Support continued work and research into ex situ cryopreservation to preserve cell lines of this species (USFWS, 2018).
- Revise the current recovery plan to include more objective and measurable recovery criteria that are related to reducing threats identified in the recovery plan, as well as update information on the species distribution and biology (USFWS, 2008).
- Support further research on: a. The effects of prescribed burning and other management tools on D. rugelii. Continue working with public land managers to increase management efforts to benefit D. rugelii on their sites. B. Additional life history needs. C. The most appropriate methodology to germinate seeds or tissue cultures, grow seedlings, and successfully out-plat seedlings to native habitat (USFWS, 2008).
- Encourage non-Federal agencies to protect and manage habitat under the Partners for Fish and Wildlife Program (USFWS, 2008).
- Complete a rangewide survey to find all sites known to be occupied by or have the potential to be occupied by D. rugelii and determine population size. Current distribution information is needed to determine where plants currently exist and to prioritize recovery actions (USFWS, 2008).
- Consider reintroduction and monitoring of D. rugelii on additional publicly owned lands with suitable habitat. Reintroduction of D. rugelii could help to increase the number of populations on protected sites and augment populations where needed (USFWS, 2008).

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES A detailed discussion of recovery actions and criteria are presented in the Recovery Plan (Service 1986). During this status review new and/or targeted potential recovery activities were identified and are included below. Recovery Activities • Increase collaboration with conservation area land managers to improve habitat conditions of occupied sites through the application of prescribed fire. Implement mechanical vegetation management such as mowing and hand removal in areas where burning is not possible or in combination with burning to restore and maintain habitat conditions for Rugel's pawpaw. • Restore habitat on public and private lands in areas where plants could occur but have not been documented and implement post-restoration surveys to determine if natural populations are present. • Prioritize and implement rescue on sites with focus on sites identified for possible rescue. • Identify and prioritize additional (re)introduction sites and establish reintroduced populations. • Identify and prioritize occupied private lands that are good candidates for conservation acquisition and work with partners to acquire high priority parcels. Monitoring/Research Activities • Develop and conduct annual surveys in occupied secure sites to evaluate long-term population trends. • Conduct surveys in areas of previously documented occurrences focusing on sites with an unknown status. • Conduct research on the effects of growing vs. dormant season burning to determine if seasonality of prescribed fire significantly influences flowering and fruiting. • Conduct studies to determine the minimum viable population size required for a selfsustaining population. • Develop and implement survey and monitoring protocol for reintroduced/augmented populations to better determine long-term survival of individuals and population viability. • Conduct further research to determine species boundaries between Rugel's pawpaw and beautiful pawpaw. • Conduct studies to identify potential overlap in timing of flowering between dwarf pawpaw and Rugel's pawpaw to determine how this may relate to incidence of interspecific hybridization. • Conduct studies to identify and evaluate insect pollinators associated with the species. • Continue propagation efforts and ensure all populations are represented in the Center for Plant Conservation's National Collection of Endangered Plants gardens (e.g., Bok Tower Gardens). • Support continued work and research into ex situ cryopreservation methods to preserve cell lines of this species. • Evaluate the effects of climate change on the species, including those that result from precipitation pattern changes and temperature rise. Outreach Activities • Increase collaboration with conservation land managers to provide annual reporting on habitat management activities and relevant observations in occupied areas. • Promote partnerships to share information, conduct collaborative research on pine flatwoods habitat conservation, and provide land managers and the interested public with information about the ecosystem, threats, recovery actions, and associated rare biota. • Actively engage and encourage private landowners to manage pine flatwoods for ecosystem health and listed species. • Seek opportunities to include the media in conservation efforts to provide information about this species to the public (USFWS, 2023).

# SPECIES ACCOUNT: *Deinandra increscens ssp. villosa* (Gaviota Tarplant)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 03/20/2000; California/Nevada (Region 8) (USFWS, 2015)

**Physical Description**

Deinandra increscens ssp. villosa has pale to deep yellow disk and ray flowers. The foliage is variable gray-green and soft hairy. The plants generally range from 12 to 35 in (30 to 90 cm) tall with stems that generally branch near the base. The lower leaves are 2 to 3.4 in (5 to 8.6 cm) long. The inflorescence is typically rounded to flattopped with the flower heads in tight groups or paired. The peduncles are generally shorter than the involucres with mostly 13 ray flowers per head, but can vary between 8 and 15 ray flowers, and generally have 16 to 32 disk flowers per head (Baldwin 2009). Each flower head of Deinandra increscens ssp. villosa and other species in the family Asteraceae produce one-seeded fruits called achenes. (USFWS, 2011)

**Taxonomy**

Baldwin (2009) states "Deinandra increscens subsp. villosa differs from subsp. increscens in having more congested and, on average, shorter (generally < 45 cm tall) capitulescences, with phyllaries shorter than associated peduncles and peduncular bracts strongly overlapping the phyllaries, sometimes forming a distinct calyculus. Compared to D. increscens subsp. increscens, D. increscens subsp. villosa often has larger heads, which can reach the largest sizes in D. increscens, with up to 14 (–15) rays and up to 32 discs per head, but head size overlaps strongly with that of D. increscens subsp. increscens. Deinandra increscens subsp. villosa is known only from Santa Barbara County, mostly from the vicinity of Point Conception to Gaviota and north to the northern slopes of the western Santa Ynez Mountains", with outlying populations at Point Arguello and a northern outlier at Lion's Head (near Point Sal) (Baldwin 2009; Baldwin, pers. comm.2010a, pers. comm. 2010b; Elvin 2010b). (USFWS, 2011)

**Historical Range**

Historically, Deinandra increscens ssp. villosa was originally known only from the immediate vicinity of the unincorporated town of Gaviota, with plants occurring up to several kilometers in either direction along the immediate coast. (USFWS, 2011)

**Current Range**

Currently, it has a highly localized distribution in western Santa Barbara County, California with seven main populations that range from the vicinity of Point Sal in the north to Gaviota in the south. (USFWS, 2011)

**Critical Habitat Designated**

Yes; 11/7/2002.

**Legal Description**

On November 7, 2002, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Deinandra increscens ssp. villosa (Gaviota Tarplant) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes three critical habitat units (CHUs), in

California (67 FR 67968-68001).

**Critical Habitat Designation**

The critical habitat designation for Deinandra increscens ssp. villosa includes three CHUs in Santa Barbara County, California. This species critical habitat encompasses approximately 9,709 acres (67 FR 67968-68001).

Sudden Peak Unit: The Sudden Peak Unit consists of a 5- km (3-mi) stretch of ridgeline in the western portion of the Santa Ynez Mountains west of Sudden Peak, and generally includes grasslands above the 215-meter (700-foot) contour line. This unit is 320 ha (791 ac) and is comprised entirely of privately owned lands. Vandenberg Air Force Base holds an easement on a portion of these private lands. This unit includes two populations of Deinandra increscens ssp. villosa that comprised over 1,000 individuals in 1998. This unit is known to support populations away from the immediate coast and is at higher elevation than any other known D. increscens ssp. villosa location (425 m (1400 ft)). As a result, the populations in this unit experience more extreme seasonal temperatures and a lack of summer fog than most other populations which occur directly on the coast.

Santa Ynez Unit: The Santa Ynez Unit consists of a 9.7-km (6-mi) stretch of ridgeline of the Santa Ynez Mountains, ranging from Canada de las Agujas east to Canada del Agua Caliente. This unit of 433 ha (1,070 ac) is comprised entirely of privately owned lands. Deinandra increscens ssp. villosa occurs at 305 m (1,000 ft) in this unit, on the sandy mountain ridgelines. This unit supports two known populations of D. increscens ssp. villosa that comprised approximately 400 individuals in 1998. The terrain here differs from most other known locations in that it is characterized primarily by slopes that intergrade with flatter areas, rather than a flat marine terrace.

Conception-Gaviota Unit The Conception-Gaviota Unit consists of a 51.5-km (23-mi) long stretch of habitat along the coast from Point Conception, east to Gaviota, and encompasses 3,176 ha (7,848 ac). At its widest point, this unit extends inland approximately 3.2 km (2 mi). This unit is comprised almost entirely of privately owned lands (98 percent). This unit also consists of State lands at Gaviota State Beach and lands in the process of being transferred to CDFG for the Gaviota Tarplant Reserve (2 percent). This unit is particularly important because it supports most of the known populations of Deinandra increscens ssp. villosa that occur along the immediate coast. This includes the Gaviota population which was once extensive but is currently in decline, two small patches discovered in 1998 between Gaviota and Point Conception, and an extensive population discovered in 2000 that ranges from Government Point to the area near Jalama Beach County Park. Given these recent observations and the proximity to existing populations, we believe that there may be additional unsurveyed areas within the unit that may support D. increscens ssp. villosa. The populations here occur on a flat marine terrace along the immediate coast and likely experience summer fog and a mild maritime climate.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Deinandra increscens ssp. villosa critical habitat consists of two components (67 FR 67968-68001):

(i) Sandy soils associated with coastal terraces adjacent to the coast or uplifted marine sediments at interior sites up to 5.6 km (3.5 mi) inland from the coast, and

(ii) Plant communities that support associated species, including needlegrass grassland and coastal sage scrub communities, particularly where the following associated species are found: Needlegrass species (Nassella spp.), California sagebrush (Artemisia californica), coyote bush (Baccharis pilularis), sawtooth golden bush (Hazardia squarrosa), and California buckwheat (Eriogonum fasciculatum).

**Special Management Considerations or Protections**

Special management considerations or protections may be needed to maintain the primary constituent elements for the two taxa within the units being designated as critical habitat. In some cases, protection of existing habitat and current ecological processes may be sufficient to ensure that populations of the plants are maintained at those sites, and have the ability to reproduce and disperse in surrounding habitat. In other cases, however, active management may be needed to maintain the primary constituent elements for the two taxa. We have outlined below the kinds of special management and protection that these two taxa would most likely require. These recommendations for management and protection are general in nature. Specific management actions should be developed according to local site conditions. Not all of these will apply to each plant taxon equally. (1) Existing soil conditions should be protected by avoiding activities that cause the erosion or compaction of soils. Maintaining an intact soil profile may be necessary to maintain edaphic features such as a horizon of permeable sandy soils on the surface layer. For example, Deinandra increscens ssp. villosa is thought to be restricted to acidic, fine sandy loams with a subsurface clay layer that may act as a reservoir of soil moisture. (2) Existing hydrologic conditions should be protected by avoiding activities that cause a change in surface or subsurface water flows upon which the plant taxa depend. For example, development of areas adjacent to a population may result in an increase in runoff and surface water flow. This alteration may affect the soil moisture content to which the local population has adapted. (3) In all plant communities where these taxa occur, invasive, non-native species, such as harding grass (Phalaris aquaticus), veldt grass (Ehrharta calycina), and iceplant (Carpobrotus edulis), should be actively managed. Invasive non-natives pose a serious threat to the survival of Deinandra increscens ssp. villosa and Eriodictyon capitatum and remaining habitat of the taxa. For example, accumulated dead leaves and stems (thatch) from nonnative grass species that dominate the habitat effectively prevent the establishment of D. increscens ssp. villosa at a site. Iceplant is known to invade native maritime chaparral vegetation occupied by Eriodictyon capitatum. Once non-native grasses and other invasive plants (e.g., iceplant) have become established, they cannot be removed without great expenditure of time and effort. (4) The composition of the native plant and animal communities associated with the taxa must be maintained. Native plant diversity may limit the ability of aggressive non-native plants to invade a population (Dukes 2002). In addition, a decline in biodiversity may increase the potential impact of invasive plants on a community (e.g., suppression of growth). Recent research suggests that grassland communities with fewer species may be more likely to decline as a consequence of invasion (Dukes 2001). In addition, native plant diversity may increase pollinator activity and therefore enhance the conservation of a plant species. Biologists have suggested that a plant population may persist as long as it occurs within an area of a diversity of plant species that are attractive to pollinators (Kwak 1988). Habitat fragmentation and isolation of species-rich grasslands, with intervening areas of no or low diversity of native plants, has been found to negatively affect plant-pollinator interactions (Stephann-Dewenter and Tscharntke 1999). (5) The local distribution of plant communities should be managed to provide for the physical requirements of the taxa (e.g., space for establishment). For some grassland areas, it may be important to maintain openings within or between coastal scrub communities that might otherwise encroach upon grassland patches that support Deinandra increscens ssp. villosa. (6) Certain areas where these taxa occur may need fencing to protect them from accidental or intentional trampling by humans and livestock. Portions of three of the five units are currently used by livestock

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollinated.

**Lifespan**

Adult: 1 year (USFWS, 2011)

**Breeding Season**

Adult: June to September (NatureServe, 2015)

**Other Reproductive Information**

Adult: SBBG completed two new studies focused on Gaviota tarplant pollinators and other factors associated with pollination of the species at the Sudden Peak/Tranquillon Mountain population/occurrence 12 (Figure 1). In the first study, Knapp et al. (2021) found that Gaviota tarplant attracts a diversity of insect flower visitors in five orders: Coleoptera (beetles), Diptera (flies), Hemiptera (true bugs), Hymenoptera (sawflies, wasps, bees, and ants), and Lepidoptera (butterflies and moths). Of a total of 110 flower visitors observed during the study, 99 of them were using Gaviota tarplant and only 11 were using other co-occurring species. Therefore, Gaviota tarplant may be a magnet species within areas it occupies, such that it increases pollination of other less attractive, co-occurring species and is the main agent drawing pollinators to occupied areas. They also found that percent cover of Gaviota tarplant and sampling month were the most important factors affecting the model for flower visitor richness and abundance. Maximum pollinator activity occurred during the months of July and August, which corresponded to the peak robustness of Gaviota tarplant observed through the month of August. Other important variables, including distance to nearest wind turbine (because the study plots are located within a wind-energy construction site), number of Gaviota tarplant flowers present, richness of flowering species present, and cover of blooming, non-Gaviota tarplant species also contributed to the best fit model. But none of these other variables were statistically significant (USFWS, 2022)

**Reproduction Narrative**

Adult: Deinandra increscens ssp. villosa (Gaviota tarplant) is a self-sterile annual plant in the sunflower family (Asteraceae) (Tanowitz 1982; Keil 1993; B. Baldwin, University of California, Berkeley, Jepson Herbarium, in litt. 2001; Baldwin 2010). Each flower head of Deinandra increscens ssp. villosa and other species in the family Asteraceae produce one-seeded fruits called achenes.

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Grasslands intergrading with coastal sage scrub (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Soil pH of 5.0 or lower, prefers marine terraces and uplifted marine sediments ranging from 150 to 1,000 feet (46 to 305 m) (USFWS, 2011; NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist

**Dependency on Other Individuals or Species for Habitat**

Adult: Deinandra increscens ssp. villosa is associated with grasslands comprised of native Nassella spp. (needlegrass), nonnative species such as Avena spp. (wild oats) and Bromus diandrus (ripgut brome), and other herbs and grasses. The grasslands throughout the range of the species are interspersed with coastal sage scrub generally dominated by Artemisia californica (California sagebrush), Baccharis pilularis (coyote brush), Hazardia squarrosa (sawtooth golden bush), and Eriogonum fasciculatum (California buckwheat) (California Natural Diversity Database (CNDDB) 2010). (USFWS, 2011)

**Habitat Narrative**

Adult: Gaviota tarplant requires grassland habitats. Occupied areas often intergrade with coastal sage scrub communities and are dominated by nonnative, Mediterranean annual grasses such as wild oat (Avena spp.), bromes (Bromus spp.), false brome (Brachypodium distachyon), and nonnative forbs like storksbill (Erodium spp.). Native grasses and forbs can also co-occur with Gaviota tarplant but are typically less dominant. Shrubs are largely absent in stands occupied by the species, although shrubs may occur in intergrade zones and other successional areas, like sawtooth goldenbush (Hazardia squarrosa), California buckwheat (Eriogonum fasciculatum), and coyote brush (Baccharis pilularis). Areas that provide suitable grassland habitats for the species include marine terraces, coastal bluffs, active and inactive cattle ranches, undeveloped plains and prairie areas, and open fields (USFWS, 2022).

***Dispersal/Migration***

**Dispersal**

Adult: High (USFWS, 2011)

**Dispersal/Migration Narrative**

Adult: Achenes of Deinandra spp. are most likely dispersed by adhesion of the sticky bracts clasping the ray achenes to animal fur or feathers (Baldwin, in litt. 2001). (USFWS, 2011)

***Population Information and Trends***

**Population Trends:**

Unknown

**Number of Populations:**

27 (USFWS, 2022)

**Population Size:**

>1,000,000 at one site (USFWS, 2022)

**Population Narrative:**

Currently, Deinandra increscens ssp. villosa has a total of 26 known occurrences grouped among 7 populations ranging from the coastal terraces on the bluffs at Lion’s Head near Point Sal to the mountains of the Western Transverse Ranges, to the coastal terraces on the bluffs at Point Conception and Gaviota (Service 2000, 2002, CNDDB 2010, CCH 2010; Baldwin 2009, 2010; Elvin 2010a, 2010b). The number of standing Deinandra increscens ssp. villosa plants has been shown to vary considerably within any given occurrence from year to year. (USFWS, 2011). Gaviota tarplant is now known from a total of 27 occurrences all within southwestern Santa Barbara County (Figure 1). Most of the occurrences are distributed across the same seven core populations identified in our 2011, 5-year review (Service 2011, pg. 6). From Gaviota, traveling north these include: 1. Gaviota Coast; 2. Hollister Ranch Coast; 3. Hollister Ranch/Santa Ynez Mountains; 4. Point Conception/Dangermond; 5. Sudden Peak/Tranquillon Mountain; 6. Point Argeullo; and 7. Point Sal/Lions Head. There are two new Gaviota tarplant occurrences, numbers 13 and 14 that are recently discovered colonies mapped along the coast, in areas north of Jalama Beach, predominantly on VSFB (VSFB 2022, pers comm). Portions of occurrence 14 were first mapped on VSFB in 2015 (ManTech SRS Technologies 2016, pg. 20; ManTech SRS Technologies 2020, pg. 12). There is also a historical herbarium record within occurrence 14 collected in 1928 (CCH2 2022, website). The rest of the colonies within occurrence 14, and all of occurrence 13, were mapped on VSFB in 2019 (ManTech SRS Technologies 2020, pg. 12 and 41). Therefore, we now recognize a new eighth population of Gaviota tarplant that we are referring to as Jalama Beach (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Degradation and loss of habitat due to agriculture and urban development (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since the time of listing, threats to Deinandra increscens ssp. villosa and its habitat by degradation and loss of habitat have increased due to agriculture and urban development (Service 2000, CNDDB 2010). Populations on Hollister Ranch, along the coast, and in the Santa Ynez Mountains are affected by trampling from cattle and horses, discing for agricultural practices, and residential development (CNDDB 2010; M. Meyer, California Department of Fish and Game (CDFG), in litt. 2010a). For instance, CDFG issued an incidental take permit (ITP) for a single family house to be located within an area known to be occupied by D. increscens ssp. villosa (CDFG ITP permit 2018-2004-042-05) in 2004. Cattle and horses continue to graze in D. increscens ssp. villosa habitat between Gaviota State Park and Jalama Beach County Park (CNDDB 2010). Cattle grazing in some areas occupied by D. increscens ssp. villosa appears to have facilitated the displacement of D. increscens ssp. villosa and favored the dominance of D. fasciculata, (fascicled tarplant) a common native tarplant in other parts of southern California (Rindlaub, in litt. 1998). (USFWS, 2011)

**Stressor:** Invasion of additional nonnative species of eucalyptus (USFWS, 2011)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Nonnative Eucalyptus trees were planted in the Gaviota area on adjacent private lands and along Highway 101 as visual screens, windbreaks, and landscaping during the early 1900s and have continued to spread since then. Several species of Eucalyptus are present on various private and public properties in the area. Some species are expanding and increasingly overtaking coastal grasslands and scrub-lands (e.g., Eucalyptus conferuminata, E. globulus) (Meyer, in litt. 2010a; Ritter, pers. comm. 2010; Ritter, in litt. 2011). (USFWS, 2011)

**Stressor:** Loss of habitat and indirect effects from wind energy development (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Lompoc Wind Energy Project is a commercial wind energy facility proposed to be constructed and operated on approximately 2,950 acres (1,194 ha) in the Sudden Peak and Tranquillion Mountain area (CH2M Hill 2007). The project is planned to include the following components: 60 to 80 wind turbine generators, new access roads and road improvements, a communication system, meteorological towers, an operations and maintenance facility, onsite electrical collection and distribution lines, an onsite project substation, a new 7.85-mile (12.6km), 115-kilovolt Pacific Gas and Electric (PG&E) power line to the Lompoc area to interconnect with the PG&E electric grid, and upgrades to existing PG&E facilities in the area. Deinandra increscens ssp. villosa occurs throughout the central and western portions of the 2,950-acre (1,194-ha) project site and all 791 acres (320 ha) of the Sudden Peak Unit of critical habitat for D. increscens ssp. villosa occur within the project site (CH2M Hill 2007, Service 2002). This proposed project would likely have direct and indirect effects to occupied D. increscens ssp. villosa habitat. Effects from this project (direct and indirect) are estimated to include loss or modification of habitat; changes in hydrology; temporary or permanent loss of individuals; changes in vegetation; and an increase in nonnative or invasive species, night-lighting, dust, noise, and vehicle emissions (CH2M Hill 2007). The effects of competition with nonnative species is most problematic immediately adjacent to habitat that has been isolated or fragmented by development (Alberts et al. 1993). The development of wind energy projects in areas occupied by D. increscens ssp. villosa may also affect individuals or seed banks for this species and are further discussed in Factor E below. There are additional leases for wind energy development within the range of D. increscens ssp. villosa (Meyer, in litt. 2011), at the north end of the range near Point Sal and at the south end of the range near Point Conception. (USFWS, 2011)

**Stressor:** Sea level rise due to climate change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Sea level rise, as a result of global climate change, has the potential to alter and diminish the habitat of Deinandra increscens ssp. villosa because of its proximity to the coastline. At the time of listing D. increscens ssp. villosa, we did not discuss the potential effects of climate change on its long-term persistence (Service 2000). Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, a rise in sea level, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). The specific manner in which climate change could affect D. increscens ssp. villosa is unknown at this time due to the general nature of these predictions.

Because five of the seven populations of D. increscens ssp. villosa occurrences are on coastal terraces, erosion of these areas and corresponding loss or decreased quality of habitat could adversely affect these populations by causing habitat conversion within and adjacent to occupied habitat areas for this species. Climate change and sea level rise may also affect individuals or seed banks for this species. (USFWS, 2011)

**Stressor:** Development and alteration of habitat from mission operations at VAFB (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Facility maintenance and development for military and private commercial purposes planned at VAFB may result in loss and alteration of habitat occupied by Deinandra increscens ssp. villosa (U.S. Air Force 2008). Deinandra increscens ssp. villosa is known to occur in and around launch sites on VAFB (CNDDB 2010, Elvin 2010b). The U.S. Air Force conducts vegetation maintenance activities around launch facilities at VAFB to reduce the chance of fires. Additionally, the potential for deposition of exhaust products from launch vehicles could adversely affect D. increscens ssp. villosa and its habitat. Mission operations (e.g., antiterrorism operations, space launches), infrastructure support activities (e.g., road and utility maintenance), and environmental management programs (e.g., grazing and invasive species removal) may affect D. increscens ssp. villosa (U.S. Air Force 2008). Missile launch operations, such as adjacent to Space Launch Complex-6, could adversely affect habitats surrounding launch facilities. In 1993, a missile was destroyed shortly after launching at VAFB, and a series of brush fires caused by burning rocket fuel burned more than 400 acres (162 ha). Large fragments of metal blasted downward toward the ground caused physical damage to the habitat on base around the launch site (Wallace 1993). In September 1997, a 500-acre (200-ha) fire and a 1,500-acre (600-ha) fire burned near occupied habitat of Eriodictyon capitatum (Los Angeles Times 1997a). Fire containment lines constructed by bulldozers in the vicinity of the species were observed after the fire (J. Watkins, U.S. Fish and Wildlife Service, pers. comm. 1997). On November 1, 1997, a 1,225-acre (495-ha) fire that was accidentally set by an explosives disposal team at VAFB was partially contained by back-burning (Los Angeles Times 1997b). Mission operations may also have direct effects to individual D. increscens ssp. villosa plants and the seed bank and are further discussed in Factor E below. While mission operations at VAFB may have some adverse effects to D. increscens ssp. villosa and its habitat, the U.S. Air Force's mission at VAFB is expected to have long-term benefits to D. increscens ssp. villosa and its habitat because, in order to accomplish its mission at VAFB, the U.S. Air Force needs to maintain extensive tracts of undeveloped and encroachment-free property. These extensive tracts of undeveloped and encroachment-free property will likely allow D. increscens ssp. villosa to persist. (USFWS, 2011)

**Stressor:** Cattle grazing (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Service also stated that cattle grazing has occurred within the habitat of D. increscens ssp. villosa and that low levels of grazing may enhance the opportunities for it to propagate successfully, as it may serve to reduce competition from nonnative species. However, some evidence indicates that heavy grazing has affected individuals of D. increscens ssp. villosa by reducing their stature and the number of seeds that can be produced. Populations on Hollister Ranch, along the coast, and in the Santa Ynez Mountains are affected by cattle and

horse grazing (CNDDB 2010; Meyer, in litt. 2010a). VAFB leases grazing allotments that overlap with portions of all three populations on the base, the allotments are managed under a rest and rotation system that minimizes adverse effects and maximizes the reproductive success of populations that are grazed (U.S. Air Force 2008). An analysis of these threats is contained in the final rule and appears to remain currently valid. (USFWS, 2011)

**Stressor:** Flower beetle (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Service stated that approximately 50 percent of the disk and ray achenes of D. increscens ssp. villosa had been observed to be infested by an unidentified flower beetle (Rindlaub, in litt. 1998). (USFWS, 2011)

**Stressor:** Genetics issues as affected by small population size (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Most species in the genus Deinandra (including D. increscens ssp. villosa specifically) are self-incompatible and cannot produce viable seeds without cross pollinating within their respective taxa (Baldwin, in litt. 2001). Evolutionary processes such as mutation, natural selection, genetic migration, and random genetic drift are known to adversely affect small populations (Barrett and Kohn 1991). Adverse effects from these evolutionary processes on self-incompatible species such as D. increscens ssp. villosa are magnified by its self-incompatibility (Keck 1959; Tanowitz 1982; Baldwin, in litt. 2001). Maintaining gene flow among the populations is essential to counter the adverse effects from the evolutionary forces mentioned above and to ensure the long-term survival and conservation of this species. Both theoretical and empirical evidence indicates that smaller populations (those also possessing lower genetic variation) tend to have higher mortality rates and reduced fecundity, which leads to demographic fluctuations (Lande 1988, Les et al. 1991, DeMauro 1993, Heywood 1993, Lacy 1997, Frankham et al. 2002). At the extreme, very small populations suffer from inbreeding depression and the adverse effects of genetic drift (Barrett and Kohn 1991, Les et al. 1991). In plant species exhibiting sporophytic self-incompatibility, such as D. increscens ssp. villosa, the potential for adverse effects from inbreeding and genetic drift are greater than in species with gametophytic self-incompatibility (Baldwin, in litt. 2001). A reduction in population size, due to demographic or environmental stochasticity or long-term fragmentation of populations, could reduce the pool of S alleles, thereby reducing successful cross-pollination and reproduction (Les et al. 1991, DeMauro 1993). (USFWS, 2011)

**Stressor:** Climate change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** It is clear that an increase in the rate of sea level rise has been predicted for the coast of California (CCC 2001, California Climate Change Center 2006, Heberger et al. 2009). In particular, beaches and coastal bluffs along the coast will be subject to greater and more frequent wave attack, with a general rule of thumb that 50 to 100 feet (15 to 30 m) of beach width will be lost from use for every foot of sea level rise by the year 2100 with an estimated rise

in sea level in Santa Barbara County at 5.28 feet (1.61 m) (CCC 2001, Heberger et al. 2009). Because many D. increscens subsp. villosa occurrences are on the terraces on coastal bluffs, erosion of these areas caused by an estimated rise in sea level could cause a loss of individual plants and seed banks in five of the seven populations of this species. See Factor A for additional discussions regarding climate change in relation to this species. (USFWS, 2011)

**Stressor:** Emergency response activities (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Many Deinandra increscens ssp. villosa populations occur on coastal bluffs or open areas in the Santa Ynez Mountains that are associated with grasslands and sparse coastal sage scrub. Many of the known populations of this species grow in and adjacent to large open areas that generally have little vegetation and a flat or level geography that also has easy access from paved roads. These features are attractive to and preferred by emergency response organizations for use as staging areas and command posts during emergency response situations such as wildfires or other law enforcement actions. Establishing staging areas and or command posts quickly and close to a developing situation is important and the agencies may not have the ability to check resource databases (e.g., CNDDB) before setting up these posts to conduct their essential operations. Establishing a staging area or command post on D. increscens subsp. villosa plants would result in the crushing of these plants and seeds. (USFWS, 2011)

**Stressor:** Nonnative, Invasive Weeds (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Nonnative, invasive weeds compete directly with native species for resources and degrade habitat quality. Further, buildup of thatch from nonnative, invasive weeds can inhibit and arrest germination of natives and suppress their seedbanks. Strauss, and other future development projects, will have ongoing operational and maintenance components that have potential to continue to adversely affect the species and its habitat via introduction and spread of nonnative, invasive weeds. Development increases habitat fragmentation, which increases edge effects around occupied areas, that results in expansion and spread of nonnative, invasive weeds and increased fire risk. In turn, shifts in the plant species community composition can adversely affect pollinators, and increased fire frequency typically results in increased spread and expansion of nonnative, invasive weeds (USFWS, 2022).

**Stressor:** Climate Change Effects (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Langridge et al. (2018) provides a comprehensive assessment of the climate changes that will affect California’s Central Coast bioregion, which includes Santa Barbara County. Anticipated changes consist of increased maximum and minimum temperatures, slightly increased precipitation with substantially increased variability, increased locally extreme rainfall events, accelerated sea level rise, and increased drought (Langridge et al. 2018, pg. 6). The tolerance of Gaviota tarplant to these climate changes is unknown. We provide specific data for expected changes in precipitation and increased maximum and minimum temperatures at four

key locations throughout the species range (USFWS, 2022).

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

**Delisting Criteria:**
Delisting criteria are not available.

**Recovery Actions:**

- Recovery actions are not available.
- Develop a recovery outline and recovery plan for Deinandra increscens ssp. villosa. (USFWS, 2011)
- Work with the U.S. Air Force at VAFB to implement site-specific management activities (e.g., refining grazing regimes, eradicating nonnative species) to maintain suitable habitat on the base for this species. (USFWS, 2011)
- Work with partners to manage threats to this species throughout its range, such as increasing efforts to remove nonnative species and planning the timing of activities that occur within and adjacent to occupied habitat. (USFWS, 2011)
- Develop conservation and land use management plans or habitat conservation plans with the County of Santa Barbara, the agricultural community, developers, local landowners and stakeholders to facilitate this species occurring and migrating throughout its historical range. (USFWS, 2011)
- Conduct updated surveys throughout the range of the species. (USFWS, 2011)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Obtain access (if possible) to all mapped Gaviota tarplant occurrences to conduct comprehensive surveys of the status of the species and threats at these locations. Include estimates of numbers of individuals present, global positioning system (GPS) mapping of occupied spatial area, co-occurring and co-dominant vegetation, presence of natives versus nonnative species, timing of phenology, and observations of potential insect pollinators. Update information in resource agency databases (CNDDB) to ensure that these data remain accurate and current. 2. Create a standardized annual, quantitative Gaviota tarplant monitoring protocol that includes the parameters outlined in item 1 above. Organize occurrence landowners and other stakeholders to commit to conducting annual monitoring for a minimum of five consecutive years, in support of the next 5-year review. 3. Conduct experimental research on strategic, applied grazing as a management tool for Gaviota tarplant recovery and nonnative, invasive weed controls. 4. Implement management activities to ameliorate threats at each occurrence, including vegetation management such as trimming and removal, applied-strategic grazing, invasive weed abatement, and erosion controls. 5. Conduct research across the species range to improve and refine our understanding of taxonomy to achieve a consensus on morphological identification of the species. Data from this assessment will ideally resolve taxonomic ambiguities to inform rapid visual identification of Gaviota tarplant in the field. This work will also help us better understand the natural spectrum of variant morphologies associated with normal phenotypic plasticity, likely resulting from different ecological conditions (such as shallow soils and interior versus coastal populations). 6. Continue conducting genetics research to better understand

and delineate Gaviota tarplant from grassland tarweed using modern molecular techniques intended for these types of resolutions. This will improve our knowledge of how these two subspecies are separated genetically and help reach a standard for how genetic data should be used to define and interpret the listed entity. 7. Continue making accessions for conservation seed banking throughout the species range, so that all populations are represented in the collections. 8. Pursue opportunities to work with landowners and other stakeholders to augment extirpated and/or declining Gaviota tarplant occurrences and locate and prioritize other areas where introduction of the species via outplanting for recovery could be feasible. New introduction projects will focus on re-establishing and maintaining connectivity of other extant populations throughout the species range (USFWS, 2022).

# SPECIES ACCOUNT: *Delphinium bakeri* (Baker's larkspur)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 2/25/2000; Pacific Southwest Region (R8)

**Physical Description**

A perennial dry season-dormant herb that grows from a thickened, tuber-like, fleshy cluster of roots, to a height of 26 inches (in) (65 centimeters (cm)). The leaves are five-lobed, occur primarily along the upper third of the stem, and are green at the time of flowering. Another distinctive feature of the leaves is that they have a whitish area in the center. The flowers are irregularly shaped. The five sepals (outermost whorl or set of floral parts) are conspicuous, bright dark blue or purplish, with the rear sepal elongated into a spur. The inconspicuous petals occur in two pairs. The lower pair is blue-purple; the upper pair is white. Seeds are produced in several dry, many-seeded fruits, called follicles, which split open at maturity on one side (USFWS, 2015).

**Taxonomy**

In the buttercup family (Ranunculaceae) (USFWS, 2015). Ewan (1942) described Delphinium bakeri based on type material collected by Milo Baker in 1939 from Coleman Valley, Sonoma County, California. In the most recent treatment, Warnock (1993) retained the taxon as a full species. (USFWS, 2000)

**Historical Range**

Marin and Sonoma Counties in California (USFWS, 2015).

**Current Range**

One natural site and three reintroduced sites in Marin County, California (USFWS, 2015).

**Critical Habitat Designated**

Yes; 4/17/2003.

**Legal Description**

On March 18, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective April 17, 2003) for Delphinium bakeri (Baker's larkspur) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes two critical habitat units (CHUs), in California (68 FR 12834-12863).

**Critical Habitat Designation**

The critical habitat designation for Delphinium bakeri includes two CHUs in Sonoma and Marin Counties, California. Approximately 1,828 ac (740 ha) of Federal, State, and private land are being designated as critical habitat. Brief descriptions are presented below. Mapping coordinates and maps depicting the CH units are available in the Final Rule. (68 FR 12834-12863; USFWS, 2003)

Unit B1: Sonoma County, California. This unit is located near Coleman Valley Road west of the town of Occidental, approximately 8 km (5 mi) from the coast. The 322 ha (796 ac) unit is bounded on the north side by Coleman Valley Road and represents an area either near or at the original type locality for Delphinium bakeri. The exact location of the type locality for D. bakeri is somewhat vague, with the location described only as “Hedrin Ranch in Coleman Valley, West of Occidental.” The location is mapped to within a 1.6 km (1 mi) radius in the CNDDB. (USFWS, 2003)

Unit B2: Marin County, California. This unit is near the Marshall-Petaluma Road in Marin County approximately 10 km (6 mi) from the coast. This 418 ha (1,032 ac) unit is bounded on the north side by Salmon Creek and contains an extensive north-facing slope that is essential to maintaining the mesic conditions needed for the conservation of Delphinium bakeri. Land in this unit is privately owned with a county right-of-way along the road. (USFWS, 2003)

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Delphinium bakeri critical habitat consists of three components (68 FR 12834-12863):

(i) Soils that are derived from decomposed shale.

(ii) Plant communities that support associated species, including, but not limited to: Umbellularia californica (California bay), Aesculus californica (California buckeye), Quercus agrifolia (coastal live oak), Baccharis pulularis ssp. consanguinea (coyotebrush), Symphorcarpos cf. rivularis (snowberry), Rubus ursinus (California blackberry), Pteridium aqulinum (braken fern), Polystichum munitum (Sword fern), Pityrogramma triangularis (goldback fern), Dryopteris arguta (coastal woodfern), Adiantum jordanii (maidenhair fern), Polypodium glycyrrhiza (licorice fern), Toxicodendron diversilobum (poison oak), Ceanothus thyrsiflorus (blueblossom ceanothus), Lithophragma affine (woodland star), and Holodiscus discolor (oceanspray).

(iii) Mesic conditions on extensive north-facing slopes.

**Special Management Considerations or Protections**

Special management considerations or protections may be needed to maintain the physical and biological features and primary constituent elements that are essential for the conservation of Delphinium bakeri within the units being designated as critical habitat. In some cases, protection of existing habitat and current ecological processes may be sufficient to ensure that populations of the plants are maintained at those sites and have the ability to reproduce and disperse in surrounding habitat. In other cases, however, active management may be needed to maintain the primary constituent elements for the species. ‘‘Special management considerations or protection’’ is a term that originates in the definition of critical habitat. The designated critical habitat units may require special management considerations or protection because remaining populations of Delphinium bakeri are extremely rare, contain few individuals, and are subject to threats which could extirpate the species. In addition to the risk due to random natural events that can result in the extinction of species with very few, small, and highly isolated populations, potential threats to the habitat of D. bakeri include overcollection, application of herbicides, and sheep grazing. Currently, no legally operative plans or agreements have been developed that address the maintenance and improvement of the primary constituent elements important to the species, or that provide management for the long-term conservation of D. bakeri. Outlined below are the most likely kinds of special management and protection that the habitat features and primary constituent elements essential to the conservation of Delphinium bakeri may require. The following actions apply to both species, unless otherwise noted: (1) In all plant communities where these taxa occur, invasive, nonnative species need to be actively controlled; (2) The quality of water must be maintained to keep it free from levels of herbicides or other chemical or organic contaminants that would be deleterious to the species; (3) Certain areas where these species occur may need to be fenced to protect them from accidental or intentional trampling by humans and livestock; (4) Aerial application of herbicides and insecticides that are likely to be deleterious to the species needs to be curtailed in the critical habitat. Exposure to deleterious herbicides and insecticides from drift needs to be avoided; (5) Existing hydrologic conditions may need to be protected by avoiding activities that cause a change in surface or subsurface water flows. (USFWS, 2003)

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Flowers from April into May (USFWS, 2015)

**Key Resources Needed for Breeding**

Adult: Bumblebees and hummingbirds for pollination (USFWS, 2015)

**Reproduction Narrative**

Adult: Baker's larkspur flowers from April into May. Known pollinators that have been observed visiting flowers of the reintroduced plants on several occasions include bumblebees (Family Apidae) and hummingbirds. Baker's larkspur is self-compatible, but requires visitation by pollinators for good quality and abundant seed set. The approximate foraging distance from their nest of most bumblebees is approximately 1 mile (USFWS, 2015).

**Habitat Type**

Adult: Terrestrial (USFWS, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Mixed woodland (USFWS, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Elevation range of 295 - 672 ft (USFWS, 2015)

**Environmental Specificity**

Adult: Very narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Baker's larkspur occurs on decomposed shale in mixed woodland at an elevation range of 295 to 672 ft, in moderately moist, shaded conditions on a shallow veneer of soil along an extensive north-facing slope. These habitat requirements limit the availability of suitable reintroduction sites with appropriate habitat conditions and compatible land use (USFWS, 2015).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Decline of >90% (NatureServe, 2015)

**Species Trends:**

Decline of >70% (NatureServe, 2015)

**Population Growth Rate:**

Low (inferred from NatureServe, 2015)

**Number of Populations:**

3 extant populations, 1 wild population, and 2 introduced populations (USFWS, 2024)

**Population Size:**

3 individuals (natural site); (USFWS, 2024)

**Population Narrative:**

As of 2018, there are three extant populations of Baker's larkspur, one historical population and two introduced populations. The single extant historical population of Baker's larkspur (CNDDB 2018, occurrence #1; along Marshall-Petaluma Road) has had fewer than five flowering plants each year since 2004. In 2018, the site contained only three plants of flowering size. However, there are signs that the habitat condition at this location has been gradually improving since the damage caused by fire and road maintenance activities in 2004 (H. Forbes, in litt. 2018a). Between 2009 and 2012, 203 adult, greenhouse-raised Baker's larkspurs were planted at three introduction sites, Marshall-Petaluma Road Private Ranch, Chileno Valley Road Private Ranch, and Soulajoule Reservoir (CNDDB 2018; occurrences #5, #6, and #7, respectively). Descriptions of the sites (all within 5 air miles of the historical occurrence) and details of the introductions can be found in the recovery plan for Baker's larkspur (USFWS 2015). As of 2018, none of the three introduced populations has been successful and only two remain extant. Although seedlings were documented at all introduction sites in the year(s) following out-planting, none of the seedlings produced on site have reached seed set (H. Forbes, in litt. 2018a). The Chileno Valley Road Private Ranch introduction site has supported 0 to 5 flowering plants each spring since 2012 but none of the plants has successfully set seed since 2013. In 2018, there were 25 adult Baker's larkspur plants at the Soulajoule Reservoir introduction site but no plants have flowered at this site since 2013. (USFWS, 2019). The Marshall-Petaluma Road population remains the only naturally occurring population of Baker's larkspur and only three flowering individuals were observed at this location in 2024 (H. Forbes unpubl. data 2024). The outplanted Baker's larkspurs in the three introduction sites have had low survivorship and population numbers have remained low at these locations (H. Forbes unpubl. data 2024). Conservation actions for this species since the last 5-year review have included seed banking, trimming invading vegetation around Baker's larkspur plants during monitoring visits, and growing Baker's larkspur plants in the nursery for future introduction efforts (H. Forbes in litt. 2024). As of 2024, the Botanical Garden has 80 Baker's larkspur plants growing in the nursery for use in future reintroduction efforts (H. Forbes in litt. 2024). The Botanical Garden also has approximately 0.5 million Baker's larkspur seeds banked at -18 degrees Celsius. Some of these seeds were collected from the naturally occurring population along Marshall-Petaluma Road (Table 1), but the majority of seeds were collected from plants grown at the Botanical Garden (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** After historical habitat loss, the most significant habitat impact activities are from maintenance crews (e.g., roadside vegetation clearing, fire control, culvert maintenance, etc.). Habitat alteration or loss as a result of establishment of nonnative vegetation presents a minor threat at this time. The three reintroduction sites were e specifically selected to avoid any current and anticipated land use conflicts, and require minimal stewardship activities (USFWS, 2015).

**Stressor:** Overutilization for commercial, recreational, scientific, or educational purposes (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Overutilization is a significant threat to this species. In 1992, all the capsules were collected from the plants at the only known site of Delphinium bakeri. Because these capsules contained the plants' seeds, all sexual reproduction for 1992 was lost. Were this collection to occur regularly or in conjunction with unrelated natural events (e.g., fire) the species may be lost (USFWS, 2012).

**Stressor:** Disease or predation (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** While most Delphinium species are toxic to cattle, the toxicity of Delphinium bakeri has not been tested; sheep grazining has been mentioned as a threat. Herbivory of Baker's larkspur by slugs, snails, and gophers is a significant threat to remaining individuals at small and vulnerable microsites (USFWS, 2015).

**Stressor:** Other Natural or Manmade Factors Affecting Its Continued Existence (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Baker's larkspur is at risk from extirpation of small populations which may have endured reduced genetic variability and range constriction due to random natural and human-caused events. This species is also likely threatened by the effects of global climate change throughout its range (USFWS, 2015).

***Recovery***

**Reclassification Criteria:**

A.1. Habitat protection: Each reintroduced site will be managed for the species and in conservation ownership (owned in fee title), protected by a conservation easement, or protected by a formal Memorandum of Understanding with the landowner. Lands containing each population must be protected with a buffer of compatible land use. Due to the physical constraints of removing the threats presented by a major road, the Marshall-Petaluma Road Historical occurrence is exempted from this buffer requirement. (USFWS, 2015)

A.2. Outreach to reduce habitat disturbance: Outreach and education to the Marin County road maintenance crews and fire crews will ensure that the Marshall-Petaluma Road Historical Occurrence will no longer be affected by road or fire maintenance activities (USFWS, 2015).

C.1. Herbivory: For the 8 years following achievement of population targets, herbivory by slugs, snails and gophers must not occur in 2 consecutive years at levels which cause a population decline at any of the sites that count toward recovery. (USFWS, 2015)

E.1. Number of Sites/Geographic Distribution: For 5 consecutive years, a total of 12 self-sustaining populations of Baker's larkspur must be distributed across its historical range. This total may include the single extant historical occurrence and any newly discovered populations in addition to reintroduced populations. Microsites within the same reintroduction site may not be considered separate populations toward this total. Populations must be distributed between the Russian River to the north, Point Reyes-Petaluma Road to the south, the Pacific coast to the west and Highway 101 to the east. Marin and Sonoma counties must each support at least two populations of the species. For the purpose of the recovery plan, populations shall be considered separate if they are separated by at least 0.25 mi. (USFWS, 2015).

E.2. Number of Individuals: A minimum of 1,000 flowering individuals must be present at each of the 12 populations annually, for 5 consecutive years, and must include at least 2 lower-than-average water years. This reproductive objective for the minimum reproducing adult population may be met by a combination of surviving transplants and naturally recruited plants that mature and produce abundant seed annually. (USFWS, 2015)

E.3. Seedling Production: Each site must produce at least four seedling cohorts within 10 consecutive years that contribute enough surviving individuals to cause a net population increase at the site. Qualifying seed cohorts must not occur more than 3 years apart. The survival of subsequent generations of seedlings to reproductive maturity that produce viable seeds would demonstrate that plants at the site are completing their life-cycle without augmentation from propagation. Failure to detect surviving seedlings that mature into reproductive individuals within 3 years would indicate that the reintroduction is not yet achieving dynamic population objectives (Guerrant 1996). (USFWS, 2015).

Recovery Priority Number: 5

**Delisting Criteria:**
Development of delisting criteria is not possible given the current lack of information about the species' biology and habitat requirements, the magnitude of current threats, and the precarious environment where the single historical population of the species occurs (USFWS, 2015).

**Recovery Actions:**

- Monitoring of all known populations (including all microsites): Monitoring of the historical and reintroduction sites is necessary to determine population status and trends. Monitoring data will also be useful in helping to make informed decisions about site management and to determine progress toward reaching recovery criteria and objectives. (USFWS, 2015)
- Reintroduction of additional populations: Reintroductions should be conducted in accordance with the Service's Draft Baker's larkspur (Delphinium bakeri) Reintroduction Plan, Marin and Sonoma Counties, California, which describes the important components of site selection methodology, transplant procedures, seeding and labeling techniques, and reporting practices and should be updated as new information is gathered. (USFWS, 2015)
- Management of habitat at all populations. Reintroduction sites will be managed for the species and will be in conservation ownership, protected by a conservation easement, or protected by a formal Memorandum of Understanding with the landowner. This requirement (per relevant recovery criteria) will result in involvement with landowners or managers who are willing to allow flexibility in stewardship/management and monitoring activities, if the need arises, to ensure the population persists on their land. Reintroduction sites should be established where they are unlikely to be subject to human-related disturbance. However, if the site has a potential for vandalism, visible attractions (e.g. flags or flagging) should be removed and the reintroduced population should be disguised by surrounding the site with natural-looking accumulations of woody debris. (USFWS, 2015)
- Conduct research into Baker's larkspur genetics, population viability, and planting techniques (USFWS, 2015).
- Outreach: Due to the severe endemism and range restriction of Baker's larkspur, wide public outreach pertaining to its conservation is not a component of this recovery plan. Any outreach to a large audience that included detailed location information could endanger the species further by inadvertently drawing collectors, resulting in trampling impacts from the public, or infringing upon the privacy of participating landowners. However, recovery of the species is dependent upon willing landowners and managers who volunteer to conduct conservation activities on their lands. (USFWS, 2015)
- Recommended Future Action: Continue monitoring of the Marshall-Petaluma Road naturally occurring population and the three existing reintroduction sites at private ranches on Marshall-Petaluma and Chileno Valley Roads, and Marin Municipal Water District's Soulajoule Reservoir. (USFWS, 2012)
- Recommended Future Action: Continue seed multiplication and propagation efforts at the Garden. (USFWS, 2012)
- Recommended Future Action: Identify additional reintroduction sites and reintroduce Delphinium bakeri to at least two additional locations within its historic range. (USFWS, 2012)
- Recommended Future Action: The implementation of an adaptive strategy is recommended, whereby detailed observations of successes and failures are recorded and used to evaluate and adapt methods on a regular basis. (USFWS, 2019)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of Baker's larkspur. Some of these recommendations have already been discussed in previous recovery documents (Service 2012, p. 15; Service 2015, pp. III-1 – III-7; Service 2019, p. 4) and remain valid. 1. Monitoring – Continue monitoring of the Marshall-Petaluma Road naturally occurring population and the three existing introduction sites at private ranches on MarshallPetaluma and Chileno Valley Roads, and Marin Municipal Water District's Soulajoule Reservoir. 2. Outreach to Marin County staff – Outreach and education to the Marin County road maintenance crews will help ensure that the naturally occurring Marshall-Petaluma Road occurrence will no longer be affected by road maintenance activities. 3. Seed banking and plant propagation – Continue seed multiplication and propagation efforts at the Botanical Garden. 4. Augment reintroduced populations with additional individuals – Conduct additional plantings and/or seeding at the three introduced sites to help bolster population numbers and improve chances of successful pollination and reproduction. 5. Identify additional reintroduction sites – Identify additional sites within the historical range of Baker's larkspur where suitable habitat conditions and compatible land use exist, for establishment of additional reintroduced populations. 6. Adaptive management – Due to the difficulty experienced thus far establishing introduced populations of Baker's larkspur, we recommend the implementation of an adaptive strategy, whereby detailed observations of successes and failures are recorded and used to evaluate and adapt methods for future introduction efforts. Research should be conducted in association with future introductions to determine what variables improve the survival of transplants. 7. Research – Conduct research on the genetic variability of Baker's larkspur to help inform future outplantings, as well as ecological research including the study of habitat requirements, life history parameters, and natural population fluctuations (USFWS, 2024).

# SPECIES ACCOUNT: *Delphinium luteum* (Yellow larkspur)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 1/26/2000; Pacific Southwest Region (R8) (USFWS, 2015)

**Physical Description**

A perennial herb that grows from fibrous roots to 56 centimeters (22 inches) tall. The leaves are mostly basal, fleshy, and green at the time of flowering, which occurs from March to May. The flowers are cornucopia shaped with five conspicuous bright yellow sepals, with the posterior sepal elongated into a spur. The inconspicuous petals occur in two pairs: the upper petals are narrow and unlobed and the lower petals are oblong to ovate. The fruit is a follicle (USFWS, 2011).

**Taxonomy**

In the buttercup family (Ranunculaceae). Although Jepson (1975) reduced D. luteum to a variety of D. nudicaule (red larkspur), it is currently recognized as a full species (Warnock 1993) (USFWS, 2011).

**Historical Range**

See current range/distribution.

**Current Range**

Historically occurred within northwestern Marin and southwestern Sonoma counties, California (USFWS, 2011).

**Critical Habitat Designated**

Yes; 3/18/2003.

**Legal Description**

On March 18, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Delphinium luteum (Yellow larkspur) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes three critical habitat units (CHUs), in California (68 FR 12834-12863).

**Critical Habitat Designation**

The critical habitat designation for Delphinium luteum includes three CHUs in Sonoma and Marin Counties, California. Approximately 2,525 ac (1,022 ha) of Federal, State, and private land are being designated as critical habitat for Delphinium luteum. (68 FR 12834-12863).

Unit L1: Bodega Bay, Sonoma County, California.

Unit L2: Estero Americano, Marin County, California

Unit L3: Estero de San Antonio, Marin County, California

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Delphinium luteum critical habitat consists of four components (68 FR 12834-12863):

(i) Plant communities, including north coastal scrub or coastal prairie communities, including but not limited to: Arabis blepharophylla (rose rockcress), Calochortus tolmei (Tolmei startulip), Mimulus aurantiacus (orange bush monkeyflower), Dudleya caespitosa (sea lettuce), Polypodium californicum (California polyploidy), Eriogonum parviflorum (sea cliff buckwheat), Toxicodendron diversilobum (poison oak), Romanzoffia californica (California mistmaiden), Hesperevax sparsiflora (evax), Pentagramma triangularis (goldenback fern), and Sedum spathulifolium (broadleaf stonecrop).

(ii) Relatively steep sloped soils (30 percent or greater) derived from sandstone or shale, with rapid runoff and high erosion potential, such as Kneeland or Yorkville series soils.

(iii) Generally north aspected areas; and

(iv) Habitat upslope and downslope from known populations to maintain disturbance such as occasional rock slides or soil slumping that the species appears to require.

**Special Management Considerations or Protections**

Special management considerations or protections may be needed to maintain the physical and biological features and primary constituent elements that are essential for the conservation of Delphinium bakeri and D. luteum within the units being designated as critical habitat. In some cases, protection of existing habitat and current ecological processes may be sufficient to ensure that populations of the plants are maintained at those sites and have the ability to reproduce and disperse in surrounding habitat. In other cases, however, active management may be needed to maintain the primary constituent elements for the two species. As noted in the Critical Habitat section, ‘‘special management considerations or protection’’ is a term that originates in the definition of critical habitat. We believe the designated critical habitat units may require special management considerations or protection because remaining populations of Delphinium bakeri and D. luteum are extremely rare, contain few individuals, and are subject to threats which could extirpate them. In addition to the risk due to random natural events that can result in the extinction of species with very few, small, and highly isolated populations, potential threats to the habitat of D. bakeri include overcollection, application of herbicides, and sheep grazing, and potential threats to the habitat of D. luteum include overcollection, road widening, sheep grazing, fire suppression, and hybridization. Currently, no legally operative plans or agreements have been developed that address the maintenance and improvement of the primary constituent elements important to the species, or that provide management for the long-term conservation of D. bakeri or D. luteum. We have outlined below the most likely kinds of special management and protection that the habitat features and primary constituent elements essential to the conservation of Delphinium bakeri and D. luteum may require. The following actions apply to both species, unless otherwise noted: (1) In all plant communities where these taxa occur, invasive, nonnative species need to be actively controlled; (2) The quality of water must be maintained to keep it free from levels of herbicides or other chemical or organic contaminants that would be deleterious to the species; (3) Certain areas where these species occur may need to be fenced to protect them from accidental or intentional trampling by humans and livestock; (4) Aerial application of herbicides and insecticides that are likely to be deleterious to the species needs to be curtailed in the critical habitat. Exposure to deleterious herbicides and insecticides from drift needs to be avoided; (5) The appropriate level of soil disturbance needs to be maintained (this applies only to Delphinium luteum); and (6) Existing hydrologic conditions may need to be protected by avoiding activities that cause a change in surface or subsurface water flows.

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: Probably at least 10 years (USFWS, 2011)

**Breeding Season**

Adult: Flowers from March to May (USFWS, 2011)

**Key Resources Needed for Breeding**

Adult: Hummingbirds (and possibly bumblebees) for pollination (USFWS, 2011)

**Reproduction Narrative**

Adult: Flowering is from March to May. Hummingbirds (and possibly bumblebees) for pollination. Lifespan is unknown, but is at least 10 years. (USFWS, 2011).

**Habitat Type**

Adult: Terrestrial (USFWS, 2011)

**Habitat Vegetation or Surface Water Classification**

Adult: Coastal prairie and coastal scrub areas, which typically have no overstory vegetation (USFWS, 2011)

**Dependencies on Specific Environmental Elements**

Adult: Moderate to steep slopes, generally near areas showing evidence of some level of ground disturbance in the past (USFWS, 2011).

**Geographic or Habitat Restraints or Barriers**

Adult: Elevations ranging from sea level to 300 ft (USFWS, 2011)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2003)

**Habitat Narrative**

Adult: The species occurs in Coastal prairie and coastal scrub areas, which typically have no overstory vegetation, on moderate to steep slopes, at elevations ranging from sea level to 300 ft, and are generally near areas showing evidence of some level of ground disturbance in the past, including landslides. Typical soil types include the Kneeland series in Sonoma County and the Yorkville series in Marin County. These soils derive from sandstone or shale, and share qualities of rapid runoff and high erosion potential (USFWS, 2011). Primary constituent elements of critical habitat include Relatively steep sloped soils (30 percent or greater) derived from sandstone or shale, with rapid runoff and high erosion potential, such as Kneeland or Yorkville series soils; generally north aspected areas, and habitat upslope and downslope from known populations to maintain disturbance that the species appears to require (USFWS, 2003).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Dispersal information is not described in the 5-year review (USFWS, 2011).

***Population Information and Trends***

**Population Trends:**

Decline of 50-70% (NatureServe, 2015)

**Species Trends:**

Decline of 30-50% (NatureServe, 2015)

**Resiliency:**

The small size of populations of yellow larkspur in the wild makes the species extremely vulnerable to stochastic events. What would generally be considered stochastic events for wideranging populations could be catastrophic for smaller populations (Gilpin and Soule 1986, pp. 25–31; Service 2000, pp. 4159–4160). There is also the potential for additional effects related to small population sizes. Small populations have a higher risk of inbreeding due to reduced numbers of individuals available for reproduction. Inbreeding can reduce fitness, making populations less able to adapt to a variable environment (Shaffer 1981, p. 133; Ellstrand and Elam 1993, p. 225). Though Koontz et al. (2001, p. 1614) found relatively high genetic diversity in yellow larkspur populations, decreasing numbers of individuals still indicates the possibility of inbreeding (USFWS, 2024)

**Representation:**

Yellow larkspur genetic representation is high, as the species has been shown to maintain high levels of genetic variation (Koontz et al. 2001, p. 1614). Yellow larkspur has been found in two soil types: Kneeland series in Sonoma County and Yorkville series in Marin County, suggesting it has some ecological representation. The most recently documented populations (those located in the 1980's or later) tend to grow on north-facing slopes in canyon complexes with steep sides (Diversity Database 2023). Ecological representation is moderate due to the high level of genetic variation but assumed narrow range of habitat suitability and limited distribution. (USFWS, 2024)

**Redundancy:**

Redundancy is often limited for local, endemic species with a naturally limited range. Larkspur Rock is currently the only stable population of yellow larkspur. Previously documented occurrences on private land may still be extant, but without access, we are unable to confirm presence/absence. A catastrophic event impacting the population at Larkspur Rock could lead to extirpation of the only protected site (or extinction in the wild, depending on the status of the other yellow larkspur occurrences). Overall, the species currently has low redundancy (USFWS, 2024)

**Number of Populations:**

2 extant (USFWS, 2024)

**Population Size:**

Approx 200 individuals (USFWS, 2011)

**Additional Population-level Information:**

Only 3 of the 11 occurrences have records since 1993. (USFWS, 2024)

**Population Narrative:**

As described in Chapter 4 of the SSA report, of the eleven total Diversity Database occurrences for yellow larkspur, only three have records since 1993: Larkspur Rock (#5), Larkspur Hill (#11), and Walker Creek (#14; Diversity Database 2024). Several of the historical populations occur on private land and access would need to be granted by landowners to survey. The Larkspur Rock location is the only extant population of yellow larkspur that is known to be stable. The Larkspur Rock population is in Sonoma County and is protected as a conservation easement and monitored annually by University of California Botanical Garden at Berkeley (hereafter Botanical Garden) staff (H. Forbes in litt. 2023). The number of plants at this location fluctuates but has remained relatively stable at about 60 individuals for the past 10 years (Service 2024a, p. 18). The Larkspur Hill location is in Sonoma County on privately-owned lands and has not been visited since 1987 but 5–10 plants were observed from the road in 1999 (Service 2019, p. 2). The yellow larkspur population at Larkspur Hill is presumed extirpated because blooming plants have not been visible from the highway since before 2011 and the property’s management practices are incompatible with yellow larkspur persistence (Service 2019, p. 2). This property is currently managed as a sheep ranch, and plants are threatened by grazing (Service 2011, pp. 5–6). The Walker Creek occurrence is a roadside population in Marin County. Two yellow larkspurs were observed at this location in 2016 and one was observed in 2018, 2021, 2022, and 2023 (Service 2019, p. 2; D. Greenberger in litt. 2023; V. Smith in litt. 2023). In the past, yellow larkspur at this location has co-occurred with red larkspur (Delphinium nudicaule) and it is believed that the single, yellow-flowered larkspur observed at this location over the past six years is the same individual and is a hybrid between yellow larkspur and red larkspur (D. Greenberger in litt. 2023; D. Smith in litt. 2023; H. Forbes in litt. 2023) (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat destruction is still considered the greatest immediate threat for Delphinium luteum, with quarry activities, erosion, and disturbance of roadside locations listed as factors (USFWS, 2011).

**Stressor:** Overutilization for commercial, recreational, scientific, or educational purposes (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** At the time of Listing Rule in 2000, unrestricted collecting for scientific or horticultural purposes or excessive visits by individuals interested in seeing rare plants was said to be a threat (65 FR 4156). Overcollecting may still be a threat. Delphinium luteum is the only known yellow flowered larkspur. Due to this distinctive morphology, it has been and continues to be of horticultural interest, and some of the historical decline to D. luteum can be attributed to overcollecting (USFWS, 2011).

**Stressor:** Disease or predation (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Predation remains a threat for populations located on sheep grazing land. Most Delphinium species are toxic to cattle but not sheep. Several populations may be threatened by sheep grazing (USFWS, 2011).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Federal Endangered Species Act is the primary Federal law that provides protection for Delphinium luteum since it was considered endangered with the Listing Rule of 2000. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent its status under the Act. Therefore, other laws and regulations have limited ability to protect the species in absence of the Act (USFWS, 2011).

**Stressor:** Risk of extirpation due to small population sizes (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The small number of individuals in the single Delphinium luteum population increases the threat of extinction of the species as a whole through stochastic demographic and environmental events. Delphinium has been reduced to a few unprotected populations with fluctuating numbers of individuals (USFWS, 2011).

**Stressor:** Climate change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Global climate change is a potential threat to Delphinium luteum. Current climate change predictions for terrestrial areas in the northern hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying. However, predictions of climatic conditions for smaller sub-regions such as California remain uncertain. It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects (USFWS, 2011).

**Stressor:** Competition with native and non-native vegetation (USFWS, 2024)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** The introduction of non-native, invasive plant species can reduce the habitat quality of native communities, including coastal scrub and coastal prairie (Ford and Hayes 2007, p. 187). Under grazing pressure, non-native perennial grasses will often replace native coastal scrub species, thus directly competing for space with native species. Invasive plant species were listed as a threat in the 2019 5-year review and continue to threaten yellow larkspur (Service 2019, p. 9). At Larkspur Rock, ripgut brome (Bromus diandrus), an invasive grass species, has been increasing in cover and is considered one of the primary threats to this population (H. Forbes in litt. 2023). Additionally, poison oak, a native species, has shaded out some areas of rock that previously supported yellow larkspur (H. Forbes in litt. 2023). Native plants may also be a threat if they outcompete yellow larkspur or negatively impact habitat suitability. (USFWS, 2024)

**Stressor:** Hybridization (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Hybridization was first listed as a threat to yellow larkspur in the 2003 critical habitat designation (Service 2003, p. 12836) and remains a threat to the species. Hybridization with other Delphinium species is a threat to the conservation of unique yellow larkspur genotypes, especially where yellow larkspurs are known to occur with the closely related, interfertile red larkspur (Diversity Database #'s 13, 14, 16, and 17; Guerrant 1978, p. 1; Service 2019, p. 9; Diversity Database 2023). (USFWS, 2024)

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 8C

Yellow larkspur may be considered for downlisting when all the following criteria are met: 1a. There are a minimum of six populations in moderate condition as defined in the current SSA. For the purposes of this recovery plan, populations will be considered separate if they are separated by at least 0.25 mile (0.4 kilometer; km). -or1b. There are a minimum of four populations in high condition as defined in the current SSA. For the purposes of this recovery plan, populations will be considered separate if they are separated by at least 0.25 mile (0.4 km)1 (USFWS, 2025) .

2. The populations described in downlisting criterion 1a or 1b are protected and management is shown to be effective by stable or increasing population trends based on a minimum of 10 years of data. (USFWS, 2025)

**Delisting Criteria:**
1. A minimum of eight populations, six of which are in high condition as defined in the current SSA, and the remaining of which are at least in moderate condition. For the purposes of this recovery plan, populations will be considered separate if they are separated by at least 0.25 mile (0.4 km). (USFWS, 2025)

2. A distance of at least 15 miles (24 km) must separate the two furthest populations described in delisting criterion 1. This span must include at least one permanent firebreak (e.g., road or

waterway) to decrease the chance of catastrophic wildfire affecting all populations2. (USFWS, 2025)

3. The populations described in delisting criterion 1 are protected and management is shown to be effective by stable or increasing population trends based on a minimum of 20 years of data. (USFWS, 2025)

4. Ex situ seed collections are established at a Center for Plant Conservation seed bank facility. The seed collections are of sufficient size and genetic diversity to support research, restoration, viability testing, and the establishment of a backup collection at the National Laboratory for Genetic Resources Preservation, Fort Collins, CO. Accessions are replenished every 15 years, unless research demonstrates that collection frequency should be more frequent. (USFWS, 2025)

**Recovery Actions:**

- Gather information on habitat needs and requirements. Little is known about the habitat needs and requirements for Delphinium luteum. All wild populations grow on north-facing rocky slopes in Sonoma or Marin counties, but the plant is grown easily in horticulture. Research to gather information about soil and moisture requirements, pollination and germination requirements and viability of the seed bank is recommended (USFWS, 2011).
- Continue captive propagation efforts for Delphinium luteum at the University of California Botanical Garden at Berkeley (USFWS, 2011).
- Write a Recovery Plan. The Act requires that all listed species have recovery plans. Delphinium luteum has been listed since 2000, development of a recovery plan would provide guidance to conservation efforts already in progress and provide criteria for successful recovery of the species (USFWS, 2011).
- Pursue communication with landowners for access to survey plants. Some of the CNDDB occurrences are on private property and have not been observed in many years. The Service recommends communicating with landowners to negotiate access to their properties to survey for plants (USFWS, 2011).
- Yearly surveys of plants. Currently there is little knowledge about the numbers of plants and populations of Delphinium luteum. The Service recommends yearly surveys of sites listed in the CNDDB in addition to sites on north-facing rocky slopes that may have unknown populations of D. luteum. With yearly surveys the Service can establish basic knowledge of the population numbers and range of the species, in addition to more information about any changes in habitat, a more comprehensive threats analysis and an estimation of the population trends of the species (declining, stable, or increasing) (USFWS, 2011).
- Find appropriate reintroduction sites. Survey for reintroduction sites on protected property and pursue landowner agreements (USFWS, 2011).
- Not available.
- 1. Reintroduce yellow larkspur to additional sites in appropriate habitat within protected areas throughout its historical range (Priority 1). (USFWS, 2025)
- 2. Develop and implement a monitoring program to identify population trajectories and environmental conditions that might be adversely affecting the species throughout its range (Priority 1). (USFWS, 2025)
- 3. Manage habitat that supports the species to reduce or eliminate threats, including control of competitive non-native vegetation, control of encroaching competitive native vegetation,

and supplemental seeding or planting throughout its range (Priority 1). (USFWS, 2025)

- 4. Collect seed from populations throughout the species' range and deposit accessions into two permanent conservation seed banks (Priority 2). (USFWS, 2025)
- 5. Conduct needed experimental research projects to enhance and improve management actions throughout the species' range. Examples include those that examine yellow larkspur genetics, assess population viability and habitat requirements, and evaluate planting techniques (Priority 3). (USFWS, 2025)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • Continue annual monitoring of Larkspur Rock population (Recovery Action 2). Yearly monitoring of the yellow larkspur population at Larkspur Rock has been conducted by Botanical Garden staff since 2011 (Service 2024a, p. 18). Annual monitoring data is used to demonstrate population trends. • Control competing vegetation at Larkspur Rock (Recovery Action 3). Habitat management at Larkspur Rock has consisted of pulling weeds and trimming poison-oak (Toxicodendron diversilobum) during annual monitoring visits by Botanical Garden staff. In the last few years, poison oak has shaded out some areas of rock that previously supported yellow larkspur, requiring additional trimming/removal to allow yellow larkspur to recolonize these areas (H. Forbes in litt. 2023). • Continue captive propagation and seed banking (Recovery Action 4). The Botanical Garden maintains a yellow larkspur seed bank that was started in 1983 from seeds collected at Larkspur Rock (Service 2011, p. 6). Botanical Garden staff have stored approximately 5,000 primarily nursery-generated seeds for use in long-term storage and for conservation projects (Botanical Garden 2023, p. 5). Additionally, Botanical Garden staff have identified ideal nursery germination conditions and have successfully grown yellow larkspur in the nursery for several decades. As of 2023, the Botanical Garden had approximately 100 plants which could be used for outplanting (Botanical Garden 2023, p. 5). Continued propagation will be crucial for future outplanting efforts which will likely be necessary to achieve recovery. • Reintroduce yellow larkspur to additional sites in appropriate habitat within protected areas throughout its historical range (Recovery Action 1). Potentially suitable habitat for yellow larkspur has been identified at Point Reyes National Seashore and on a Wildlands Conservancy property in Jenner Headlands. Further coordination and planning with appropriate land managers are required prior to project initiation (Holly Forbes pers. comm. 2023). • Conduct research on the habitat requirements for yellow larkspur (Recovery Action 5). Research conducted in conjunction with future reintroductions in areas with varying microhabitats (type/level of disturbance, slope, aspect, plant community composition, etc.) would clarify habitat requirements for this species and help identify suitable locations for future outplantings. • Pursue communication with landowners for access to survey plants. Some of the Diversity Database occurrences are on private property and have not been observed in many years. Communicating with landowners to negotiate access to their properties to survey for plants would allow the Service to confirm the presence/absence of these historical populations (USFWS, 2024)

# SPECIES ACCOUNT: *Dicerandra christmanii* (Garrett's mint)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 9/21/1989; Southeast Region (R4)

**Physical Description**

Dicerandra christmanii is a small, fragrant shrub that reaches 50 cm in height (Huck et al. 1989). Both its floriferous and vegetative shoots are stiff and ascend from a ramose (many branched, branching), woody base. Its taproot is branched with extensive, spreading, fibrous roots. The leaves of Garrett's mint are sessile and have rounded apices, cuneate bases, entire margins and glandularpitted upper and lower surfaces (Huck et al. 1989). Leaves found on the determinate, flowering shoots are narrowly ovate to narrowly oblong. Those that subtend the cymes are 2 to 8 mm long and 0.5 to 1.8 mm wide, while those that do not subtend the cymes are approximately 5 to 11 mm long, and 1 to 2.5 mm wide. The leaves of overwintering, vegetative shoots are similarly shaped, but larger. The inflorescence is a verticillaster (Huck et al. 1989), with each cyme containing 1 to 3 flowers. The calyx is 6.5 to 10 mm long, approximately 2 mm wide (at midpoint), and bordered with an indistinct white band. The corolla is funnel shaped and abruptly bent to about 90 degrees. Its tube is 7 to 10 mm long, and its limb (from geniculum to distal edge of upper lobe) is 5 to 10 mm long. The corolla buds yellow, but at maturity, it is a pale cream (eventually fading to white). It has vivid purple-red markings that are often trellise-patterned on the upper lobe, but irregularly spotted on the lower lobe. The upper lobe is a recurving, cleft standard, and the lower lobe is tripartite (three parted) with a recurving middle petal. The flowers have four, paired stamens, which are exerted slightly beyond the lower corolla lip (Huck et al. 1989). The filaments are white, the anther sacs are brilliant yellow, and the connective is widened and may be covered with a few small, reddish and yellow glands at the basal end. The pollen is white and sticky. The pistil is white and has a slender, hirtellous style. The fruit is a schizocarp of four ovoid, brown, smooth nutlets. (USFWS, 1999)

**Taxonomy**

Specimens of D. christmanii were first collected by Garrett in 1948 east of Sebring and originally identified as D. frutescens by Ward (1979), Wunderlin (1984), and Huck (1987). D. christmanii was named as a distinct species in 1989 (Huck et al. 1989). (USFWS, 1999)

**Historical Range**

The historic distribution of Garrett's mint was along a 6-km section of an ancient yellow-sand ridge that has only been fragmented within the last 40 to 60 years (Menges et al. 2001). (USFWS, 2009)

**Current Range**

In Highlands County, Florida, between Lake Jackson and Lake Istokpoga. (USFWS, 1999)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Flowers from July to November, primarily in September and October (USFWS, 1999)

**Reproduction Narrative**

Adult: Dicerandra christmanii flowers from July to November, primarily in September and October (Huck et al. 1989). Like other Dicerandra species, it has spurred anthers which must be triggered by insects for the pollen to be released and dispersed (FWS 1987). This pollination process occurs mainly through bee-flies (Exoprosopa fasciata), and few other insects visit the plant (Huck et al. 1989). (USFWS, 1999)

**Habitat Type**

Adult: Pine Scrub/Oak-hickory scrub

**Environmental Specificity**

Adult: Very Narrow (inferred from USFWS, 1999)

**Habitat Narrative**

Adult: Dicerandra christmanii is found within openings in sclerophyllous oak scrub (Huck et al. 1989). As a "gap" species, it prefers open areas and does not grow vigorously when in shaded conditions. The species occurs on well-to excessively drained yellow sands of Astatula and Tavares soil types and is found where the seasonal high water table is at least 1 to 2 m deep. (USFWS, 1999)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: The seeds do not have mechanisms for wind dispersal and generally fall close to the plant (R. Huck, personal communication, 1996). Some Dicerandra species have been shown to use water as a dispersal agent, sometimes having their seeds carried by streams (Huck 1987). However, the limited distributions of D. christmanii, D. frutescens, and D. immaculata indicate that this mechanism is not effective in South Florida. Given this limited dispersal, colonization of a newly disturbed area by D. christmanii depends on whether or not it is present in the seedbank. The lifespan of seeds in the seedbank is unknown. (USFWS, 1999)

***Population Information and Trends***

**Number of Populations:**

Four

**Population Size:**

3,891

**Population Narrative:**

The loss of scrub on the Lake Wales Ridge habitat was the primary reason for listing Garrett's mint as endangered. Garrett's mint is known from four sites, all occurring in a 6-km (3.7 mi) (north to south) by 3-km (1.9 mi) (east to west) area of Highlands County, Florida (FNAI 2009). The species is poorly represented on conservation land. Only one of the four occurrences is located within a protected area at the Flamingo Villas unit of the LWRNWR (Service 1999a, FNAI 2009). Three of four occurrences are located on private land. The area in the vicinity of these occurrences has been largely converted to citrus groves and scattered single family residences. Fire suppression continues to be a threat to Garrett's mint populations because the species thrives in the open conditions (gaps between shrubs) created and maintained by fire (Menges et al. 1999; Evans et al. 2004; Menges et al. 2006; Evans et al. 2008). At Flamingo Villas, estimates of the number of plants in the population began in 1994. From 1994 to 1998, the number of plants ranged from 2,266 to 3,507 (Menges and Weekly 1999). In 2009, a complete census of the population located 3,891 plants (Bok Tower Gardens 2010). Work is still required to complete land acquisition, control unauthorized access, remove trash, and restore the scrub vegetation with prescribed fire. Garrett's mint occurs at 'Carter Creek East', also known as 'Sebring Railroad East Scrub', a parcel targeted for acquisition by the Florida Forever program (FDEP 2008). The site is a 40-acre block of scrub located adjacent to a railroad track in a relatively remote area with no nearby public roads (Schultz et al. 1999). A large and thriving population of Garrett's mint was extant on this site as of October 2010 (C. Peterson, Bok Tower Garden, pers. comm. 2010). The occurrence in the vicinity of Moon Ranch Road is in an area lightly developed with single-family residences. Access for surveys was denied in 2009 (Bok Tower Gardens 2010). Remaining nearby scrub habitat may still support Garrett's mint. The occurrence in the vicinity of Snyder Road is extant along the roadside and on parcels that still contain habitat. Plants on the roadside are subjected to occasional mowing. The population consisted of a mere 88 plants in October 2009. Most of the surrounding area is converted to citrus groves and heavily disturbed (Bok Tower Gardens 2010).

***Threats and Stressors***

**Stressor:** Habitat destruction or modification
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species is restricted to xeric scrub habitats in one or more of the interior Central Florida counties of Polk, Highlands, Hendry, Osceola, and Lake, where habitat destruction from development continues to occur and development pressure remains high. Areal extent of post-Columbian xeric upland habitat loss on the Lake Wales Ridge is estimated to exceed 85 percent (Weekley et al. 2008a). Increasing pressure from population growth is likely to result in further loss of these habitats going forward. Carr and Zwick (2016) analyzed existing land use and landscape patterns to identify areas (including central Florida) most likely for development to accommodate a growing human population. They suggests that Florida's 2070 population will be early 15 millionpersons greater than in 2010, for an estimated total of 33,721,828. Using these figures, they estimated relative losses to agriculture, open space, and conservation to other land uses. If trends continue, they estimate 34 percent of land will be developed by 2070, up from 19 percent in 2010. At the same time, conservation lands will increase less than 1 percent (from 9,269,000 acres in 2010 to 9,525,000 acres by 2070). Overall, loss of habitat to development, primarily on private lands, will likely continue in Central Florida, eliminating populations and reducing the area of suitable habitat for these species. Therefore, habitat on protected lands are critical for the recovery of this scrub plants. (USFWS, 2019

**Stressor:** Lack of adequate fire management
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Fire is necessary to maintain the scrub habitats upon which this species depends. Historically, lightning-induced fires were a vital component in maintaining native vegetation within the scrub community. Fire suppression started on a regional scale on the Central Florida ridges about 80 years ago. Due to the extent of residential and agricultural development throughout Central Florida, fire has all but disappeared from the region as a widespread, natural phenomenon. Prescribed fire is a crucial management component for maintenance of all scrub habitats. Because of the difficulties of applying prescribed fire on an ever-increasing urban landscape, imperiled species on unmanaged sites will almost certainly disappear over time (Turner et al. 2006). In managed areas, prescribed fire is essential to manage habitats and restore or maintain suitable conditions for scrub species. (USFWS, 2019)

**Stressor:** Limited geographic range
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species occurs occur within a relatively limited geographic range in Central Florida. The limited geographic range in combination with the loss of habitat has resulted in a highly fragmented landscape where the remaining scrub areas and their residing species have become more and more isolated from each other, thereby making resiliency, redundancy, and representation more challenging to achieve. The effects of habitat fragmentation on species richness have been exhaustively studied (MacArthur and Wilson 1967, Diamond 1975, 1978; Simberloff and Abele 1976, 1982; Zimmerman and Bierregaard 1986). For most taxonomic groups, large habitat patches in close proximity to each other provide for the greatest species diversity and minimize extinction probabilities. On the contrary, small patches that are isolated are less likely to preserve species that would otherwise be common in the mosaic of communities that existed before isolation. Since at least the Pleistocene, Florida scrub has been characterized by an insular, discontinuous distribution, but the degree of habitat fragmentation seen today is unprecedented and certainly will contribute to increases in extinction rates among scrub-dependent plants and animals. (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**
1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations required to ensure 20 to 90 percent probability of persistence for 100 years (USFWS, 1999)

2. When these populations, within the historic range of D. christmanii are adequately protected from further habitat loss, degradation, and fire suppression (USFWS, 1999)

3. When these sites are managed to maintain the seral stage of xeric oak scrub that supports D. christmanii (USFWS, 1999)

4. When monitoring programs demonstrate that these sites support sufficient population sizes, are distributed throughout the historic range, and are sexually or vegetatively reproducing at sufficient rates to maintain the population (USFWS, 1999)

**Delisting Criteria:**
1. At least 20 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)

2. Populations (as defined in criterion 1) in yellow sand scrub habitats are distributed across the known range of the species. (USFWS, 2019)

3. Populations are protected and managed via a conservation mechanism to a degree that enough suitable habitat is present for the species to remain viable for the foreseeable future. (USFWS, 2019)

**Recovery Actions:**
- Determine current distribution of D. christmanii. Conduct surveys for additional populations of D. christmanii. Maintain distribution of known populations and suitable habitat in GIS database. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Monitor existing populations of D. christmanii. Develop monitoring protocol to assess population trends for D. christmanii. Develop a quantitative description of the population structure of D. christmanii. Monitor re-introduced plants. (USFWS, 1999)
- Provide public information about D. christmanii. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. However, caution should be taken to avoid revealing specific locality information of D. christmanii. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of D. christmanii and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)
- Habitat-Level Recovery Actions: Prevent degradation of existing habitat. Secure habitat through acquisition, landowner agreements, and conservation easements. Manage and enhance habitat. Restore areas to suitable habitat. Conduct habitat-level research projects. Monitor habitat/ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)

# SPECIES ACCOUNT: *Dicerandra cornutissima* (Longspurred mint)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 11/1/1985; Southeast Region (R4) (USFWS, 2015

**Physical Description**

A pungently aromatic, low shrub from a woody taproot. Leaves are opposite, needle-like, mostly ascending, with margins that are sometimes slightly wavy. The inflorescence appears as a narrow system of axillary clusters, each with 1-5 flowers. Flower petals are rose-purple, strongly 2-lipped, about 13 mm long. (Based on Kral 1983.) (NatureServe, 2015).

**Taxonomy**

Distinct species; one of six in Florida (NatureServe, 2015). Dicerandra is a genus of seven species in the mint family (Lamiaceae or Labiatae) (USFWS, 1987).

**Historical Range**

Originally found in Marion and Sumter Counties (USFWS, 2008).

**Current Range**

Currently known to occur at four sites in Marion County: CFG, along the I-7S right-of-way, Marion Oaks subdivision, and Ocala Waterways Estates subdivision (USFWS, 2008).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 1987)

**Dependency on Other Individuals or Species**

Adult: Apidae spp. (USFWS, 1987)

**Key Resources Needed for Breeding**

Adult: Insect pollinators (USFWS, 1987)

**Reproduction Narrative**

Adult: The three perennial species of Dicerandra are obligate outcrossers that reproduce entirely by seed (Huck 1984). Each has spurred anthers, which must be triggered by insect pollen vectors (usually the Apidae) for pollen to be released and dispersed (Huck 1984).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Longleaf pine-turkey oak scrub/sandhill, slash pine-palmetto scrub (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Scattered in openings (natural or artificial) in longleaf pine-turkey oak scrub/sandhill or on low rises in slash pine-palmetto scrub. (Based on Kral 1983.) (NatureServe, 2015). The habitat occupied by this species needs periodic prescribed fires. D. cornutissima grows well in open, sandy patches usually along roadside edges (USFWS, 2008).; D. cornutissima is endemic to sand pine scrub habitat that can best be described as scrub composed of overstory of older mature sand pine (Pinus clausa), with an open to thick understory of sand live oak (Quercus geminate), Chapman's oak (Q. chapmanii), myrtle oak (Q. myrtifolia), saw palmetto (Serenoa repens), scrub palmetto (Sabal etonia), Florida rosemary (Ceratiola ericoides), and the state listed Garberia heterophylla (Herring 2005). The ground cover component of this habitat is composed of patchy occurrences of lichens ( Cladina evansii, Cladina subtenuis, and Cladonia leporine), as well as grasses such as wiregrass (Aristida stricta), arrowfeather threeawn (Aristida purpurescens ), and sandy field beaksedge (Rhynchospora megalocarpa). D. cornutissima grows well in open, sandy patches usually along roadside edges. Although D. cornutissima occurs in a fire-adapted habitat, the timing of fires related to the plants survivorship and reproduction is not known (Herring 2005). At CFG, D. cornutissima mostly occurs within sand pinedominated scrub that has a mosaic of sandhill throughout the site (Herring 2005). The overstory is open, consisting of mostly sand pine, but longleaf pines are occasionally found. Fire suppression in the sandhill has led to an invasion of sand pine, but prescribed burning of this area needs to be conducted carefully, since response of D. cornutissima is unknown (Herring 2005). Menges (1992) found that a similar species, D. frutescens, a short-lived perennial is killed by fire and reestablishes vigorously from seed. Weekley (2006) notes its close relative D. christmanii is also killed by fire and reestablishes from seed. There has recently been research (K. Holsinger, University of Connecticut, unpublished data, 2008) to show that longer intervals of fire (more than 12 years) may be optimum for these species. Therefore, research on the similar D. frutescens, which grows in yellow sand scrub at Archbold Biological Station on the Lake Wales Ridge, should be considered to elucidate the effects of fire on Dicerandra species and help refine prescribed burning activities (A. Johnson, FNAI, personal communication, 2008). Further east on the CFG, along the I-75 right-of-way, and Marion Oaks and Ocala Waterway Estates subdivisions, D. cornutissima occurs along roadside edges, its preferred habitat (Herring 2005). Care must be taken along these edges to not move dirt, mow, and establish fire lines with heavy equipment (Herring 2005). There are plans at CFG to manage the scrub habitat using mechanical means to open the habitat and reduce the sand pine. Due to the close proximity of I-75 to this site, prescribed burning is extremely difficult. The OGT recently completed a management plan for CFG that has goals and objectives to protect, enhance, and increase D. cornutissima found on the site (FDEP 2007). (USFWS, 2016)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Not available

**Species Trends:**

Unknown (USFWS, 2008)

**Number of Populations:**

6 (USFWS, 2023)

**Population Size:**

~37,134 to 42,874 (USFWS, 2023)

**Adaptability:**

Low (inferred from NatureServe, 2015)

**Population Narrative:**

the species status is unknown; the last comprehensive population survey was completed in 1991. During the 2005 FNAI survey, a total of 731 plants were documented on the FDOT 1-75 right-of-way. Four sites of D. cornutissima are known to occur in Marion county, FL (USFWS, 2008). This species has few individuals and a very restricted range, and is experiencing a reduction in habitat from development pressures (NatureServe, 2015).; D. cornutissima was originally found in Marion and Sumter Counties. Currently D. cornutissima is only known to occur at four sites in Marion County: CFG, along the I-75 right-of-way, Marion Oaks subdivision, and Ocala Waterways Estates subdivision. A survey of the historic locations of D. cornutissima in Sumter County was conducted in 1984 and no plants were found (Wunderlin 1984). Florida Natural Areas Inventory (FNAI) has a record of D. cornutissima south of Marion Oaks along a powerline in Sumter County in 1988. The site along the powerline was discovered after the recovery plan was written in 1987. The recovery plan states that there was no suitable habitat left at the sites surveyed in 1984 in Sumter County, although suitable habitat may still exist between Sumter County and southern Marion County. (USFWS 1987, Wunderlin 1984). Other FNAI records include plants on private lands in Marion County near Rainbow Lakes Estates in 1993 and along State Road 200 (Bahia Oaks development) in 1991. No surveys of these sites have occurred since the early 1990s. Adjacent protected lands (Ross Prairie State Forest, Halpata Tastanaki Preserve, and Potts Preserve) have been surveyed the past five years but no D. cornutissima have been located in suitable habitat at these locations (A. Johnson, FNAI, personnel communication, 2008). (USFWS, 2018). Current distribution includes six extant D. cornutissima populations on public and private lands in Marion and Sumter counties, Florida. Based on the most recent estimates, there may be approximately 37,134 to 42,874 or more individuals in those six populations (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Habitat destruction remains the greatest threat to D. cornutissima. Populations along the I-75 right-of-way have been impacted by road construction, exotic plant invasion, and other road-related activities. The other two remaining sites are on private property and are susceptible to destruction due to urban development. Without natural caused or prescribed fires, sand pine creates a dense overstory, making the habitat unsuitable for D. cornutissima (USFWS, 2008).

**Stressor:** Invasive species (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The introduction of cogon grass along the I-75 right-of-way as well as on a few sites in the CFG in areas occupied by D. cornutissima has reduced the amount of suitable habitat for this species (USFWS, 2008).

**Stressor:** Fire suppression (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species occurs mainly along areas that have been naturally maintained with fire. Where fire has been suppressed for long periods, canopy cover increase and understory vegetation increases, reducing open sandy patches. The majority of sites containing D. cornutissima are degraded due t fire exclusion or lack of mechanical vegetative management (USFWS, 2008).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Florida Administrative Code 5B-40 (Preservation of Native Flora in Florida) provides the Florida Department of Agriculture and Consumer Services with limited authority to protect these plants (primarily from the standpoint of illegal harvest) on state and private lands. Only a few populations of D. cornutissima are located on protected land (CFO) where they are being managed. The FDOT is managing the I-75 right-of-way by controlling exotics however the right-of-way would not be considered protected land. CFO was acquired by the State of Florida in 1991, after Congress de-authorized the Cross Florida Barge Canal construction and transferred all the lands to the State. CFO has an approved unit management plan in place to protect D. cornutissima (FDEP 2007). FDOT currently manages for D. cornutissima along the I-75 right-of-way by working with their contractors that mow this right-of-way to avoid routine mowing outside the highway clear zone (approximately 36 feet from the travel lanes) and to control the cogon grass found on the right-of-way. A monitoring and management program should be established, including experimentation with different regimes of vegetation management outside the clear zone and re-establishment of an extirpated cluster of D. cornutissima that occurred within the southbound rest area before the construction. Two of the populations occur on private lands with little to no protection. The Service's Partners for Fish and Wildlife program could work with these landowners to better manage and protect these populations. (USFWS, 2018)

***Recovery***

**Reclassification Criteria:**
Ten separate, self-sustaining populations of the species are established at secure sites in peninsular Florida. This numerical goal is subject to revision as information becomes available on the population biology of each species and as suitable sites are found (USFWS, 1987).

**Delisting Criteria:**
20 separate, self-sustaining populations are established at secure sites in peninsular Florida (USFWS, 2008).

**Recovery Actions:**
- Protect and manage existing population (USFWS, 1987).
- Conserve germ plasm (USFWS, 1987).
- Establish and manage new populations (USFWS, 1987).
- 1. Revise the current recovery plan to include more objective and measurable recovery criteria that are related to reducing and/or eliminating threats to D. cornutissima as well as updated information on the species distribution, biology, and management needs. (USFWS, 2018)
- 2. Support further research on: a) the effects of prescribed burning and other management tools on D. cornutissima. Continue working with public land managers to increase management efforts to benefit D. cornutissirna on their sites. b) Additional life history needs. Additional information is needed on how cogon grass and other invasive plants affect D. cornutissima plants and what the effects of the herbicides used to eradicate cogon grass have on this species. c) The most appropriate methodology to germinate seeds, grow seedlings, and successfully out-plant seedlings to native habitat. d) The various pollinators ( e.g., Hymenoptera and Lepidoptera), as well as how different ant species assist with seed dispersal. (USFSW, 2018)
- 3. Encourage non-Federal agencies to protect and manage habitat under the Partners for Fish and Wildlife Program. (USFWS, 2018)
- 4. Complete a rangewide survey to find all known and potential sites occupied by D. cornutissima and determine population size. Current distribution information is needed to determine where plants currently exist and to prioritize recovery actions. (USFWS, 2018)
- 5. Consider reintroduction and monitoring of D. cornutissima on additional publicly owned lands with suitable habitat. Reintroduction of D. cornutissima could help to increase the number of populations on protected sites and augment populations \Vhere needed. (USFWS, 2018)
- Revise the current recovery plan to include more objective and measurable recovery criteria that are related to reducing and/or eliminating threats to D. cornutissima as well as updated information on the species distribution, biology, and management needs (USFWS, 2008).
- Support further research on A. The effects of prescribed burning and other management tools on D. cornutissima. Continue working with public land managers to increase management efforts to benefit D. cornutissima on their sites. B. Additional life history needs. Additional information is needed on how cogon grass and other invasive plants affect D. cornutissima plants and what the effects of the herbicides used to eradicate cogon grass have on this species. C. The most appropriate methodology to germinate seeds, grow seedlings, and successfully out-plant seedlings to native habitat. D. The various pollinators (e.g. Hymenoptera and Lepidoptera), as well as how different ant species assist with seed

dispersal (USFWS, 2008).
- Encourage non-Federal agencies to protect and manage habitat under the Partners for Fish and Wildlife Program (USFWS, 2008).
- Complete a rangewide survey to find all known and potential sites occupied by D. cornutissima and determine population size. Current distribution information is needed to determine where plants currently exist and to prioritize recovery actions (USFWS, 2008).
- Consider reintroduction and monitoring of D. cornutissima on additional publicly owned lands with suitable habitat. Reintroduction of D. cornutissima could help to increase the number of populations on protected sites and augment populations where needed (USFWS, 2008).

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES • Collaboration with conservation land managers to increase habitat suitability of occupied habitat by promoting beneficial management options to increase population persistence wherever additional opportunities present themselves. • Encourage landowners whose populations are under a habitat management plan to monitor occupied habitat for increased data of long-term trends. • Engage Duke Energy Corporation to encourage routine powerline vegetation maintenance activities to benefit species through seasonal timing and education (USFWS, 2023).

# SPECIES ACCOUNT: *Dicerandra frutescens* (Scrub mint)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 12/2/1985; Southeast Region (R4)

**Physical Description**

The scrub mint is a dense or straggly, low-growing shrub (Kral, 1983). It reaches 50 cm in height and grows from a deep, stout, spreading-branching taproot. Its branches are mostly spreading, and sometimes are prostrate. Its shoots have two forms, one which is strictly leafy and overwintering, and another which is flowering and dies back after fruiting. The leaves vary in shape. They can be narrowly oblongelliptic, linear-elliptic, or linear-oblanceolate (Kral 1983). The upper surface of the leaves is dark green, with the midrib slightly impressed. The lower surface is slightly paler, with the midrib slightly raised. They are 1.5 to 2.5 cm long, 2 to 3 mm wide, subsessile, flattish but somewhat fleshy, narrowly or broadly rounded at the apical end, have entire margins, and are not revolute. Scrub mint has an inflorescence that is elongated and interrupted, and, at least half of the flowering shoot is floriferous (Kral 1983). The calyx, at anthesis, is approximately 9 to 10 mm long, nearly erect, proximally and medially green, and distally tinged with red, with a broad white zone around the orifice. The corolla is 1.9 to 2.0 cm long, with an erect tube that is approximately 7 mm long. The external surface of the throat and limb is white or yellowish white. The upper lip is marked internally with a trellis pattern of lines and dots of deep purple, while the lower lip is maculate with larger, concentric spots from lobe bases to base of the lip. The flower has two pairs of stamens, with one pair slightly longer than the other (Kral 1983). The filaments are white, and the anthers are purple. Styles are almost white and bent forward or curved downward (usually above the anthers). (USFWS, 1999)

**Taxonomy**

Dicerandra frutescens was named by Lloyd Shinners (1962); his circumscription of the species was modified by Huck (1981), who reassigned specimens from Sumter and Marion counties to a new species, Dicerandra cornutissima. Kral (1982), working independently of Huck, came to the same conclusion. (USFWS, 1999)

**Historical Range**

Historically distributed more or less contiguously along a high yellow-sand ridge that has only been fragmented within the last 40 to 60 years (Menges et al. 2001). (USFWS, 2009)

**Current Range**

Dicerandra frutescens is endemic to a very limited portion of the Lake Wales Ridge in Highlands County, Florida, and is found at four localities. The mint occurs at Archbold Biological Station; in the Sun 'n' Lakes Estates subdivision east of US highway 27 and southeast of the town of Lake Placid; at YMCA Camp Florida on the west side of Grassy Lake southeast of the town of Lake Placid; and on a sand ridge along the northwest shore of Lake Placid. All four of these areas are native vegetation which are surrounded by agricultural and residential areas. (NatureServe, 2015. )

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexually, with outcrossing (USFWS, 1999)

**Dependency on Other Individuals or Species**

Adult: Needs insects for pollination (USFWS, 1999)

**Other Reproductive Information**

Adult: Scrub mint is insect pollinated and requires insect visits for seed production (Evans et al. 2004). Exprosopa fasciata (Diptera: Bombyliidae), a bee-fly is the dominant pollinator, accounting for 95 percent of all visits at Archbold Biological Station (ABS) . (USFWS, 2019).

**Reproduction Narrative**

Adult: Dicerandra frutescens has perfect flowers (Kral 1983) and reproduces sexually, with outcrossing (Huck 1981). It is not capable of spreading clonally (Menges 1992), but has been shown to root easily from cuttings of vegetative growth (FWS 1987). Growth containing flowers or flower buds will also root, but will often flower then die (FWS 1987). Its flowers have spurred anthers, which require triggering by insects to release and disperse pollen (FWS 1987). Though visited by a variety of insects (Huck et al. 1989), the scrub mint is pollinated mainly by bee-flies (Menges 1992). Its flowering occurs from August through winter, and fruit production occurs from September through winter (Wunderlin 1984). (USFWS, 1999)

**Habitat Type**

Adult: Scrub vegetation

**Environmental Specificity**

Adult: Dicerandra frutescens is a gap-utilizing species; it inhabits open areas in the vegetation. It does not tolerate shading by other plants. (USFWS, 1999)

**Habitat Narrative**

Adult: Dicerandra frutescens is mostly restricted to excessively drained, yellow sandy soils of the Astatula and Paola soil types (Menges 1992). However, it has been found on a moderately well-drained, yellow sand of the Orsino type (Menges 1992). In these soil types, scrub mint occurs adjacent to or within disturbed areas in sand pine scrub, oak scrub and sandhill habitats (FWS 1987, Menges 1992). It occupies sites with shallow litter layers that have an incomplete, or non-existent, tree and shrub canopy (Menges 1992). (USFWS, 1999)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: The scrub mint's seed dissemination mechanisms are unknown, though they possibly include passive dispersal (E. Menges, Archbold Biological Station, personal communication 1997). It is possible that the seeds are not dispersed far from the parent plant, since seed dispersal in the related Lakela's mint (Dicerandra immaculata) is known to be very limited. Observations of an introduced population of Lakela's mint at Hobe Sound NWR indicate that the seedlings occur a maximum distance of 2 m from parent plants (Race 1994). Scrub mint's seeds survive in the seed bank for at least 2 years (E. Menges, Archbold Biological Station, personal communication 1997), and if dispersal in scrub mint is similarly limited, then persistence in the seed bank may be an important strategy that this species uses for colonizing newly disturbed areas. (USFWS, 1999)

***Population Information and Trends***

**Number of Populations:**
14

**Population Size:**
~5,000

**Population Narrative:**
In the most recent FNAI Element Tracking Summary (FNAI 2015), scrub mint was known from 14 occurrences, 7 of which were on managed areas. The other seven occurrences were located on private land and their status was unknown. Based on 2008 aerial images, it appeared that four occurrences were likely extirpated or heavily disturbed and another five were possibly still extant based on remaining habitat in the area where they were previously recorded. Scrub mint populations are dependent on fire for long-term persistence (Menges et al. 2006). There is an inverse relationship between time-since-fire and multiple demographic and reproductive factors, including mortality of adult plants, growth and maturation rates, plant fecundity, number of pollinator visits, and seedling recruitment. Populations begin to decline six years after a fire (Menges et al. 2006; Evans et al. 2008). A population viability analysis (PVA) indicated that population growth rates decline below the replacement level of 1.0 (on average) in populations that remain unburned more than five years (Menges et al. 2006). Most demographic parameters peak at 3 to 5 years post-fire, after which populations experience a long, slow decline (Menges and Weekley 1999). Stochastic simulations using both regular and stochastic fire regimes predicted that fire return intervals of 6 to 12 and 6 to 21 years, respectively, were optimal for minimizing extinction risk. (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species is restricted to xeric scrub habitats in one or more of the interior Central Florida counties of Polk, Highlands, Hendry, Osceola, and Lake, where habitat destruction from development continues to occur and development pressure remains high. Areal extent of post-Columbian xeric upland habitat loss on the Lake Wales Ridge is estimated to exceed 85 percent (Weekley et al. 2008a). Increasing pressure from population growth is likely to result in further loss of these habitats going forward. Carr and Zwick (2016) analyzed existing land use and landscape patterns to identify areas (including central Florida) most likely for development to accommodate a growing human population. They suggests that Florida's 2070 population will be early 15 millionpersons greater than in 2010, for an estimated total of 33,721,828. Using these figures, they estimated relative losses to agriculture, open space, and conservation to other land

uses. If trends continue, they estimate 34 percent of land will be developed by 2070, up from 19 percent in 2010. At the same time, conservation lands will increase less than 1 percent (from 9,269,000 acres in 2010 to 9,525,000 acres by 2070). Overall, loss of habitat to development, primarily on private lands, will likely continue in Central Florida, eliminating populations and reducing the area of suitable habitat for these species. Therefore, habitat on protected lands are critical for the recovery of this scrub plants. (USFWS, 2019)

**Stressor:** Lack of adequate fire management
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire is necessary to maintain the scrub habitats upon which this species depends. Historically, lightning-induced fires were a vital component in maintaining native vegetation within the scrub community. Fire suppression started on a regional scale on the Central Florida ridges about 80 years ago. Due to the extent of residential and agricultural development throughout Central Florida, fire has all but disappeared from the region as a widespread, natural phenomenon. Prescribed fire is a crucial management component for maintenance of all scrub habitats. Because of the difficulties of applying prescribed fire on an ever-increasing urban landscape, imperiled species on unmanaged sites will almost certainly disappear over time (Turner et al. 2006). In managed areas, prescribed fire is essential to manage habitats and restore or maintain suitable conditions for scrub species. (USFWS, 2019)

**Stressor:** Limited geographic range
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species occurs occur within a relatively limited geographic range in Central Florida. The limited geographic range in combination with the loss of habitat has resulted in a highly fragmented landscape where the remaining scrub areas and their residing species have become more and more isolated from each other, thereby making resiliency, redundancy, and representation more challenging to achieve. The effects of habitat fragmentation on species richness have been exhaustively studied (MacArthur and Wilson 1967, Diamond 1975, 1978; Simberloff and Abele 1976, 1982; Zimmerman and Bierregaard 1986). For most taxonomic groups, large habitat patches in close proximity to each other provide for the greatest species diversity and minimize extinction probabilities. On the contrary, small patches that are isolated are less likely to preserve species that would otherwise be common in the mosaic of communities that existed before isolation. Since at least the Pleistocene, Florida scrub has been characterized by an insular, discontinuous distribution, but the degree of habitat fragmentation seen today is unprecedented and certainly will contribute to increases in extinction rates among scrub-dependent plants and animals. (USFWS, 2019)

**Stressor:** Drought
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Drought exacerbates declines due to lack of fire and prevents strong post-fire recovery of scrub mint populations. Regeneration of populations from seed after fire appears to be lower due to reduced seedling survival when a ‘dry’ year follows a fire. At ABS, a burn in 2006

was followed by a drought period and did not result in a strong population recovery as observed following other fire events. Since 2005, the scrub mint populations at ABS have been declining. Few seedlings were recruited in 2006 and 2007 (E. Menges pers. comm. 2008). Although 188 seedlings recruited early in 2008, less than half (48.4 percent) survived the spring drought (C. Weekley, pers. comm. 2008). (USFWS, 2009)

***Recovery***

**Reclassification Criteria:**
1. Enough demographic data are available to determine the appropriate numbers of self-sustaining populations required to ensure 20 to 90 percent probability of persistence for 100 years (USFWS, 1999)

2. When these populations, within the historic range of D. frutescens, are adequately protected from further habitat loss, degradation, and fire suppression (USFWS, 1999)

3. When these sites are managed to maintain the seral stage of xeric oak scrub that supports D. frutescens (USFWS, 1999)

4. When monitoring programs demonstrate that these sites support populations of sufficient sizes, are distributed throughout the historic range, and are sexually or vegetatively reproducing at sufficient rates to maintain the population (USFWS, 1999)

Recovery Priority Number: 2

**Delisting Criteria:**
1. At least 20 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)

2. Populations (as defined in criterion 1) in yellow sand scrub habitats are distributed across the known range of the species. (USFWS, 2019)

3. Populations are protected and managed via a conservation mechanism to a degree that enough suitable habitat is present for the species to remain viable for the foreseeable future. (USFWS, 2019)

**Recovery Actions:**
- Determine current distribution of D. frutescens. Conduct surveys of D. frutescens. Maintain distribution of known populations and suitable habitat in GIS database. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Continue research on life history characteristics of D. frutescens. Although recent work on D. frutescens can be used to infer answers to some life history questions, much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species more specific biological information is needed. (USFWS, 1999)

- Monitor existing and reintroduced populations of D. frutescens. (USFWS, 1999)
- Provide public information about D. frutescens. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. However, caution should be taken to avoid revealing specific locality information of D. frutescens. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of D. frutescens and other rare species require a self-sustaining, secure, number of natural populations. (USFWS, 1999)
- Habitat-Level Actions: Prevent degradation of existing habitat. Restore areas to suitable habitat. Conduct habitat-level research projects. Monitor habitat/ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • Determine the condition of the unprotected occurrences on private land whose status is currently unknown. • Acquire or secure permanent easements on lands with existing populations from willing sellers and restore scrub habitat on these sites, including the implementation of prescribed fire and vegetation thinning by hand. • Advocate for and support the application of prescribed fire to maintain xeric scrub habitat for scrub mint. • Advocate for and support the use of small-scale, hand removal of woody shrubs and tree species around scrub mint populations either in combination with or independent of prescribed fire. • Conduct a taxonomic study of the Dicerandra genus within Central Florida using a multidata approach (e.g., morphology, genetics, geography, ecological factors, etc.). • Continue demographic monitoring and expand to additional occurrences, especially those that are protected. • Evaluate and strengthen ex situ efforts for scrub mint. • Service recovery leads should maintain open lines of communication with State land managers and provide updates as appropriate to ensure proper management of occurrences. (USFWS, 2021)

# SPECIES ACCOUNT: *Dicerandra immaculata* (Lakela's mint)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

Lakela's mint is a small, fragrant shrub that can be differentiated from other Dicerandra by its spotless, lavender-rose colored flower. Lakela's mint reaches 20 inches (in) tall (Kral 1982). Its growth is bushy when in open sun but becomes lax when in shade. It forms small mats or domes of ascending to spreading or sprawling branches. The primary branches arise from a stout, deep, woody-branched taproot, and its numerous innovations arise from spreading or sprawling older growth. The main leaves are spreading (horizontal) or ascending (pointing upward), while those in the inflorescence (flower cluster) are sometimes reflexed (pointing downward) (Kral 1982). All leaves are linear, oblong-linear, linear-elliptic, linear-lanceolate or linear-oblanceolate in shape. They are 0.75–1.2 in long, 0.08-0.16 in wide, smooth, flattened, subsessile, narrowly rounded at the apical end, often slightly emarginate, and entire, though larger leaves can be minutely serrulate at the apical end. The inflorescence is usually 6-10 in long (Kral 1982). Its flowering cymes overlap and each has one, three, or five flowers. The calyx body is 0.28-0.31 in long and is usually purplish, becoming white or roseate toward the orifice. The corolla is about 0.75 in long, immaculate (not spotted), and is a bright lavender-rose. The upper corolla lip is broadly ovate to obovate, about 0.28 in long, apically upswept, and broadly rounded-emarginate. The lower lip is broadly obovate, trilobate, 0.35-0.40 in long, and downswept. The lateral lobes are spreading, oblong, broadly rounded, or oblique-truncate, and the medial lobe is emarginate. The anthers are exserted, and the style is projecting. (USFWS, 2016)

**Taxonomy**

The color of the corolla, lavender-rose to purplish, and its lack of spots separate Lakela's mint from other species of the Dicerandra genus (Service 1985). A new variety, D. immaculata Lakela var. savannarum, was described from southern St. Lucie County and is separated from D. immaculata var. immaculata by its wider leaves and lax habit (Huck 2001). With the original description of Dicerandra immaculata (Lakela 1963), Lakela briefly described and named a white-flowered form she found in the populations. She named this form D. immaculata forma nivea Lakela. In accordance with 50 CFR Subpart B, section 17.12(g), when we listed Lakela's mint as an endangered species, all lower taxonomic units were considered included as the listed entity. Thus the taxon D. immaculata forma nivea was treated as endangered at the time of listing. Although described as a different, but still lower taxonomic rank than species, the same endangered status applies to the more recently described D. immaculata var. savannarum. (USFWS, 2016)

**Historical Range**

The historic range of Lakela's mint is extremely small, encompassing an area only one-half mile wide by three miles long in southern Indian River and northern St. Lucie Counties (USFWS,1999).

**Current Range**

The current range of Lakela's mint is limited to St. Lucie and southern Indian River Counties in Florida, with an additional introduced site in Martin County. (USFWS, 2008)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

Adult: Seedling recruitment occurs primarily from December through March but can occur at any time of the year (Peterson et al. 2009). Leafing occurs from February to August. Anthesis occurs primarily from September to November and sporadically throughout the year. Fruiting occurs primarily from October to December and sporadically throughout the year (Austin et al. 1980). Mortality rates increase during September through December (Peterson et al. 2009). Plants appear to become reproductive at 1 to 2 years of age (Peterson et al. 2009). However, Lakela's mint has very low germination rates and germination is inconsistent (Peterson et al. 2009). Experimental germination trials seem to indicate that fire may increase germination success (Peterson et al. 2007); however, Huck (in litt. 2008) cautioned that fire does not trigger germination and should be used with care. Lakela's mint only reproduces through seeding and needs insects for pollination. Its flowers have spurred anthers, which require triggering by insect vectors to release and disperse pollen (Service 1987). Not all of the insect species responsible for the pollination of this mint are known, but it is thought that bees may pollinate the plants (Huck 1987). Seed dispersal of Lakela's mint is limited. Introduced colonies at the Hobe Sound National Wildlife Refuge (NWR) have dispersed no more than 6.5 feet from parent plants (Race 1994). In addition, Austin et al. (1980) indicated that areas of disturbed sandy soils within the vicinity of Lakela's mint colonies provided no evidence of recolonization. Oliveira et al. (2007) indicated that closely related taxa occur in close physical proximity to one another, which supports seed dispersal hypotheses; there is a lack of long-distance seed dispersal except by intermittent rainfall events that transported fruits along waterways, by high winds from hurricanes, or by the rise and fall of sea level during the Pleistocene as new habitat formed (Huck and Chambers 1997, Oliveira et al. 2007). It is interesting to note that all of the perennial taxa, including Lakela's mint, have very narrow geographic distributions, whereas the annuals are more widely distributed and none are listed or considered rare.

**Habitat Type**

Adult: Scrub

**Environmental Specificity**

Adult: Narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Lakela's mint is found in light shade or clearings in scrub in a limited area along the Atlantic coastal ridge in south Florida (Service 1987). Lakela's mint is a "gap" species. It abounds in open sunlight, but becomes straggly and weak as woody plants and saw palmetto invade open areas (Kral 1982). It occupies sites with varying degrees of litter, from partly covered to bare sand. These bare sands are probably created through a combination of wind action and fires. The mint has been observed growing on both white and yellow sands of the following soil series: Astatula sands, Paola sands, and St. Lucie sands (Service 1985). These soils are deep, nearly level to sloping, occur on high, dune-like ridges, and are acidic. Intensive site maintenance, including removal of vines, invasive species, grass competitors, and small trees and limbs that over-shade the plants, improves habitat conditions and provides additional capacity to support more individuals (Peterson et al. 2007). However, if not managed as such, overgrowth of the habitat reduces the amount of sunlight available and increases competition from other plants for nutrients and light, rendering long-term proliferation of the species unlikely without fire or other disturbance. Habitat conditions in and around the existing populations of D. immaculata var. savannarum also continue to deteriorate, resulting in population decline (Barry et al. 2007).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2008)

**Number of Populations:**

14 (5 natural and 9 introduced) (USFWS, 2021)

**Population Size:**

6,100 - 9,660

**Adaptability:**

Very sensitive to disturbance and successional canopy closure. (NatureServe, 2015)

**Population Narrative:**

Like other Dicerandra species, Lakela's mint is protected from insect herbivory by its essential oils (McCormick et al. 1993). Likewise, the variety savannarum also has essential oils, although it contains three compounds that are not present in Lakela's mint (Peterson et al. 2009). The cut leaves of one of its relatives, scrub mint (Dicerandra frutescens), have been shown to repel ants, and only Pyralid moths are known to feed on it (Eisner et al. 1990). Whether Lakela's mint is protected to this degree has not been verified. Though resistant to insect feeding, Lakela's mint populations have been adversely affected by mildew. Mildew grows on the nectary glands and can cause destruction of the fruits, destroying the viability of seeds before dispersal (Austin et al. 1980, Robinson 1981). Because of urban development, the overall distribution of Lakela's mint is significantly reduced. Trends in spatial distribution show increasing fragmentation of Lakela's mint as the coastal ridge has become developed and fire has been suppressed. Spatial distribution of Lakela's mint may be affected by disturbance factors. All Dicerandra mints, including Lakela's mint, in the southeastern United States tend to grow on disturbed sites, such as eroded dunes, sides of scraped dirt roads, fire lanes, unsodded banks, drainage ditches with loose sand, steep river banks, and gopher tortoise holes (Huck 1987, Huck in litt. 2008). On the Hallstrom Farmstead, plants are generally clustered in two areas on the property at tree-line edges next to sand paths or sandy openings (Peterson 2007a). The Service has observed that the distribution of the other remaining large natural population is similar. During fall 2006, 29 private properties in coastal scrub within the vicinity of the Hallstrom Farmstead and south to Indrio Road were surveyed (Peterson 2007b, Peterson et al. 2007). Only one new mint site was identified from this effort, and it contained approximately 10 plants (Peterson et al. 2007). It is presumed that this colony is part of one of the originally identified Florida Natural Areas Inventory sites (Peterson 2007b, Peterson et al. 2007). Additionally, two other sites containing the mint were brought to our attention (Peterson 2007b, Peterson et al. 2007). These small colonies were estimated to each contain 15-50 individual plants (Peterson 2006). All of these new sites are at risk of being developed and rescue efforts to obtain and preserve genetic material have taken place. At least one of the sites has already been cleared for development (Peterson et al. 2007). The population where it is believed that Dr. O. Lakela first collected the original type specimen for the species 45 years ago has disappeared (Huck in litt. 2008). Additionally, 53 private parcels encompassing over 100 acres along the Atlantic coastal ridge from Midway Road south to County Line Road in St. Lucie County and additional areas in Martin County south to Sewall's Point were surveyed to determine if the variety occurs in other locations, but no new populations were observed (Barry et al. 2007). At least seven sites where Lakela's mint occurred have been extirpated, including one that contained the new variety. In total, there are seven extant sites where populations naturally occur and four introduced populations. However, two of the sites where they occur naturally are slated to be developed. Four of the natural sites are privately-owned and three are on public lands. The four introduced populations (two populations of Lakela's mint and two of the new variety) are all on public lands. Trend data indicate declines in populations of both Lakela's mint and the variety savannarum. The total population of Lakela's mint is estimated to be between 6,100 and 9,660 plants (Peterson et al. 2009). When first discovered in 1995, approximately 200 individuals of the new variety were counted (Huck 2001). Due to drought and over-shading from competing plants, the natural population steadily declined to 89 individuals in 2005 and to nearly zero plants in 2012 (Peterson and Richardson in press). Lakela's mint occupies open areas in scrub, so prescribed burning or equivalent management is necessary to maintain the quality of its habitat. The way this species responds to disturbance and the frequency of disturbance needed are not known. Lakela's mint is a narrow ranging species, historically occurring in just two Florida counties along the Atlantic Coastal Ridge (southern St. Lucie and northern Indian River Counties). Introductions in Martin County and northern Indian River County have increased the species' range from approximately 3 to 59 mi (4.8 to 95 km) long. In 1996, the Savannas mint variety was discovered in southern St. Lucie County (Huck 2001). Introductions of this variety have increased its range from approximately 0.5 to 4 mi (0.8 to 6.4 km) long. There are currently 14 populations (5 natural and 9 introduced) of Lakela's and Savannas mint (Table 1; Peterson et al. 2009; Peterson 2017a, 2018, 2019, 2020, 2021a, 2021b, 2021c; Eastwick 2020). Since the previous status review (Service 2008), three populations have been introduced (one Lakela's mint and two Savannas mint) (Table 1; Peterson 2017a, 2020). However, the last remaining natural population of Savannas mint has been extirpated, portions of two Lakela's mint populations on private sites have been extirpated, and two populations of Lakela's mint entirely on private property are in danger of development and currently for sale (Table 1; Peterson et al. 2009; Peterson 2018, 2019, 2020; Service biologist observations 2020, 2021). Despite recovery efforts and the increase in number of introduced populations, only a few of the Lakela's mint populations are large enough to withstand stochastic events (Service 2019a), and even large populations are observed to decline rapidly in unsuitable habitat and weather conditions (Peterson et al. 2009; Peterson 2020). (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2008)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Continued habitat loss, fragmentation, and changes in land use threaten the existence of Lakela's mint. Although a few populations are on sites that are publicly owned, populations on private sites are threatened with destruction or habitat modification due to improper or lack of management.-Just since July 2006, HBS has rescued plants from two sites slated for development that were identified as a result of the survey effort from the Hallstrom Farmstead south to Indrio Road, one containing 2 plants and the other containing 56 (Peterson et al. 2007). The germplasm waSTI) aced in the National Collection, but the sites where these plants naturally occurred have now been lost. One of these sites was near the Hallstrom Farmstead, but because recent surveys in the surrounding area have yielded no positive results it is presumed that all adjacent colonies have been lost to development (Peterson et al. 2007). - Two additional plant rescues have been initiated since July 2006, and HBS is in the process of tagging and removing seeds and cuttings from all individuals on the sites with the hope of removing as many adult plants as possible (Peterson et al. 2007). One site containing 50-100 plants will be cleared to become a retention pond as part of a road project, and a bridge and development will be built through the other property that contained over 500 healthy plants and seedlings (Peterson et al. 2007). The only two locations where the variety is known to occur naturally are on private lands and both are threatened with destruction as a result of lack of management, dumping, or development (Peterson et al. 2007). Because of these threats, some of the plants were rescued, propagated, and introduced onto protected land in 2005, and germplasm was placed in the National Collection for preservation of genetic material (Peterson et al. 2007). However, it is probable that both of these natural populations will be extirpated. - Between 2005 and 2060 Florida's population is projected to double from approximately 18 to 36 million people (Zwick and Can 2006). Assuming a similar pattern of development at current gross urban densities for each county, this translates into the need to convert an additional 7 million acres of undeveloped land into urban land uses (Zwick and Carr 2006). It is projected that the coastal counties of Florida will be almost entirely built out by 2060 (Zwick and Carr 2006). Within the range of Lakela's mint, the model predicts that the human population will grow from just below 130,000 to nearly 285,000 in Indian River County and from 232,000 to over 563,000 in St. Lucie County between 2005 and 2060 (Zwick and Can 2006). Therefore, habitat loss, degradation, and fragmentation continue to threaten the species. (USFWS, 2008)

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Generally, managing agencies have limited regulatory tools. The Act provides protection for this species and its habitat through section 7 (interagency cooperation). Lakela's mint is also listed by FDACS as endangered (5B-40.0055 Regulated Plant Index), but this legislation does not provide any direct habitat protection. Existing federal regulations prohibit the removal or destruction of listed plant species on Federal lands. State regulations require both written permission from the owner or legal representative and a permit issued by FDACS to collect or remove plants listed as endangered on the Florida Regulated Plant Index. However, these regulations afford no protection to listed plants on private lands. In some situations, existing regulatory mechanisms do not appear to be adequate, as several private properties with mints have been developed, and the only option for the plants was to rescue them prior to clearing. Because this plant occurs in habitat along the Atlantic coastal ridge, which is desirable

real estate for development due to its elevation, this species remains vulnerable where it occurs on private property. (USFWS, 2008)

**Stressor:** Land management practices (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Land management practices such as canopy reduction are vitally important to maintaining and working towards recovery of Lakela's mint. Even though some sites are protected from development, habitat degradation may still be a concern at these sites. This species occurs in scrub habitat along the Atlantic coastal ridge, which is typically maintained by fire (Peterson 2007b). On many privately owned scrub sites, fire has historically been suppressed, and habitat has not received regular maintenance. If sites are not regularly maintained, vines tend to overtake the mints, competition for light, water, and nutrients from grasses and invasive species becomes too great, and limbs and small trees limit the amount of available sunlight necessary for survival (Peterson 2007b). Invasive plant species that impact the mints include, but are not limited to, Brazilian pepper (Schinus terehinthifolius), rosary pea (Abrus precatorius), natal grass (Rhynchelytrum repens), and guinea grass (Panicum maximum). (USFWS, 2008)

**Stressor:** Other natural or manmade factors (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Vegetation restoration and management programs are costly, and the availability of funding is never assured; therefore, habitat modification from inadequate management on protected lands remains an imminent, though moderate, threat. Degradation to habitat can also occur from damage by feral hogs (Sus scrofa), as cited in recent reports that assessed three Florida state parks (Engeman et al. 2003, 2004). Also, the species' limited distribution renders it vulnerable to random natural events, such as hurricanes and drought. (USFWS, 2008)

***Recovery***

**Reclassification Criteria:**
Not defined. (USFWS, 1999; USFWS, 2019)

Recovery Priority Number: 2C

**Delisting Criteria:**
1. When at least 20 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (Factor A) (USFWS, 2019)

2. When populations (as defined in criterion 1) in coastal sand pine scrub habitat are distributed across the historical range of the species in order to maintain and enhance the species geographic patterns of genetic diversity. (Factor A) (USFWS, 2019)

3. When populations (as defined in criterion 1) must be protected via a conservation mechanism and managed such that enough suitable habitat is present for the species to remain viable for the foreseeable future. (Factors A, D, E). (USFWS, 2019)

**Recovery Actions:**

- 1. Determine current distribution of D. immaculata. A comprehensive survey of D. Immaculata's range was completed in fall 1996. Taxonomic questions still exist with a newly located population at the Martin County border that make a definitive distribution difficult. (USFS, 1999)
- 2. Protect and enhance existing populations. Much of the native xeric uplands on the Atlantic coastal ridge has been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- 3. Conduct research on life history characteristics of D. immaculata. To effectively recover this species, more specific biological information is needed. (USFWS, 1999)
- 4. Monitor existing populations of D. immaculata. Develop monitoring protocol to assess population trends for D. immaculata. Develop a quantitative description of the population structure of D. immaculata. Monitor re-introduced plants. (USFWS, 1999)
- 5. Provide public information about D. immaculata. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society,and private landowners be appropriately informed about this species. However, caution should be taken to avoid revealing specific locality information of D. immaculata. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of D. immaculata and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)
- Habitat-level Recovery Actions: Prevent degradation of existing habitat. Extensive habitat loss, degradation, and fragmentation have already occurred throughout the range of this species. Both urbanization and fire suppression have decreased the available habitat. To date, there are no protected sites for this species in its historic range. - Restore areas to suitable habitat. Native habitats that have been disturbed or that have experienced a long history of fire suppression may be good candidates for future reserves. - Conduct habitat-level research projects. Study the response of D. immaculata to various land management practices, such as prescribed fire regimes, vegetative thinning, and control of exotic/invasive vegetation. - Monitor habitat/ecological processes. Monitor the effects of land management actions, such as prescribed fire, mechanical disturbance, etc., on the habitats where D. immaculata occurs. - Provide public information about xeric vegetative communities and its unique biota. (USFWS, 1999)
- Continue to survey potential habitat and pursue conservation agreements/implement management recommendations and/or acquire land. This is a high priority action, particularly for D. immaculata var. savannarum. • Include D. immaculata var. savannarum in conservation programs to conserve the genetic diversity found in the entire genus (Oliveira et al. 2007) • Write a management plan after acquisition of the portion of property containing the Lakela's mint at the HBOI property. (USFWS, 2008)
- Identify additional reintroduction sites and establish reintroduced populations; population augmentations should also be implemented. • Continue monitoring for both reintroduced and natural populations. • Propagation efforts should continue and clones of the original

"parent" should be placed throughout the Halistrom site to augment the population. • Where private sites are being developed, efforts should be continued to rescue individual plants and use them for propagation or to augment populations on protected sites. (USFWS, 2008)

- Federal, state, and local agencies, botanical gardens, and conservation organizations should convene to evaluate the current status of protection and the level of implementation of management practices at each site and to discuss current levels of support, threats to habitat and individual plants, and any obstacles to management and recovery. (USFWS, 2008)
- Evaluate the effects of climate change on the species, including those that result from precipitation pattern changes and temperature rise. (USFWS, 2008)
- To re-create open soils, managers should consider implementing mechanical disturbance, such as scratching or raking around plants, removing competitive plants in the vicinity of mints, or lightly disking larger areas, after mints flower but before the fruits drop (approximately two months after blooming) (Huck in litt. 2008). • Work with staff at Savannas Preserve State Park to understand habitat requirements of this species. • Conduct research on the response of Lakela's mint to fire and fire prescriptions necessary to benefit the species. • Continue seed germination studies and make efforts to develop additional outplanting techniques, especially those that may alleviate dessication of plants during dry conditions. • Demographic studies such as long-term survival and potential correlations with rainfall cycles and other variables should be examined. (USFWS, 2008)
- Opportunities should be sought where possible to include the media in the first Hallstrom Farmstead augmentation to provide information about this species to the public. • Conduct additional research on the biology, ecology, genetics, and management needs of the species. (USFWS, 2008)
- Partnerships should be promoted to share information, conduct collaborative research on coastal scrub habitat conservation, and provide land managers and the interested public with information about the ecosystem, threats, recovery actions, and associated rare biota. • Continue management actions to include removal of debris and exotics, canopy and vine reduction, controlling public access, re-creation of open areas and loose sands, and the careful reintroduction of prescribed fire into the ecosystem. (USFWS, 2008)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • Increase land management actions to include removal of hardwoods, debris and exotics, canopy and vine reduction, and reintroduction of prescribed fire into the ecosystem. • Conduct research on the response of Lakela's and Savannas mint to fire and fire prescriptions necessary to benefit the species. • Collaborate with partners and stakeholders on development of long-term habitat improvement and maintenance plans specific to the mints on public lands. • Develop a long-term, regular monitoring program for both reintroduced and natural populations. • Continue long-term spatial seedling recruitment and survival research. • Continue seed predation studies to determine if seed predators are a significant threat to the survival of the species. • Perform further research on pollinator species significance in the recovery and survival of Lakela's mint and Savannas mint. Explore potential connection between lack of pollination to seeds found with fungus. • Continue propagation efforts; clones of the original "parent" should be placed throughout the Hallstrom site to augment the population. • Continue seed germination studies and make efforts to develop additional outplanting techniques, especially those that may alleviate desiccation of plants during dry conditions. • Perform demographic studies such as long-term survival and potential correlations with rainfall cycles and other climate variables. • Continue to survey potential habitat and pursue conservation agreements, implement management recommendations, and/or acquire land, particularly for D. immaculata var. savannarum (Savannas mint). • Increase outreach efforts to raise awareness of this native species and the natural scrub habitat. • Promote partnerships to share information, seek funding, conduct collaborative research on coastal scrub habitat conservation, and provide land managers and the interested public with information about the ecosystem, threats, recovery actions, and associated rare biota. • Identify additional reintroduction sites and establish reintroduced populations; implement population augmentations. • Where private sites are being developed, efforts should be continued to rescue individual plants and use them for propagation or to augment populations on protected sites. • Conduct additional research on the biology, ecology, genetics, and management needs of the species. • Conduct a taxonomic study of the Dicerandra genus within Central Florida using a multidata approach (e.g., morphology, genetics, geography, ecological factors, etc.). (USFWS, 2021)

# SPECIES ACCOUNT: *Diplacus vandenbergensis (=Mimulus fremontii var. v.)* (Vandenberg monkeyflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 9/25/2014; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

Vandenberg monkeyflower is a small, annual herbaceous plant that grows from 0.5 to 10 inches (in) (1.2 to 25.4 centimeters (cm)) tall. The stems are glandular and usually green with purplish tinting. Leaves are obovate (narrowly elliptic) and reach 1.2 in (3 cm) in length. Plants produce a single flower or plants are branched producing multiple flowers. The tubular yellow flowers are bilaterally symmetrical, with the distal ends of the petals forming a unique structure that is likened to a face; hence the common name monkeyflower. Seed capsules are ovoid and reach 0.5 in (1.3 cm) in length. The capsule splits open longitudinally from the tip to release approximately 20 to 100 seeds. (USFWS, 2013)

**Taxonomy**

Vandenberg monkeyflower was first described as Mimulus fremontii (Benth.) A. Gray var. vandenbergensis D.M. Thompson (Thompson 2005, p. 134) as a member of the Scrophulariaceae (figwort family). This is the name and family placement we have previously followed. Molecular systematics studies examining members of the Scrophulariaceae, including Mimulus, determined that this genus and a few others constituted a separate monophyletic group warranting recognition at the family rank as Phrymaceae (Beardsley and Olmstead 2002, pp. 1193-1101; Olmstead 2002, p. 18). Placement of Mimulus in the family Phrymaceae is recognized by species experts, is used in the recent flora of California (Thompson 2012, pp. 988-998), and will be treated as such in the upcoming volume of the Flora of North America. In 2012, Barker et al. (2012) recognized a redefined genus Diplacus that includes 46 taxa previously segregated as Mimulus, including Vandenberg monkeyflower as Diplacus vandenbergensis (D.M. Thompson) Nesom (Barker et al. 2012, p. 29). The citation in Barker et al. (2012, p. 29) attributes the nomenclatural combination at the species rank to Nesom in Phytoneuron 2012-47: 2, which was published electronically on the same day as Barker et al. (2012). The Start Printed Page 64842current citation for Vandenberg monkeyflower is at the species rank as Diplacus vandenbergensis (D.M. Thompson) G.L. Nesom. This combination is accepted by species and genus experts and will be used in the upcoming treatment in the Flora of North America. Accordingly, we will use the correct name (Diplacus vandenbergensis) and family attribution (Phrymaceae) throughout this and subsequent documents. (USFWS, 2013)

**Historical Range**

Historical locations for Vandenberg monkeyflower are known from Santa Rita Valley, Lower Pine Canyon, Lower Santa Lucia Canyon in Santa Barbara County, California. (USFWS, 2013)

**Current Range**

Endemic to the eastern portion of Burton Mesa (Wilken 2010 in Elvin 2010) in Santa Barbara County, California. Mimulus fremontii var. vandenbergensis is bounded by Purisima Hills to the north and east, Santa Ynez River to the south, and the mesa edge on the west side of Santa Lucia Canyon, including the tributary canyons to the west (e.g., Lakes, Oak, and Pine Canyons).

The habitat and soils that it grows on are only found in a crescent-shaped area approximately 10.7 km long by 3.0 km wide that comprises less than 6,070 ha or 60.7 square km (Elvin 2010). (NatureServe, 2015)

**Critical Habitat Designated**

Yes; 9/10/2015.

**Legal Description**

On August 11, 2015, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective September 10, 2015) for Diplacus vandenbergensis (Vandenberg monkeyflower) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes four critical habitat units (CHUs), in California (80 FR 48142-48170).

**Critical Habitat Designation**

The critical habitat designation for Diplacus vandenbergensis includes four CHUs in Santa Barbara County, California. This species critical habitat encompasses approximately 5,755 acres (ac) (2,329 hectares (ha)). Brief descriptions are presented below. Maps depicting the CH units are available in the Final Rule. (80 FR 48142-48170).

Unit 1: Vandenberg: Unit 1 is within the geographical area occupied by Vandenberg monkeyflower at the time of listing and consists of 223 ac (90 ha). Unit 1 is located adjacent to and between two extant occurrences (Oak Canyon and Pine Canyon, which are located on Vandenberg AFB) and is known to support suitable habitat for Vandenberg monkeyflower.

Unit 2: Santa Lucia: Unit 2 is within the geographical area occupied by Vandenberg monkeyflower at the time of listing, is currently occupied by the species, and consists of 1,484 ac (601 ha). This unit includes State lands (96 percent) within the Reserve, relatively small portions of local agency lands (for example, school districts, water districts, community services districts) (less than 1 percent) and private lands (3 percent). Unit 2 contains the appropriate vegetation structure of contiguous chaparral habitat with canopy gaps (PCE 1) and loose, sandy soils (PCE 2) that support Vandenberg monkeyflower. The eastern boundary of Vandenberg AFB delineates the western boundary of this unit. Unit 2 includes most of the Vandenberg and Santa Lucia Management Units of the Reserve. Unit 2 extends from Purisima Hills at the northern extent through the width of Burton Mesa to the agricultural lands south of the Reserve, and to the eastern boundary of the Vandenberg and Santa Lucia Management Units where these units abut Vandenberg Village.

Unit 3: Encina: Unit 3 is within the geographical area occupied by Vandenberg monkeyflower at the time of listing and consists of 2,024 ac (819 ha). This unit contains State-owned lands (72 percent), including most of the Encina Management Unit of the Reserve, local agency lands (1.2 percent), and privately owned lands such as areas adjacent to the Clubhouse Estates residential development (27 percent) (see Table 1 above). Unit 3 contains the appropriate vegetation structure of contiguous chaparral habitat with canopy gaps (PCE 1) and loose, sandy soils (PCE 2) that support Vandenberg monkeyflower. Unit 3 extends from approximately the Purisima Hills to the north, through the Reserve and to the agricultural lands just south of the Reserve boundary, and is between Vandenberg Village and State Route 1 to the east and the residential communities of Mesa Oaks and Mission Hills to the west.

Unit 4: La Purisima: Unit 4 is within the geographical area occupied by Vandenberg monkeyflower at the time of listing and consists of 2,024 ac (819 ha). Unit 4 contains mostly State-owned lands (89 percent) consisting of most of La Purisima Mission SHP and a small portion of the La Purisima Management Unit of the Reserve that is north of La Purisima Mission SHP. This unit also contains private land to the east of La Purisima Mission SHP (11 percent), and a small portion of local agency lands (less than 1 percent) (see Table 1 above). Unit 4 contains the appropriate vegetation structure of contiguous chaparral habitat with canopy gaps (PCE 1) and loose, sandy soils (PCE 2) that support Vandenberg monkeyflower. This unit extends approximately from the Purisima Hills in the north to the southern boundary of La Purisima Mission SHP, and between the residential communities of Mesa Oaks and Mission Hills to the west and to just east of, and outside, the State Park’s eastern boundary.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Diplacus vandenbergensis critical habitat consists of two components (80 FR 48142-48170):

(i) Native maritime chaparral communities of Burton Mesa comprising maritime chaparral and maritime chaparral mixed with coastal scrub, oak woodland, and small patches of native grasslands. The mosaic structure of the native plant communities (arranged in a mosaic of dominant vegetation and sandy openings (canopy gaps)) may change spatially as a result of succession, and physical processes such as windblown sand and wildfire.

(ii) Loose sandy soils on Burton Mesa. As mapped by the Natural Resources Conservation Service (NRCS), these could include the following soil series: Arnold Sand, Marina Sand, Narlon Sand, Tangair Sand, Botella Loam, Terrace Escarpments, and Gullied Land.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the specific areas within the geographic area occupied by the species at the time of listing contain physical and biological features that are essential to the conservation of the species and that may require special management considerations or protection. All areas proposed as critical habitat will require some level of management to address the current and future threats to the physical and biological features essential to the conservation of Vandenberg monkeyflower. In all areas, special management is needed to ensure that the habitat is able to provide for the growth and reproduction of the species. The habitat where Vandenberg monkeyflower occurs faces threats from urban development, maintenance of existing utility pipelines, anthropogenic fire, unauthorized recreational activities, and most substantially the expansion of invasive, nonnative plants (see Factors A and E in the proposed listing rule). Management activities that may reduce these threats include, but are not limited to: (1) Protecting from development lands that provide suitable habitat; (2) minimizing habitat fragmentation; (3) minimizing the spread of invasive, nonnative plants; (4) limiting authorized casual recreational use to existing paths and trails (as opposed to off-trail use that can spread invasive species to unaffected areas); (5) controlled burning; and (6) encouraging habitat restoration. These management activities would limit the impact to the physical or biological features for Vandenberg monkeyflower by decreasing the direct loss of habitat, maintaining the appropriate vegetation structure that provides the sandy openings that are necessary components of Vandenberg monkeyflower habitat, and minimizing invasive, nonnative plants spreading to areas where they currently do not exist. Preserving large areas of contiguous suitable habitat throughout the range of the species should maintain the mosaic structure of the Burton Mesa chaparral that may be present at any given time, and maintain the genetic and demographic diversity of Vandenberg monkeyflower. (USFWS, 2013)

***Life History***

**Food/Nutrient Resources**

**Competition**

Adult: Veldt grass, eucalyptus, and pine groves (USFWS, 2015)

**Food/Nutrient Narrative**

Adult: The Vandenberg monkeyflower competes with non-native species such as veldt grass, eucalyptus, and pine groves (USFWS, 2015)

**Reproductive Strategy**

Adult: Mixed mating (USFWS, 2015); seed-banking annual (NatureServe, 2015)

**Lifespan**

Adult: One year (inferred from USFWS, 2015)

**Dependency on Other Individuals or Species**

Adult: Pollinators to achieve seed production; namely smaller solitary bees to medium and larger social bees (USFWS, 2015)

**Reproduction Narrative**

Adult: The Vandenberg monkeyflower is a seed-banking annual plant (NatureServe, 2015). It reproduces with a "mixed mating" strategy and, as an annual plant, lives no more than one year. It is dependent on pollinators to achieve seed production, particularly small to large-sized bees (USFWS, 2015).

**Habitat Type**

Adult: Coastal scrub, chaparral, and woodlands (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Elevation 30-122 m; restricted to the Burton Mesa region (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Moderately sparse (inferred from USFWS, 2014). Restricted to the Burton Mesa region is andy openings of coastal scrub, chaparral, and woodlands (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2015)

**Habitat Narrative**

Adult: The Vandenberg Monkeyflower inhabits coastal scrup, chaparal, and woodland areas The species is restricted to the Burton Mesa region in sandy openings of coastal scrub, chaparral, and woodlands from 30-122 m in elevation (Elvin 2010). (NatureServe, 2015). Its spatial arrangement is relatively sparse, and habitat connectivity is named as a key resource needed for habitat (USFWS, 2015). The species is an herbaceous annual plant, endemic to the Burton Mesa landform in southwestern Santa Barbara County, California. It occurs on sandy soils, in openings within the canopy of Burton Mesa maritime chaparral habitat. The species needs contiguous stands of Burton Mesa maritime chaparral habitat, canopy openings within this habitat type, loose sandy soils derived from the Burton Mesa Dune Sheet, insect pollinators, adequate annual precipitation, appropriately timed first seasonal rains, and suitable temperature regimes (USFWS, 2024).

***Dispersal/Migration***

**Dispersal**

Adult: High (inferred from USFWS, 2014)

**Dependency on Other Individuals or Species for Dispersal**

Adult: Small mammals (USFWS, 2015)

**Dispersal/Migration Narrative**

Adult: Seeds are primarily dispersed by gravity, along with wind and water over relatively short distances. Long-distance dispersal of seeds occurs in numerous ways, including vertebrate dispersal (e.g. small mammals, by adhesion or ingestion), wind dispersal of seeds (in updrafts and storms, or by secondary dispersal over the substrate), wind dispersal of plants (tumble-plant dispersal), and water dispersal High dispersal is inferred based on discussion and implied relevancy of the surprisingly long flight distances of its pollinators (USFWS, 2014; USFWS, 2015).

**Additional Life History Information**

Adult: Gravity is also named as a means of dispersal (USFWS, 2015)

***Population Information and Trends***

**Population Trends:**

Declining (NatureServe, 2015)

**Species Trends:**

Not available

**Number of Populations:**

7 (NatureServe, 2015)

**Population Size:**

2,000 total individuals observed in 2006; size may vary considerably year to year (NatureServe, 2015)

**Additional Population-level Information:**

The variety was named in 2005 so it is difficult to assess long term trends (NatureServe, 2015)

**Population Narrative:**

There are 7 known populations of this species. While species level trends are not available, a decline has been observed at the population level. Total population size was 2,000 individuals in 2006 and estimated to be similar in 2009, but acknowledged to likely vary considerably from year to year due to the species' status as a seed-banking annual. One population was destroyed in 2007 while the remaining populations are vulnerable to multiple stressors, notably invasion of non-native species. Long-term trends have been difficult to assess, in part because the variety was named in 2005 (NatureServe, 2015).

***Threats and Stressors***

**Stressor:** Habitat destruction and alteration (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The majority of remaining Burton Mesa chaparral where Vandenberg monkeyflower occurs is within Federal or State-owned lands and is protected from development. Therefore, large-scale future development of remaining Burton Mesa chaparral is not likely to occur and thus is not a significant threat to Vandenberg monkeyflower. However, smaller-scale private property development; access to easements; maintenance of utility, oil, and gas pipelines; fire and fire suppression; and authorized and unauthorized recreational activities may continue to take place throughout Burton Mesa. Some of these activities may occur within Burton Mesa chaparral or adjacent to occurrences of Vandenberg monkeyflower, resulting in the destruction and possible removal of Vandenberg monkeyflower habitat and creating open areas for nonnative plants to invade. Therefore, the direct destruction and alteration of chaparral habitat is likely to continue on a relatively small scale and is thus considered a threat to Vandenberg monkeyflower both currently and in the future. (USFWS, 2014)

**Stressor:** Utility and pipeline maintenance (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Utility and pipeline structures occur within the Burton Mesa Ecological Reserve (Reserve), and access routes through the Reserve service the Plains Exploration and Production Company oil processing plant, which surrounds the La Purisima Management Unit of the Reserve. Additionally, local land use agencies and public works agencies retain other utilities and pipelines, and easements for access. For example, the Vandenberg Village Community Services District has several structures (including water tanks, a water processing plant, wells, and water lines and sewer lines) located within the Reserve (Gevirtz et al. 2007, p. 63). These existing facilities or structures at times require routine maintenance to ensure proper operation. As a result, vehicles and foot traffic could occur at or adjacent to these structures and potentially result in trampling of habitat and other soil surface disturbance, which in turn could result in ground disturbance that removes Burton Mesa chaparral and creates open areas in the vegetation that act as pathways for nonnative plants to expand or invade. There is no indication that ongoing maintenance activities of existing pipelines and utilities have directly impacted Vandenberg monkeyflower habitat. However, utility maintenance actions could result in ground disturbance that removes Burton Mesa chaparral, creating open areas in the vegetation that act as pathways for nonnative plants to invade. (USFWS, 2014)

**Stressor:** Invasive, non-natice species (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasive, nonnative plants occur and are expanding throughout the Burton Mesa. More specifically, at least one of the four most problematic invasive plants occurs within or adjacent to suitable habitat at each of the nine extant occurrences of Vandenberg monkeyflower and at one potentially extirpated location. Invasive plants have demonstrated the ability to reduce the diversity of native vegetation and convert the native shrublands into nonnative-dominated vegetation. (USFWS, 2014)

**Stressor:** Anthropogenic fire (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Because of the human presence and infrastructure on Burton Mesa, the frequency of human-caused wildfires is likely greater than the frequency of historical fires on the mesa. An increased fire frequency in Burton Mesa chaparral would tend to favor the establishment of nonnative vegetation in open areas at the expense of native vegetation. However, the primary threat to Vandenberg monkeyflower and its habitat from fire is the post-fire expansion of invasive, nonnative plants, regardless of the fire frequency. Because an abundance of nonnative plants already occurs on the mesa, and invasive plants rapidly invade open areas, any fire that occurs within or adjacent to Vandenberg monkeyflower habitat is likely to result in an increase of invasive, nonnative vegetation. Likewise, fire suppression activities that include clearing vegetation in fuel breaks or spreading retardant would increase the likelihood of nonnative species invading suitable Vandenberg monkeyflower habitat, as well as enhance the habitat conditions for invasive species expansion. Additionally, because the presence of invasive, nonnative plants creates a positive feedback mechanism, the greater the percent cover of nonnative vegetation, the more likely fires will occur on Burton Mesa. Based on the information presented in this section, the current threat from anthropogenic fire and associated fire suppression activities to Vandenberg monkeyflower habitat described above is expected to continue into the future. (USFWS, 2014)

**Stressor:** Recreation (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Recreation is enumerated among the threats and stressors to this species. Recreational activities that occur throughout Burton Mesa include authorized uses such as hunting, hiking, biking, wildlife observation, and leashed-dog walking. Additionally, off-road vehicle (ORV) use is authorized on Vandenberg AFB (Air Force 2011a, p. 6), but it is not permitted on the Reserve (Gevirtz et al. 2007, p. 70) or La Purisima Mission SHP (California State Parks 1991, p. 109). ORV use and other casual recreational activities may contribute to soil disturbance and increase the potential for invasive, nonnative plants to be introduced and further spread across Burton Mesa, including into locations where Vandenberg monkeyflower and its suitable habitat occurs (USFWS, 2014).

**Stressor:** Climate change (USFWS, 2014)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change is enumerated among the threats and stressors to this species. Climate change may have potential impacts on Vandenberg monkeyflower and its habitat, such as increased temperatures and decreased precipitation that would likely reduce suitable habitat. Scientific measurements spanning several decades demonstrate that changes in climate are occurring, and that the rate of change has increased since the 1950s (FR, 2014).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number of 8

1. Annual abundance within at least two populations displays stable1 or increasing trends, based on a minimum of 10 years of data. The two populations include the Vandenberg population, within which there are at least 21 extant occurrences, and one of the other populations (either Burton Mesa or La Purísima), and that population includes at least six extant occurrences. (USFWS< 2024)

2. If either of the two needed populations drops below 75 percent of the established three-year average2 of reproductive individuals (baseline), in any single year, adequate funding and resources are available and supplemental seeding and/or other management endeavors (such as invasive weed abatement) will be implemented as necessary to augment the population and increase reproductive output until the population(s) rise back above 75 percent. (USFWS, 2024)

3. The two necessary populations are effectively managed to ameliorate the species threats, with population trends being the primary evidence that all of its biological needs are being met. Vandenberg monkeyflowers' biological needs are described in the SSA (Service 2022, pg. 20-24). (USFWS, 2024)

4. An ex-situ recovery seed bank (a collection of Vandenberg monkeyflower seed stored in a facility to preserve the species and serve as a backup in the event of catastrophic loss) is established and maintained over time. The recovery seed bank will adequately represent the genetic diversity from at least the two requisite populations, and seed from all known occurrences within each population should be included. Seed collections should be made over multiple years (no fewer than three different years). The primary recovery seed bank will be stored in an institution approved by the Center for Plant Conservation with the capability to test germination as needed to ensure viability, and a secondary, reserve collection will be stored in a long-term storage facility, such as the National Laboratory for Genetic Resources Preservation. (USFWS, 2024)

**Delisting Criteria:**
1. Annual abundance within one additional (for three total) population displays stable or increasing trend based on a minimum of 10 years of data. As with the downlisting criteria, the Vandenberg population supports at least 21 extant occurrences, and the other two populations (Burton Mesa and La Purísima) each support at least six occurrences. (USFWS, 2024)

2. If either of the three needed populations drops below 75 percent of the established three-year average of reproductive individuals, in any single year, adequate funding and resources are available and supplemental seeding and/or other management endeavors (such as invasive weed abatement) will be implemented as necessary to augment the population and increase reproductive output until the population(s) rise back above 75 percent. (USFWS, 2024)

3. The three necessary populations are effectively managed to ameliorate the species threats, with population trends being the primary evidence that all of its biological needs are being met. (USFWS, 2024)

4. The established ex-situ recovery seed bank continues to be maintained over time, and adequately represents the genetic diversity from all three requisite populations, with seed from all known occurrences within each population included. Germination testing occurs as needed to ensure viability. Additional accessions of Vandenberg monkeyflower seed are made periodically, and collections managers conduct bulking activities if necessary to supply seeds for restoration and other outplanting projects. (USFWS, 2024)

**Recovery Actions:**

- The Air Force has an approved Integrated Natural Resources Management Plan (INRMP) on Vandenberg Air Force Base in 2011. Included are the following components: (1) Development. The Air Force is not likely to construct new launch facilities within suitable habitat near human-populated areas, and the future siting of community facilities is expected to occur in a manner that capitalizes on existing infrastructure and circulation systems (Air Force 2009a, p. 32). Thus, no specific conservation measures have been proposed to minimize the threat of development to Vandenberg monkeyflower or its habitat on Base. (2) Utility Maintenance and Miscellaneous Activities. Construction of new facilities is not likely to occur within Vandenberg monkeyflower habitat; however, existing utilities will require periodic maintenance. No specific conservation measures were proposed in the addendum to the INRMP (Air Force 2012). The main objective is to avoid any impacts to habitat, when possible, by either confining the work to existing disturbed areas or rerouting the work to avoid suitable habitat completely, and minimize the impact as much as possible (Air Force 2012, p. 2). For Vandenberg monkeyflower, the Air Force would avoid impacting Burton Mesa chaparral as much as possible if utility maintenance is required in suitable habitat. (3) Invasive, Nonnative Plants. The INRMP (Air Force 2011a) includes an Invasive Plant Species Management Plan that identifies the threat of invasive, nonnative plants on Base, and proposes removal methods to limit further spread and assist in restoration of habitat degraded by invasive species. In most cases, the Air Force would utilize chemical application to manage for invasive plants (Air Force 2011a, p. 43). Although the INRMP identified invasive, nonnative plants as a threat and calls for their removal, it did not identify which nonnative species, and which areas on Base, were a priority for treatment. In the 2012 addendum to their INRMP, the Air Force identifies veldt grass as the most problematic invasive, nonnative plant on Base for Vandenberg monkeyflower. As part of this addendum, the Air Force also identified their 10-year funding program, which included more than $500,000 to treat veldt grass, starting in 2009 and continuing through 2019 (Air Force 2012). While the Air Force does not specify precisely where, when, or how much veldt grass will be treated or removed in specific years, they state that a substantial portion of this effort will focus on areas within the range of Vandenberg monkeyflower (Air Force 2012, p. 1). Through 2012, the Air Force has chemically treated approximately 141 acres (57 ha) of invasive, nonnative plants, mostly treating pampas grass within Burton Mesa chaparral but not near extant Vandenberg monkeyflower occurrences (treatment was to benefit Eriodictyon capitatum (Lompoc yerba santa)). Other invasive, nonnative plants treated included veldt grass, iceplant, Eucalyptus spp. (Eucalyptus), and Pinus spp. (Pine)). Only a small proportion of this chemical removal occurred within Burton Mesa chaparral at two locations where Vandenberg monkeyflower occurs (Lake and Pine Canyons) (Lum in litt. 2013). (4) Fire. For fires that would affect Vandenberg monkeyflower and its habitat, the Air Force developed a GIS layer incorporating all potential suitable habitat areas, which has been made available to fire response crews for use during actual fire events. Multiple conservation measures that address the potential threat of fire are included in the addendum (Air Force 2012, p. 2), including the following: (a) Established roads, both paved and unpaved, would be used to the greatest extent possible as fire lines unless an emergency dictates otherwise. (b) Burned areas would be assessed after a fire for rehabilitation options within 10 days of the area being declared safe for entry. (c) Vandenberg monkeyflower habitat affected by wildfire and rehabilitation projects will be monitored, which would include recommendations for nonnative species control. (d) Following any significant wildfire event within the range of Vandenberg monkeyflower on Base, a Burn Area Emergency Response (BAER) project will be initiated. This generally includes implementation of erosion control, native vegetation restoration, firebreak rehabilitation, and invasive species management. Additionally, the addendum proposes to incorporate portions of Vandenberg monkeyflower habitat in a controlled burn program (Air Force 2012, p. 2). (5) Recreation. No conservation measures have been proposed to address the threat of recreation to Vandenberg monkeyflower. (USFWS, 2013)

- Burton Mesa Ecological Reserve (Reserve): The State Lands Commission signed a 49-year lease of the Burton Mesa Ecological Reserve on January 20, 2000. The purpose of the lease is to manage, operate, and maintain these sovereign lands for the sensitive species and habitats they support . The CDFW developed a management plan for the Reserve that guides management of habitats, species, and programs to achieve the mission of CDFW to protect and enhance wildlife values. Conservation measures are proposed in the management plan, contingent upon available funding and staffing. (1) Development. Because new development would not occur on the Reserve, there are no conservation measures to implement that would minimize this threat to Vandenberg monkeyflower. (2) Utility Maintenance and Miscellaneous Activities. Several public utilities and local governmental agencies provide services to the local community and use the Reserve to accomplish their roles. Within the Reserve, agencies responsible for conducting maintenance activities submit maintenance plans for all scheduled activities to CDFW, who in turn may request conservation measures (such as modifying the size and frequency of actions) to minimize impacts on natural resources (3) Invasive, Nonnative Species. The Reserve's management plan encourages minimizing the impact and presence of invasive, nonnative plants, including monitoring and removing nonnative plants; preventing new introductions by working with public utilities, local governmental agencies, and recreationists that use the Reserve; and restoring disturbed and degraded areas with native species. (4) Fire. The CDFW management plan for the Reserve calls for coordination among the Santa Barbara County Fire Department, enforcement agencies, local governmental agencies, and adjacent small and large landowners to ensure that fire risk is reduced, that new development projects adjacent to the Reserve are reviewed by CDFW staff and address fuel reduction needs and requirements, and that appropriate and efficient post-fire remediation takes place, where needed. Reducing the risk of fire would limit the potential for wildfire to occur within Vandenberg monkeyflower habitat, and thus reduce the impact of fire suppression activities and the impact of invasive, nonnative plants invading the habitat post-fire. No controlled burns within Vandenberg monkeyflower habitat have occurred to date. (5) Recreation. CDFW developed a trails plan that shows existing trails within the Reserve as well as proposed new trail construction; seasonal trail closures or restrictions may occur to protect sensitive resources such as wildlife breeding locations or rare plant assemblages that vary from year to year (Gevirtz et al. 2007, p. 70). This system of trails would reduce the risk of authorized recreational uses directly impacting suitable Vandenberg monkeyflower habitat. The management plan calls for maintaining public access to the Reserve through pedestrian hiking trails by providing a network of trails, including loop trails, linking interesting areas while protecting resources, and preventing unauthorized uses (Gevirtz et al. 2007, p. 231).

- La Purisima Mission State Historic Park: A general management plan for La Purisima Mission SHP was completed in 1991, and an ecosystem characterization of La Purisima Mission SHP was completed in 2005. Directives specific to La Purisima Mission SHP that concern the habitat where Vandenberg monkeyflower occurs include preserving Burton Mesa chaparral, protecting and managing rare and endangered plants in perpetuity, controlling nonnative plants that have become established, and developing a prescribed-burn plan. Conservation measures are proposed in the general management plan, as outlined below, with implementation contingent upon available funding and staffing. (a) Development. There are multiple existing structures within the park, and any new structures must provide for visitors' needs without competing for attention with historical buildings or the natural setting. All new development must be sensitive to that purpose of providing appropriate visitor facilities without detracting from the historical and natural setting of La Purisima Mission. Burton Mesa chaparral habitat areas are designated as low-intensity use areas. Therefore, any new development is unlikely to impact Vandenberg monkeyflower or its habitat in the park. (b) Invasive, Nonnative Species. California State Parks' resource management programs try to remove or control invasive, nonnative species and reestablish indigenous native species. (c) Fire. In 2007, California State Parks initiated development of a wildfire management plan that would include management strategies to protect the existing infrastructure (buildings) and protect cultural resources and biological resources of the park (which would include Vandenberg monkeyflower habitat), as well as informing fire suppression agencies of the areas with high-value resources and the limits of fire suppression activities in those areas. No prescribed burns currently occur within the park. (d) Recreation. Consideration will be given to designating trails for specific types of uses and constructing new trail segments to avoid conflicts (California State Parks 1991, p. 65). The trail system requires continual brush and erosion control, in which California State Parks often relies on numerous volunteers such as scouts and environmental groups to assist the park each year in various projects, from litter pickup to trail construction. A designated trail system would reduce the risk of authorized recreational uses directly impacting Vandenberg monkeyflower habitat. However, the best available information indicates that recreational activities are currently having minimal to no effect on Vandenberg monkeyflower habitat at La Purisima Mission SHP
- 1. Manage habitat that supports the species to reduce or eliminate threats, including but not limited to seeding for augmentation; supplemental irrigation and shading for temperature reduction to offset future climate change effects; invasive weed removal and abatement; mechanical disturbance; vegetation thinning and removal to open canopy and maintain desired cover; and import, transfer, and redistribution of sand. (Priority 1) (USFWS,

2024)

- 2. Develop and implement a standardized annual monitoring protocol to identify population trajectories and environmental conditions that might be adversely affecting the species. (Priority 1) (USFWS, 2024)
- 3. Secure currently unprotected habitat where the species occurs or could occur from future destruction and development. (Priority 2) (USFWS, 2024)
- 4. Encourage partners to incorporate conservation measures for the species and its habitat into their projects and into all local and regional, strategic planning documents and programs. (Priority 3) (USFWS, 2024)
- 5. Collect seed from all three populations and deposit accessions into permanent conservation seed banks. (Priority 2) (USFWS, 2024)
- 6. Conduct experimental research projects, including those that examine the roles of biotic and abiotic environmental effects, natural soil seed banks, disturbance regimes, invasive weed management techniques, herbivory and seed predation, genetics, effects of fire and controlled burns, and the species' pollination system. (Priority 2) (USFWS, 2024)

# SPECIES ACCOUNT: *Dodecahema leptoceras* (Slender-horned spineflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 9/28/1987; Pacific Southwest Region (R8) (USFWS, 2015)

**Physical Description**

An annual plant that has a distinctive basal rosette of leaves ranging from 3 to 8 centimeters (cm) (1.2 to 3.1 inch (in)) in diameter. The leaves frequently become reddish at maturity. The flower stalks are branched and erect 3 to 10 cm (1.2 to 4 in) tall . Flowers are arranged in clusters along the flower stalks and each cluster is surrounded by an involucre (a ring of modified leaves beneath a flower cluster). Characteristic of this species, each of the 6 involucre segments has an awn at its base as well as at its apex. This feature distinguished this genus from the closely related genera Chorizanthe and Centrostegia (Reveal and Hardham 1989, p. 86). The flowers are white to pink, 1.2 to 2 millimeters (mm) (0.5 to 0.8 in) long, each producing a single achene (a dry single-seeded fruit), 1.7 to 2 mm (0.06 to 0.08 in) long (USFWS, 2010).

**Taxonomy**

In the buckwheat family (Polygonaceae). At the time of listing, the species was classified as Centrostegia leptoceras A. Gray. A reassessment of the distinct morphology of the involucre and relationships to other closely related taxa resulted in a taxonomic revision. The current recognized name for slender horned spineflower is Dodecahema leptoceras (A. Gray) Reveal and Hardham (Reveal and Hardham 1989, p. 85) (USFWS, 2010).

**Historical Range**

See current range/distribution.

**Current Range**

Southwestern California, in the foothills of the San Gabriel Mountains in Los Angeles County, the San Bernardino Mountains in San Bernardino County, and the San Jacinto Mountains in western Riverside County (USFWS, 2010).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

<u>Adult:</u> The level of gene similarity (or homozygosity) detected in this species indicates that Dodecahema leptoceras has a mixed mating system (e.g., seed is produced both through pollination between flowers on a single plant and between flowers on different plants), but the latter condition, outcrossing, is more prevalent. The level of gene similarity (or homozygosity) detected in this species indicates that Dodecahema leptoceras has a mixed mating system (e.g., seed is produced both through pollination between flowers on a single plant and between

flowers on different plants), but the latter condition, outcrossing, is more prevalent (USFWS, 2010).

**Habitat Type**

Adult: Terrestrial (USFWS, 2010)

**Habitat Vegetation or Surface Water Classification**

Adult: Alluvial scrub on sandy and gravelly soils in sandy wash systems (USFWS, 2010)

**Geographic or Habitat Restraints or Barriers**

Adult: Elevation range of 656 to 2,296 feet (USFWS, 2010)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2010)

**Habitat Narrative**

Adult: Species habitat is alluvial scrub on sandy and gravelly soils in sandy wash systems, at elevations ranging from 656 to 2,296 feet, in areas where intermittent, scouring flood events occur (USFWS, 2010). Soils are riverbed alluvium high in silt and low in organic matter (NatureServe, 2015).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Dispersal may be by small animals or sheet flows during heavy rains (USFWS, 2010).

***Population Information and Trends***

**Population Trends:**

Decline of 70-90% (NatureServe, 2015)

**Species Trends:**

Decline of >50% (NatureServe, 2015)

**Number of Populations:**

15 occurrences are extant, 13 are presumed extant, 7 are possibly extirpated, and 9 are extirpated (USFWS, 2022)

**Population Size:**

2500 - 10,000 individuals (NatureServe, 2015)

**Population Narrative:**

The alluvial terrace habitat where this species lives has been severely altered, degraded and destroyed over the past 100 years. The long-term trend is a decline of 70-90%; the short-tern trend is a decline of >50%. Thousands of individuals at the San Jacinto River and Temescal Canyon sites. A total of 35 occurrences are known, however, only 19 are non-historic. While several populations are known to be extirpated or historic, between 1/3-2/3 of the story of loss and decline is known. In other words, it is suspected that more decline is occurring than researchers know about (NatureServe, 2015).. Of the 11 spineflower occurrences in Los Angeles County, 1 is extant, 2 are presumed extant, 3 are possibly extirpated, and 5 are extirpated. of the 17 spineflower occurrences in Riverside County, 8 are extant, 7 are presumed extant, 1 is possibly extirpated, and 1 is extirpated. of the 16 spineflower occurrences in San Bernardino County, 6 are extant, 4 are presumed extant, 3 are possibly extirpated, and 3 are extirpated (Table 2). Two occurrences are new since 2010 (USFWS, 2022). We reviewed data from the CNDDB, CCH2, Habitat Conservation Plans, project-related surveys, and the Forest Service to update spineflower occurrence numbers and status. Our 2010 5-year review identified 36 occurrences of spineflower. Twenty were presumed extant, 3 were possibly extirpated, and 13 were extirpated (Table 1). This 2022 review of new information finds that there are 44 occurrences of spineflower. Eight occurrences that were not considered in the 2010 5-year review have been either (1) discovered since 2010, or (2) were known to others but not included in our last review. Across the range of spineflower in Los Angeles, Riverside, and San Bernardino counties, 15 occurrences are extant, 13 are presumed extant, 7 are possibly extirpated, and 9 are extirpated (Table 1). Since 2010, conservation land acquisition has occurred at or adjacent to three occurrences of spineflower. The spineflower is also a covered species under the draft Upper SAR HCP and the 2020 Wash Plan, which will implement measures to help conserve and manage for the species (USFWS, 2022).

### *Threats and Stressors*

**Stressor:** Habitat destruction or modification (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The current threats to habitat are urban and agricultural development, mining, altered hydrology, off-highway vehicle activity, trash dumping, fire, invasive nonnative plants, and other habitat degrading activities (USFWS, 2010).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Endangered Species Act is the primary Federal law that has provided protection for this species since its listing as endangered in 1987 (USFWS 1987, pp. 36265-36270). Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent its status under the Act (USFWS, 2010).

**Stressor:** Climate change (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change refers to a shift in the mean or variability in measures of climate (e.g., precipitation or temperature) that persists for an extended period of time, typically a decade or more, due to natural variability, human activity, or both (IPCC 2013, p. 1450). In our 2010 5- year review, we considered climate change a threat to spineflower (Service 2010, pp. 24–25). Since 2010, scientists have used downscaled climate models to project changes in temperature and

precipitation in California under a range of future climate scenarios (Kalansky et al. 2018, entire; Pierce et al. 2018, entire). Temperature has increased throughout Southern California over the past century, and warming is expected to continue (Table 3) (Hall et al. 2018, pp. 10–11). Wet and dry precipitation extremes are projected to increase in the future, although models project small mean changes compared to historical precipitation variability (Hall et al. 2018, p. 13). Models also project increases in the frequency of atmospheric-river storms, which deliver intense precipitation and can cause severe flooding (Dettinger 2011, p. 519). However, droughts are also projected to become more frequent and intense and will be exacerbated by higher temperatures (USFWS, 2022).

**Stressor:** Dumping and trash (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In our 2010 5-year review for spineflower, we identified trash dumping as a threat at three spineflower occurrences but noted that the incidence of trash dumping could be higher than reported (Service 2010, p. 16) (USFWS, 2022).

**Stressor:** Rangewide altered hydrology (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Rangewide altered hydrology and other ongoing threats are still present at spineflower occurrences. Thirty-six percent of occurrences (16 of 44) are extirpated or possibly extirpated due to development and altered hydrology, and 30 percent of occurrences (15 of 44) have not been observed for over 10 years (i.e., are presumed extant) (USFWS, 2022).

***Recovery***

**Reclassification Criteria:**
Not available.

Recovery Priority Number: 7C

**Delisting Criteria:**
Not available.

**Recovery Actions:**

- There is no final approved recovery plan for this species (USFWS, 2010).
- Monitor known and historical occurrences as well as suitable habitat to determine presence and condition of Dodecahema leptoceras.
- Identify opportunities to work with private landowners to encourage conservation actions for Dodecahema leptoceras on sites that are not conserved. This could be done through the Partners for Fish and Wildlife Program as well other cooperative programs.
- Determine by experimental means and field studies the extent to which the presence of invasive nonnative plants impacts growth and persistence of Dodecahema leptoceras.
- Identify pollen and seed (fruit) vectors and their habitat requirements. Incorporate these requirements into habitat management considerations for Dodecahema leptoceras.

- Identify the structure and dynamics of the seed bank of Dodecahema leptoceras

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS To recover slender-horned spineflower, we need to conserve additional spineflower habitat and enhance or restore degraded habitat. To accomplish these actions, we also need additional monitoring, surveys, and site assessment across the species' range. We recommend that the following actions be completed over the next 5 years to enhance habitat and manage threats to slender-horned spineflower. We recognize that conservation of this species will require cooperation and coordination with partners. 1. Monitor known and historical occurrences to determine presence and condition of spineflower. Evaluate threats and develop site-specific recommendations to prioritize management actions. 2. Model suitable habitat across the range of spineflower and prioritize areas for further survey. Work with interested landowners to survey suitable habitat where spineflower has not been detected. 3. Collect spineflower seed from occurrences outside the Wash Plan area and conserve seed in an off-site conservation seed bank. 4. Enhance spineflower habitat using the site-specific recommendations developed under action 1. 5. At spineflower occurrences that are not conserved, identify opportunities to work with landowners to acquire lands or encourage conservation actions for spineflower. 6. Over the next 10 years, identify adaptive management and monitoring approaches from the Spineflower Working Group that could be applied range-wide, especially in regard to invasive species management and hydrological conditions (USFWS, 2022).

# SPECIES ACCOUNT: *Dudleya abramsii ssp. parva* (Conejo dudleya)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 2/28/1997; Pacific Southwest Region (R8)

**Physical Description**

A succulent dicot, rosette-forming perennial herb with vernal leaves (summer deciduous), an inflorescence stem 5 to 18 centimeters long, and pale yellow-green flowers that often exhibit flecks of red on the keel. The roots are constricted at irregular intervals . (USWS, 2015)

**Taxonomy**

In the stonecrop family (Crassulaceae). Dudleya parva was recognized as a distinct species by Munz and Keck in 1959 and 1968, Nakai in 1983, and Moran in 1980 (McCabe in litt. 2008a). In 1991, Bartel published a revision treating D. parva as a subspecies of D. abramsii (Bartel 1991) based on similarities between the flowers of D. abramsii and D. parva noted by Reid Moran (1948). However, D. parva and D. abramsii have differing micromorphological leaf surface characters, caudex diameters, and wound responses that appear to clearly separate the two (McCabe in litt. 2008a). The name of this species has been returned to Dudleya parva (from Dudleya abramsii ssp. parva) as of November 2006. (USFWS, 2015)

**Historical Range**

See current range/distribution.

**Current Range**

Known locations are in a narrow band of recorded occurrences along a 10-mile stretch of land from the western portion of the Simi Hills, through Mountclef Ridge, to the Conejo Grade in Ventura County, California (USFWS, 2015).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: Unknown; up to 24 years in cultivation (USFWS, 2015)

**Breeding Season**

Adult: Blooms in late spring (May-June) (USFWS, 2015)

**Key Resources Needed for Breeding**

Adult: Bees and flies for pollination (USFWS, 2015)

**Reproduction Narrative**

Adult: Blooms in late spring (May - June), and is pollinated by bees and flies. D. parva tends to exhibit a higher degree of auto-fertility and is prone to pollinator unreliability, short and unpredictable reproductive seasons, small population size, and high population turnover. D. parva will hybridize with some of the other Dudleya species (e.g., D. pulverulenta), which is typical of the Dudleya genus. Seeds sprout in the winter when there is ample precipitation and continue to grow throughout the rainy season. The plants may spread slowly underground by roots or stems, and any stem within 2 to 3 cm (0.8 to 1.2 in) of a centrally established individual may be a clone of that individual (USFWS, 2015).

**Habitat Type**

Adult: Terrestrial (USFWS, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Scattered rock outcrops in grassland and cactus dominated coastal sage scrub habitat (USFWS, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Elevations ranging from 60 to 450 meters (USFWS, 2015)

**Environmental Specificity**

Adult: Very narrow (inferred from USFWS, 2015)

**Habitat Narrative**

Adult: On a broad scale, suitable habitat for Dudleya parva is comprised of coastal sage scrub and valley and foothill grassland with clay or volcanic soils, at elevations ranging from 60 to 450 meters (180 to 1350 ft), and on slopes ranging from 0 to 90 degrees, but most commonly on north-facing slopes of approximately 10 degrees. This species is highly localized in its distribution, occurring exclusively in thin-soiled substrate over rocky outcrops derived from the Miocene Conejo volcanics (USFWS, 2015).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Dispersal information is not available (inferred from USFWS, 2015).

***Population Information and Trends***

**Population Trends:**

Stable (inferred from USFWS, 2015)

**Species Trends:**

Stable (inferred from USFWS, 2015)

**Number of Populations:**

14 (USFWS, 2015)

**Population Size:**

~150,000 individuals (USFWS, 2015)

**Population Narrative:**

The population boundaries and numbers for Dudleya parva exhibit some annual fluctuations; however, the species has generally remained in the same suitable habitat areas noted at the time of listing in 1997. Since the time of listing, the number of documented individuals within the noted occurrences of the species has increased in some cases, while decreasing somewhat in others; however, the information gathered from the more recent population surveys seems to show that overall the species has remained at relatively constant levels since the time of listing. While many of the sites occur on private lands and could not be adequately surveyed, the numbers of plants that were seen on public lands have substantially increased in a few areas. Observed increases from different population surveys does not represent an actual increase in the number of plants, but rather is likely a result of the more thorough surveys (USFWS, 2015).

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat encroachment from new or existing development, fire suppression activities, human recreational activities (such as hiking, rock climbing, biking, and horseback riding) continue to be a threat (USFWS, 2015).

**Stressor:** Overutilization for commercial, recreational, scientific, or educational purposes (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Due to the accessibility of some of the habitat sites to the public and the appeal of Dudleya species to horticulturalists, collection still constitutes a threat to the species. However, due to the vernal nature of this species (leaves wither and fall off in the summer), it may be slightly less attractive to collectors than non-vernal species (USFWS, 2015).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Endangered Species Act is the primary Federal law that has provided some level of protection for Dudleya parva since its listing as threatened in 1997. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent its status under the Act (USFWS, 2015).

**Stressor:** Other natural or manmade factors affecting its continued existence (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The low numbers of individuals and limited range of Dudleya parva make it particularly vulnerable to extinction from random human-caused or natural events. Dudleya

parva is potentially threatened by: (1) pre-fire fuel-reduction activities, such as removal of native vegetation and disturbance of soils that can reduce habitat quality; (2) the wildfire itself, in which the intense heat can kill or set back the growth of individuals; and (3) fire suppression activities, including the disturbance of native vegetation and soils during the grubbing of fire lines and the dropping of fire retardants, the latter of which increases soil nitrogen and stimulates the growth of non-native grasses that could compete with D. parva (USFWS, 2015).

**Stressor:** Climate change effects (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The 2009 5-year review (Service 2009 p.14) introduced climate change as a threat to Dudleya abramsii ssp. parva. Threats resulting from climate change may be complex, and include physical stress, death by erosion, increased competition, and increased likelihood of fire. Expected climate change for the Los Angeles area predicts rising annual and extreme high temperatures (Hall et al. pp. 10-11) and more episodic rainfall with more extreme floods and drier droughts (Hall et al. pp. 11-14, 18). Changes in climate could threaten Dudleya abramsii ssp. parva in several ways. First, although the species is dormant in the dry part of the year, more intensely dry summers with long-term drought could kill plants (Burgess (in litt. 2022). Second, more intense precipitation and erosion could cause slope slippage, destroying plants. Third, with changing climate, non-native annual grasses are expected to increase in dominance both as a result of increased fire frequency (Hall et al. 2018 p. 53) and with increasing annual temperatures (Sandel and Dangremond 2012 entire). The increased annual grass dominance can both promote more fire and may have negative competitive effects on Dudleya abramsii ssp. parva. Because it characteristically occurs in rocky areas with sparse vegetation that does not carry fire well, this may not negatively affect the species. However, if non-native annual grass cover does increase and fires do increase in frequency or intensity at Dudleya abramsii ssp. parva occurrences, the species could be negatively impacted. The threat of climate change on Dudleya abramsii ssp. parva remains (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
Not applicable.

**Delisting Criteria:**
1. All current sites (including seedbanks) are fully protected and managed with the primary intention of preserving the populations in perpetuity (USFWS, 1999).

2. All current sites (including seedbanks) are shown to be self-sustaining over a minimum of 10 years (USFWS, 1999).

**Recovery Actions:**
- Protect and secure populations and habitat on unprotected lands. Habitat for the listed plants must be protected and secured in perpetuity, from identified threats of loss. Methods for securing lands include permanent conservation easements established through land use decisions, in-fee purchase, gifts of easement, or fee interest by property owner (USFWS, 1999).

- Manage and monitor protected areas. The process of evaluating past and current management and making adjustments as needed is termed “adaptive management.” Public and private conservation lands should be adaptively managed to maximize their potential to support listed species and their habitats. (USFWS, 1999)
- Survey historic locations and other potential habitat where species may occur, Surveys of the potential albeit limited, habitat within the species range should be done. Several California Natural Diversity Database occurrence records for the listed species are represented only by observations. Information on population status, threats, and abundance is also needed for these sites. Information gathered from the additional details will be used to provide lead agencies to determine protective land use designation for the listed plant species . Data gathered will assist in determining the range of site characteristics, population vigor, and species viability to help establish minimum population standards for rare plant reserves, and consequently, for recovery. (USFWS, 1999)
- Conduct biological and ecological research to define life history strategies and population dynamics to guide recovery/conservation efforts. A better understanding of the population dynamics and identification of ecological factors that may be affecting those dynamics are needed to develop appropriate management plans to recover the plant species. (USFWS, 1999).
- Develop outreach plans to conserve the species. Outreach is an important component of implementing this recovery plan. This plan should be developed to enhance the public’s understanding of issues related to conservation and recovery of the listed species. Participation from both public and private entities should be encouraged for the establishment of conservation plans for the listed species. (USFWS, 1999)
- Recommendation for Future Action from 2015 5-Year Review: Conduct new, up-to-date, extensive population surveys of known occurrences and areas of suitable habitat. - Develop and implement monitoring and adaptive management plans for known existing occurrences. Monitoring should occur at intervals of 3 years and include population abundance surveys, habitat condition assessment, and documentation of existing and potential threats. - Update and expand knowledge of the species’ life history and specific habitat requirements (USFWS, 2015).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: The recommendations for future actions largely mirror those of the 2015 5-year review (Service pp.22-23): 1. Conduct thorough population surveys of known occurrences and areas of suitable habitat. 2. Develop and implement a monitoring plan for known existing occurrences. Monitoring should include population abundance surveys, habitat condition assessment, and documentation of existing and potential threats. 3. Work with public and private landowners to raise public awareness of the species to support appropriate conservation measures. 4. Update and expand knowledge of the species’ life history and specific habitat requirements. 5. Improve the completeness of coverage of Dudleya abramsii ssp. parva in conservation seed banks, with more occurrences over more years (USFWS, 2023).

# SPECIES ACCOUNT: *Dudleya cymosa ssp. marcescens* (Marcescent dudleya)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 01/29/1997; California/Nevada (Region 8) (USFWS, 2015)

**Physical Description**

A perennial herb that forms a rosette of succulent leaves in the spring, withering in summer. The rosette leaves are 1.5 to 4 centimeters (0.6to 1.6 inches) long, 5 to 12 millimeters (2.0 to 4.7 inches) wide; the caudex (stem) is 2 to 7 centimeters (0.8to 2.8 inches) thick, flowering stems are 4 to 10 centimeters (1.6 to 4 inches) tall and the corolla is bright yellow, to yellow with red markings, to bright red (Munz 1974; Hickman 1993). (USFWS, 1999)

**Taxonomy**

Dudleya cymosa was described by Charles Antoine Lemaire in 1858 as Echeveria cymosa based on a collection sent to him by horticulturist Louis de Smet of Ledeburg, Belgium; unfortunately, the type locality is unknown and the type specimen has been lost (Moran 1951). Britton and Rose (1903) included this species in their newly described genus Dudleya, as D. cymosa (Moran 1951). Other subspecies of D. cymosa range throughout the Sierra Nevada, the coast ranges, the transverse ranges, and the northern portion ofthe peninsular ranges. Dudleya cymosa ssp. marcescens differs from other subspecies of D. cymosa in that its rosette leaves wither in the summer, but do not fall off (i.e., they are marcescent). (USFWS, 1999)

**Historical Range**

See current range/distribution.

**Current Range**

Dudleya cymosa ssp. marcescens is endemic to the Santa Monica Mountains in California and is known from a 24-km (15-mi) stretch between Hidden Valley and Malibu Creek State Park (Raven et al. 1986). The total area that encompasses all of the known D. cymosa ssp. marcescens occurrences is approximately 230 square km (88 square mi) (USFWS, 2009).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Dependency on Other Individuals or Species**

Adult: Dudleya cymosa ssp. marcescens is pollinated by hummingbirds and bees, and produces an abundant amount of small seed. (USFWS, 2009)

**Breeding Season**

Adult: May to June (USFWS, 2009)

**Reproduction Narrative**

Adult: Flowering generally occurs between May and June and produces fruits with five follicles that split open to release abundant small seeds in late summer or early fall (Skinner and Pavlik 1994, Dorsey 2007). Dudleya cymosa ssp. marcescens is pollinated by hummingbirds and bees, and produces an abundant amount of small seed. Pollination services to D. cymosa ssp. marcescens may be less than for other Dudleya taxa because they grow on rock faces with no other flowering plants to attract pollinators. The seeds of D. cymosa ssp. marcescens range from 0.2 to 1.2 millimeters (0.008 to 0.047 inch) in diameter (Wall 2008). Compared with other rare Dudleya taxa found in the Santa Monica Mountains, D. cymosa ssp. marcescens had a relatively low reproductive output and low seed germination that may put it in greater danger of extinction than other rare Dudleya taxa (Dorsey 2007). (USFWS, 2009)

**Habitat Type**

Adult: Terrestrial (USFWS, 2009)

**Habitat Vegetation or Surface Water Classification**

Adult: Sheer volcanic cliffs and canyon walls in canyons with perennial streams (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Grows with mosses and lichens in places too step for soil to form (NatureServe, 2015)

**Environmental Specificity**

Adult: Very narrow (USFWS, 2009)

**Dependency on Other Individuals or Species for Habitat**

Adult: Riefner and Bowler (1995) hypothesize that the fog-capturing lichen found in the coastal bluffs and cliffs of California may trap Dudleya seeds, provide nutrients and water, and may protect young plants from snail and slug herbivory. (USFWS, 2009)

**Habitat Narrative**

Adult: suitable habitat for Dudleya cymosa ssp. marcescens is generally located on the lower reaches of volcanic rock outcrops adjacent to streams, chaparral, and coast live oak (Quercus agrifolia) woodland (CNDDB 2008, NPS 2003). In most locations, the topographic relief has prevented deep soil formation; therefore, this species may be the only flowering plant occurring in a microhabitat that is otherwise dominated by mosses, lichens, and ferns (CNDDB 2008). The mosses and lichens may play a crucial role in trapping D. cymosa ssp. marcescens seeds and allowing them to germinate and establish on the volcanic outcrops (Riefner and Bowler 1995, Riefner and Wishner 2000). (USFWS, 2009)

***Dispersal/Migration***

**Dependency on Other Individuals or Species for Dispersal**

Adult: Animals (USFWS, 2009)

**Dispersal/Migration Narrative**

Adult: The grouping of the plants along the watershed corridor may indicate a dispersal mechanism that is driven by water or short-distance wind dispersal. The seeds of D. cymosa ssp.

marcescens are very small in size and may be easily transported by water, wind, or animals within and outside of the watershed (Wall 2008). (USFWS, 2009)

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

14 (USFWS, 2023)

**Population Size:**

>6,000 total (USFWS, 2023)

**Population Narrative:**

According to EO records available through the CNDDB, field surveys from the National Park Service (NPS), and seed collection studies, 13 sites currently or historically supported Dudleya cymosa ssp. marcescens. The most recent surveys, completed in 2003 by NPS and in 2005 by Dorsey, indicate that the total number of individuals of D. cymosa ssp. marcescens throughout its range is approximately 12,000. (USFWS, 2009). At the time of listing in 1997 (Service 1997), there were 7 known occurrences of Dudleya cymosa ssp. marcescens. The number of known occurrences has gradually increased to 14 (Table 1, Service 1999 p. 27, Service 2009 p. 6, Dorsey et al. 2013 pp. 29-41; CNDDB 2023 (last updated 2015), Guilliams and Hasenstab-Lehman 2021 pp. 35-37). Most of these occurrences have been recently confirmed as extant (Guilliams and Hasenstab-Lehman 2021 pp. 35-37). Nine of the occurrences are at least partially on public land, and thirteen of the fourteen occurrences are in the fire footprint of the 2018 Woolsey Fire (Guilliams and Hasenstab-Lehman 2021 p. 27). Unpublished data suggest that several known occurrences of Dudleya cymosa ssp. marcescens are more extensive than currently documented and that there may be several undocumented occurrences (Devlin Gandy pers. comm. 2023). If the undocumented occurrences are verified, the range of the species would extend by 1.5 km (1 mi) to the west and 4.5 km (3 mi) to the east (USFWS, 2023). Twelve of the 14 known occurrences were surveyed in 2020 and a total of 6,148 individuals were found (Table 2, Guilliams and Hasenstab-Lehman 2021 pp. 35-37, 42-43). Two of the occurrences were not surveyed because they could not be located. The study also assessed trends in abundance and concluded that two thirds of the surveyed occurrences were stable and one third were declining over time. No occurrences were considered to be increasing. Some of the occurrences were scored as “stable” despite having fewer individuals over time (EO 7, EO 13), because it was felt they were in the process of recovering from moderate effects of the 2018 Woolsey Fire. In general, declines can be attributed to the effects of the Woolsey Fire, which burned 11 of the 12 occurrences observed during the 2020 surveys (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Recreation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Dudleya cymosa ssp. marcescens habitat is often used for rock climbing and rappelling (Service 1997). These activities have the potential to destroy the moss substrate that the species depends on and can tear out individual plants. Rock climbing and rappelling may occur on both public and private land where D. cymosa ssp. marcescens occurs. Popular rock climbing areas located in the vicinity of known D. cymosa ssp. marcescens occurrences include Planet of the Apes Wall, Ghetto Wall, Echo Cliffs, and Century Lake Canyon (The Mountain Project 2008, Rockclimbing.com 2008).

**Stressor:** Vandalism (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** On April 27, 2009 the Service was notified by NPS staff that large swaths of moss that support Dudleya cymosa ssp. marcescens had been damaged at the Seminole Hot Springs occurrence (Sagar 2009). The moss appeared to be scraped away from the rock face to form pictures and initials (Figure 3). An unknown number of individual plants have been damaged or destroyed by the disturbance (Figure 4). The site appears to be used as a local social gathering place, and will likely suffer recurring damage if some type of protective action is not taken (e.g. closing the site to public access, posting signage, etc.).

**Stressor:** Development (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In the rule listing the species, we also discussed that occurrences are located on both public and private lands, and that individuals of Dudleya cymosa ssp. marcescens on private lands may be threatened by development. One occurrence on private land, Seminole Hot Springs, is owned by the Mountains Restoration Trust, a non-profit land trust dedicated to preserving natural land in the Santa Monica Mountains. This site is protected from development, but is threatened by recreational activities as demonstrated by the damage to the moss substrate observed in 2009. For the other six occurrences on private lands, local zoning designations can provide some information about the potential for development at each site. Private lands that support D. cymosa ssp. marcescens individuals are primarily zoned for open space or agriculture, with certain parcels in Ventura County falling under the Santa Monica Mountains Overlay Zone, which provides protections for sensitive species including D. cymosa ssp. marcescens. (USFWS, 2009)

**Stressor:** Overutilization (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing in 1997, we discussed that species of Dudleya are collected by professional horticulturalists as well as amateur collectors and gardeners (Service 1997). We believe that collection still may constitute a threat to the species. Although we do not have specific reports of vandalism for D. cymosa ssp. marcescens, we believe that, due to the accessibility of certain populations to the public, collection still constitutes a threat to the species. (USFWS, 2009)

**Stressor:** Fire (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing Dudleya cymosa ssp. marcescens in 1997, we discussed that fire can be a natural or human caused factor affecting D. cymosa ssp. marcescens (Service 1997). The ecosystems of the Santa Monica Mountains have evolved with periodic lightning-caused fires that were generally small in size and intensity, but occurred at frequent intervals (NPS 2007b). With the expansion of human settlement, it has been suggested that large fires are the result of effective suppression of small fires (NPS 2007b). Fire has been observed to reduce moss substrate that D. cymosa ssp. marcescens requires (Dedero 1992). Furthermore, it may be assumed that large fires pose a greater threat to D. cymosa ssp. marcescens because large fires may have a greater flame height and burn temperature that may impact the rocky outcrops that might otherwise be unaffected by small fires with lower flame heights and burn temperatures. Large fires may also burn through the entire range of the species whereas small fires would cover less area. (USFWS, 2009)

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the northern hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Hayhoe et al. 2004, Cayan et al. 2005, IPCC 2007). Based on modeling, they predicted that species' distributions will shift in response to climate change, and that species will "move" or disperse to higher elevations and northward, depending on the ability of each species to do so. While we lack adequate information to make specific and accurate predictions regarding how climate change, in combination with other factors such as small population size, will affect Dudleya cymosa ssp. marcescens, small-ranged species, such as D. cymosa ssp. marcescens, are generally more vulnerable to extinction due to these changing conditions (Pimm and Raven 2000, Loarie et al. 2008). Some Dudleya taxa have evolved characteristics such as facultative leaf withering (McCabe et al. in prep. 2008) and switching between CAM and C3 photosynthesis pathways (Thorghton et al. 1977), which allow them to live in water-limited environments and adapt to climate fluctuations. These characteristics may benefit the species in the face of a changing climate. (USFWS, 2009)

**Stressor:** Climate change effects (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The 2009 5-year review introduced climate change as a threat to Dudleya cymosa ssp. marcescens (Service 2009 p. 13). Effects of climate change for the Los Angeles area include predicted rising annual and extreme high temperatures (Hall et al. pp. 10-11) and increased episodic rainfall with more extreme floods and drier droughts (Hall et al. pp. 11-14, 18). Changes in climate could threaten Dudleya cymosa ssp. marcescens through habitat degradation or migration, mortality through drought or erosion, and increased non-native annual grasses leading to greater competition or fire susceptibility (Service 2009 p. 13). Recently, the current effects of non-natives and erosion were assessed to be low for the taxon (Guilliams and

Hasenstab-Lehman 2021 pp. 42-43). As climate changes and vegetation shifts, optimal habitat for Dudleya cymosa ssp. marcescens may also shift, and the taxon may not be able to disperse far and fast enough to match the vegetation shift. Although the taxon is dormant in the dry part of the year, more intensively dry summers with long-term drought could kill plants. Conversely, more intense precipitation could cause increased erosion on the steep cliff habitat of Dudleya cymosa ssp. marcescens, destroying plants. Non-native annual grasses are expected to increase in dominance because of increased fire frequency (Hall et al. 2018 p. 53) and with increasing annual temperatures (Sandel and Dangremond 2012 entire). The increased annual grass dominance can in turn both promote more fire and may have more negative competitive effects on Dudleya cymosa ssp. marcescens. Because the taxon characteristically occurs on steep cliffs with sparse vegetation that does not carry fire well, this may not negatively affect the taxon. However, if non-native annual grass cover does increase and fires do increase in frequency or intensity at Dudleya cymosa ssp. marcescens occurrences, the taxon could be negatively impacted. The threat of climate change on Dudleya cymosa ssp. marcescens remains (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

Recovery Priority Number: 6

**Delisting Criteria:**
1. All the current sites (including seedbanks) are fully protected and managed with the primary intention of preserving the populations in perpetuity. (USFWS, 2009)

2. All the current sites (including seedbanks) are shown to be self-sustaining over a minimum of 10 years. (USFWS, 2009)

**Recovery Actions:**
- Protect and secure all current sites of these plant species (including seedbanks). (USFWS, 1999)
- Manage and monitor protected areas where plants occur. (USFWS, 1999)
- Manage and monitor protected areas where plants occur. (USFWS, 1999)
- Conduct biological and ecological research to define life history strategies, population dynamics, and to guide recovery/conservation efforts. (USFWS, 1999)
- Develop public outreach plans to enhance the public’s understanding of conservation needs of these endangered and threatened plant species. (USFWS, 1999)
- Establish a monitoring strategy to understand the population and demographic dynamics of Dudleya cymosa ssp. marcescens. The minimal survey data that is available indicates that many of the populations may be stable or increasing. However, without population data at all sites, abundance trends cannot be determined; without demographic data, population stability cannot be presumed. At a minimum, all known occurrences should be surveyed for abundance and demographics. If survey results indicate that populations are stable or increasing, and all occurrences have multiple age classes, indicating regular recruitment, the species may be considered to be self-sustaining. If survey results indicate that populations

are declining or demographics show a single age class, further monitoring will be required to determine population trends. (USFWS, 2009)

- Work with the National Park Service and California Department of Parks and Recreation to identify Dudleya cymosa ssp. marcescens occurrences on public lands that may be degraded by recreational activities such as climbing, and conduct a study to clearly identify impacts to the species caused by recreational activities. If impacts are identified, install fencing, signage, or other mechanisms to eliminate threats to the plants and their habitat. (USFWS, 2009)
- Work with rock climbing leaders, organizations, and websites to make them aware of the sensitive species that may occur in the vicinity of their climbing areas. Explore the possibility of establishing “best climbing practices,” such as avoiding vegetation on rock faces, and not establishing new climbing sites on rock faces that are vegetated. (USFWS, 2009)
- Work with the Mountains Restoration Trust and other partners to reduce impacts to the individuals and habitat at Seminole Hot Springs by installing signage, installing fencing, closing the area to visitors, or using other means to eliminate recreational threats. (USFWS, 2009)
- Work with private landowners at locations where zoning may permit development to raise awareness of the species. Cooperation with landowners is crucial to monitoring and protecting Dudleya cymosa ssp. marcescens occurrences on private lands. (USFWS, 2009)
- Work with Ventura County and Los Angeles County to educate them about Dudleya cymosa ssp. marcescens, so that when issuing development permits the counties are able to identify developments that may impact the species and encourage measures that would protect the species. (USFWS, 2009)
- Survey previously uninvestigated areas with potentially suitable habitat within and adjacent to the known range of Dudleya cymosa ssp. marcescens to determine if habitat and individuals are present. (USFWS, 2009)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Continue genetic, common garden, and other analyses to determine if Dudleya cymosa ssp. marcescens is a valid narrow taxon, or part of the range of variation of a more widespread and abundant taxon. 2. Conduct thorough surveys of known occurrences, adjacent areas, and other areas of suitable habitat to potentially increase the extent of known occurrences and document new occurrences. Develop and implement a monitoring plan. Monitoring should include population abundance surveys, habitat condition assessment, and documentation of existing and potential threats. 3. Work with public and private entities to prevent damage to plants and to raise public awareness to support appropriate conservation measures. 4. Update and expand knowledge of the taxon’s life history and specific habitat requirements, especially regarding fire. 5. Improve the completeness of coverage of Dudleya cymosa ssp. marcescens in conservation seed banks, with more occurrences over more years (USFWS, 2023).

# SPECIES ACCOUNT: *Dudleya cymosa ssp. ovatifolia* (Santa Monica Mountains dudleyea)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 01/29/1997; California/Nevada (Region 8) (USFWS, 2015)

**Physical Description**

A perennial herb that forms a rosettes of evergreen, succulent leaves. Leaves are 2 to 5 cm (0.8 to 2.0 in long, 1.5 to 2.5 cm (0.6 to 1.0 in wide; floral stems are 4 to 15 cm (1.6 to 6.0 in tall; corollas are pale yellow (Munz 1974). The ovateleaves have a maroon underside. (USFWS, 1999; NatureServe, 2015)

**Taxonomy**

Dudleya cymosassp. ovatifolja was originally described as Dudleya ovatifolia by Britton (1903) based on a collection made by H.M. Hall in 1902. The type locality is listed as “Sierra Santa Monica,” thought to be Topanga Canyon, Los Angeles County (Moran 1951). The species was subsequently recognized as Cotyledon ovatifolia and Echeveria ovatifolia (Fedde 1904 and Berger 1930 respectively, cited in Moran 1951) when different generic concepts were used in the family Crassulaceae. Moran (1957) published the currently accepted combination of Dudleya cyrnosa ssp. ovatifolia. Nakai (1983) considered plants from near Agoura, Los Angeles County to be distinct from Dudleya cyrnosa ssp. ovatifolia. Subsequently, (Nakai 1987) published the new name D. cymosa ssp. agourensis. Nakai distinguished the new subspecies from the other on the basis of number and shape ofrosette leaves, pedicel length, and degree of spreading in petal apices. Nakai (1987) considered D. cymosa ssp. agourensis to differ from D. cymosa ssp. ovatfolia in having a simple- to several-branched caudex and glaucous elliptical basal leaves. Nakai (1987) noted that D. cyrnosa ssp. ovatifolia has an unbranched caudex and green, ovate basal leaves. Bartel (1993) apparently considered these differences consistent, and included D. cyrnosa ssp. agourensis in D. cymosa ssp. ovatifolia in his treatment of the genus Dudleya, for the Jepson Manual. (USFWS, 1999)

**Current Range**

Currently, there are four populations of what the Service considered to be Dudleya cymosa subsp. ovatifolia at the time of listing in Los Angeles and Orange Counties. This includes two in the Santa Monica Mountains, one in the Santa Ana Mountains, and one in Agoura Hills. (USFWS, 2009)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Dependency on Other Individuals or Species**

Adult: The Dudleya species which have small yellow to orange flowers (including D. cymosa subsp. ovatifolia) are pollinated by bees and flies, while species with larger red flowers are pollinated mostly by hummingbirds. (USFWS, 2009)

**Breeding Season**

Adult: May to June (USFWS, 2009)

**Reproduction Narrative**

Adult: The flowering season is from May through June for D. cymosa subsp. agourensis and from March through May for D. cymosa subsp. ovatifolia (Dorsey 2007). The Dudleya species which have small yellow to orange flowers (including D. cymosa subsp. ovatifolia) are pollinated by bees and flies, while species with larger red flowers are pollinated mostly by hummingbirds. A study performed on Dudleya cymosa subsp. ovatifolia ex situ found that the average number of fruits produced per individual was 19 and the maximum number of seeds per fruit was 114. (USFWS, 2009)

**Habitat Type**

Adult: Terrestrial (USFWS, 2009)

**Habitat Vegetation or Surface Water Classification**

Adult: North-facing slopes and cliffs in chaparral communities and deep canyon bottoms (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Typically found on sedimentary conglomerate rock; persists in exposed dry habitat (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2009)

**Habitat Narrative**

Adult: On a broad scale, suitable habitat for Dudleya cymosa subsp. ovatifolia is generally located on sedimentary and conglomerate rock on canyon bottoms and shaded slopes in drainages along the south-facing slope of the Santa Monica Mountains (Dorsey 2007). In the Santa Ana Mountains, it occurs on shaded sandstone cliffs (Roberts 2008). Adjacent plant communities include coastal scrub and chaparral (CNDDB 2008b). In most locations, the topographic relief has prevented deep soil formation; therefore, this species may be the only flowering plant occurring in a microhabitat that otherwise supports mosses, lichens, and clubmoss (Selaginella spp.) (Dorsey 2007, CNDDB 2008b). (USFWS, 2009)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

4 (USFWS, 2009)

**Population Narrative:**

Currently, there are four populations of what the Service considers to be Dudleya cymosa subsp. Ovatifolia. (USFWS, 2009)

***Threats and Stressors***

**Stressor:** Development (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The threat of habitat encroachment from new or existing development surrounding several of the known Dudleya cymosa subsp. ovatifolia (and D. cymosa subsp. agourensis) population sites continues to be a threat. Due to an increase in residential and commercial development in the surrounding and adjacent areas (City of Agoura Hills 2009), such fire suppression activities may be an increasing threat to both D. cymosa subsp. ovatifolia and D. cymosa subsp. agourensis (see Appendix 1 and 2) (Halsey 2006, Service 2007, Halsey in litt. 2008). However, because most occurrences are on rocky outcrops with little vegetative cover, we believe the threat is low at this time. (USFWS, 2009)

**Stressor:** Roadside scraping (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Roadside scraping for weed abatement has modified habitat for D. cymosa subsp. ovatifolia. Since most individuals occur on rocky substrates, the Service believe this threat would be confined to the margins of the populations that are along existing road edges. (USFWS, 2009)

**Stressor:** Recreation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Recreational activities such as rock climbing and hiking were not discussed at the time of listing as a threat to the species. The Service considers this to be a new threat at certain locations. In Orange County, the Modjeska Peak occurrences (EOs #9 and 12) are located near a dirt road that is used by the public to access the peak, and Soza and Boyd (1999) noted the vulnerability of these occurrences and the presence of trash and footprints at EO #12; however, these occurrences are now thought to be a different Dudleya taxon (Roberts 2008). The Modjeska Canyon occurrence (EO #1) is inaccessible, and no visible signs of disturbance were seen in 1999 (Soza and Boyd 1999). Disturbance from recreational activities is also noted in CNDDB (2009) as a potential threat for the two populations in the Santa Monica Mountains, Los Angeles County. A site visit in 2009 confirmed that the Malibu Canyon population (EO #10) is being impacted by rock climbing activity (Marek in litt. 2009); the extent of recreational impacts on the Topanga Canyon population is unknown at this time. (USFWS, 2009)

**Stressor:** Collectors (USFWS, 2009)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Dudleya species were included in the Smithsonian's list of Commercially Exploited Endangered and Threatened Species in the Continental United States, citing private collectors as a threat; although no specific reference to D. cymosa subsp. ovatifolia was made, D. cymosa subsp. marcescens was considered endangered by the authors and thus included (Ayensu and DeFillips 1978). Collection for horticultural purposes by professional horticulturists and amateur collectors and gardeners was identified as a threat to all of the Dudleya taxa including D. cymosa subsp. ovatifolia (inclusive of plants now identified as D. cymosa subsp. agourensis) in the 1997 final listing rule (Service 1997). (USFWS, 2009)

**Stressor:** Fire suppression and fuel modification (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Despite efforts to suppress fires in coastal southern California, the present fire frequency of every 15 years or less is substantially higher than it was historically, which, for coastal scrub, is thought to be every 50 to 100 years (Keeley 2006). Over a period of 60 years, most of the area in the Santa Monica Mountains has burned an average of three to five times, with an average interval of every 12.4 to 20.7 years (Radtke et al. 1982). An increase in fire frequency can result in type-conversion of chaparral and coastal sage scrub communities to annual invasive grasses which aggressively compete with native species for resources. However, because the specific sites where Dudleya cymosa subsp. ovatifolia grow are on rocky outcrops and would not support dense stands of chaparral or coastal sage scrub (Christy Brigham, Santa Monica Mountains National Recreation Area, pers. comm. 2009; CNDDB 2008a, b; Marek in litt. 2009), the Service believes that impacts from wildfires on the Dudleya taxa would likely be less severe than on the surrounding native plant communities. The practice of discing for fire prevention and suppression is unlikely to directly affect D. cymosa subsp. ovatifolia because it inhabits rocky outcrops. The spraying of fire retardant has been demonstrated to affect native species in grassland habitats outside California because they facilitate the growth of annual grasses (Larson and Newton 1996, Bell 2003). The impacts from their use on sites where D. cymosa subsp. ovatifolia occurs are unknown at this point in time. (USFWS, 2009)

**Stressor:** Competition with non-native species (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In recent site visits, competition with non-native grasses has not been noted as a concern at any of the sites (Marek in litt. 2009, Roberts in litt. 2009, Soza and Boyd 1999). Jade plant (Crassula argentea), a non-native species from South Africa, was observed growing in Topanga Canyon within EO #2 by McCabe (Sagar in litt. 2008); its impacts on the Dudleya cymosa subsp. ovatifolia population are unknown. (USFWS, 2009)

**Stressor:** Stochastic extinction (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** The Service now considers Dudleya cymosa ssp. ovatifolia to be threatened by stochastic events due to the small size and isolation of the populations. Conservation biology literature commonly notes the vulnerability of taxa known from small populations (Shaffer 1981, 1987; Meffe and Carroll 1997; Primack 1998). It is generally accepted that small populations have higher probabilities of extinction than larger populations because their low numbers make them susceptible to inbreeding, loss of genetic variation, high variability in age and sex ratios, demographic stochasticity, and random naturally occurring events such as wildfires, floods, droughts, or disease epidemics (Menges 1991, Ellstrand and Elam 1993, Shaffer 1981, 1987; Soulé 1987; Meffe and Carroll 1997; Primack 1998). Isolation often acts in concert with small population size to increase the probability of extinction. Isolated populations are more susceptible to long-term/permanent extirpation by accidental or natural catastrophes because the likelihood of recolonization following such events is negatively correlated with the extent of isolation (Wilcox and Murphy 1985, Meffe and Carroll 1997). Human development exacerbates the risk of stochastic extinction because it further isolates and fragments remaining populations as time goes on. (USFWS, 2009)

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Hayhoe et al. 2004, Cayan et al. 2005, IPCC 2007). Due to the elevation and coastal location of the Santa Monica Mountains, this area is expected to become one of these potential future refugia and greatly increase in diversity (Loarie et al. 2008). We recognize that climate change is an important issue with potential effects to listed species and their habitats. While we lack adequate information to make specific and accurate predictions regarding how climate change, in combination with other factors such as small population size, will affect small-ranged species that are restricted to soils of limited distribution, such as Dudleya cymosa subsp. ovatifolia and D. cymosa subsp. agourensis, we acknowledge that they are more vulnerable to extinction due to these changing conditions (Pimm and Raven 2000, Loarie et al. 2008). (USFWS, 2009)

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 6

**Delisting Criteria:**
1. All current sites are fully protected and managed with the primary intention of preserving the populations in perpetuity. (USFWS, 2009)

2. All current sites are shown to be self-sustaining over a minimum of 10 years. (USFWS, 2009)

**Recovery Actions:**
- Protect and secure all current sites of these plant species (including seedbanks). (USFWS, 1999)
- Manage and monitor protected areas where plants occur. (USFWS, 1999)

- Manage and monitor protected areas where plants occur. (USFWS, 1999)
- Conduct biological and ecological research to define life history strategies, population dynamics, and to guide recovery/conservation efforts. (USFWS, 1999)
- Develop public outreach plans to enhance the public's understanding of conservation needs of these endangered and threatened plant species. (USFWS, 1999)
- Develop and implement monitoring and adaptive management plans for known existing occurrences of Dudleya cymosa subsp. ovatifolia and D. cymosa subsp. agourensis populations. Monitoring should occur at intervals of 3 years and include population abundance surveys, habitat condition assessment, and documentation of existing and potential threats. (USFWS, 2009)
- Work with private landowners and local agencies to protect and manage Dudleya cymosa subsp. ovatifolia and D. cymosa subsp. agourensis on private property. If development is proposed or planned near D. cymosa subsp. ovatifolia and D. cymosa subsp. agourensis, recommend measures to protect the species such as creating large buffer zones between development and plants and invasive plant prevention and control. (USFWS, 2009)
- Work with local fire departments to: a) develop or modify fire management plans for when fires occur in or near the habitat of each species and b) prevent or limit discing of soil in fire management zones near Dudleya cymosa subsp. ovatifolia and D. cymosa subsp. agourensis habitat to prevent the spread of invasive, nonnative plants. (USFWS, 2009)
- Once additional information concerning the status of populations and current threats is obtained, consider whether: a) a change in status for Dudleya cymosa subsp. ovatifolia may be warranted and, b) candidate status may be warranted for D. cymosa subsp. agourensis. (USFWS, 2009)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Regularly monitor Dudleya cymosa subsp. ovatifolia and Dudleya cymosa subsp. agourensis populations to evaluate population trends. 2. Improve the completeness of coverage of Dudleya cymosa subsp. ovatifolia, Dudleya cymosa subsp. agourensis, and undescribed taxa in conservation seed banks, with more occurrences over more years. 3. Confirm recent taxonomic changes, including the undescribed taxa in the Santa Ana Mountains, and recognize the segregation of the recognized undescribed taxa, Dudleya cymosa subsp. ovatifolia, and Dudleya cymosa subsp. agourensis. 4. Determine with more detail the distribution and status of all taxa in the Santa Ana Mountains that were considered part of Dudleya cymosa subsp. ovatifolia since listing. (USFWS, 2021)

# SPECIES ACCOUNT: *Dudleya verityi* (Verity's dudleya)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 01/29/1997; California/Nevada (Region 8) (USFWS, 2015)

**Physical Description**

A perennial herb that forms a rosette of succulent leaves. Flowering stems are 5-15 cm tall, bearing lemon-yellow flowers. This plant forms colonies of up to 100 rosettes. (NatureServe, 2015)

**Taxonomy**

Dudleya verityi (Verity's dudleya) was described by Kei Nakai (1983) based on a collection he made in 1978 in Long Grade Canyon, Santa Monica Mountains, Ventura County. Raven and Thompson (1966) had assumed these plants to represent a southern extension of D. farinosa. During preparation ofthe 1977 revision ofthe flora, Dave Verity recognized these plants as representing a distinct species, and he subsequently encouraged Kei Nakai to review the taxonomy ofthe species. (USFWS, 1999)

**Historical Range**

See current range/distribution.

**Current Range**

All known occurrences are within eastern Ventura County, California, along north-facing volcanic rock outcrops on the lower slopes of the west end of the Santa Monica Mountains in coastal sage scrub. The entire distribution of the species is scattered over a 6.4-km (4-mi) stretch of land along the northern slope of Conejo Mountain and on north-facing volcanic outcrops in the vicinity of the California State University Channel Islands campus. (USFWS, 2009)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Dependency on Other Individuals or Species**

Adult: The cushion lichen, Niebla ceruchoides, appears to provide a nursery habitat for seed capture and germination for D. verityi (Riefner 1992) (see cover photo). The Dudleya species which have small yellow to orange flowers (including D. verityi) are pollinated by bees and flies, while species with larger red flowers are pollinated mostly by hummingbirds (Levin and Mulroy 1985, Aigner 2004). (USFWS, 2009)

**Breeding Season**

Adult: May to June (USFWS, 2009)

**Reproduction Narrative**

Adult: Dudleya verityi blooms in late spring (May-June) (California Native Plant Society (CNPS) 2008) and has floral stalks 5 to 15 cm (2.0 to 5.9 in) tall with lemon-yellow corollas and petal tips recurved to 90 degrees (Service 1999). The cushion lichen, Niebla ceruchoides, appears to provide a nursery habitat for seed capture and germination for D. verityi (Riefner 1992). The Dudleya species which have small yellow to orange flowers (including D. verityi) are pollinated by bees and flies, while species with larger red flowers are pollinated mostly by hummingbirds (Levin and Mulroy 1985, Aigner 2004). (USFWS, 2009)

**Habitat Type**

Adult: Terrestrial (USFWS, 2009)

**Habitat Vegetation or Surface Water Classification**

Adult: Forest/Woodland, Shrubland/chaparral, Woodland - Hardwood

**Geographic or Habitat Restraints or Barriers**

Adult: Based on CNDDB (2008) records and recently mapped coordinates onto Google Earth (2008), known occurrences of Dudleya verityi prefer elevations ranging from 60 to 350 m (200 to 1150 ft) Dudleya verityi prefers slopes ranging from 20 to 90 degrees, and most commonly with north-facing exposures (CNDDB 2008, Sagar 2008). (USFWS, 2009)

**Spatial Arrangements of the Population**

Adult: Scattered (USFWS, 2009)

**Environmental Specificity**

Adult: Very narrow. Specialist or community with key requirements scarce. (NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from USFWS, 2009)

**Dependency on Other Individuals or Species for Habitat**

Adult: There is evidence that mosses and lichens aid in seed recruitment and germination by providing nutrients, moisture, substrate, and protection against snails and slugs (Riefner and Bowler 1995, Riefner et al. 2003). (USFWS, 2009)

**Habitat Narrative**

Adult: In general, Dudleya taxa typically inhabit ocean bluffs, sheer cliffs, and rock outcrops including open habitat soils that have nutrient poor substrates and little vegetation (Riefner et al. 2003). This species is highly localized in its distribution, occurring exclusively in thin-soiled substrate over rocky outcrops derived from the Miocene Conejo volcanics (Service 1999). Based on CNDDB (2008) records and recently mapped coordinates onto Google Earth (2008), known occurrences of Dudleya verityi prefer elevations ranging from 60 to 350 meters (200 to 1150 feet). Dudleya verityi prefers slopes ranging from 20 to 90 degrees, and most commonly with north-facing exposures (CNDDB 2008, Sagar 2008). The entire distribution of the species is scattered over a 6.4-km (4-mi) stretch of land along the northern slope of Conejo Mountain and on north-facing volcanic outcrops in the vicinity of the California State University Channel Islands campus. (USFWS, 2009)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Long term trends indicate a decline of <50% to relatively stable, while short-term trends suggest declines of 10-30% (NatureServe, 2015)

**Number of Populations:**

8 (USFWS, 2023)

**Population Size:**

Thousands (USFWS, 2023)

**Adaptability:**

Low (inferred from USFWS, 2009)

**Population Narrative:**

As a result of 2003 surveys (Sagar 2008) which reported an additional six occurrences, the number of occurrences is now currently at nine (CNDDB 2008, Sagar 2008). Due to its location in a highly developable area and a very narrow distribution short-term trends indicate a decline of 10-30% and long term trends of relatively stable to declines less than 50% (NatureServe, 2015). (USFWS, 2009; NatureServe, 2015). At the time of listing in 1997 (Service 1997), there were 3 known occurrences of D. verityi. This number is now increased to a total of 8 CNDDB Element Occurrences ([EO] Table 1, CDFW 2023), and one possible unassigned occurrence (Dorsey et al. 2013, p. 61). An EO is a group of plants separated by at least 400 meters (1/4 mi) from the closest group of plants of the same species. The increase in the number of occurrences since listing was recognized in the Service 2009 5- year review and in Dorsey et al. 2013, but at the time of these publications CNDDB EO numbers had not yet been assigned to all of them. This resulted in different identification numbers being used for the same occurrences among the publications that differ somewhat from the current CNDDB EO numbers. We cross-walked the identification numbers in Table 1 above. Eight of nine occurrences are known since at least 2003, and it is unlikely that additional occurrences will be found beyond the small, known geographic range of the species. We presume that all the occurrences are currently extant (CDFW 2023). More than half of the occurrences are partially or fully on private land, with limited or no access for surveys. Several of the occurrences are relatively close to adjacent occurrences and may be merged in the future, particularly EO# 1 and EO# 4, and EO# 3 and the unassigned occurrence also on Conejo Mountain. The areas between these occurrences are on private land and not available for survey. EO# 1 has a range of hybrids between D. verityi and D. lanceolata as well as pure D. verityi (Guilliams and Hasenstab-Lehman 2020, pp. 34-36). EO# 5 may contain only hybrid plants between the two species (Dorsey et al. 2013, pp. 58 and 65), but no genetic analysis of the EO# 5 occurrence has been conducted. We discuss hybridization further in the threats section below (USFWS, 2023). Abundance: Information about total population size for D. verityi was not given when we listed the species (Service 1997). Most of the occurrences and individuals are at least partially on private land, and have limited or no accessibility for surveys. Botanists surveyed at least parts of most of the occurrences in 2003, and estimated that the species had a total of approximately 15,000 individuals (Table 2). This is the most comprehensive data regarding D. verityi abundance available. Three occurrences (EO# 1, EO# 2, and EO# 6) had population surveys in the same three years2003, 2010, and 2021. It is unknown how similar survey efforts were between years. Each of these occurrences had decreasing numbers of plants from 2003 to 2010, with total numbers of 13,450 in 2003 and 3,479 in 2010 (Table 2). These occurrences were also visited immediately after the 2013 Springs Fire burned over all occurrences of the species, causing severe mortality estimated at over 90% of the known individuals of the species (CNDDB 2023). The 2013 postfire count was described as a “brief visit”, and there was a total of only about 10 plants visible among these three occurrences (Dorsey et al. 2013, p. 66). Numbers of plants were not given for each separate occurrence, and CNDDB (2023, not included in Table 2 below) reports this total only as 11-50 plants for EO# 2, without giving numbers for EO# 1 or EO# 6. It is likely that at that time there were individuals which had the leaves burned off and were still alive but undetected. Botanists conducted a 2021 survey of the same three occurrences (EO# 1, EO# 2, and EO# 6), and found a total of 1,016 plants. Because of the decrease in numbers between 2003 and 2010 and the continued effects of the Springs Fire, all occurrences are characterized by CNDDB as decreasing (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Rock quarry (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Historically, the lower slopes of Conejo Mountain near occurrence number 2 have been the site for quarrying of construction-grade rock. This land is zoned by the County of Ventura for mineral extraction and there are abandoned, active, and proposed quarry operations within the distribution of Dudleya verityi (Service 1997, 1999). However, the quarrying near occurrence number 2 remains as the only current quarry operation within the distribution of D. verityi, and even though we are not aware of any individuals of D. verityi that have been affected by these actions, the current quarry operation has violated some of their county permit requirements and has mined beyond the permit boundaries (C. Danko, Ventura County Planning Division, pers. comm. 2009). In addition, the quarry operation, once back in compliance with county requirements, may request to expand its operation. Therefore, the activities and the effects of this quarry to D. verityi or its habitat remain unclear and therefore continue to be a threat. (USFWS, 2009)

**Stressor:** Development (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the current time, habitat encroachment from new or existing development activities surrounding several of the known Dudleya verityi occurrences continues to be a threat to the species and its habitat. For the most part, D. verityi and associated habitat is located in areas where impacts from development itself may not directly affect the species or its habitat. However, the associated human impacts to the land (e.g., hiking, mountain biking) in these areas adjacent to new or existing developments could result in D. verityi and associated lichen communities to be trampled and/or dislodged. Additionally, erosion from such activities may

cause changes in the substrate which may change the microhabitat necessary for the lichen communities to persist. (USFWS, 2009)

**Stressor:** Collection (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** An incident of vandalism of chalk dudleya (Dudleya pulverulenta) occurred near a public access location in Topanga Canyon, California in 1999, illustrating that collection of Dudleya species continues to be a threat to members of this genus (Farris 1999). Even though we are unaware of any collection of Dudleya verityi, occurrence number 1, 5, and 7 are especially prone to collection given the ease of accessibility and proximity to existing development and roads. (USFWS, 2009)

**Stressor:** Caterpillar predation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Damage from caterpillars eating the inside of the stems of plants within the Dudleya genus has been reported in many locations. These hollow roots and stems were first noticed in some Dudleya individuals as early as 1990 and have been reported as far south as the considerably isolated Isla Zapato in Mexico, leading to speculation that it is a native caterpillar that is responsible for the damage (McCabe 2008b). (USFWS, 2009)

**Stressor:** Air quality (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Air pollution impacts to coastal sage scrub have been documented in the Santa Monica Mountains as a threat to the viability and functioning of the habitat (O'Leary 1990). The diverse lichen flora associated with D. verityi contains species that are considered rare and disappearing from southern California (Riefner 1992). The cushion lichen (Niebla ceruchoides) appears to provide a nursery habitat for seed capture and germination for D. verityi (Riefner 1992). The population of Niebla on Conejo Mountain is the largest on the mainland (it is also known from the California Channel Islands). Lichens are sensitive to air pollutants and have been eliminated from many areas during the past century (Hale 1983). Studies in California have shown a strong correlation between the increases in smog and the loss of the regional lichen flora (Sigal and Nash 1982). With Ventura County's improvements in air quality, air pollution is not the threat it was at the time of listing. However, until studies have been performed to determine the levels of smog that would impair the ability for the cushion lichen, Niebla ceruchoides, to persist, air quality may continue to be a threat to D. verityi. (USFWS, 2009)

**Stressor:** Fire suppression, fuel modification, wildfire survivability, and invasive species (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** At the time of listing in 1997, we discussed general threats to several species within the Dudleya genus, including the effects of fire (Service 1997). Natural fire regimes of these areas have been affected, consequently having drastic effects on the grassland, coastal sage scrub, chaparral, and oak woodland ecosystems and the species that reside there (Keeley et al. 1999). In some cases, D. verityi is threatened by direct removal during fuel modification and fire-break efforts that occur in the vicinity of the habitat for this species due to the large number of residences and buildings that exist in close proximity to the existing distribution of this species (Service 1997, 1999; Sagar 2008). Additionally, fire that reduces or eliminates the lichen community could dramatically reduce the extent and number of populations of D. verityi. Lichens grow very slowly and persist for long periods of time (Hale 1983). The population structure of D. verityi depends on mature lichen individuals (Service 1999). Therefore, an extremely hot fire could remove the necessary substrate for the species to germinate and would modify D. verityi habitat for an uncertain period of time. Although the plants probably have the ability to survive small, low-intensity fire, there is a high probability that the plants may not survive a larger, high intensity fire. Increased fire suppression over the last century in a large portion of southern California increases the chance of having these larger, more intense fires (Keeley et al. 1999) and thus high intensity fires may pose a threat to the species. (USFWS, 2009)

**Stressor:** Stochastic extinction (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, we noted that due to the limited number of individuals and the restricted range of Dudleya verityi, this species is under threat of extinction from naturally occurring events, such as fire, drought, disease, or rock slides (Service 1997). As a result of the number of individuals and range of D. verityi, the genetic viability and thus resilience of the species to human-caused or natural disasters may be greatly reduced (Menges 1991, Ellstrand and Elam 1993). (USFWS, 2009)

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the northern hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). The Santa Monica Mountains and Simi Hills are expected to increase in diversity becoming potential future refugia for some species (Loarie et al. 2008). Increases in species diversity in these higher elevations and northern locations due to climate change have the potential to result "…in new species mixes, with consequent novel patterns of competition and other biotic interactions…" with unknown consequences to the species which currently exist there (Loarie et al. 2008). While we lack adequate information to make specific and accurate predictions regarding how climate change, in combination with other factors, such as low numbers of individuals, will affect Dudleya verityi, small ranged species such as D. verityi are more vulnerable to extinction due to these changing conditions (Loarie et al. 2008). (USFWS, 2009)

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

Recovery Priority Number: 5C

**Delisting Criteria:**
1. All the current sites (including seedbanks) are fully protected and managed with the primary intention of preserving the populations in perpetuity. (USFWS, 2009)

2. All the current sites (including seedbanks) are shown to be self-sustaining over a minimum of 10 years. (USFWS, 2009)

**Recovery Actions:**
- Protect and secure all current sites of these plant species (including seedbanks). (USFWS, 1999)
- Manage and monitor protected areas where plants occur. (USFWS, 1999)
- Survey historic locations and other potential habitat where the six plant species may occur. (USFWS, 1999)
- Conduct biological and ecological research to define life history strategies, population dynamics, and to guide recovery/conservation efforts. (USFWS, 1999)
- Develop public outreach plans to enhance the public's understanding of conservation needs of these endangered and threatened plant species. (USFWS, 1999)
- Conduct new, up-to-date extensive population survey of existing and potential habitat sites. Potential partners include the National Park Service (Santa Monica Mountains Recreation Area), California State Parks, and California State University, Channel Islands. (USFWS, 2009)
- Develop and implement monitoring and adaptive management plans for known existing occurrences. Monitoring should follow Sahatjian's (2008) monitoring methodology. Update and expand knowledge of species life history and specific habitat requirements. (USFWS, 2009)
- Work on public outreach and education with private land owners in the area; develop incentives aimed at conservation of the species. Seek input from public and other stakeholders on the management and preservation of the species. Cooperative agreements and coordinated planning and management efforts could assist in conservation efforts. (USFWS, 2009)
- Work closely with agencies to implement a species monitoring and public outreach program, in addition to implementing new conservation measures for the species (e.g., fencing off certain areas, etc.) and preserving additional potential habitat for the species. (USFWS, 2009)
- Work with county planning departments to develop a species conservation plan; if development does occur, onsite protection should be required. (USFWS, 2009)
- Investigate air quality impacts on cushion lichen, Niebla ceruchoides. (USFWS, 2009)
- Investigate Dudleya verityi (and suspected hybrids) growing and reproducing on the clay tile roofs at California State University Channel Islands campus near occurrence number 5 to determine whether these plants are in fact D. verityi, and not hybrids. (USFWS, 2009)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Continue genetic and morphometric analyses to determine the extent of hybridization with other Dudleya species, and deposit voucher specimens of the variation at all occurrences in herbaria. 2. Conduct thorough surveys within all known occurrences and areas of suitable habitat. 3. Conduct surveys to determine if there are additional plants in areas between the currently mapped occurrences, and if occurrences can be merged. 4. Develop and implement a monitoring plan for all occurrences. Monitoring should include population abundance surveys, habitat condition assessment, and documentation of existing and potential threats. 5. Work with public and private entities to gain access to occurrences, prevent damage to plants, and raise public awareness to support appropriate conservation measures. 6. Update and expand knowledge of the species' life history and specific habitat requirements, especially the relationship to lichens that are important for recruitment. Continue the work to enhance lichen abundance that is currently being performed so that successful outplanting to the field can occur, which would help increase overall population abundance and resiliency against severe wildfires. 7. Continue the recovery actions of supplemental watering and lichen transplantation until the pre-Springs Fire lichen habitat is reestablished. 8. Increase the number of D. verityi accessions in conservation seed banks, so that all known occurrences are represented in the collections. (USFWS, 2023).

# SPECIES ACCOUNT: *Echinacea laevigata* (Smooth coneflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/8/1992; Southeast Region (R4) (USFWS, 2015). Reclassified to Threatened on August 5, 2022

**Physical Description**

A rhizomatous perennial herb, which grows to a height of about 1.5 m, with smooth stems, few leaves and pink to purplish flowers. This species flowers from May to mid-July and fruits from late June to September (Gaddy 1991) (NatureServe, 2015).

**Taxonomy**

It belongs to the aster family (Asteraceae) was first described in 1903, under the name Brauneria, by Boynton and Beadle from material collected in South Carolina in 1888; it was transferred to the genus Echinacea in 1929 (Small 1933, McGregor 1968) (USFWS, 1995).

**Historical Range**

The reported historical range of smooth coneflower included Pennsylvania, Maryland, Virginia, North Carolina, South Carolina. Georgia, Alabama. and Arkansas (USFWS, 1995).

**Current Range**

Current range: Georgia, South Carolina, North Carolina, Virginia. Reports from Alabama and Arkansas are believed to have been misidentifications (Gaddy 1991); also an apparent false report from Maryland (NatureServe, 2015).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual, vegetative (USFWS, 1995)

**Breeding Season**

Adult: May through July (NatureServe, 2015)

**Key Resources Needed for Breeding**

Adult: Insect pollinators; bare soil that is rich in magnesium and/or calcium; disturbance (USFWS, 1995)

**Reproduction Narrative**

Adult: Flowering occurs May through July; fruiting occurs June to October. Seldom produces viable seeds. Rhizomatous/Cormophyte (NatureServe, 2015). Gaddy (1991) stated that reproduction was apparently only by sexual means and that no vegetative reproduction had been observed. However, vegetative reproduction has been reported from the Chattahoochee

National Forest in Georgia (Robert Joslin, U.S. Forest Service, personal communication, 1994) and from the Sumter National Forest in South Carolina (Lonnette Edwards, U.S. Forest Service, personal communication. 1995). Pollinators for this species are unknown; however, Edwards and Madsen (1993) have documented preliminary list of insect visitors to South Carolina populations of smooth coneflower (see Appendix A). Smooth coneflower appears to need bare soil that is rich in magnesium and/or calcium for seedling germination and growth. Some form of disturbance (such as fire) is also essential (USFWS, 1995)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Prairie, oak-savannas, cedar barrens, limestone bluffs (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Full or partial sun (NatureServe, 2015); periodic fire (USFWS, 1995)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Formerly, a plant of prairie-like habitats or oak-savannas maintained by natural or Native American-set fires. Now, primarily occurs in openings in woods, such as cedar barrens and clear cuts, along roadsides and utility line rights-of-way, and on dry limestone bluffs. Usually found in areas with magnesium and calcium-rich soils. Requires full or partial sun. Associated species include: Juniperus virginiana and Eryngium yuccifolium. This species is disturbance dependent (NatureServe, 2015). Smooth coneflower occurs in community types described by Schafale and Weakley (1990) as xeric hardpan forests and diabase glades or in Virginia dolomite woodlands or glades as described by Rawinski (1994). Optimal sites for smooth coneflower are characterized by abundant sunlight and little competition in the herbaceous layer (Gaddy 1991). Natural fires, as well as large herbivores, are part of the history of the vegetation in this species' range (USFWS, 1995).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seeds are probably dispersed by seed-eating birds or small mammals (USFWS, 1995).

***Population Information and Trends***

**Population Trends:**

Decline of 30-70% (NatureServe, 2015)

**Species Trends:**

Stable (USFWS, 2011)

**Number of Populations:**

68 (USFWS, 2011)

**Population Size:**

2500 - 100,000 individuals (NatureServe, 2015)

**Population Narrative:**

Remaining populations appear to be small in numbers which may result in low genetic diversity. Since the species' discovery, more than 2/3rds of the historical populations have been lost. Known from 61 populations in 8 states. However, when it was listed, it was known from fewer than 25 sites in 4 states. This species has experienced a long-term decline of 30-70%. A site in North Carolina is probably the largest, with an estimated 2000 individuals. Total estimated population size is 2,500 - 100,000 individuals. Species is limited to 4 states, 10 counties and about 20 populations in a narrow band from Georgia through the Carolinas to Virginia. There are a few restored populations in Georgia and South Carolina. (NatureServe, 2015). Based on survey information gathered at individual populations throughout the range of the species, it appears that the Echinacea laevigata is stable. Peters et al. (2009) found that the species displays a relatively high level of diversity based on analyses across the range of populations. A total of 68 populations are considered extant while 32 populations are believed to be extirpated or historical (USFWS, 2011).

***Threats and Stressors***

**Stressor:** Habitat destruction and degradation (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Echinacea laevigata is threatened range-wide by the suppression of fire and the ecological succession (competition and/or shading by woody species) that occurs in areas that are not burned on a regular basis. Echinacea laevigata also is threatened by timber operations. Sites located within utility rights of-way are threatened by herbicide use and/or mowing during critical growth periods. The destruction of habitat, resulting from development or land conversion also threatens this species, but to a lesser degree than the factors listed above. The invasive plant, Pueraria lobata (kudzu), occurs at one Echinacea laevigata population in SC. Lespedeza cuneata (Sericea lespedeza) is problematic at some roadside locations in NC (USFWS, 2011).

**Stressor:** Longhorn beetle (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The non-native longhorn beetle (Hemierana marginata) has been identified at some Echinacea laevigata populations in NC. This beetle chews into the flowering stems causing flowers to die before they produce viable seeds. The insect also may burrow into the base of the plant killing the plant (Laura Gadd, NC Plant Conservation Program, Raleigh, NC, pers. comm.) (USFWS, 2011).

***Recovery***

**Reclassification Criteria:**

1. 12 geographically distinct, self-sustaining populations are protected across the species' range, including some populations in at least two counties in VA, two counties in NC and two counties in SC and one county in GA (USFWS, 2011).

2. Managers have been designated for each population (USFWS, 2011).

3. Management plans have been developed and implemented (USFWS, 2011).

4. Populations have been maintained at stable or increasing levels for five years (USFWS, 2011).

Recovery Priority Number: 5

**Delisting Criteria:**
1. At least 15 geographically distinct, self-sustaining populations are protected in at least two counties in VA, two counties in NC, two counties in SC and one county in Georgia (GA) (USFWS, 2011).

2. Management plans have been developed and implemented for each site (USFWS, 2011).

3. Populations (as measured by number of adult plants) have been stable or increasing for 10 years (USFWS, 2011).

4. Permanent conservation ownership and management of at least 10 populations are assured by legally binding instruments (USFWS, 2011).

**Recovery Actions:**
- Maintain cultivated sources for the species and provide for long-term maintenance of selected populations in cultivation (USFWS, 1995).
- Implement protective management for extant populations (USFWS, 1995).
- Survey suitable habitat for additional populations and potential reintroduction sites; reestablish populations within the species' historic range (USFWS, 1995).
- Protect viable populations through a range of protection tools (management agreements, acquisition, registry, cooperative agreements, etc.) (USFWS, 1995).
- Monitor existing populations (USFWS, 1995).
- Conduct research on the biology of the species and on suitable management tools for maintaining the natural ecosystem in which it occurs (USFWS, 1995).
- Revisit known populations that have not been visited in the past three years in order to monitor the population size, habitat conditions and to document any potential threats to the viability of each site; discuss conservation options with landowners and managers where appropriate; report findings to the appropriate NHP (USFWS, 2011).
- Search for additional populations in appropriate habitat (USFWS, 2011).
- Identify those populations/subpopulations that will contribute toward long term recovery and determine their status (increasing, stable or decreasing) (USFWS, 2011).
- Prioritize protection of unprotected sites that are critical for recovery and protect them (USFWS, 2011).
- Develop conservation agreements with applicable landowners to ensure recovery objectives are met (USFWS, 2011).

- Determine which sites have management plans and how they are being implemented and develop and implement management plans for the remaining sites that are deemed to be critical to the recovery of the species (USFWS, 2011).
- Develop monitoring protocols and initiate long-term population monitoring that will demonstrate if a site is stable or not (USFWS, 2011).
- Determine the management techniques for sustaining populations, such as fire frequency and seasonality (USFWS, 2011).
- Conduct further genetic analysis of populations not included in the research by Peters, et al (2009) (USFWS, 2011).
- Organize a meeting of land managers, researchers and other interested parties to discuss the recovery of this species (USFWS, 2011).
- Collect seeds and develop propagation protocols according to Center for Plant Conservation guidelines (USFWS, 2011).
- Conduct research on general biology of the species including life history and reproductive biology (breeding systems, seed production and seedling survivorship) (USFWS, 2011).
- Secure funding to accomplish the actions listed above (USFWS, 2011).

# SPECIES ACCOUNT: *Echinocactus horizonthalonius var. nicholii* (Nichol's Turk's head cactus)

***Species Taxonomic and Listing Information***

**Commonly-used Acronym:** NTHC

**Listing Status:** Endangered; 11/28/1979; Southwest Region (R2)

**Physical Description**

The NTHC is a small, blue-green to gray-green, barrel cactus that is globose, becoming more columnar as it grows. Large individuals range in height from 41 to 51 cm (16 to 20 inches) tall and range in diameter from 13 to 20 cm (5 to 8 inches) wide. Individuals are single-stemmed with 8 ribs that spiral around the base to the apex. Each areole has three central spines, one black that curves downwards and two red or basally gray that curve upwards, and 5 radial spines that tend to be black or partially gray. Flowers are 4 to 7 cm (1.5 to 2.7 inches) in diameter when fully opened (Chamberland 1995; Turner et al. 1995). One to five bright pink fruits are produced in May and June (Benson 1982) and are covered with wooly, white hairs at the apex of the stem, becoming dry with maturity. (USFWS, 2009)

**Taxonomy**

Baker (2007, 2009) is conducting a multivariate analysis to compare the degree of morphological variation of stem characters within populations of variety nicholii to populations within E. horizonthalonius throughout its known range to determine if these characters are significantly different to the full suite of characters. Baker's results suggest that there are three distinct varieties within the species E. horizonthalonius: variety nicholii in the Sonoran Desert population, variety horizonthalonius in the Chihuahuan Desert, and an unnamed variety in San Luis Potosí, Mexico. However, more populations need to be measured in order for the results to be conclusive (M. Baker, pers. comm. 2009) (USFWS, 2009).

**Historical Range**

It is endemic to the Sonoran Desert (Pima and Pinal Counties, , Arizona, and Sonora, Mexico). (USFWS, 2009)

**Current Range**

Populations occur in the Waterman Mountains and Koht Kohl Hills in Pima County, Arizona; the Vekol Mountains including those near the vicinity of the Vekol Mine in Pinal County, Arizona; and a population in the Sierra del Viejo Mountains in Sonora, Mexico (USFWS, 2009). The NTHC occurs in isolated mountain ranges that extend from southcentral Arizona in Pima and Pinal Counties to a disjunct location in Sonora, Mexico. The plant is found almost entirely on Horquilla limestone. (USFWS, 2021)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Food/Nutrient Narrative**

Adult: Extremely slow-growing; takes 10 years to reach a height of 2 inches (NatureServe, 2015).

**Reproductive Strategy**

Adult: Sexual: cross-pollination (USFWS, 2009)

**Lifespan**

Adult: 35 - 95 years (USFWS, 2009).

**Breeding Season**

Adult: April - July (USFWS, 2009)

**Key Resources Needed for Breeding**

Adult: Soil seed bank (USFWS, 2009)

**Reproduction Narrative**

Adult: Flowering occurs during mid-April to July, with 90 percent of blooms occurring in June (USFWS 1986). One to five bright pink fruits are produced in May and June (Benson 1982). The NTHC is self-incompatible, requiring pollen from another plant for pollination. Individual lifespan is estimated between 35 and 95 years (USFWS 1986; Schmalzel and Francisco 2000). Each fruit generally contain less than 100 seeds (K. Rice, pers. comm. 2008). The Schmalzel and Francisco (2000) study found that individuals reach maturity (i.e. bloom for the first time) at 2 cm (0.78 inches) tall and 8 cm (3.2 inches) wide. Preliminary studies examining population age-structure suggest that an immature cactus takes 11 to 13 years to reach a diameter of 2 cm (0.78 inches). Seeds are incorporated into a soil seed bank until favorable conditions for germination are present (Ecker 1991; Rojas-Aréchiga and Vázquez-Yanes 2000; Godinez-Alvarez et al. 2003; notes from S. Brack, Mesa Garden, courtesy of Desert Botanical Garden files) (USFWS, 2009).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Sonoran desert scrub (USFWS, 2009; NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 730 - 1,250 m elevation (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (USFWS, 2009; see dispersal/migration narrative)

**Environmental Specificity**

Adult: Narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Occurs in Sonoran desert scrub on dissected alluvial fans at the foot of limestone mountains, and on inclined terraces and saddles on limestone mountain sides at 730 -1,250 m. It has been found to grow almost exclusively on Pennsylvania-aged Horquilla limestone (USFWS 2009; NatureServe, 2015). The environmental specificity is narrow (specialist or community with key requirements common) (NatureServe, 2015). It occurs on 0 - 30 percent slopes with a north, west, and south-facing exposure. Grows in open areas and partially to shaded areas underneath the canopy of shrubs and trees, or shouldered next to rocks on steep slopes and within limestone outcrops. Occurs in Parkinsonia microphylla scrub with Ambrosia deltoidea, Carnegiea gigantea, Cylindropuntia acanthocarpa, Encelia farinosa, Fouquieria splendens, Krameria grayi, and Opuntia phaeacantha (Baker 2007). Other dominant associated plant species include Larrea tridentata, Ambrosia deltoidea, Krameria grayi, and Opuntia sp. (USFWS 1986; NatureServe, 2015).

***Dispersal/Migration***

**Dispersal**

Adult: Low (inferred from USFWS, 2009)

**Dispersal/Migration Narrative**

Adult: Seedlings often establish around the base of the "mother" plant and can give the appearance of small clumps (USFWS, 2009).

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2019)

**Number of Populations:**

4-5 (USFWS, 2021)

**Population Size:**

<1,300 (USFWS, 2021)

**Population Narrative:**

As of 2020, there are thought to be fewer than 1,300 total individuals (an estimated 1,024 live and 288 dead), most of which occur in the Waterman Mountains of Pima County Arizona. The status of NTHC on the Tohono O'odham Nation is uncertain. Despite surveys since the 1980s and continuing periodically through 2020, no new populations have been located outside of the four historical areas (the Waterman Mountains and Koht Kohl Hills in Pima County, Arizona; the Vekol Mountains in Pinal County, Arizona; and the Sierra del Viejo Mountains in Sonora, Mexico). A potential fifth population of 83 plants that morphologically resemble the NTHC occur in central Sonora (Van Devender and Reina-Guerrero 2012, entire). Their taxonomic status remains uncertain and until verified, the population is not considered the listed entity (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2019)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** Habitat desctruction to the Waterman Mountains population is no longer adversely affecting var. nicholii. As of 2018, the BLM has completed most of the recovery actions from the Recovery Plan. The establishment of IFNM with the signing of the Presidential Proclamation, permanently protects natural resources within the 906.5 ha (2,240 ac) encompassing var. nicholii's habitat. In accordance with the proclamation, IFNM is withdrawn from all forms of mineral extraction and recreational off-road vehicles (Service 2009, BLM 2011, 2013). In implementing recovery actions, BLM has acquired 148.9 ha (368 ac) out of 222.5 ha (550 ac) of patented land held by a private owner within occupied habitat and continues to pursue acquisition of remaining private acreages (BLM 2011; D. Tersey BLM, pers. comm. 2018). (USFWS, 2019)

**Stressor:** Herbivory (USFWs, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Recovery Plan stated that moderate levels of grazing did not appear to affect the var. nicholii because cows seem to avoid stepping on the plants (Service 1986). Moderate grazing continues throughout var. nicholii's habitat (Service 2012). During the summer months, cattle may congregate under large trees for shade in dense patches of var. nicholii and disturb its habitat (K. Robertson, FWS, pers. obs., 2018). We have little evidence (observed or documented) of cows stepping on the cactus or damaging its tissue. BLM manages the Agua Dulce Grazing Allotment to promote var. nicholii conservation. Livestock waters are currently located next to existing roads, but BLM will move or replace those that cause habitat impacts. BLM will place any future water developments in locations to move cattle outside of occupied areas with the intent to reduce or minimize any impacts (BLM 2013; Service 2012). However, any potential effects from livestock grazing, as well as bighorn sheep and other small mammals have not been fully evaluated and should be considered in a thorough threats assessment. (USFWS, 2019)

**Stressor:** Climate change (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change is considered a threat to var. nicholii due to effects from hotter temperatures and increased aridity (Service 2009). Climate change has resulted in some species shifting their range to higher elevation or higher latitude (Hannah et al., 2005; Chen et al., 2011). For southwestern plants, scientists are finding migration may occur in all directions depending on the species' ability to adapt, and having available, connected habitat (Stills et al., 2015; Krause and Pennington 2012; Notaro et al., 2012). Variety nicholii grows on mountain slopes that could presumably support more plants in the future if they remain cooler and soils retain more moisture than those on the valley floor. Alternatively, as temperatures and aridity increase, these exposed areas may become hotter, drier and ultimately unsuitable in the future. With the limiting presence of Horquilla limestone on a few mountain ranges, changes in the suitability and amount of available habitat for the taxon could cause dramatic reductions in its range. Gaining a better understanding of its adaptive capacity and conserving the distinct geographic areas where it occurs will allow opportunities for the taxon to endure into the future. (USFWS, 2019)

**Stressor:** Invasive plant species (USFWS, 2019)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In the 5-year Status Review, we identified the spread of invasive grass, Cenchrus ciliaris as a significant threat to var. nicholii habitat. Cenchrus ciliaris had expanded into a 7.2 ha (18 ac) area on the north side of Waterman Mountains, including a location near hundreds of var. nicholii increasing the fire risk (Service 2009). There have been recurrent efforts to control Cenchrus ciliaris by manual removal through various volunteer organizations (2005-2009) and BLM contracted annual herbicide sprayings (2008-2009). In 2010, the BLM organized a mechanical reshaping and contouring of the area that was followed by restoration efforts through 2012 (J. Scheuring, Friends of Ironwood Forest, pers. comm., 2013). Cenchrus ciliaris has been effectively brought under control through continued removal and spot treatment which eliminated its threat to nearby var. nicholii. In 2016, several var. nicholii seedlings were found growing in the restoration area. (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**
The criterion for downlisting to threatened status is permanent protection of 75 percent of the known habitat according to the steps outlined in the Recovery Plan. (USFWS, 1986)

Recovery Priority Number: 3

**Delisting Criteria:**
1. Conserve and protect all existing var. nicholii individuals and habitat for their pollinators (approximately a 600 meter (0.37 mi) radius around each plant) in three or more extant populations through land protection, land management actions, and restoration techniques (i.e., actions that enhance habitat quality, support increased germination, and establishment). Each var. nicholii population must have available habitat of sufficient quality and size for natural population dynamics and long-term expansion, to support a viable seed bank, as well as, habitat for pollinators, allowing pollen exchange within populations. Variety nicholii habitat is defined as areas that contain the appropriate geology, elevation, soil type, Sonoran Desert native plants and trees, native pollinators, with minimal ground disturbance and limited non-native invasive grass species. (USFWS, 2019)

2. Each var. nicholii population must be self-sustaining, with annual recruitment exceeding mortality over any 20 years of a 30-year period. Long-term monitoring every 3–5 years demonstrates that the annual total estimated population size among three or more extant populations is maintained at or greater than 3,700 individuals for a minimum of 20 years over a 30-year survey period. Threats must be managed so that populations can be maintained at target levels (a minimum of 3,700 total individuals) for a minimum of 20 years over the 30year period. Expected yearly fluctuations in plant abundance due to changes in precipitation, fire, or other causes, may result in two monitoring events during the time period that does not meet these targets. (USFWS, 2019)

3. Develop a long-term ex-situ (off-site) var. nicholii conservation program that includes maintenance of seeds for conservation and recovery at seed storage facilities, captive propagation, germination trials, guidelines for supplementing natural populations, and

postintroduction monitoring that demonstrates the introduced var. nicholii are fully functioning in their environment, including flowering, seed production, and survival. (USFWS, 2019)

**Recovery Actions:**

- Maintain, protect, and enhance natural populations. It is important and crucial to the preservation of the Nichol Turk's head cactus to protect populations in the wild. To do this, a continuing program of law enforcement, monitoring, and management must be implemented and coordinated among Federal agencies, the State of Arizona, and private individuals or organizations. (USFWS, 1986)
- Study populations in their natural habitat at existing sites. An in-depth knowledge of the plant's ecology and biology is needed to understand its habitat requirements. With this information, sound management decisions can be made and implemented to sustain healthy, natural populations. The use of a well documented and accessible living collection could provide a source of material for these types of studies. (USFWS, 1986)
- Develop a comprehensive trade management plan (CTMP) for all cacti. Prior to development of trade management strategies, studies are necessary to determine what species are in the trade, the overall trend of trade in listed cacti, the feasibility of reducing the collecting pressure on the wild populations by promoting a commercial artificial propagation program, and to determine strategies for effective implementation of law enforcement responsibilities of ESA, CITES, Lacey Act, and State laws. These studies should be national in scope and address all cacti. Completion of subtasks 31 through 34 will result in development of an FWS policy on the cactus trade problem and will allow the drafting of a CTMP. (USFWS, 1986)
- Develop public awareness, appreciation, and support for the preservation of the Nichol Turk's head cactus. Education of the public is a vital part of the recovery process. The cooperation of the public is essential for the ultimate success of the foregoing recovery measures. Public interest groups, especially local ones such as botanical gardens native plant societies, cactus societies, and The Nature Conservancy chapters need to be involved. The visibility of their support can be instrumental in shaping public opinion. Specific strategies would include lectures, pamphlets, letters, etc., concerning conservation of threatened and endangered plant species. (USFWS, 1986)
- Recommended Action from 2009 5-Year Review: The 1986 NTHC Recovery Plan should be revised to incorporate new information that has been gathered since it was finalized. The recovery criteria should be revised to address newly identified threats to the subspecies. Criteria for delisting should be established. Threats should be discussed relative to the five-factor analysis regarding their impact to the subspecies and its habitat (USFWS, 2009).
- Recommended Action from 2009 5-Year Review: Establish a systematic monitoring protocol to more effectively evaluate the status of the subspecies across its known range. Expand the area being monitored to include a larger sample size that is more representative of the Waterman Mountains population. Monitoring should be designed to establish long-term population trends and investigate effects of climate change (USFWS, 2009).
- Recommended Action from 2009 5-Year Review: Studies should be conducted to obtain the quantified data in order to support the recovery criteria using the best scientific and commercial data available. Studies should focus on: ecological factors that influence distribution, density-dependence issues, resource requirements for survival, seedling establishment and dispersal, pollination, demographic trends, population biology, and the amount and condition of suitable habitat (USFWS, 2009).

- Recommended Action from 2009 5-Year Review: Evaluate the genetics of this subspecies to better understand its evolutionary history and relationship to E. horizonthalonius, and to assess genetic variation within and between the populations. This information would provide a better understanding of its historical range and taxonomic classification (USFWS, 2009).
- Recommended Action from 2009 5-Year Review: Establish a cooperative partnership with OVIS and develop a conservation agreement to survey and (if found) study the cactus in the Sierra del Viejo Mountains in Sonora, Mexico (USFWS, 2009).
- Recommended Action from 2009 5-Year Review: The USFWS should coordinate cooperative agreements with the Tohono O'odham Nation and ensure that partnerships continue to help protect and conserve the cactus on Tribal land (USFWS, 2009).
- Recommended Action from 2009 5-Year Review: The USFWS should coordinate and establish cooperative partnerships with private landowners to implement conservation of the cactus on their land (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Our recommended future actions from the 2009 5-year Status Review remain relevant, and we provide those below with some modifications. We also recommend additional actions to improve our understanding of climatic changes on the status of the NTHC and address data needs to improve long-term species management decisions. 1. Understand trends in survival and mortality of individuals and populations. Cactus species are known to have recruitment events following sufficient precipitation; however, long-term monitoring of the NTHC demonstrates that its response to precipitation and higher temperatures are not as straightforward. With the persistent drought, it is important to continue to investigate demographic trends in order to tease out how mortality rates increase with variable climate patterns. 2. Expand the monitoring area to include a larger sample size that is representative of all populations. Locate demographic plots at sites differing in aspect and slope, and better reflect the representation and redundancy of the cactus. Explore other types of sampling methods (distant sampling transects) to compare information about demographics and changes in habitat. 3. Examine habitat suitability, including the taxon's ability to persist in all populations. Results would guide management decisions on important areas for enhancement or future recovery actions for the cactus' persistence in the future. 4. Conduct germination studies and captive propagation to support future re-establishment of plants in their native habitat, in the event we need to supplement the population or create refugia populations. 5. Evaluate the genetics of this subspecies to better understand its evolutionary history and relationship to E. horizonthalonius, and to assess genetic variation within and between the populations. This information would provide a better understanding of its historical range and taxonomic classification. 6. Invest and support studies examining other potential stressors (invasive grasses, herbivory, disease, and habitat disturbance) to the cactus. For example, placement of cameras and / or fencing could improve our understanding of the roll of herbivores in cactus decline. 7. The Service should continue to enhance and maintain our partnership with the Tohono O'odham Nation to cooperatively achieve long-term conservation of the NTHC on Tribal land. 8. Establish a cooperative partnership with private landowners in Sonora, Mexico that enables information exchange and advances conservation efforts to document, study, and protect the cactus. (USFWS, 2021)

# SPECIES ACCOUNT: *Echinocereus reichenbachii var. albertii* (Black lace cactus)

***Species Taxonomic and Listing Information***

**Commonly-used Acronym:** BLC

**Listing Status:** Endangered; 11/28/1979; Southwest Region (Region 2)

**Physical Description**

A spin succulent with solitary stems (or sometimes 5-12), the larger green, cylindroid, 7.5 - 15 cm long, 2.5 - 5 cm diam.; ribs about 12 to 18; areoles narrowly elliptic, 1.5 mm long vertically, typically 2 - 4.5 mm apart; central spines none or 1, 2 - 3 mm long, very dark purple, much smaller than the radials, but otherwise similar to them, straight (plants from Kleberg County were found that have well developed central spines, while they are weakly developed or absent in specimens from Jim Wells and Refugio Counties); radial spines white with dark purple tips, 14 - 16 per areole, closely pectinate, 3 - 4 (6) mm long, 0.2 - 0.35 mm diam., circular in cross section; flower 5 - 7.5 cm diam., 2 - 6 cm long; areoles of floral tube with conspicuous fine wool and weak spines; sepaloids with green midribs and pink margins; petaloids pink to light purple, largest oblanceolate, 2.5 - 3.5 cm long, + 9 mm broad, short acuminate, entire; filaments pale yellow or pink, + 9 mm long; anthers yellow, 1.5 mm long, oblong; style pink, 20 - 30 mm long, 1 - 2 mm greatest diam.; stigmas 16 - 20, green + 6 mm long, broad; ovary in anthesis + 9 mm long; fruit green (with pink tinge?) with short spines and soft conspicuous, deciduous, long wool in areoles, + 15 mm long, 9 mm diam.; seeds strongly tuberculate, asymmetrical, 1.5 mm long, 1 mm broad, 0.7 mm thick (Benson, 1982) (USFWS, 1986)

**Taxonomy**

The scientific name for BLC is Echinocereus reichenbachii (Terscheck) F. Haage var. albertii L.D. Benson. This variety was described from a specimen collected in 1965 in Jim Wells County (USFWS 1987). Some disagreement exists about the taxonomy of the group of Echinocereus with large pink flowers, and there are several synonyms for BLC, including E. melanocentrus (Lowry) and E. fitchii (Britton and Rose) subspecies albertii (L. D. Benson) W. Blum and Mich. Lange (Poole et al. 2007) (Table 2). Some cacti specialists lumped the BLC variety albertii with a very similar counterpart, E. reichenbachii var. fitchii. Blum et al (1998) recognized the taxon albertii but placed it within the species fitchii as a subspecies (E. fitchii ssp albertii). Others have called it a separate subspecies (Poole et al. 2007). There are distinct morphological differences between E. reichenbachii var. albertii and E. reichenbachii var. fitchii. Echinocereus reichenbachii var. fitchii has 4-7 central spines of a brownish-red color while the variety albertii (BLC) has 0-1 central spines (except the Refugio County population that lacks a central spine) and appears more blackish in coloration (Poole et al. 2007). These two varieties are also geographically disjunct, with E. reichenbachii var. fitchii occurring in thorn shrublands atop limestone soils, calcareous sandy loams, or saline clays in Jim Hogg, Starr, Zapata, and Webb Counties, and in Mexico, while E. reichenbachii var. albertii grows on sandy soils in Refugio, Jim Wells, and Kleberg Counties (Poole et al. 2007). Even with these distinctions, Zimmerman and Parfitt (2003) did not recognize any varieties of E. reichenbachii, in part due to the interfertile nature of the taxa, and also due to pure populations not existing sympatrically (Poole et al. 2007). Poole et al. (2007) pointed out that many geographically isolated taxa have not developed genetic barriers and therefore, when placed in contact with cacti of the same origin, can cross freely. (USFWS, 2009)

**Historical Range**

The historic range extends from east-central Jim Wells County on the most southwestern edge of the range to northeastern Kleberg County near Ricardo at the most southeastern point, and up to southern Refugio County at the most northern extent. This range encompasses parts of Jim Wells, Kleberg, Nueces, San Patricio, and Refugio Counties in south Texas (USFWS, 2009).

**Current Range**

Current range is Atascosa, Jim Wells, Kleberg, McMulen, and Refugio Counties in south Texas (USFWS, 2009).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect (USFWS, 2009)

**Breeding Season**

Adult: Flowers from March through June, with peak in mid-April to early May (USFWS, 2009).

**Key Resources Needed for Breeding**

Adult: Bees and wasps have been observed visiting flowers (USFWS, 2009).

**Reproduction Narrative**

Adult: Although pollinators have not been researched, bees and wasps have been observed visiting flowers (USFWS, 2009). Species is self-incompatible (USFWS, 1986).

**Habitat Type**

Adult: Terrestrial (USFWS, 1986)

**Habitat Vegetation or Surface Water Classification**

Adult: Openings in mesquite brush occurring along streams of the coastal plain (USFWS, 1986).

**Dependencies on Specific Environmental Elements**

Adult: Sandy loam or silt soil (USFWS, 1986)

**Geographic or Habitat Restraints or Barriers**

Adult: Elevation of 50 meters or less (USFWS, 1986)

**Environmental Specificity**

Adult: Very Narrow (USFWS, 1986)

**Habitat Narrative**

Adult: Terrestrial species; habitat is described as openings in mesquite brush occurring along streams of the coastal plain at 50 meters or less in elevation, in sandy loam or silt soil and in both level and poorly drained or sloped and well drained (USFWS, 1986).

***Dispersal/Migration***

**Motility/Mobility**

Adult: N/A

**Dispersal/Migration Narrative**

Adult: Seeds fall to the ground or are washed down by rainfall as the seed decomposes. Seed dispersal mechanisms are thought to be unspecialized, but native ants have been observed mining BLC seeds, carrying them back to their mounds, an discarding the seeds outside of the colony. Other seed-dispersal mechanisms may include fur-bearing mammals inadvertently picking up seeds in disperse seeds through their rooting activities (USFWS, 2009).

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2019)

**Species Trends:**

Declining (USFWS, 2019)

**Number of Populations:**

6 natural, 1 introduced (USFWS, 2019)

**Population Size:**

Uncertain (USFWS, 2019)

**Population Narrative:**

The 5-year review (USFWS 2009) indicates that six populations of black lace cactus have been found from east-central Jim Wells County to north-east Kleberg County to Refugio County (pp. 11–13). By 2009, only two extant populations were known, in Kleberg and Refugio counties. The status of the Jim Wells population, last observed in 1989, was unknown (p. 5). All extant and historic populations occurred on privately owned land (p. 4). At the Kleberg site, 43,441 individuals were reported in 1983 and 19,250 in 1985. A large portion of the site was cleared in 1986. Since then, 13,250 individuals were reported in 1987, 1,160 in 2001, and 824 in 2002. Similarly, 82,500 individuals were reported from the Refugio site in 1987 and 1,527 in 2004. The Jim Wells population had about 16,000 individuals in one sub-population in 1985; a second subpopulation was cleared, but about 48 individuals survived. Although these population censuses did not use consistent methods, and the relative numbers of juveniles and reproductive adults was not reported, all populations have apparently declined. (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Habitat destruction (USFWS, 1986)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** It is common practice in the region to clear brush tracts for cultivation for improved pasture with the planting of coastal Bermuda grass. Brush clearing has partly or completely destroyed three known populations and has recently occurred near several others. Land owners of presently known populations are apparently unaware of the cactus, so land improvements could destroy present populations without the land owners even knowing it (USFWS, 1986).

**Stressor:** Grazing by cattle (USFWS, 1986)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Grazing of natural brush tracts has a negative impact on populations. For the grazed population in Jim Wells County, it was observed that cattle trample plants in open ground with few plants surviving to maturity. The only cacti present were those protected by other vegetation (USFWS, 1986).

**Stressor:** Collection (USFWS, 1986)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Collecting is always a serious threat to any small desirable species of cactus, particularly when combined with large showy flowers as found in this species (USFWS, 1986).

**Stressor:** Predation or trampling (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Individual BLC plants have been uprooted by feral hogs and kicked over by cattle. However, no other severe disturbances caused by these mammals or other animals have been noted with the exception of the presence of red imported fire ants (RIFA). Some BLC individuals at the Refugio County site have been noted to be partially or entirely covered by mounds of RIFA. There is potential that these non-native ants could pose threats to the base or quite possibly the root system of the cacti. Also, RIFA may out-compete native ant species and potentially interfere with the role these natives play in seed dispersal. The level of threat to the continued existence of BLC due to feral hog rooting and cattle trampling is unknown, although observations at the Refugio County population site indicate that this type of impact occurs in a scattered manner (USFWS, 2009).

**Stressor:** Pesticide use to control insects (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Chemical eradication techniques used for the RIFA might also negatively affect natural pollinators of the species and/or native ants and could potentially contribute to an overall decrease in any treated BLC population (USFWS, 2009).

***Recovery***

**Reclassification Criteria:**
1. Black lace cactus is documented in 10 or more protected, viable populations, with at least three viable populations in each of three recovery units. Populations and metapopulations are delineated by unpopulated gaps of at least 1 km (0.6 mi). However, as described in Section III.a., viable populations that expand and merge with other populations may be counted as separate populations for the purpose of meeting this criterion. (USFWS, 2019)

2. Viable populations have 1,100 or more mature individuals. Mature individuals have flowered at least once or are judged capable of flowering. Population censuses should be conducted during the peak of flowering and fruiting, from mid-April through May. (USFWS, 2019)

3. Protected populations occur on lands that are legally protected and managed to conserve the region's native flora and fauna, including black lace cactus and its habitats. Examples include, but are not limited to, conservation easements on private lands, lands owned and managed for conservation by non-profit organizations, publicly owned land managed for conservation purposes, and legally binding long-term management agreements with private landowners. (USFWS, 2019)

**Delisting Criteria:**
Periodic monitoring indicates that the downlisting criteria have been met and that demographic trends have subsequently remained stable or have increased over a period of 25 years. (USFWS, 2019)

**Recovery Actions:**
- Remove threats to Echinocereus reichenbachii var. albertii populations by enforcement of existing regulations and management of the habitat for protection of the variety. Because of the rarity of this variety, it should be protected from collecting by enforcement of existing regulations and its habitat should be managed to ensure the continued existence of self-sustaining populations. (USFWS, 1986)
- Initiate studies on the ecology and population biology of the black lace cactus. In-depth knowledge of the population biology and ecology of the black lace cactus is needed. Some of this information may be critical to future management of the variety. (USFWS, 1986)
- Determine the genetic relationships among the three populations and between Echinocereus reichenbachii var. albertii and other closely related taxa. Knowing the level of classification of E. reichenbachii var. albertii is not so important as understanding its relationship to its closest relatives. Reliable characteristics that can be used to identify flowering or sterile specimens are essential for enforcement of trade regulations. Determination of the distinctness of the taxon is also imperative since considerable expenditures may be necessary to protect and maintain it in perpetuity. Genetic studies using isozymes and/or flavanoids combined with a thorough morphological analysis can provide evidence on the distinctness or indistinctness of the gene pool within or among the populations under study, and with populations of closely related taxa. (USFWS, 1986)
- Develop a comprehensive trade management plan for all cacti. Studies are needed to determine what species are in trade, the overall trend of trade in listed cacti, and the feasibility of reducing collecting pressure on wild populations by promoting a commercial, artificial propagation program. These studies should be national in scope and address all

cacti. The results will be used to develop policy and a comprehensive trade management plan for all cacti. Strategies for effective implementation of law enforcement responsibilities under ESA, CITES, Lacey Act, and State laws need to be developed. (USFWS, 1986)

- Develop cultivated stocks for commercial distribution. Cultivated stocks can be developed by authorized, responsible and/or licensed agencies, e.g., botanical gardens, universities, etc., for sale to licensed commercial distributors if information from the trade study indicates this is a practical method of reducing collecting pressure. Such trade will be subject to applicable Federal or State permits and reporting requirements. (USFWS, 1986)
- Determine delisting criteria. Before the variety can be downlisted to threatened, at least two of the three known populations should be established as safe sites. Criteria for delisting will be established only after the success of management at permanently protected populations can be evaluated and a search for additional populations has been conducted. (USFWS, 1986)
- Develop public awareness, appreciation, and support for preservation of the black lace cactus. The full recovery of the black lace cactus, and of other endangered species, depends on the attitude and support of the public. Educational materials and presentations should be used to gain public appreciation of the endan- gered species, and support for the program to save it. (USFWS, 1986)
- Recommended Action from 2009 5-Year Review: Thorough, systematic searches for new BLC populations are needed throughout the species' range. Potential habitat should be identified and surveyed, once landowner permission has been granted. Although saline soils underlie all three BLC sites, more indepth soils investigation at the known populations may help to further characterize specific soils and geologic properties that would aid in identifying areas in which to concentrate future population searches. In light of taxonomic controversy regarding the E. reichenbachii-fitchii complex, a thorough systematic review, including genetic studies of the species complex, should be conducted. (USFWS, 2009)
- Recommended Action from 2009 5-Year Review: Collaborative studies should be done to investigate life history requirements, including reproductive biology, and propagation techniques. Experimental studies need to address current and potential threats including impacts of insecticide on cacti pollinators and native seed dispersers such as ants and direct threats to BLC from non-native red imported fire ants, as well as from native insects. Feral hog activity levels within BLC populations should be monitored to ascertain the level of damage that occurs from uprooting of, and potentially from foraging on, BLC caused by these animals. In addition, the role of fire in the management of the species should be examined. (USFWS, 2009)
- Recommended Action from 2009 5-Year Review: All known populations of BLC exist on private lands. The Service and TPWD should pursue development of conservation plans with current landowners, along with investigating potential for permanent conservation easements. The assessment of appropriate conservation/management measures should be collaborative between landowners, resource agencies, and researchers. Evaluation of the species' status, degree of threats, and level of protection at known population sites is needed on a more frequent and regular basis. Landowners should be informed of new management strategies. (USFWS, 2009)
- Recommended Action from 2009 5-Year Review: Public education should be implemented to educate others about this endangered species and to protect the species from becoming a target of illegal take and distribution. Information about the regulations governing take and propagation of wild and nursery species for trade should be distributed to appropriate

partners. Refugia specimens should be grown and maintained to further aid in propagation studies and to enhance the ability of nurseries, botanical gardens, and the general public to identify the species, if encountered. (USFWS, 2009)

- Recommended Action from 2009 5-Year Review: The recovery plan for the species needs to be revised to incorporate all new information on biology, ecology, and management recommendations. Objective and measurable recovery criteria for down- and delisting of the species should be developed which also address all listing factors relevant to the species. (USFWS, 2009)

# SPECIES ACCOUNT: *Enceliopsis nudicaulis var. corrugata* (Ash Meadows sunray)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

Enceliopsis nudicaulis var. corrugata is a perennial plant in Asteraceae (sunflower family) that forms clumps 3.9 to 15.7 inches (in) (10 to 40 centimeters (cm)) high that rise from a stout, woody root-stock (Mozingo and Williams 1980, p. 21). The varietal name corrugata refers to leaf margins that are strongly ruffled-corrugate, especially towards the margins (Cronquist 1972, p. 246; Mozingo and Williams 1980, p. 21). The ray flowers are yellow and number 11 to 23. (USFWS, 2011)

**Historical Range**

See current range/distribution.

**Current Range**

Enceliopsis nudicaulis var. corrugata is endemic to the Ash Meadows area of Nye County, Nevada. The range of E. nudicaulis var. corrugata encompasses the Ash Meadows National Wildlife Refuge (Refuge) and adjacent Bureau of Land Management's (BLM) Ash Meadows Area of Critical Environmental Concern (ACEC) and private lands. (USFWS, 2011)

**Critical Habitat Designated**

Yes; 5/20/1985.

**Legal Description**

On May 20, 1985, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Enceliopsis nudicaulis var. corrugata (Ash Meadows sunray) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat units (CHU), in Nevada (50 FR 20777-20794).

**Critical Habitat Designation**

The critical habitat designation for Enceliopsis nudicaulis var. corrugata includes one CHU in Nye County, Nevada (50 FR 20777-20794).

Nevada, Nye County, Ash Meadows.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Enceliopsis nudicaulis var. corrugata critical habitat consists of one component (50 FR 20777-20794):

Known primary constituent elements include dry washes or whitish saline soil associated with outcrops of pale whitish limestone.

***Life History***

**Food/Nutrient Resources**

**Dependency on Other Individuals or Species**

Adult: Enceliopsis nudicaulis var. corrugata flowers attract at least 21 floral visitors, 19 which are bee taxa (BIO-WEST 2009, pp. 2-5). (USFWS, 2011)

**Breeding Season**

Adult: March to May (USFWS, 2011)

**Reproduction Narrative**

Adult: Inflorescence buds begin developing in February and flowers open from late March to late May (Mozingo and Williams 1980, p.21; Pavlik and Moore 2010, p. 51). Enceliopsis nudicaulis var. corrugata flowers attract at least 21 floral visitors, 19 which are bee taxa (BIO-WEST 2009, pp. 2-5). In 2008, the average E. nudicaulis var. corrugata plant output was 12.7 inflorescences and 11.5 infructescences; while in 2009, plant output averaged 18.5 inflorescences and 15.5 infructescences (Pavlik and Moore 2010, p. 52). Inflorescences that developed earlier in the season produced significantly more seeds than those developing later (Pavlik and Moore 2010, p. 52). Plants approximately produced 17.4 mature seeds per bud (Pavlik and Moore 2010, p. 88, Table 16). (USFWS, 2011)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Alkali shrub-scrub, salt desert scrub, desert pavement, pale limestone outcrops, dry washes, spring and seep areas (USFWS, 2011)

**Geographic or Habitat Restraints or Barriers**

Adult: Found at elevations between 617 to 719 m (2,200 to 2,360 ft) (USFWS, 2011)

**Environmental Specificity**

Adult: Narrow/specialist

**Habitat Narrative**

Adult: Enceliopsis nudicaulis var. corrugata occurs between 2,200 and 2,360 feet (ft) (671 and 719 meters (m)) above mean sea level and occurs across a broad range of Refuge habitats including occasionally moist alkaline soils, spring and seep areas, and dry desert washes (Morefield 2001, p. 1; BIO-WEST 2011, p. 113). Enceliopsis nudicaulis var. corrugata most often occupies intermittently flooded to upland mesic Alkali Shrub-Scrub habitat in alkali-clay soil and is occasionally a component of Salt Desert Scrub and Desert Pavement (embedded, tightly packed gravel) habitats (BIO-WEST 2011, p. 113). (USFWS, 2011)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**
Not available

**Number of Populations:**
30 (USFWS, 2011)

**Population Size:**
79,508 (USFWS, 2011)

**Adaptability:**
Low (inferred from USFWS, 2011)

**Population Narrative:**
Results from the 2008-2010 Refuge wide survey (BIO-WEST 2011, p. 114) estimate that 79,508 individuals are present on the Refuge in 30 minimum scale occurrences (0.1 mi (0.16 km) distance) or 1 maximum scale occurrence (0.6 mi (1 km) distance). (USFWS, 2011)

***Threats and Stressors***

**Stressor:** Groundwater withdrawal (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Refuge encompasses over 23,000 ac (9,172 ha) of spring-fed wetlands and alkaline, desert uplands. More than 50 seeps and springs occur on the Refuge. At the time of listing, groundwater withdrawal was a major threat to the entire Ash Meadows ecosystem. Local groundwater pumping at Ash Meadows (prior to the establishment of the Refuge) was responsible for the destruction of many populations of plants and animals and their wetland habitats. Enceliopsis nudicaulis var. corrugata depends on near-surface water for its survival; therefore, it is reasonable to conclude that additional declines in groundwater levels in the Ash Meadows area (e.g., due to groundwater pumping) would negatively affect populations of this species. A number of measures have been implemented since the 1970’s that, in part, have reduced the risk of groundwater level declines at the Refuge. The significance of the remaining threat posed by groundwater pumping will be evaluated below with respect to each of these measures. (USFWS, 2011)

**Stressor:** Road construction (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, Enceliopsis nudicaulis var. corrugata population numbers had been reduced by the loss of habitat from road construction. Since listing, the Service has ceased road construction and maintains only defined Refuge roads that allow for administrative, visitor, and private landowner access. Truckers often use Refuge roads to avoid the need to obtain permits required to transport loads through California (Service and DOT 2011, p. 27). A

transportation study is being completed by the Refuge to identify transportation improvements and management strategies, improve safety, reduce operations and maintenance costs, ensure accessibility, and address traffic circulation needs (Service and Department of Transportation (DOT) 2011, pp. 1-98). Due to ceased road construction and initiation of a transportation study, road construction is no longer a threat to Enceliopsis nudicaulis var. corrugata. (USFWS, 2011)

**Stressor:** Off-highway vehicle (OHV) activity (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Prior to listing, OHV activity was a threat to Enceliopsis nudicaulis var. corrugata. OHV races were permitted on BLM land in the Ash Meadows area. Since listing, OHV activity is prohibited on the Refuge and has been limited by the construction of fencing around the perimeter of the Refuge in 1995 (Service 2006, pp. 9, 103). Periodically, illegal OHV activity, likely due to downed sections of fencing and fence cutting, occurs on the Refuge (Baldino, pers. comm. 2010). Within the BLM ACEC, OHV activity is confined to existing roads, trails, and dry washes (BLM 1998a, Chapter 2 p. 2-32; Map 2-10). Signs and fences are not present to designate the BLM ACEC from the other bordering BLM land, making it unclear to the public that the BLM land surrounding the Refuge has a special ACEC designation (Baldino, pers. comm. 2010). Due to the periodic illegal OHV activity on the Refuge and undefined ACEC designation, OHV activity is still a threat to Enceliopsis nudicaulis var. corrugata. (USFWS, 2011)

**Stressor:** Trampling by resident wild and free-roaming horses (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The final listing rule described trampling by wild and free-roaming horses as a threat to Enceliopsis nudicaulis var. corrugata. Since then, in 1995, a fence was constructed around the perimeter of the Refuge (Service 2006, pp. 9, 103). As a result, wild horse activity on the Refuge was stopped. In 1998, the BLM established the Ash Meadows ACEC that surrounds the Refuge and established the appropriate management level (AML) for wild horses as zero (BLM 1998b, p. 7 Table 2-5). Fences are not present to keep horses out of the designated ACEC and they have been seen infrequently near the area (Baldino, pers. comm., 2011). Thus, inspection and maintenance of the exclusionary fence on the Refuge is necessary to prevent re-invasion (Service 2006, p. 99). Due to these positive management practices, trampling by wild and freeroaming horses is no longer a threat to E. nudicaulis var. corrugata on the Refuge, but occasionally may be a threat to E. nudicaulis var. corrugata within the BLM ACEC. (USFWS, 2011)

**Stressor:** Non-native plant species (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since listing, non-native plants species have been identified as a threat to Enceliopsis nudicaulis var. corrugata. An estimated 42 percent of all species listed under the Act are considered to be at risk primarily due to non-native species (Pimental et al. 2005, p.1). Non-native plants directly compete with native plants for water, nutrients, and sunlight and indirectly by altering ecosystem processes such as hydrology, productivity, nutrient cycling, and fire regime (D’Antonio and Vitousek 1992, pp.63-87; Levine et al. 2003, pp. 775-781; Brooks et al. 2004,

pp.677-688). Approximately 100 non-native species occur on the Refuge; 66 of them non-native plant species (Service, 2006, p. 7, pp. 52-53). Of these Tamarix ramosissima Ledeb. (saltcedar), Acroptilon repens (L.) DC. (Russian knapweed), Bassia hyssopifolia (Pall.) Kuntz (fivehorn smotherweed), Centaurea melitensis L. (Malta starthistle), and Bromus rubens L. (red brome) could potentially threaten E. nudicaulis var. corrugata. (USFWS, 2011)

**Stressor:** Wildfire (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since listing, nine wildfires have burned on the Refuge (Sunderman and Weisburg 2011, p. 3). The three largest wildfires (Fairbank fire in 2000 which was 744 ac (301 ha); Longstreet fire in 2004 which was 1,401 ac (567 ha); and Meadows fire in 2005 which was 267 ac (108 ha) were all partially in Enceliopsis nudicaulis var. corrugata habitat and burned prior to initiation of weed treatments in non-native plant species patches of Tamarix ramosissima. Non-native plant species alter ecosystem dynamics such as fire regimes. For example, on the Refuge, Bromus rubens is an annual, nonnative grass, that could increase its dominance on the landscape under climate change predictions. In turn, this would increase the density of fine fuels and create an environment more susceptible to fire (Chambers and Pellant 2008, p. 31). With the exhaustion of SNPLMA funding for non-native plant species treatments and opportunity for them to re-invade, wildfire frequency may increase through alteration of the fire regime. In addition, non-native plant species such as Bromus rubens could invade sparsely vegetated Enceliopsis nudicaulis var. corrugata habitat, thus providing a vector to carry fire into a habitat that may have less tendency to burn. The threat of wildfire is not easily accessed and is dependent on many other factors, thus we conclude that it is a potential threat to E. nudicaulis var. corrugata. (USFWS, 2011)

**Stressor:** Surface mining (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Refuge is located in the Ash Meadows mining district (Tingley 1998, p. 20), which has the largest clay production of any district in Nevada (BLM 1998a, p. 3-75). At the time of listing, surface mining was identified as a threat to two other listed plant species, Grindelia fraxinopratensis and Astragalus phoenix. Surface mining also poses a threat to Enceliopsis nudicaulis var. corrugata which co-occurs in many places with A. phoenix. Currently, only mining for clay minerals occurs in the Ash Meadows area. The playa sediments covering much of the Refuge contain clays and other minerals that could be classified as locatable minerals under the Mining Law of 1872, as amended (BLM and Service 2000, p. 3-1). Under the Mining Act of 1872, surface disturbance and impacts to rare species that do not have Federal protection are permissible as long as operations comply with all pertinent Federal and State laws. New mineral claims and mining could cause direct loss of E. nudicaulis var. corrugata habitat as well as indirect impacts due to diverting or draining water from occupied habitat. (USFWS, 2011)

**Stressor:** Solar development (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Since listing, solar development has been identified as a threat to Enceliopsis nudicaulis var. corrugata, specifically due to impacts from groundwater withdrawal. The Amargosa Valley has been selected as a Solar Energy Zone (SEZ) to be evaluated for its environmental and resource sustainability for larger-scale solar energy production (Department of Interior (DOI), 2009, p. 1). The Refuge is located about 20 mi (32 km) southeast of the SEZ (DOE/EIS 2010, pp. 11.1-21). The SEZ is a proposed area of 31,625 acres (12,798 ha) and maximum solar development of this area is assumed to be 80 percent over a period of 20 years on 25,300 ac (10,239 ha) (DOE/EIS 2010, pp. 11.1-1 to 11.1-3). In November 2010, the BLM approved the construction of the first solar project in the SEZ: Solar Millennium, LCC on Amargosa Farm Road. This project is on 6,320 ac (2,558 ha) of land and will use dry-cooled technology. Total annual operational water usage is 400 ac-ft (493,393 m3) per year, but will require 600 ac-ft (740,089 m3) a year during construction (BLM 2010b, p.4; Service 2010a, p. 4). Application 79699 is an application for a change in the manner of use and place of use of 400 afy under existing Permit 15893 (Certificate 5717). Changing the use of 400 ac-ft (493,393 m3) per year of water from irrigation to industrial use for this solar project and the solar projects that will follow is likely to have an impact on the groundwater supply. Agricultural water use allows some water to percolate back into the groundwater system (return flow). Water used for industrial utility-scale solar energy production likely will evaporate and not recharge to the aquifer. Additionally, no significant return flow is anticipated from solar mirror washing operations or other water uses given the average low humidity and high temperatures in the Mojave Desert. Small declines in spring discharge, changes in water temperature, and adjustments in soil or water chemistry resulting from solar projects groundwater withdrawals in the basin would negatively affect Enceliopsis nudicaulis var. corrugata. (USFWS, 2011)

**Stressor:** Predation (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Pavlik and Moore (2010, pp. 38, 52) noted that both jackrabbit (Lepus californicus) and insect herbivory had a dramatic effect on E. nudicaulis var. corrugata. 6.7 percent of marked E. nudicaulis var. corrugata plants in 2008 and 51.7 percent of marked E. nudicaulis var. corrugata plants in 2009 had inflorescences removed by jackrabbits, as evidenced by droppings around affected plants (Pavlik and Moore 2010, p. 52). In addition, insect achene predators severely damaged 91.7 percent of infructescences in 2008 and 78.3 percent of infructescences in 2009 (Pavlik and Moore 2010, p. 52). (USFWS. 2011)

**Stressor:** Stochastic events (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Small, endemic populations with limited geographic distribution like Enceliopsis nudicaulis var. corrugata have a higher risk of extinction due to demographic and environmental uncertainty and natural catastrophes (Shaffer 1987, pp. 69-75; Lande 1993, pp. 911-927). Enceliopsis nudicaulis var. corrugata is known only from the Ash Meadows area. All mapped occurrences of E. nudicaulis var. corrugata are restricted to the Refuge. Drought and wildfire are the most likely stochastic events that could adversely affect E. nudicaulis var. corrugata, as this species is dependent on groundwater and moisture retained in the soil and susceptible to being destroyed by a single, large fire. We conclude that stochastic events are a threat to E. nudicaulis

var. corrugata. (USFWS, 2011)

**Stressor:** Climate change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Enceliopsis nudicaulis var. corrugata is dependent on the springs and seeps of the Refuge. The potential effects of climate change on the regional aquifer system that supports E.nudicaulis var. corrugata are unclear. Current climatic models are predicting warmer air temperatures due to elevated levels of atmospheric carbon dioxide and increased drought and flood frequency (Intergovernmental Panel on Climate Change (IPCC) 2007, pp. 2-3). Other effects of climate change include, but are not limited to, changes in types of precipitation (Knowles et al. 2006, p. 4557), earlier spring run-off (Stewart et al. 2005, p. 1152), longer and more intense fire seasons (Chambers and Pellant 2008, pp. 31-32), increases in exotic species invasions (Hawkins et al. 2008, p. 37; Bradley et al. 2010, pp. 310-318), and more frequent extreme weather events (IPCC 2007, p. 13). The springs and surface streams that support Enceliopsis nudicaulis var. corrugata are perennial and originate from a regional aquifer that includes runoff from the Spring Mountains approximately 100 mi (161 km) northeast (USGS 2003, pp. 7-9). As a result of warming, more winter precipitation is falling as rain, and has altered spring stream flow. Snowmelt driven stream flow in spring is about 10 to 15 days earlier than 50 years ago, which increases the frequency of drought by decreasing groundwater recharge and summer water reserves (IPCC 2007; Chambers and Pellant 2008, p. 30). Increasing temperatures and drought frequency could adversely affect Enceliopsis nudicaulis var. corrugata by causing physiological stress, altering phenology, reducing recruitment events and seedling establishment, and altering fire frequencies. At this time, it is difficult to predict local climate change impacts to E. nudicaulis var. corrugata; thus, while the information indicates that climate change has the potential to affect and threaten its ecosystem in the long-term, there is much uncertainty regarding the attributes that could be affected and their timing, magnitude, and rate of change. (USFWS, 2011)

***Recovery***

**Reclassification Criteria:**
1. All non-native animals and plant species must be eradicated from essential habitat. These non-native species currently include sailfin mollies, mosquitofish, largemouth bass, black bullheads, bullfrogs, crayfish, turban snails, wild horses, salt cedar, and Russian olive. (USFWS, 2011)

2. Secure and protect the Ash Meadows aquifer so that all spring flows return to historic discharge rates, and the water level in Devil’s Hole is maintained at a minimum level of 1.4 feet below the copper washer. (USFWS, 2011)

3. The essential habitat must be secure from detrimental human disturbances including mining, OHVs, and introduction of non-native species. (USFWS, 2011)

Recovery Priority Number: 9

**Delisting Criteria:**
1. Criteria shown above for downlisting from endangered to threatened. (USFWS, 2011)

2. Secure, protect, and maintain in natural vegetation corridors and adjacent buffer areas for gene flow and dispersal of listed plants within the essential habitat. (USFWS, 2011)

3. Native plant communities and aquatic communities have been reestablished to historic structure and composition within all essential habitats. (USFWS, 2011)

4. All of the listed plant species and the four candidate plants species are present in all the sites that they have historically occupied as identified in Appendix A, Table XV, and within each critical habitat unit, the listed plant has a frequency value equal to or greater than the frequency value determined by Task 644 needed as an indicator of a self-sustaining plant population. (USFWS, 2011)

**Recovery Actions:**
- Secure habitat and water sources for the Ash Meadows ecosystem. (USFWS, 1990)
- Conduct research on the biology of the species. (USFWS, 1990)
- Conduct management activities within essential habitat. (USFWS, 1990)
- Reestablish populations/monitor new & existing populations. (USFWS, 1990)
- Determine/verify recovery objectives. (USFWS, 1990)
- The Recovery Plan should be updated using the most recent and best scientific management information available. (USFWS, 2011)
- Surveys for Ash Meadows threatened and endangered plant species, including Enceliopsis nudicaulis var. corrugata, should be performed in the BLM ACEC to determine species occurrences and habitat locations. In addition, habitat surveys around roads, trails, and dry washes will verify the impact OHV activity has on this species population. (USFWS, 2011)
- Research on the life history strategies of Enceliopsis nudicaulis var. corrugata should be prioritized. Research should focus on demography, recruitment events, and seed longevity in the seed bank. (USFWS, 2011)
- Seed from all listed plant species, including Enceliopsis nudicaulis var. corrugata, on the Refuge should be collected and stored for ex situ conservation. Ex situ studies of seed and seedling biology should be conducted to enhance germination and propagation techniques. (USFWS, 2011)
- Additional research is needed on the sensitivity and requirements of the species on groundwater and soil moisture throughout the growing season. (USFWS, 2011)
- The Refuge is implementing many restoration projects that could benefit Enceliopsis nudicaulis var. corrugata; however minimal monitoring specific to listed plants is conducted. To document recovery of listed plants, these projects should include pre and post site sampling to verify and quantify the restoration actions as benefiting the species. (USFWS, 2011)
- Environmental analyses on new solar projects in Amargosa Valley should include detailed assessments of the potential effects on the springs and groundwater table within the Refuge. The Service should participate in the review of these documents to ensure that they adequately disclose all potential impacts to Enceliopsis nudicaulis var. corrugata and the Ash Meadows ecosystem. (USFWS, 2011)
- Long-term funding should be secured for long-term non-native plant species treatments on the Refuge. (USFWS, 2011)

- Mineral rights should be purchased or transferred for perpetuity to the Service or a program needs to be established to renew the mineral withdrawal every 20 years. In addition, existing mining claims should be acquired whenever possible. (USFWS, 2011)
- Property and rights, such as conservation easements, should be acquired on private property that likely contains listed plant species. (USFWS, 2011)
- Research and develop a jackrabbit exclusion study to determine the impacts jackrabbits are having on reproduction of Enceliopsis nudicaulis var. corrugata. If a significant affect to E. nudicaulis var. corrugata is found, a jackrabbit control plan should be established. (USFWS, 2011)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: (optional, but may be helpful to identify priorities for management actions and information needs for next 5-year review) 1. Monitor compliance with the January 12, 2018 Nevada Revised Statute Order 1197A, Curtailment of New Appropriations of Groundwater within the Amargosa Valley Hydrographic Basin 230, to ensure groundwater levels in Devils Hole can support the population. Order 1197 is no longer in effect. Water levels in Devils Hole are affected by pumping centers in Amargosa Desert and the Ash Meadows groundwater basins (Halford and Jackson 2020); 2. Collaborate with the Ash Meadows NWR to implement the Desert National Wildlife Refuge Complex – Ash Meadows, Desert, Moapa Valley, and Pahranagat National Wildlife Refuges Final Comprehensive Conservation Plan and Environmental Impact Statement, Volume I – August 2009 (Service 2009) and also the Draft Ash Meadows Natural Resource Management Plan in review (Service, 2020); 3. Support Ash Meadows sunray (Enceliopsis nudicaulis var. corrugata) research at the Ash Meadows NWR to monitor the population as identified in the Recovery Plan for the Endangered and Threatened Species of Ash Meadows (Service 1990); and 4. Monitor the future activity of mineral rights in the Ash Meadows area. The BLM ACEC surrounding the refuge is withdrawn from mining and entry until 2029 (PLO# 7737, signed November 2nd, 2009), but requires renewal every 20 years. Mining can still occur on private inholdings within the refuge, but no active mining permits exist at this time. (USFWS, 2020)

# SPECIES ACCOUNT: *Eremalche kernensis* (Kern mallow)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

Annual herb, with erect stem about two to four inches high; white to rose-pink or lavender hollyhock-like flowers (Fish and Wildlife Service 1990). (NatureServe, 2015)

**Taxonomy**

Treated as Eremalche kernensis by some, including the USFWS. The distinctiveness of this taxon is in question (Roxanne Bittman, California Natural Diversity Database, June 2000). (NatureServe, 2015)

**Historical Range**

See current range/distribution.

**Current Range**

California endemic, occurring only in Kern County (Skinner 1997). (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Habitat Type**

Adult: Grasslands (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Inhabits chenopod scrub, valley and foothill grassland; 70-1000 m (Skinner 1997). (NatureServe, 2015)

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

6 - 20 (NatureServe, 2015)

**Population Narrative:**

Known from fewer than twenty occurrences (Skinner 1997). (NatureServe, 2015)

***Threats and Stressors***

**Stressor:** Climate change (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change is a potential threat to E. kernensis. It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects (USFWS, 2013).

**Stressor:** Effects of nitrogen deposition (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Nitrogen is considered a limiting factor in the soils of many terrestrial ecosystems. Nitrogen deposition "hotspots" have been identified downwind of large and expanding metropolitan centers and large agricultural operations in California. Increased soil nitrogen from anthropogenic sources such as automobile exhaust, can lead to increased plant productivity in Nlimited soils. In areas where non-native nitrophilic (i.e., nitrogen-loving) plants have been introduced (such as Bromus madritensis ssp. rubens or red brome), this increased productivity can result in competitive exclusion, whereby the faster growing nitrophilic species out-compete the native vegetation. Smaller-statured forbs (like E. kernensis) can be particularly vulnerable. The increased productivity of non-native annual grasses can also lead to increased fire frequency due to the build-up of fuel. The habitats in which Eremalche kernensis occurs are not fire-adapted, and the native vegetation does not recover quickly after burning (USFWS, 2013).

**Stressor:** Grazing and competition (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Grazing and competition from non-native plant species are threats to the species, although grazing, when done appropriately, may be an important tool in eliminating competition from both non-native and native competitors of Eremalche kernensis(USFWS, 2013).

**Stressor:** Habitat destruction and modification (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Threats to habitat of Eremalche kernensis include conversion to agriculture (including grazing) and urbanization (on privately owned lands); the occurrences on public lands are protected from direct effects of urbanization and agricultural land conversion, but in some areas are still subject to other threats including oil and gas exploration and conveyance, solar power developments, off-road vehicle use and mineral exploration and extraction (USFWS, 2013).

**Stressor:** Potential loss of pollinators (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** While it is unknown whether honeybees specifically function as pollinators of E. kernensis, if the causes of colony collapse disorder result in a decline in any E. kernensis pollinators, the species' genetic diversity could be further reduced (USFWS, 2013).

***Recovery***

**Reclassification Criteria:**
1. Secure and protect specified recovery areas from incompatible uses: a. 95% of occupied habitat on public lands; b. 75% of population and 75% of occupied habitat in Lokern. 2. Management Plan approved and implemented for recovery areas in the Lokern Area that include survival of the species as an objective. 3. Population monitoring in specified recovery areas shows stable or increasing populations through a precipitation cycle. (USFWS, 2020)

**Delisting Criteria:**
1. Secure and protect specified recovery areas from incompatible uses: a. 90% or more each of population and occupied habitat in Lokern; b. Two or more distinct populations outside the Lokern Natural Area. 2. Management Plan approved and implemented for all protected areas that include survival of the species as an objective. 3. Population monitoring in specified recovery areas shows no decline after downlisting. If declining, determine cause and reverse trend. (USFWS, 2020)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: The following recommendations for future actions are from the 2013 five-year review, scientific literature, and as a result of discussions with species experts. 1. Conduct more robust genetic testing to determine the distinction between Kern mallow (Eremalche parryi ssp. kernensis) and the closely-related Parry's mallow (Eremalche parryi ssp. parryi). 2. A comprehensive evaluation should be completed for all known occurrences (both extant and extirpated). The site-specific evaluation should include, at minimum, whether the species is present, estimated population/occurrence extent, extent of suitable habitat, and an in-depth analysis of threats at that location. Field surveys for the evaluation should be timed for favorable conditions, such as in the first wet year following a drought. 3. Conduct yearly surveys utilizing a standardized methodology to determine trends in the range-wide status of the species as well as population/occurrence abundance. 4. Monitor known populations of Kern mallow during multiple precipitation/drought cycles to gain a better understanding of the ecology of the species and how it interacts with grazing and with other species (both native and non-native). (USFWS, 2020)

# SPECIES ACCOUNT: *Eriastrum densifolium ssp. sanctorum* (Santa Ana River woolly-star)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 09/28/1987; California/Nevada (Region 8) (USFWS, 2015)

**Physical Description**

Eriastrum densifolium subsp. Sanctorum is a subshrub occasionally reaching 1 m (3.3 ft) in height. Plants have gray-green stems and leaves. The light gray-green leaves generally curve upward. The leaves are irregularly divided to the midrib in 2 to 6 narrow lobes and are up to 50 mm (2 in) long (Patterson 1993, p. 826). The bright blue funnel-shaped flowers are usually longer than 25 mm (1.0 in), but may be up to 30 mm (1.4 in) long or occasionally as short as 20 mm (0.8 in). The petals of the flowers (corolla) are lavender-blue becoming pinkish-purple with age (Munoz 1991). The congested inflorescences (flower stalks) contain 20 flowers each. The seeds are contained in capsules. (USFWS, 2010)

**Taxonomy**

Four other subspecies of Eriastrum densifolium have been recognized. A key feature that distinguishes E. d. subsp. Sanctorum from other subspecies is the length of the tube forming the base of the corolla that is up to 30 mm (1.2 in); corolla tube lengths in the other subspecies do not exceed 20 mm (0.8 in) (Patterson, 1993). (USFWS, 2010)

**Historical Range**

Historically, E. d. subsp. sanctorum occupied about 110 km (60 mi) of habitat along the Santa Ana River from elevations of about 150 m (500 ft) in the vicinity of Santa Ana Canyon in Orange County up to about 600 m (2,000 ft) at the base of the San Bernardino Mountains, through Riverside County (USFWS 1987, p. 36266). Eriastrum densifolium subsp. sanctorum may have occupied alluvial fan sage scrub habitats in Orange County as far downstream as Santiago Canyon (Craig 1934, p. 390; Mason 1945, p. 75; Zembal and Kramer 1984, p. 2). The subspecies is considered extirpated from Orange County and Riverside County (Zembal and Kramer 1985, p. 3; USFWS 1987, p. 36268). At listing, Eriastrum densifolium subsp. sanctorum occurred in isolated stands along the Santa Ana River in San Bernardino County between 360 and 600 m (1,200 and 2,000 ft) in elevation. (USFWS, 2010)

**Current Range**

Eriastrum densifolium subsp. sanctorum is endemic to the Santa Ana River drainage of southern California. Since listing, 12 new occurrences were detected, and Eriastrum densifolium subsp. sanctorum was also rediscovered within Riverside County just downstream of the border with San Bernardino County. (USFWS, 2010)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (self-incompatible) (USFWS, 2010)

**Lifespan**

Adult: 5 to 10 years (USFWS, 2010)

**Dependency on Other Individuals or Species**

Adult: Many species of insects and birds visit Eriastrum densifolium subsp. sanctorum flowers, but pollination is effected by comparably few of these. The primary pollinators include the solitary digger bee (Micranthophora flavocincta), giant flower-loving fly (Rhaphiomidas acton subsp. acton), California bumblebee (Bombus californicus), white-lined sphinx moth (Hyles lineata), black-chinned hummingbird (Arhilochus alexandri), and Anna's hummingbird (Calypte anna) (Muñoz 1991, p. 59). (USFWS, 2010)

**Breeding Season**

Adult: May to August (USFWS, 2010)

**Reproduction Narrative**

Adult: Eriastrum densifolium subsp. sanctorum flowers between May and August but most heavily in June (Muñoz 1991, p. 22). In artificial crossing experiments, self-pollination produced negligible fruit or seed set, indicating that E. d. subsp. sanctorum is self-incompatible (Muñoz 1991, p. 9; Brunell 1999, p. 250). Many species of insects and birds visit Eriastrum densifolium subsp. sanctorum flowers, but pollination is effected by comparably few of these. The primary pollinators include the solitary digger bee (Micranthophora flavocincta), giant flower-loving fly (Rhaphiomidas acton subsp. acton), California bumblebee (Bombus californicus), white-lined sphinx moth (Hyles lineata), black-chinned hummingbird (Arhilochus alexandri), and Anna's hummingbird (Calypte anna) (Muñoz 1991, p. 59). Eriastrum densifolium subsp. sanctorum plants have an average life span of approximately 5 years with some plants surviving at least 10 years (Burk et al. 1998, p. 21). (USFWS, 2010)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Chaparral, coastal scrub (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Flooding provides habitat and seed dispersal (USFWS, 2010)

**Geographic or Habitat Restraints or Barriers**

Adult: Prefers low annual cover, well-lighted areas with slight surface disturbance; found at elevations below 600 m (2,000 ft) (USFWS, 2010)

**Spatial Arrangements of the Population**

Adult: Patchy (USFWS, 2010)

**Environmental Specificity**

Adult: Very narrow. Specialist or community with key requirements scarce. (NatureServe, 2015)

**Habitat Narrative**

Adult: Eriastrum densifolium subsp. Sanctorum thrives in open, well-lighted areas of sand alluvial terraces, where shrublands persist between infrequent flood events (Zembal and Kramer 1984, p. 8; Wheeler 1988, p. 3; Burk et al. 1998, p. 20). The perennial vegetative cover is relative low (seldcom over 50%); annual cover is also fairly low (Zembal and Kramer 1984, p. 4). This species is found in disjunct stands within this habitat and tends to occupy areas with slight disturbance (Zembal and Kramer 1984, p. 4). Eriastrum densifolium subsp. sanctorum is known to occur patchily on the higher floodplain terraces. E. d. ssp. sanctorum colonizes washed sand deposits created by sporadic stream flow action and its habitat is maintained by periodic flooding, scouring, and sediment deposition (Wheeler 1998, p. 16). It thrives in nutrient poor sands of early seral stage habitat that have more than 97% sand particles. Eriastrum densifolium subsp. austromontanum occurs at elevations from 1,200 to 1,800 m (4,000 to 8,000 ft). Most commonly associated perennial plants include Eriogonum fasciculatum, Eriodictyon trichocalyx, Croton californicus, and Lepidospartum squamatum (Zembal and Kramer 1985). (USFWS, 2010)

***Dispersal/Migration***

**Dispersal**

Adult: Typically low, but may be high during flooding events (USFWS, 2010)

**Dispersal/Migration Narrative**

Adult: Dispersal of Eriastrum densifolium subsp. sanctorum seed is limited in the absence of flooding. The majority of seeds fall within 0.3 m (1 ft) of the parent plant and the wetted seed coat forms a mucilaginous mass that readily attaches the seed to the surrounding soil particles (Burk et al. 1989, p. 21). Those seeds not immediately shed from the fruits are retained within capsules that may remain on the plant for several seasons (Wheeler 1991, p. 116). In times of flooding, seeds or capsules may be transported down the floodplain for some distance, thereby facilitating some gene flow between populations. (USFWS, 2010)

***Population Information and Trends***

**Population Trends:**

Long-term trends indicate a rapid decline of 70 to 90%, while short-term trends suggest a decline of 50 to 70% (NatureServe, 2015)

**Number of Populations:**

23 occurrences (USFWS, 2010)

**Population Narrative:**

There are currently 23 extant or presumed extant occurrences of Eriastrum densifolium subsp. sanctorum, 2 more than documented in the 2010 5-Year Review (Figure 1; Appendix A). Several occurrences are in need of monitoring as there are no survey records for decades, making it hard to accurately determine the occupancy at these occurrences. (USFWS, 2023)

***Threats and Stressors***

**Stressor:** Floodplain development (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At listing, urban and agricultural development was identified as a threat impacting habitat occupied by Eriastrum densifolium subsp. sanctorum (USFWS 1987, p. 36269). Prior to listing, the Devore occurrence (EO 15) was extirpated by agricultural development and discing (CNDDB 2010a, p. 9). Since listing, additional mainstem and tributary occurrences across the species distribution in San Bernardino, Riverside, and Orange Counties have been directly impacted or extirpated by development related activities: Verdemont (EO 18) in Cajon Creek Wash may have been eliminated when disced in 2005; Highland Avenue (EO 3) in Lytle Creek Wash was extirpated by construction of California Freeway 210 (Foothill Freeway); Jensen Quarry (EO 27) in Sunnyslope was extirpated by construction of the Oak Quarry Golf Club; and the sole Orange County occurrence, Weir Canyon Road (EO 2), may have been extirpated by construction of a nearby subdivision (CNDDB 2010a, p. 220). Adverse effects from development continue to be a threat to E. d. subsp. sanctorum occurrences, and impacts from current and planned development projects in the Santa Ana River floodplain habitat. These developments within the floodplain impact the species by displacing it from limited suitable habitat. Floodplain development projects also affecting the hydrological regime. (USFWS, 2010)

**Stressor:** Aggregate mining (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At listing, aggregate mining was identified as a threat impacting habitat occupied by Eriastrum densifolium subsp. sanctorum (USFWS 1987, p. 36268). Aggregate mining activities directly eliminate habitat and can degrade or fragment suitable habitat. Mining operations were quite active at the time of listing and impacted over 1,500 acres (ac) (600 hectares (ha)) of the Santa Ana River wash according to accounts shortly after listing (USFWS 1998, p. 3837). Since listing, threats associated with aggregate mining remain a threat at many mainstem and tributary occurrences. There are mining activities indicated as threats near 4 of the 21 occurrences: Institution Road North (EO 33), Institution Road South (EO 4), and Line Avenue (EO 20) in Cajon Creek Wash, and Santa Ana Wash (EO 5) on the Santa Ana River mainstem (CNDDB 2010). Though no new aggregate mining is currently planned for the Santa Ana River mainstem, the level of impact to Eriastrum densifolium subsp. sanctorum associated with ongoing aggregate mining is unknown. (USFWS, 2010)

**Stressor:** Alteration of hydrology (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At listing, it was predicted that Seven Oaks Dam would greatly reduce peak flow volumes and sediment loads that would drastically reduce the frequency of scouring and depositional events in the floodplain and allow most of the alluvial fan sage scrub communities on the Santa Ana River Wash to succeed to a uniform mature phase, reducing the seedling establishment of Eriastrum densifolium subsp. sanctorum in downstream habitats (USFWS 2008, p. 3). Absence of these scouring and depositional events could preclude all but the mature seral stages in the alluvial fan sage scrub. Since listing, this subspecies continues to be threatened

rangewide by floodplain modifications that alter hydrology, which directly and indirectly eliminate or impair habitat function. The habitat of the Santa Ana River and its tributaries receives little natural disturbance. Sheet flood flows probably occur once every 100 to 200 years and the scouring of such flows appear to maintain the alluvial fan scrub vegetation (USFWS 1986, p. 12181). Flood events are now confined to trenches and channels in Lytle Creek and the Santa Ana River, replacing the alluvial floodplain and the associated alluvial terraces. Constructed flood control channels prevent water from flowing out onto adjacent banks, providing the scouring and redeposition needed by Eriastrum densifolium subsp. sanctorum. The deeper water in these channels serves to increase the flow velocity and increases channel incision with less alluvial deposition. Flood control channels serve to promote mature successional stages of alluvial fan sage scrub, which provides poor establishment potential for E. d. subsp. sanctorum (Wheeler 1991, p. 56). Six occurrences are affected by grading for flood control: Line Avenue (EO 20), Santa Ana Wash (EO 5), Riverside Avenue (EO 21), Alamo Street (EO 22), Fairmont Park Golf Course (EO 24), and Weir Canyon Road (EO 2). Additionally, the construction of Seven Oaks Dam has removed much of the fluvial dynamics from the mainstem of the Santa Ana River and precludes natural scouring and deposition in the future. As discussed in the Habitat section above, the inhibition of flooding events allows for the seral maturation of the alluvial fan sage scrub. This mature scrub then inhibits the establishment of E. d. subsp. sanctorum seedlings, which could ultimately lead to local extirpations. All 14 occurrences on the Santa Ana River are adversely impacted by altered hydrology resulting from the Seven Oaks Dam. In all, 15 of the 21 extant occurrences are threatened by alterations of hydrology. (USFWS, 2010)

**Stressor:** Off-highway vehicles (OHVs) (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** OHV use directly damages plant communities and the soil horizon of Eriastrum densifolium subsp. sanctorum occurrences, thereby degrading habitat. Large flat expanses of alluvial fan sage scrub habitat that support E. d. subsp. sanctorum are also attractive to recreationists for OHV use. Impacts from OHV use is known to occur throughout the species' range and specifically at 11 of the 21 occurrences in Cajon Creek Wash (EOs 33, 4), Lytle Creek Wash (EO 19), and the Santa Ana River mainstem (EOs 5, 1, 25, 29, 21, 22, 24, and 31) (CNDDB 2010). Unauthorized OHV use continues to degrade alluvial fan sage scrub habitat areas within Cajon Creek Wash, Lytle Creek Wash, and the mainstem of the Santa Ana River. Control of these activities rests with local landowners and jurisdictions. Three occurrences are conserved and afforded protection under the Western Riverside County Multiple Species Habitat Conservation Plan (Western Riverside County MSHCP) (EOs 22, 24, and 31). We anticipate that some impacts from OHVs will be ameliorated through active management with future implementation of the Woolly-Star Preserve Area Multiple Species Habitat Management Plan (WSPA). (USFWS, 2010)

**Stressor:** Hybridization (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Hybridization was not discussed in the listing rule as a threat to Eriastrum densifolium subsp. sanctorum. Though hybridization, or the occurrence morphological intermediates (with E. d. subsp. elongatum or E. d. subsp. austromontanum) had been suspected since the 1930s, genetic verification did not occur until the occurrences in Lytle Creek were compared to those in

the Santa Ana River utilizing enzyme electrophoresis (Brunell and Rieseberg 1993). Similarly, hybridization was thought to occur with E. d. subsp. elongatum near the confluence of Lytle Creek and Cajon Creek (Verdemont (EO 18), Institution Road North (EO 33), and Institution Road South (EO 4)) (Craig 1934, p. 390; Burk et al. 1989, p. 20). The upper reaches of those washes seem to support E. d. subsp. elongatum while the listed entity is found downstream toward the Santa Ana River. Eriastrum densifolium subsp. austromontanum has also been thought to hybridize with E. d. subsp. sanctorum at La Cadeña Dr. and Lytle Creek (La Cadeña Drive (EO 29) and La Loma Hills (EO 30)) (DeGroot 2008, p. 1; Brunell and Whitkus 1997, p. 545). Though gene flow between E. d. subsp. sanctorum populations in the Santa Ana River and intermediates of Lytle Creek Wash likely took place in the recent past (150 years), they now appear isolated (Brunell and Rieseberg 1993, p. 5). The extent of threat from hybridization remains unknown. Hybrids have been confined to lower Lytle Creek Wash and the Santa Ana River at its confluence with Lytle Creek. Hybridization is a potential threat at 7 of the 21 occurrences. (USFWS, 2010)

**Stressor:** Climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Global climate change was not addressed as a threat in the final listing rule for the Eriastrum densifolium subsp. sanctorum. Since listing, it has become apparent that potential threats exist to biota of the United States from ongoing, accelerated climate change (IPCC 2007). Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying are predicted for the foreseeable future (Field et al. 1999, pp. 1–63; Cayan et al. 2005, pp. 1–47; IPCC 2007). Significant temperature increases create a stressor for endemic species. This stressor enhances pressures from competitors, nonnative species, habitat change, low water supply, and disease. Species must somehow adapt to these pressures in situ (in place) or shift their geographic range (Cayan et al. 2009, p. 45). Such a shift in range for narrow endemic species such as Eriastrum densifolium subsp. sanctorum could exceed the tolerance of the subspecies. Additionally, there is very little available alluvial fan sage scrub habitat in the Santa Ana River basin to assist this subspecies with a range shift. Though we know little of the adaptive ability of E. d. subsp. sanctorum, climate change could potentially pose a significant rangewide threat to the subspecies. (USFWS, 2010)

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

Recovery Priority Number: 6C

**Delisting Criteria:**
Delisting criteria are not available.

**Recovery Actions:**
- Recovery actions are not available.
- Work with partners, such as the Service's Partners for Fish and Wildlife Program to identify opportunities for conservation or preservation for Eriastrum densifolium subsp. sanctorum

occurrences on private lands. Property easements or purchases of parcels could also be made through the Act's section 6 funding and other programs. (USFWS, 2010)

- Ensure natural recruitment of Eriastrum densifolium subsp. sanctorum is sufficiently documented following extreme fluvial events (i.e., floods) to assure long-term sustainability. (USFWS, 2010)
- Determine occurrences where genetic distinctness exists between occurrences in Cajon Creek, Lytle Creek, and the Santa Ana River mainstem that comprise the range of known hybrid of Eriastrum densifolium subsp. sanctorum. (USFWS, 2010)
- Develop a final recovery outline for Eriastrum densifolium subsp. sanctorum. (USFWS, 2010)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The recommended actions listed below are to be initiated over the next 5 years. The actions are intended to reduce threats to Eriastrum densifolium subsp. sanctorum and provide information to better understand the biological and physical factors limiting the population growth and distribution. We recognize that conservation of this subspecies will require cooperation and coordination with partners to minimize impacts from current threats, aid future restoration, and maximize effectiveness of limited funding. 1. Work with partners to identify opportunities for conservation or preservation of E. d. subsp. sanctorum occurrences on private lands. Support land acquisition to meet Habitat Conservation Plan goals. Work with local, State, and Federal partners to identify and leverage funding (i.e., section 6) to acquire suitable habitat. 2. Conduct rangewide surveys for E. d. subsp. sanctorum to help update the distribution and current baseline conditions. 3. Identify seed accessions within the California Botanical Garden (formerly Rancho Santa Ana Botanical Garden) seed bank and complete seed collection and viability testing. 4. Conduct small-scale E. d. subsp. sanctorum plant seeding experiments. 5. Determine extent of genetic differences between E. d. subsp. sanctorum populations. 6. Conduct experiments to determine how to restore Riversidean Alluvial Fan Sage Scrub habitat to help facilitate recolonization of E. d. subsp. sanctorum to alluvial benches (USFWS, 2023).

# SPECIES ACCOUNT: *Erigeron decumbens* (Willamette daisy)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 2/24/2000; Pacific Region (R1)

**Physical Description**

The Willamette daisy is a taprooted perennial herb. It grows 1.5 to 6 cm (0.6 to 2.4 inches) tall, with erect to sometimes prostrate stems at the base. The basal leaves often wither prior to flowering and are mostly linear, 5 to 12 cm (2 to 5 inches) long and 3 to 4 mm (0.1 to 0.2 inches) wide. Flowering stems produce two to five heads, each of which is daisy-like, with pinkish to pale blue ray flowers and yellow disk flowers. The morphologically similar Eaton's fleabane (E. eatonii) occurs east of the Cascade Mountains, while the sympatric species Hall's aster (Aster hallii) flowers later in the summer. In its vegetative state, the Willamette daisy can be confused with Hall's aster, but close examination reveals the reddish stems of Hall's aster in contrast to the green stems of the Willamette daisy (Clark et al.1993) (USFWS, 2016).

**Taxonomy**

In the sunflower or daisy family (Asteraceae). Thomas Nuttall (1840) described Erigeron decumbens based on a specimen he collected in the summer of 1835. The autonym E. decumbens var. decumbens was automatically established by Cronquist (1947) when he described E. decumbens var. robustior. Recent revisions of the Erigeron genus (Strother and Ferlatte 1988, Nesom 1989) treat the plant as a variety, E. decumbens var. decumbens. According to Strother and Ferlatte (1988), E. decumbens var. decumbens is geographically limited to the Willamette Valley and the morphologically similar E. decumbens var. robustior is restricted to Humboldt and western Trinity Counties, California. (USFWS, 2010).

**Historical Range**

See current range/distribution.

**Current Range**

Occurs only in the southern end of the Willamette Valley, Oregon. Historically had ranged further north near Portland. Generalized range of 7400 sq. km. (USFWS, 2016)

**Critical Habitat Designated**

Yes; 11/30/2006.

**Legal Description**

On October 31, 2006, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective November 30, 2006) for Erigeron decumbens var. decumbens (Willamette daisy) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes nine critical habitat units (CHUs), in Oregon and Washington (71 FR 63862-63977).

**Critical Habitat Designation**

The critical habitat designation for Erigeron decumbens var. decumbens includes nine CHUs in Benton, Lane, Linn, Marion, and Polk Counties, Oregon. This species critical habitat encompasses approximately 718 ac (291 ha). Brief descriptions are presented below; detailed coordinates and maps are included in the Final Rule (71 FR 63862-63977; USFWS, 2006).

Units WD–1A and 1B encompass approximately 41.2 ac (16.7 ha) of Federal land occurring in northern Polk County. This unit is located adjacent to Highway 22, approximately 5.6 mi (9 km) northeast of the City of Dallas.

Unit 2 for Erigeron decumbens var. decumbens (Unit WD–2) Unit WD–2 encompasses approximately 12.2 ac (4.9 ha) of private land occurring in southern Marion County. This unit occurs south of SE Triumph Road and east of SE Boedigheimer Road.

Unit WD–3 encompasses approximately 58.3 ac (23.6 ha) of private land occurring within northern Linn County. This site is located north of SE Kingston Lyons Drive and on both the east and west sides of Huntly Road, and is primarily owned by TNC.

Unit WD–4 encompasses approximately 9.3 ac (3.8 ha) of private and City of Corvallis land occurring in Benton County. This unit is located north of SW Reservoir Avenue and south of NW Oak Creek Drive. Approximately half of the habitat within this unit is located on City of Corvallis land and half on private land.

Unit WD–5 consists of approximately 38.5 ac (15.6 ha) of private land, south of Corvallis, in Benton County. This unit is located along Muddy Creek, just to the west of Cutler Lane.

Unit WD–6 encompasses approximately 85.4 ac (34.6 ha) of critical habitat, with an estimated 89 percent on Federal land and 11 percent occurring on private land. This unit is located in Eugene, along Ken Neilsen Road and West 11th Avenue. The federally owned land includes both BLM and Army Corp of Engineers lands.

Unit WD–7A consists of approximately 22.3 ac (9 ha) of critical habitat, primarily on Federal land, with 2 percent occurring on private land. WD–7A is located to the west of Green Hill Road and to the north of West 11th Avenue, and is managed by the Army Corp of Engineers.

Subunits WD–8A and 8B consist of approximately 135.9 ac (55 ha) of Federal and private lands in West Eugene, Oregon. These subunits are located near the intersection of Willow Creek and West 18th Avenue. An estimated 45 percent of this area occurs on private land with approximately 55 percent occurring on BLM land.

Subunit WD–9A encompasses an estimated 90 ac (36.4 ha) of private land and is located approximately 1.2 mi (2 km) east of the intersection of Pine Grove Road and Crow Road.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Erigeron decumbens var. decumbens critical habitat consists of one component (71 FR 63862-63977):

(i) Early seral upland prairie, wet prairie, or oak savanna habitat with a mosaic of low-growing grasses and forbs, and spaces to establish seedlings or new vegetative growth; an absence of dense canopy vegetation; and undisturbed subsoils.

**Special Management Considerations or Protections**

Because Erigeron decumbens var. decumbens does not tolerate the presence of woody vegetation, habitat management will be required for the long-term persistence of this species. Further investigation is needed to determine the most appropriate techniques for managing available habitat. Also, due to the low reproductive capability of the species, conservation of the E. decumbens var. decumbens will likely depend on artificially augmenting populations in areas where woody vegetation has been removed (Clark 2000, pp. 9-10). (USFWS, 2006)

Expanding Erigeron decumbens var. decumbens populations will require more investigation into the roles of sexual and vegetative reproduction of this species. If sexual reproduction proves to be most important for population recruitment, mangers will need to focus on strategies that promote flowering, seed production, and seedling establishment (Clark 2000, p. 9). However, if vegetative regeneration is predominant, managers will need to focus on activities that promote ramet (refers to individual plants in a clump, each portion of which is identical with the original parent plant) production (Clark 2000, p. 9). Clark et al. (1995b, pp. 22-23) found that vegetative propagation is a viable technique for E. decumbens var. decumbens; populations may also be increased by sowing seeds under appropriate conditions, although this technique appeared to be less effective than vegetative propagation. (USFWS, 2006)

Erigeron decumbens var. decumbens is at risk of inbreeding depression and site extirpation across their respective ranges because populations are small and isolated from one another. This species will benefit from reestablishing prairie plant patches in proximity to core populations. (USFWS, 2006)

Many remaining populations of Erigeron decumbens var. decumbens populations occur in road rights of ways and are adversely affected by maintenance activities such as mowing or spraying of herbicides at the wrong time of year. (USFWS, 2006)

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollinated (USFWS, 2016)

**Breeding Season**

Adult: The Willamette daisy typically flowers throughout June and July (USFWS, 2016)

**Reproduction Narrative**

Adult: The Willamette daisy typically flowers throughout June and July with pollination carried out by syphrid flies and solitary bees (Clark et al.1995). The daisy produces and subsequently disperses large quantities of wind-dispersed seed in July and August. The seeds of the daisy are achenes, like those of other Erigeron species, and have a number of small capillary bristles (the pappus) attached to the top, which allow them to be distributed by the wind. Due to the small size and number of these bristles, the seeds do not fly well in the wind, so seed distribution is quite restricted. The Willamette daisy is capable of spreading vegetatively through rhizomes over very short distances of less than 10 cm (4 inches) and is commonly found in large clumps scattered throughout a site (Clark et al.1993). Willamette daisy responds positively to late spring and early summer rains. Studies conducted at the Willow Creek Preserve indicate that not all individuals of the Willamette daisy bloom every year, and that some individuals may remain dormant for an entire growing season (Kagan and Yamamoto 1987) (USFWS, 2016).

**Habitat Type**

Adult: Vally Prairie (USFWS, 2016)

**Environmental Specificity**

Adult: Narrow. Specialist or community with key requirements common. (Natureserve, 2015)

**Habitat Narrative**

Adult: The Willamette daisy is typically occurs where woody cover is nearly absent and where herbaceous vegetation is low in stature (Clark et al.1993; USFWS 2010a). It occurs in both wet prairie grasslands and drier upland prairie sites. The wet prairie grassland community, which was historically maintained by periodic flooding and fires, is characterized by the dominance of tufted-hairgrass, California oatgrass, and a number of Willamette Valley endemic forbs. It is a flat, open, seasonally wet prairie with bare soil between the pedestals created by the bunching Deschampsia cespitosa (Kagan and Yamamoto 1987). On drier upland prairie sites, associated species commonly include Symphotrichum hallii, Festuca idahoensis ssp. roemeri and Toxicodendron diversilobum (Meinke 1982, Clark et al.1993). Willamette daisy prefers heavier soils, and has been found on the following soil associations: Bashaw, Briedwell, Chehulpum, Dayton, Dixonville, Dupee, Hazelair, Marcola, Natroy, Nekia, Pengra, Philomath, Salkum, Saturn, Stayton, and Witzel (USFWS, 2016).

***Dispersal/Migration***

**Dispersal**

Adult: Wind dispersed (USFWS, 2016)

**Dispersal/Migration Narrative**

Adult: The daisy produces and subsequently disperses large quantities of wind-dispersed seed in July and August (USFWS, 2016).

***Population Information and Trends***

**Population Trends:**

Unknown (NatureServe, 2015; USFWS, 2016)

**Number of Populations:**

17 (USFWS, 2016)

**Population Size:**

1000 - 10,000 individuals (NatureServe, 2015)

**Population Narrative:**

The Willamette daisy is endemic to the Willamette Valley of western Oregon. Herbarium specimens show a historical distribution of Willamette daisy throughout the Willamette Valley; frequent collections were made in the period between 1881 and 1934, yet no collections or observations were recorded from 1934 to 1980 (Clark et al.1993). The species was rediscovered in 1980 in Lane County, Oregon. At the time of listing, 28 occurrences of Willamette daisy were recognized with a total of 286 acres of occupied habitat (USFWS 2000). In 2010, the total acreage considered to be occupied was 233 at 39 sites (USFWS 2010a). In 2010, Willamette daisy was believed to be extant at 37 sites that comprise 17 populations (USFWS 2010b). Of these, 3 populations had been augmented and Willamette daisy had been introduced to 5 new sites since the time of listing. Three of the extant populations are the direct result of recent introductions, and 5 natural populations have been discovered since the time of listing. Willamette daisy is believed to be extirpated or the status is unknown at 11 sites where it was previously documented. Of these sites, 8 were known at the time of listing, including 5 that represented individual populations and 3 that likely contributed to larger populations. Current population estimates are based on available information from 2004 to 2010 (USFWS 2010b). For most sites, long-term data needed to detect population trends is not available. In some cases, documentation of the number of plants at a site is not available. Where sites are within 3 km (2 miles) of each other, they are generally considered to be subpopulations that comprise a larger population (i.e., metapopulation) based on pollinator travel distance (USFWS 2010a). Of the 17 currently known populations, only 2 include protected sites that support relatively large subpopulations (i.e., with over 2,000 plants) known to have been stable for 8 years or more (USFWS 2010b). Trend data is not available for most sites, and many sites are not formally protected. Recovery criteria outlined for downlisting have not been met in any of the recovery zones. Almost all previously identified threats to the species still remain. Significant progress has been made to store genetic material, and efforts to collect and store seed will likely continue. Population size may fluctuate substantially from year to year. Monitoring at the Oxbow West site, near Eugene, found 2,299 Willamette daisy plants in 1999, 2,912 plants in 2000, and only 1,079 plants in 2001 (Kaye and Brandt 2005). The population at Baskett Butte declined to 48% of the original measured population between 1993 and 1999 (Clark 2000; Clark et al.1995). Detecting trends in Willamette daisy populations is complicated by the biology and phenology of the species. For instance, Kagan and Yamamoto (1987) found it difficult to determine survival and mortality between years because of irregular emergence and sporadic flowering from year to year. They suggested that some plants probably lie dormant during some years, as indicated by the sudden appearance of large plants where they were not previously recorded, and the disappearance and later re-emergence of large plants within monitoring plots. In addition, Clark et al.(1993) stated that non-reproductive individuals can be very difficult to find and monitor due to their inconspicuous nature, and that the definition of individuals can be complicated when flowering clumps overlap (USFWS, 2016).

***Threats and Stressors***

**Stressor:** Development (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Like many native species endemic to Willamette Valley prairies, the Willamette daisy is threatened by habitat loss due to urban and agricultural development (USFWS, 2016).

**Stressor:** Encroachment/woody succession (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat

**Narrative:** Secondary successional encroachment of habitat by trees and brush is a threat to this species (USFWS, 2016).

**Stressor:** Competition (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Competition with non-native weeds is listed as a threat to this species (USFWS, 2016).

**Stressor:** Small populations (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Extinction/lack of genetic diversity
**Narrative:** Small population sizes (Kagan and Yamamoto 1987, Clark et al.1993) are listed as a threat to this species (USFWS, 2016).

**Stressor:** Private land (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The Service (USFWS 2000) estimated that habitat loss is occurring at 80% of remaining 84 remnants of native prairies occupied by Willamette daisy and Kincaid's lupine. The Service (USFWS 2000) also stated that 24 of the 28 extant Willamette daisy populations occur on private lands and, "without further action, are expected to be lost in the near future."

***Recovery***

**Reclassification Criteria:**
1. Distribution and abundance. The distribution of populations should reflect the extent of the species' historical geographic distribution to the extent practicable. Subpopulations contributing to larger interacting populations should be within pollinator flight distance (3 kilometers [2 miles]) of each other. See Table IV-3 in the Recovery Plan for distribution and abundance goals for this species. (USFWS, 2010)

2. Population trend and evidence of reproduction. The number of individuals in the population shall have been stable or increasing over a period of at least 10 years. The term "stable" in this context does not mean that the population size is static over time; over a period of 10 years, the number of individuals in the population may exhibit natural year-to-year variability, but the trend must not be declining. Populations must show evidence of reproduction by seed set or presence of seedlings. (USFWS, 2010)

3. Habitat quality and management. Sites supporting populations of listed plants considered in Criterion 1 above must meet these criteria: (a) Prairie quality. Sites supporting populations of the listed plant species must be managed for high quality prairie habitat. High quality prairie habitat consists of a diversity of native, non-woody plant species, low frequency of aggressive non-native plant species and encroaching woody species, and essential habitat elements (e.g., nest sites and food plants) for native pollinators. See Appendix D of the Recovery Plan for suggested criteria for evaluating prairie quality and diversity. (b) Security of habitat. For each

listed species, a substantial portion of the habitat for the populations should either be owned or managed by a government agency or private conservation organization that identifies maintenance of the species and the prairie ecosystem upon which it depends as the primary management objective for the site, or the site must be protected by a permanent or long-term conservation easement or covenant that commits present and future landowners to the conservation of the species. (c) Management, monitoring, and control of threats. Each population must be managed appropriately to ensure the maintenance or restoration of quality prairie habitat for each species and to control threats to the species. Use of herbicides, mowing, burning or livestock grazing in management should be implemented with appropriate methods and timing to avoid impacts to listed plant species. Management should be coordinated with adjacent landowners to minimize effects of pesticide drift, changes in hydrology, timber harvest, or road/utility maintenance. Species that may hybridize with Sidalcea nelsoniana or Lupinus sulphureus ssp. kincaidii should be managed as appropriate to avoid contact with these taxa. Other potential threats relating to scientific research, overcollection, vandalism, recreational impacts, or natural herbivory/parasitism should be successfully managed so as not to significantly impair recovery of the species. (USFWS, 2010)

Recovery Priority Number: 2C

**Delisting Criteria:**
Delisting will be considered when all of the following conditions have been met: (USFWS, 2010)

1. Distribution and abundance. The distribution of populations should reflect the extent of the species' historical geographic distribution to the extent practicable. See Table IV-3 in the Recovery Plan for distribution and abundance goals for this species. (USFWS, 2010)

2. Population trend and evidence of reproduction. The number of individuals in the population shall have been stable or increasing over a period of at least 15 years. Stable does not mean that the population size is static over time; over a period of 15 years, the number of individuals in the population may exhibit natural year-to-year variability, but the trend must not be declining. Populations must show evidence of reproduction by seed set or presence of seedlings. (USFWS, 2010)

3. Habitat quality and management. Sites supporting populations of listed plants considered in Criterion 2 above must meet these criteria: (a) Prairie quality. Same as Downlisting Criterion 1. (b) Security of habitat. Same as Downlisting Criterion 1. (c) Management, monitoring, and control of threats. Same as Downlisting Criterion 1. (USFWS, 2010)

4. Genetic material is stored in a facility approved by the Center for Plant Conservation. The stored genetic material in the form of seeds must represent the species' geographic distribution and genetic diversity through collections across the full range of the species. Collections from large populations are particularly important as reservoirs of genetic variability within the species. (USFWS, 2010)

5. Post-delisting monitoring plans and agreements to continue post-delisting monitoring are in place and ready for implementation at the time of delisting. Monitoring of populations following delisting will verify the ongoing recovery of the species, provide a basis for determining whether the species should be again placed under the protection of the Endangered Species Act, and

provide a means of assessing the continuing effectiveness of management actions. (USFWS, 2010)

**Recovery Actions:**

- Details of the Recovery Actions are available in the 2010 Recovery Plan. Presented below is the introductory paragraph only. (USFWS, 2010)
- 1. Preserve, restore, and manage populations and habitat for the listed prairie species covered by this plan. The listed prairie species of western Oregon and southwestern Washington addressed by this plan are now found only in small, highly fragmented upland and wet prairie habitat remnants. The first step in the recovery of these species is to identify and protect the remaining populations with the greatest potential for restoration. The next step is to augment and, if necessary, reintroduce populations to restore connectivity between those that are currently isolated from one another to restore gene flow and create a population structure that provides for resiliency in a dynamic natural environment. Recovery for all of these species will depend upon the successful establishment of a network of protected populations in managed, suitable prairie habitats distributed across their historical range. As a large portion of the remnant prairie habitats within the range of these species is in private ownership, recovery will to a large extent depend upon the successful development of partnerships with private landowners and support of their efforts to protect, restore and manage native prairie habitats in the region. (USFWS, 2010)
- 2. Coordinate recovery actions to benefit other listed species and nonlisted prairie species of conservation concern. The extensive loss of both wet and upland prairie habitats throughout the geographic region addressed by this draft recovery plan has resulted in the concurrent declines of many of the native plants and animals associated with these ecosystems. In this plan we have attempted to focus not only on the recovery of the listed prairie species, but to extend these recovery efforts to the ecosystems upon which they depend. The recommended actions for restoring and reconnecting prairie habitats in western Oregon and southwestern Washington are intended to extend benefits beyond the threatened or endangered species addressed in the plan to all of the native prairie species in these regions, including nonlisted prairie species that are recognized as in decline. Proactive efforts to restore prairie systems should contribute to the arrest or reversal of these declines, thereby preventing the need to list these species in the future. Particularly on sites where listed species co-occur with nonlisted species of conservation concern, landowners or managers should be made aware so as to tailor management actions to avoid inadvertent negative impacts on any such species. Coordination with other agencies, private landowners, or other interested parties will help ensure that the recovery actions outlined in this plan benefit the habitat and populations of other native prairie species. (USFWS, 2010)
- 3. Promote protection of listed species and prairie restoration on private lands. More than 90 percent of the land in the Willamette Valley is in private ownership. The restoration of prairie systems and their native plant and animal communities can therefore only be successful with the participation of private landowners. Without active management, populations of both listed and nonlisted species endemic to prairie habitats are almost certain to experience further declines. Working with private landowners and providing incentives to participate in the recovery effort for these species are critical elements of the recovery strategy. (USFWS, 2010)
- 4. Cultivate partnerships with both public and private agencies and organizations to promote the conservation of prairie ecosystems and listed prairie species. A diverse group

of agencies and organizations are involved in recovery activities for the native prairies in western Oregon and southwestern Washington, including, but not limited to, the U.S. Fish and Wildlife Service, the Willamette Valley National Wildlife Refuge Complex, the U.S. Bureau of Land Management, U.S. Army Corps of Engineers, Confederated Tribes of Grand Ronde, Oregon Department of Transportation, City of Eugene, The Nature Conservancy, Oregon State University, Institute for Applied Ecology, Greenbelt Land Trust, McKenzie River Land Trust, Oregon Oak Communities Working Group, Washington Native Plant Society, Oregon Native Plant Society, Heritage Seedlings, and Berry Botanic Garden. Information regarding the recovery efforts for the prairie species should be shared with city and county planning, parks, and natural resource departments throughout the region covered by this recovery plan. City and county governments are the primary agencies that determine future land uses, and their participation is important for the recovery and restoration of the prairies and their associated listed species. Some local agencies are already making significant contributions toward prairie restoration; the West Eugene Wetlands are an excellent example of a significant conservation accomplishment achieved through a partnership of federal and local governments and private landowners/organizations. Plans, data, and information pertinent to the recovery of the prairie species must be synthesized and shared effectively between all agencies, groups, and individuals to leverage collective conservation efforts and achieve recovery. (USFWS, 2010)

- 5. Revise and update recovery plan as needed. Based on the results of the recommended research and monitoring efforts and the evaluation of the relative success or failure of different management techniques, the recovery plan should be revised periodically as needed to reflect this increased knowledge and improve the efficacy of future recovery actions. The scientific validity of the recovery criteria should also be reviewed and refined, if necessary, as more accurate species-specific data become available to assist with refining recovery criteria. (USFWS, 2010)
- 6. Develop post-delisting monitoring plans for each listed species prior to delisting. To ensure the continuing recovery of the listed species and adequacy of management actions to maintain the species at viable levels into the foreseeable future, a post-delisting monitoring plan must be developed and ready for implementation prior to delisting of any threatened or endangered species. Such a monitoring plan must be designed to be continued for a minimum of 5 years following the delisting action. (USFWS, 2010)
- Recommendation for Future Action from 2019 5-Year Review: Action 1: Survey and Monitor: • Maintain information about what is currently known about the locations of extant and extirpated sites. •Maintain map with historical and extant populations and potential introduction sites. •Survey known and potential extant populations where status of populations or possible extirpation is unknown; identify and assess factors that appear to be driving population trends at occupied sites. • Monitor key populations and identify factors that may be driving population trends at occupied sites. (USFWS, 2019)
- Recommendation for Future Action from 2019 5-Year Review: Action 2: Habitat Protection, Management and Restoration: • Select populations and lands on which to focus protection, management and restoration recovery actions. • Work with landowners to restore, manage and reduce threats to significant sites. • Work with partners to explore and develop opportunities to protect key populations on private lands. • Work to secure significant unprotected sites. (USFWS, 2019)
- Recommendation for Future Action from 2019 5-Year Review: Action 3: Seed Collection, Propagation and Banking: • Continue on-going seed collection efforts for propagation and banking. • Identify sites for additional seed collection. • Increase seed availability through

cultivation and propagation at facilities that can manage genetic diversity and any necessary isolation. (USFWS, 2019)

- Recommendation for Future Action from 2019 5-Year Review: Action 4: Research: • Conduct demographic studies to determine how Willamette daisy responds to restoration and management treatments. •Research genetic and reproductive biology questions related to progeny fitness, demographic trends and the breeding system for use in developing seed transfer and augmentation guidelines, and to evaluate inbreeding depression concerns. •Research effects of climate change and voles on Willamette daisy populations and develop recommendations for responses to these threats. (USFWS, 2019)
- Recommendation for Future Action from 2019 5-Year Review: Action 5: Augment Small Populations and Reintroduce Willamette Daisy to Suitable Habitats: • Identify protected populations that would be likely to benefit from augmentation and suitable habitats in strategic locations between secure populations that could be used as reintroduction sites. • Implement augmentation projects; develop management plans with landowners, as needed. • Implement (re)introduction projects; develop management plans with landowners, as needed. (USFWS, 2019)

# SPECIES ACCOUNT: *Eriodictyon altissimum* (Indian Knob mountain balm)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 1/17/1995; California/Nevada (Region 8)

**Physical Description**

Indian Knob mountainbalm (Eriodictyon altissimum) is a narrowly endemic, perennial shrub in the Namaceae (nama) family. It grows up to 5.5 meters (m or 18 feet [ft]) tall. Indian Knob mountainbalm has dark green, linear leaves with revolute (strongly rolled under) margins. The inflorescences are scorpioid cymes, where the oldest flower in the arrangement terminates the main axis and continues to branch and curl over in a one-sided coil, like a scorpions' spiraling tail. The individual flowers occur on pedicels, are purple, and are funnelform in shape with five lobes (USFWS, 2024)

**Taxonomy**

First collected on Indian Knob by Philip V Wellsin 1960, and was described by him two years later (Wells 1962). In the waterleaf family (Hydrophyllaceae). (USFWS, 1998) Recognized by Kartesz (1994 checklist and 1999 floristic synthesis); Kartesz notes (pers. comm. to Larry Morse, 25Nov99) that "this appears to be a large-flowered expression of Eriodictylon angustifolium, but is probably worthy of recognition as a species." Skinner and Pavlik (1994) note that its taxonomic relationship to E. angustifolium needs clarification. The 2nd edition of The Jepson Manual (Baldwin et al. 2012) accepts it as distinct. (NatureServe, 2015)

**Historical Range**

Endemic to western San Luis Obispo County, California (USFWS, 2019b)

**Current Range**

Known from sevel locations in San Luis Obispo County, California (USFWS, 2019b)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual and asexual (USFWS, 1998)

**Lifespan**

Adult: Long-lived (USFWS, 1998)

**Breeding Season**

Adult: March to July (USFWS, 2024)

**Other Reproductive Information**

Adult: Indian Knob mountainbalm blooms March through July. It has capsule fruits with four valves (and two separate chambers), and most members of the genus generally produce many seeds (Hannan 2021, website; Keil 2022, pp. 555–556). However, seed production in Indian Knob mountainbalm is considered low to absent. The species has both above-ground stems and underground rhizomes. A single genetic individual can spread vegetatively via the rhizomes, producing a colony (genet) of identical above-ground stems ([ramets], Guilliams and Hasenstab-Lehman 2021, pp. 1–2). This clonality can pose challenges in the field when trying to assess the actual number of individuals present in a given stand because groupings of Indian Knob mountainbalm ramets likely contain few distinct individuals (USFWS, 2024).

**Reproduction Narrative**

Adult: The Indian Knob mountain balm is believed to be relatively long-lived; slow-growing lichens can be found attached to its woody stems. Fruits contain a single ovule and seed set is low in those plants in which it has been recorded (John Chesnut, pers. comm. 1997). It is not known if Indian Knob mountain balm is self-compatible; however, it is possible that some colonies are also composed of a single clone. In addition to sexual reproduction, this species regenerates by root sprouts. (USFWS, 1998)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Forest/Woodland, Shrubland/chaparral, Woodland - Hardwood (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Prefers sandstone ridges (NatureServe, 2015)

**Environmental Specificity**

Adult: Very Narrow (USFWS, 1998)

**Habitat Narrative**

Adult: Indian Knob mountain balm occurs in soils derived from marine sandstones containing tar deposits referred to as “tarsands” and, in the northern part of its range, on Baywoodfine sands and weathered ancient dune soils. This species co-occurs with Morro manzanita in several locations in maritime chaparral. Vanderwier (1987) did a detailed study ofthe chaparral and oak woodland communities at the type locality forIndian Knob mountain balm. (USFWS, 1998). Indian Knob mountainbalm occurs on sandstone substrates largely derived from ancient sand dunes within the San Luis Range, in western San Luis Obispo County, California. It occurs in maritime chaparral habitat types, where it is a local component of these plant communities originating from the Indian Knob landform (located roughly north-northeast of the City of Pismo Beach). This landform is located between the cities of San Luis Obispo and Pismo Beach. Its range extends from the community of Los Osos, roughly southeast to the City of Pismo Beach (USFWS, 2024)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**
Stable (USFWS, 2009)

**Number of Populations:**
5 extant (USFWS, 2024)

**Population Size:**
>6,400 individuals in 2016 (USFWS, 2019b)

**Population Narrative:**
In 2019, Indian Knob mountainbalm is still known from seven occurrences, six of which are in protected areas and one (the largest) mostly in a protected area, with a total population count of 6,489+ individuals in 2016. Two occurrences are likely extirpated. A figure is available in the 5-Year Review depicting known geographic distributin in western San Luis Obispo County, California. One new occurrence (Occurrence 8) is new. (USFWS, 2019b). Indian Knob mountainbalm is currently known from six EOs (CNDDB 2024b, website), and 20 georeferenceable herbarium specimens from CCH2 (CCH2 2024, website). Of the six EOs, we presume one is likely extirpated (EO number 3, see p. 7; CNDDB 2024b, website). We are not able to ascertain the status of Indian Knob mountainbalm at the CCH2 documented locations. We also lack updated census or survey information to report about the species abundance throughout its range and are unable to assess population status trends, even at the spatial scale of individual occurrences (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Habitat loss (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, loss of habitat due to development, surface mining, and oil well drilling was identified as the primary threat to Eriodictyon altissimum. Since the time of listing, the threat of habitat loss due to development in the Los Osos area and surface mining, and oil well drilling in and around Indian Knob has been reduced to the point that we no longer consider this to be a significant threat to the species. The populations outside of Montaña de Oro State Park, with the exception of element occurrence 1 (Broderson), are now protected. Element occurrences 4 and 6 now are found within a Department ecological reserve and the majority of the plants in occurrence 5 (Indian Knob) are protected under a conservation easement held by the City of San Luis Obispo. (USFWS, 2009)

**Stressor:** Non-native invasive plants (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Modification of habitat due to the spread of invasive, non-native plant species was also a concern at the time of listing. Absent site-specific information from the implementation of management and monitoring programs, it is difficult to determine the actual severity of invasive, non-native species. No management plans or monitoring programs have been developed and implemented to detect change on conserved lands. Absent the type of information that would be collected and analyzed as part of such programs, it is not possible for us to determine if the occurrences are being adversely affected by competition from non-native invasive plant species. It does appear from anecdotal observations that all occurrences (except element occurrence 1) are stable and have not been significantly affected by competition from non-native invasive plant species. At element occurrence 1, veldt grass (Ehrharta calycina) appears to be degrading habitat, but its effect on Eriodictyon altissimum is unknown. (USFWS, 2009)

**Stressor:** Stochastic extinction (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, we did not discuss stochastic extinction as a threat. The conservation biology literature commonly notes the vulnerability of taxa known from one or very few locations and/or from small and highly variable populations (e.g., Shaffer 1981, 1987; Primack 2006; Groom et al. 2006). In particular, although the plants are long-lived, the small sizes of all but the Indian Knob population may make it difficult for those populations to persist if conditions are not suitable for the establishment of new individuals. (USFWS, 2009)

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the northern hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). Recently, the potential impacts of climate change on the flora of California were discussed by Loarie et al. (2008). Based on modeling, they predicted that species’ distributions will shift in response to climate change and that the species will “move” or disperse to higher elevations and northward, depending on the ability of each species to do so. Increases in species diversity in these higher elevations and northern locations due to climate change have the potential to result “…in new species mixes, with consequent novel patterns of competition and other biotic interactions…” with unknown consequences to the species which currently exist there (Loarie et al. 2008). While, we lack adequate information to make specific and accurate predictions regarding how climate change, in combination with other factors such as small population size, will affect Eriodictyon altissimum; small ranged species, such as E. altissimum, are more vulnerable to extinction due to these changing conditions (Loarie et al. 2008). (USFWS, 2009)

***Recovery***

**Reclassification Criteria:**
1. At least five occurrences from throughout its range are on lands secure from human-induced threats. (USFWS, 1998)

2. Surrounding habitat is protected in amounts adequate to permit management of the vegetation community using prescribed fire, if it is deemed beneficial to the species. (USFWS, 1998)

3. Populations are projected to be self-sustaining and either stable or increasing as determined by long-term monitoring and research results. (USFWS, 1998)

**Delisting Criteria:**
When the downlisting criteria have been met for a species, the species can be considered for delisting if:

1. Threats are reduced or eliminated so that occurrences are capable of persisting without significant human intervention or perpetual endowments are secured for management necessary to maintain the continued existence of the species. The most outstanding management needs currently are: a) integrate, or find a replacement for, a fire regime as a means of revitalizing declining or senescing colonies; b) manage adjacent shrub habitat through thinning to provide sufficient space for the species to expand in numbers, and c) educational signing to deter the public from cutting shrubs along trails; (USFWS, 2019a)

2. The occurrences remain viable for at least 15 years to demonstrate long-term viability under a range of environmental conditions. Rangewide surveys in 2016 and 2017 provide a baseline for numbers of stems or individuals, and in some cases, additional information regarding vigor of individuals, as measured by size. These data should provide a basis for monitoring occurrence attributes to determine viability over time; (USFWS, 2019a)

3. An ex situ collection of plant material is established in a Center for Plant Conservation-affiliated botanic garden. A soil seedbank would typically provide a strategy for a species to regenerate populations in the face of stochastic events as well as natural senescence. However, this species is suspected to have low seed production. Research on seed production and viability will be undertaken in the near future. Whether reproduction through banked seed proves to be efficacious or not, reproduction through vegetative propagation (e.g. cuttings) also holds potential as a means of replenishing occurrences, should it be necessary in the future. (USFWS, 2019a)

**Recovery Actions:**
- Secure populations and habitat on unprotected lands. Methods for securing lands include in-fee purchase, gifts of easement or fee interest by the property owner, deed restrictions (provided restrictions cannot be changed privately without the knowledge of Federal, State and County agencies), acquisition of property rights (e.g., development rights) or permanent conservation easements. (USFWS, 1998)
- Manage secured lands to control or eliminate other known threats. Although habitat alteration through development is currently the most substantial and irreversible threat facing all of the species in this plan, the management of lands secured from development will remain a formidable task, made more so in those cases where the secured habitats are adjacent to high density residential and urban development. (USFWS, 1998)
- Evaluate potential threats and conduct management-oriented research. Conduct habitat-oriented research for Morro Bay species. Conduct species-specific research. Evaluate research results and use in future management. (USFWS, 1998)

- Determine population dynamics and effects of recovery efforts. Studies should be conducted to learn the number and size of successful self sustaining populations for the species to establish criteria for its reclassification. (USFWS, 1998)
- Develop and implement an education/information program. The benefits of protecting native species and their habitats and maintaining native biological communities should be explained clearly to all concerned parties. (USFWS, 1998)
- Reevaluate recovery criteria and revise recovery plan based on expanded knowledge from research, monitoring, and management. The scientific validity of the recovery criteria and recovery plan should be reviewed and revised as more information becomes available. The criterion of maintaining sufficient numbers of populations or conservation areas should be assessed, and the success or failure of management actions should be evaluated. (USFWS, 1998)
- Recommendations for Future Actions from 2019 5-Year Review:  Little is known about the biology and ecology of Indian Knob mountainbaim in 2019. Therefore, coordinated conservation and research are needed to further understand the species, and to restore and maintain the five extant occurrences. These efforts should include: • Management actions to benefit the occurrences. • Searches for additional locations. • Introduction of Indian Knob mountainbalm into living collections at botanic gardens. • Seed collection for seed banking, with a subset of seeds used to investigate germination requirements, including cues associated with fire-following species. • Collection and cultivation of cuttings along with seeds to develop protocols for propagation of the species. • Studies of genetic diversity and reproductive biology, potential barriers to recruitment, and the species' relationship with fire. In particular, genetic diversity within and among the occurrences should be investigated. (USFWS, 2019b)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Obtain access to all six known Indian Knob mountainbalm occurrences (CNDDB 2024b, website) to conduct comprehensive surveys of abundance, assess the overall status of the species, and evaluate current threats to the species at each location. Include estimates of the total number of Indian Knob mountainbalm individuals present at each location, using the metric provided in Guilliams and Hasenstab-Lehman 2021 (pp. 17–18) and map the total occupied area using global positioning system (GPS). Collect other pertinent ecological and demographic data including cooccurring and co-dominant species, estimate of canopy cover, presence and abundance of nonnative, invasive species, timing of phenology, and observations of any potential insect pollinators. Provide data and interpreted findings to the Service and CDFW to ensure that resource databases and species relevant updates remain both accurate and current. 2. Conduct experimental research to better understand Indian Knob mountainbalm's reproductive biology. Specifically, investigate germination cues related to fire, seed bank dynamics, and seed viability. We also need to better understand why seed production is low to near absent, in wild populations and which environmental cues or conditions may stimulate production of seed. 3. Conduct experimental research to determine the most effective/optimal management techniques to apply to extant, wild populations of Indian Knob mountainbalm to ensure both persistence and expansion of the species within currently occupied areas. In particular, we must evaluate the use of prescribed burns and other disturbance techniques to stimulate new plant growth and regenerate senescent stands. 4. Work with partners who own or hold conservation easements on occupied Indian Knob mountainbalm sites and help them develop and implement conservation and recovery actions through habitat management plans for their properties. Support these partners and assist them to acquire and secure adequate funding and other endowments to manage the species and its habitat for conservation and recovery in perpetuity. 5. Conduct introductions at suitable sites that include long-term management strategies to ensure success and persistence of the species at introduced locations. Develop protocols for propagation of the species from both cuttings and seed. 6. Make adequate accessions of Indian Knob mountainbalm seed for conservation banking so that all known occurrences are represented in the established collections. Conduct seed bulking activities, if feasible, to have an ample source of seed for recovery efforts and to serve as a backup in the event of stochastic loss and possible extirpation (USFWS, 2024).

# SPECIES ACCOUNT: *Eriodictyon capitatum* (Lompoc yerba santa)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 03/20/2000; California/Nevada (Region 8) (USFWS, 2015)

**Physical Description**

An evergreen shrub, growing to about 3 m tall with narrow, leathery leaves. Lavender flowers are tubular, borne in head-like, densely hairy clusters. Blooms May-August. (NatureServe, 2015)

**Taxonomy**

Since the time of listing, a phylogenetic study provided evidence supporting the transfer of the genus Eriodictyon from the waterleaf family (Hydrophyllaceae) to the borage family (Boraginaceae) (Jepson Online Interchange 2010). (USFWS, 2011)

**Historical Range**

According to records available through the CNDDB (2010) and the Consortium of California Herbaria (Consortium) (2010), all historical collections and unvouchered observations of Eriodictyon capitatum are from the southwestern corner of Santa Barbara County. Other studies (Elam 1994, Jacks et al. 1984) recognized seven populations of E. capitatum based on the number of “Element Occurrences” (occurrences) at the time and as defined by CNDDB criteria. five populations are from three geographically distinct areas referred to here as Solomon Hills, west Burton Mesa, and Santa Ynez Mountains (USFWS, 2011)

**Current Range**

Eriodictyon capitatum is endemic to southwestern Santa Barbara County, California. It is found in three areas of the county: on Vandenberg Air Force Base, on the west crest of the Santa Ynez Mountains on Hollister Ranch, and on Graciosa Ridge in the Solomon Hills southeast of Orcutt. The entire range extent covers about 365 sq mi. (NatureServe, 2015)

**Critical Habitat Designated**

Yes; 11/7/2002.

**Legal Description**

On November 7, 2002, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Eriodictyon capitatum (Lompoc yerba santa) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes three critical habitat units (CHUs), in California (67 FR 67968-68001).

**Critical Habitat Designation**

The critical habitat designation for Eriodictyon capitatum includes three CHUs in Santa Barbara County, California. This species critical habitat encompasses approximately 9,709 acres (67 FR 67968-68001).

**Primary Constituent Elements/Physical or Biological Features**

The primary constituent elements of critical habitat for Eriodictyon capitatum are the habitat components that provide: (i) Soils with a large component of sand and that tend to be acidic; and (ii) Plant communities that support associated species, including maritime chaparral, particularly where the following associated species are found: Dendromecon rigida (bush poppy), Quercus berberidifolia (California scrub oak), Quercus parvula (Santa Cruz Island scrub oak), and Ceanothus cuneatus (buck brush); and in southern bishop pine forests that intergrade with chaparral Arctostaphylos spp. (manzanita) and Salvia mellifera (black sage). (67 FR 67968-68001):

**Special Management Considerations or Protections**

Special management considerations or protections may be needed to maintain the primary constituent elements for the two taxa within the units being designated as critical habitat. In some cases, protection of existing habitat and current ecological processes may be sufficient to ensure that populations of the plants are maintained at those sites, and have the ability to reproduce and disperse in surrounding habitat. In other cases, however, active management may be needed to maintain the primary constituent elements for the two taxa. We have outlined below the kinds of special management and protection that these two taxa would most likely require. These recommendations for management and protection are general in nature. Specific management actions should be developed according to local site conditions. Not all of these will apply to each plant taxon equally. (1) Existing soil conditions should be protected by avoiding activities that cause the erosion or compaction of soils. Maintaining an intact soil profile may be necessary to maintain edaphic features such as a horizon of permeable sandy soils on the surface layer. For example, Deinandra increscens ssp. villosa is thought to be restricted to acidic, fine sandy loams with a subsurface clay layer that may act as a reservoir of soil moisture. (2) Existing hydrologic conditions should be protected by avoiding activities that cause a change in surface or subsurface water flows upon which the plant taxa depend. For example, development of areas adjacent to a population may result in an increase in runoff and surface water flow. This alteration may affect the soil moisture content to which the local population has adapted. (3) In all plant communities where these taxa occur, invasive, non-native species, such as harding grass (Phalaris aquaticus), veldt grass (Ehrharta calycina), and iceplant (Carpobrotus edulis), should be actively managed. Invasive non-natives pose a serious threat to the survival of Deinandra increscens ssp. villosa and Eriodictyon capitatum and remaining habitat of the taxa. For example, accumulated dead leaves and stems (thatch) from nonnative grass species that dominate the habitat effectively prevent the establishment of D. increscens ssp. villosa at a site. Iceplant is known to invade native maritime chaparral vegetation occupied by Eriodictyon capitatum. Once non-native grasses and other invasive plants (e.g., iceplant) have become established, they cannot be removed without great expenditure of time and effort. (4) The composition of the native plant and animal communities associated with the taxa must be maintained. Native plant diversity may limit the ability of aggressive non-native plants to invade a population (Dukes 2002). In addition, a decline in biodiversity may increase the potential impact of invasive plants on a community (e.g., suppression of growth). Recent research suggests that grassland communities with fewer species may be more likely to decline as a consequence of invasion (Dukes 2001). In addition, native plant diversity may increase pollinator activity and therefore enhance the conservation of a plant species. Biologists have suggested that a plant population may persist as long as it occurs within an area of a diversity of plant species that are attractive to pollinators (Kwak 1988). Habitat fragmentation and isolation of species-rich grasslands, with intervening areas of no or low diversity of native plants, has been found to negatively affect plant-pollinator interactions (Stephann-Dewenter and Tscharntke 1999). (5) The local distribution of plant communities should be managed to provide for the physical requirements of the taxa (e.g., space for establishment). For some grassland areas, it may be important to maintain openings within or between coastal scrub communities that might otherwise encroach upon grassland patches that support Deinandra increscens ssp. villosa. (6) Certain areas where these taxa occur may need fencing to protect them from accidental or intentional trampling by humans and livestock. Portions of three of the five units are currently used by livestock

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (outcrossing) and asexual (vegetative) (USFWS, 2011)

**Dependency on Other Individuals or Species**

Adult: While pollination ecology has not been specifically studied for E. capitatum, other Eriodictyon taxa are known to be pollinated by wasps, butterflies, and a variety of bee taxa, especially from the genera Anthophora, Bombus, Chelostoma, Hylaeus, Osmia, and Nomadopsis (Moldenke 1976). (USFWS, 2011)

**Breeding Season**

Adult: May to August (USFWS, 2011)

**Reproduction Narrative**

Adult: Eriodictyon capitatum is capable of both sexual and asexual reproduction. The importance of sexual reproduction in maintaining populations is unclear. Research indicates that E. capitatum is a self-incompatible species; intentionally cross-pollinated flowers produced a mean of 1.77 seeds per fruit, and intentionally self-pollinated flowers produced a mean of 0.03 seed per fruit (Elam 1994). This species spreads vegetatively through the production of rhizomes (underground stems), and thus producing colonies of ramets (genetically identical stems) from only a few individuals. The lavender flowers are tubular and clustered in heads that bloom from May to August. While pollination ecology has not been specifically studied for E. capitatum, other Eriodictyon taxa are known to be pollinated by wasps, butterflies, and a variety of bee taxa, especially from the genera Anthophora, Bombus, Chelostoma, Hylaeus, Osmia, and Nomadopsis (Moldenke 1976). (USFWS, 2011)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Shrubland/chaparral (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Highly acidic soils with high water-retaining capacity on inland sites (USFWS, 2011)

**Environmental Specificity**

Adult: Very narrow. Specialist or community with key requirements scarce. (Natureserve, 2015)

**Habitat Narrative**

Adult: Eriodictyon capitatum occurs within two different habitat types. Near the coast, it occurs within maritime chaparral and coastal sage scrub on sandstone soils from the Orcutt, Marina, and Oceano series. In this habitat type, it typically occupies disturbed areas near roads or exposed ridgetops (Jacks et al. 1984). On sites that are farther inland, Eriodictyon capitatum is found on diatomaceous Monterey shales. The structurally dominant Pinus muricata is one species that occurs at these sites. These sites have characteristic soils that are highly acidic and have a high water-retaining capacity (Cole 1974). Eriodictyon capitatum apparently can tolerate and may be encouraged by minor disturbance (Savage 1978, CNPS 1987, Myers 1987). (USFWS, 2011; NatureServe, 2015)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Declining by 8.5% since 2006 (USFWS, 2011)

**Number of Populations:**

5 (USFWS, 2011)

**Population Size:**

1,520 (USFWS, 2011)

**Population Narrative:**

During surveys for E. capitatum, approximately 1,520 individuals were documented within known populations (SRS 2010). Overall, since 2006, there was an 8.5 percent decrease in the total number of individuals. This decline in the number of individuals has been attributed to low rainfall in previous years (SRS 2010). (USFWS, 2011)

***Threats and Stressors***

**Stressor:** Habitat degradation (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The increased use of the launch facilities at Vandenberg AFB due to nationwide Department of Defense base closures was identified as a threat to this species at the time of its listing (Service 2000). According to the final listing rule (Service 2000), increased use of Vandenberg AFB would potentially result in the loss or alteration of Eriodictyon capitatum habitat. Wildfires were cited as one example of how habitat could be lost or altered. In 1993, debris from a missile that was intentionally destroyed shortly after launching caused several fires and burned more than 162 ha (400 ac). In September of 1997, a 200-ha (500-ac) fire and a 600-ha (1,500-ac) fire burned near habitat occupied by E. capitatum (Los Angeles Times 1997a). In November of 1997, a 495-ha (1,225-ac) fire was accidently started on Vandenberg AFB by an Air Force explosives disposal team and was partially contained by setting a backfire through a population of E. capitatum (Los Angeles Times 1997b). Although increased use of Vandenberg AFB could result in the loss or alteration of E. capitatum habitat (e.g., wildfires), the number of

launches per year is restricted. Habitat alteration and loss from development for military and commercial purposes was also identified as a threat to this species at the time of its listing (Service 2000). Habitat fragmentation within the Burton Mesa area continues. The original extent of Burton Mesa chaparral was approximately 9,000 ha (22,000 ac); by 1938, the extent had been reduced to 5,890 ha (14,554 ac), and by 1988, less than 3,500 ha remained (8,649 ac) (Davis et al. 1988). The only population of Eriodictyon capitatum on Vandenberg AFB that could be threatened by future development would be the 35th Street population. However, at this time, there are no plans to develop this area (Lum pers. comm. 2010). This population is also subject to disturbance from human activities because of its close proximity to paved and unpaved roads and the cantonment area. At present, it appears that the destruction and alteration of habitat due to an increased use of Vandenberg AFB remains a threat to E. capitatum. (USFWS, 2011)

**Stressor:** Non-native species (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** On Vandenberg AFB, Ehrharta calycina (veldt grass) was planted to stabilize sand dunes in the 1950s; with the aid of the prevailing onshore winds, it rapidly spread across Vandenberg AFB and onto Burton Mesa between 1979 and 1996 (Air Force 1996). This species spreads rapidly, both vegetatively and through a persistent seedbank, and is extremely difficult to eradicate once it has become established (Bossard et al. 2000). Carpobrotus edulis and C. chilensis are other nonnative species that threaten to alter the maritime chaparral habitat by forming dense mats (Odion et al. 1992). The Eriodictyon capitatum population located at 35th Street is the only population on Vandenberg AFB whose habitat is actively managed (e.g., removal of nonnative and invasive plant species). This population is located next to paved and unpaved roads and the cantonment area. Nonnative species such as Cortaderia jubata, Pinus radiata (Monterey pine), and Eucalyptus globulus (eucalyptus) have all invaded E. capitatum habitat in this area. The alteration of habitat due to an increase in nonnative species is still a threat to E. capitatum populations located on Vandenberg AFB. There is no information available on nonnative species that may threaten the populations of E. capitatum located in the Solomon Hills and Santa Ynez Mountains. (USFWS, 2011)

**Stressor:** Altered fire regime (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat for Eriodictyon capitatum may be altered by the increase in Ehrharta calycina and subsequent increases in the frequency of wildfires. Invasive plants such as E. calycina can change the fuel properties of a site, which can in turn affect fire behavior, and ultimately alter fire regime characteristics such as frequency, intensity, extent, and seasonality of fire. If the regime changes subsequently promote the dominance of the invaders, then an invasive plant-fire regime cycle may be established, and restoration to preinvasion conditions becomes more difficult (Brooks et al. 2004). Although the natural fire return interval is unknown, because of its low elevation and infrequent lightning strikes, it was probably greater than the 20 to 30-year fire return interval found across most of Vandenberg AFB (Hickson 1988). A shorter fire return interval than the one that naturally occurs could negatively impact native plant species by destroying plants before seed set occurs or destroying the seed bank. (USFWS, 2011)

**Stressor:** Oil extraction and energy activities (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Although we did not discuss it in Factor A in the rule to list Eriodictyon capitatum, we discussed elsewhere in the rule that oil extraction and refinement (e.g., maintenance activities, hazardous waste cleanup) are activities taking place at the Solomon Hills site where this species occurs. Since the time of listing, several activities have been conducted within habitat for this species in the Solomon Hills. In 2007 and 2010, projects to maintain well pads and adjacent roads were undertaken by Breitburn Energy Company. The purpose of these projects was to trim or remove E. capitatum stems that had encroached onto cleared well pads, oil drilling and processing equipment, wells, power poles, and other areas. During such activities, only stems that are in areas where they pose a fire safety risk or operational constraint are removed. At this time, it does not appear that oil extraction and energy development activities are a threat to E. capitatum. (USFWS, 2011)

**Stressor:** Development of Hollister ranch (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** While development on Hollister Ranch is considered low-density (approximately 50 single-family homes as of 2009), these residential homes are often associated with other development including accessory buildings, agricultural development, reservoirs and roads, all of which have increased the demand on limited water resources and have resulted in the alteration and degradation of portions of the natural landscape (County of Santa Barbara Planning and Development Department 2009). An undated botanical survey (Hollister Ranch Conservancy 2003) indicates that E. capitatum occurs on six contiguous parcels in the western portion of Hollister Ranch. Of these six parcels, an undeveloped parcel has been sold and a second parcel has a completed residence and is available for purchase (Hollister Ranch Realty 2010). All six of these parcels are located within designated critical habitat for the species and could be developed. Development on Hollister Ranch is regulated under CEQA and requires the lead agency (i.e., County of Santa Barbara) to avoid or mitigate a project's significant environmental impacts if alternatives or mitigation measures are feasible. However, determination of the adequacy of avoidance or mitigation strategies is at the discretion of the County of Santa Barbara. Therefore, we believe that development is a threat to the population of E. capitatum located on Hollister Ranch. (USFWS, 2011)

**Stressor:** Stochastic extinction (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** As stated in the 2000 final listing rule, we continue to believe that the existence of five populations of Eriodictyon capitatum and the species' restricted distribution place this species at risk of extinction from stochastic events. The conservation biology literature commonly notes the vulnerability of taxa known from very few locations and/or from small and highly variable populations (e.g., Shaffer 1981, 1987; Groom et al. 2006; Primack 2006). This vulnerability can arise due to uncertainty with stochastic events, such as environmental stochasticity, natural

catastrophes, genetic stochasticity, and demographic stochasticity. Populations of E. capitatum are subject to all of these stochastic events. Elam (1994) found that two of the six populations she studied were uniclonal. Because E. capitatum is self-incompatible and cannot produce viable seed, a uniclonal population can be extirpated by both environmental stochasticity (e.g., prolonged drought) and natural catastrophes (e.g., wildfire). Furthermore, genetic stochasticity can result in a loss of genetic variation and subsequently decrease population viability. (USFWS, 2011)

**Stressor:** Climate change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, we did not discuss the potential effects of climate change on the long-term persistence of Eriodictyon capitatum. Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, Intergovernmental Panel on Climate Change 2007). It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects. While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to Eriodictyon capitatum at this time. (USFWS, 2011)

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

Recovery Priority Number: 11

**Delisting Criteria:**
Delisting criteria are not available.

**Recovery Actions:**
- Recovery actions are not available.
- Complete a Recovery Outline and Species Action Plan for Eriodictyon capitatum as a first step in preparing a recovery plan for the species. (USFWS, 2011)
- Develop a survey protocol for Eriodictyon capitatum. Because of its clonal habit, surveyors may develop their own methods or may avoid counting the number of individuals. Creating a survey protocol would encourage documentation of the number of plants and would allow comparison across the species range. (USFWS, 2011)
- Work with representatives from Breitburn Energy Company, CDFG, and Hollister Ranch to ensure that management of their lands is consistent with the long-term persistence of Eriodictyon capitatum at those sites. In addition, maintain contact with these representatives to ensure that survey information is updated on a regular basis. (USFWS, 2011)
- Conduct genetic testing in collaboration with representatives from the Air Force, Breitburn Energy Company, CDFG, and Hollister Ranch. Genetic testing can determine if a population is uniclonal or multiclonal. This information could aid in developing appropriate

management decisions and conservation strategies for each population. (USFWS, 2011)
- Discuss with conservation experts if cross-pollination of uniclonal populations with multiclonal populations would be an appropriate management strategy to increase the amount of viable seed produced. This would aid in increasing genetic diversity within uniclonal populations. (USFWS, 2011)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Throughout this document, our own use of the word stem refers to all vertical vegetative parts including ramets. However, in our analysis of reports prepared by other observers, it was often impossible to determine the intended use of the words “stem,” “ramet,” “individual,” and “plant,” and it was often confusing and not consistent from one observer to the next (e.g., ManTech 2020a, p. 18). In accordance with IUCN (2014, p. 23–24) recommended guidelines for colonial and modular organisms, we recommend counting the number of all vertical stems (including ramets) and reporting that number as vertical stems along with a statement of this method. Little is known about the biology and ecology of Lompoc yerba santa in 2021. Therefore, coordinated conservation and research are needed to further understand the species, and to restore and maintain the 11 known occurrences. These efforts should include: • Implement management actions to reduce threats and benefit the occurrences of Lompoc yerba santa. • Conserve and protect habitat in vicinity of and near existing occurrences, with particular attention to maritime chaparral on Burton Mesa, Vandenberg Space Force Base. • Conduct searches for additional locations of Lompoc yerba santa, including use of helicopters and drones for searching large expanses of potential habitat and potential habitat in difficult terrain. Priority should be given to searching in vicinities of occurrences 12 (Jack and Laura Dangermond Preserve) and 13 (Upper LaSalle Canyon, Vandenberg Space Force Base). • Collect tissue samples from occurrence 12 for genetic analyses. • Continue seed collection for seed banking. In coordination with Santa Barbara Botanic Garden and contingent upon results of previous sampling, multicolonal locations should be visited to determine if seed production is occurring, in particular at occurrences 2, 13 and 14 as a matter of urgency (these three occurrences are on Vandenberg Space Force Base). • Collect and cultivate cuttings and seeds to develop protocols for propagation and outplanting for long-term restoration success. In consideration of the threat of climate change with severe drought and increased temperatures, the methods employed for outplanting in arid lands by Abella et al. (2012, entire), Abella et al. (2015, entire), Abella (2017, entire) and Abella et al. (2020, entire) should be considered. • Study genetic diversity and reproductive biology, pollinator network and potential network disruption, potential barriers to recruitment, and the species’ relationship with fire. • Introduce Lompoc yerba santa into living collections at botanic gardens. (USFWS, 2021)

# SPECIES ACCOUNT: *Eriogonum apricum (incl. var. prostratum)* (Ione (incl. Irish Hill) buckwheat)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

Low-growing, herbaceous perennial; Polygonaceae. (NatureServe, 2015)

**Historical Range**

Known only from an approximate 16-kilometer (km) (10-mile (mi)) stretch along the Ione Formation in western Amador County. Although little information is available to determine the historical extent of either E. apricum variety, and there has been a loss of natural occurrences within the range, the species still persists throughout its estimated historical range. All of the historical and current occurrences are between the village of Buena Vista in the south and Highway 16 in the north 6 (CNDDB 2008). At the time of listing, it was suggested that the range of E. apricum var. apricum may extend to cover portions of Sacramento County (Service 1999, p. 28406); however, surveys conducted in 2001 have placed all of the E. apricum var. apricum plants in Amador County (Service 2005, p. 15). (USFWS, 2010)

**Current Range**

Ione Formation, Amador Co, California. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Habitat Type**

Adult: Chaparral (Natureserve, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Coarse, very acidic, nutrient-poor soils with cement-like, iron oxide crusts (NatureServe, 2015).

**Environmental Specificity**

Adult: Very Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits coarse, very acidic, nutrient-poor soils with cement-like, iron oxide crusts. On these soils - developed under a tropical or subtropical climate 35-57 million years ago - a distinctive, low-growing chaparral community occurs, usually surrounded by taller, more common chaparral types. Eriogonum apricum is restricted to otherwise barren red clays within these "Ione chaparral" communities. Most populations occur between 90 and 280 m elevation.

(NatureServe, 2015)

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

6 - 20 (NatureServe, 2015)

**Population Narrative:**

Occupies a total of approximately 4 hectares (Fish and Wildlife Service 1999). 6 sites ranked above C; 10 total EOs in NDDB. According to Fish and Wildlife Service (1999), there are nine occurrences. (NatureServe, 2015)

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The primary threat to Eriogonum apricum habitat is mining for silica sand, clay, lignite, common sand and gravel. Development for commercial or residential development, clearing for agriculture, and fire protection are lesser threats (USFWS, 2010).

**Stressor:** Stochastic events and climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Events such as disease outbreaks, reproductive failure, extended drought, landslides, or a combination of several such events, could destroy part of a single population or entire populations. A local catastrophe could also decrease a population to so few individuals that the risk of extirpation due to genetic and demographic problems inherent to small populations would increase. Climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying. However, predictions of climatic conditions for smaller sub-regions such as California remain uncertain. It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects (USFWS, 2010).

***Recovery***

# SPECIES ACCOUNT: *Eriogonum codium* (Umtanum Desert buckwheat)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 05/23/2013; Pacific Region (Region 1) (USFWS, 2016)

**Physical Description**

A low, mat-forming woody perennial. Slow-growing and long-lived. Leaves are covered with dense white hairs. Flowers are yellow. (NatureServe, 2015)

**Taxonomy**

Species from Washington state published in: Reveal, J.L., Caplow, F.E., Beck, K.A. 1997. Eriogonum codium (Polygonaceae: Eriogonoideae), A new species from south-central Washington. Rhodora. 97: 350-356. (NatureServe, 2015)

**Historical Range**

Umtanum desert buckwheat was discovered in 1995 during a botanical survey of the Hanford installation (Reveal et al. 1995, p. 353). It is unknown if the historic distribution of Umtanum desert buckwheat was different than the species' current distribution, but it is likely the species has been confined to this location during at least the last 150 years (USFWS, 2013).

**Current Range**

One ridgeline, Benton County, southeastern Washington. (NatureServe, 2015) Found only on the Hanford Reach of the Columbia River. The only known population of Umtanum desert buckwheat occurs along the top edges of the steep slopes on Umtanum Ridge (USFWS, 2013).

**Critical Habitat Designated**

Yes; 12/20/2013.

**Legal Description**

On December 20, 2013, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Eriogonum codium (Umtanum Desert buckwheat) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in Washington (78 FR 76995-77005; 78 FR 24008-24032).

**Critical Habitat Designation**

The critical habitat designation for Eriogonum codium includes one CHU in Benton County, Washington. This species critical habitat encompasses approximately 334 acres (ac) (139 hectares (ha)) (78 FR 76995-77005; 78 FR 24008-24032).

This critical habitat unit was mapped using Universal Transverse Mercator, Zone 11, North American Datum 1983 (UTM NAD 83) coordinates. These coordinates establish the vertices of the unit boundaries. The maps in this entry, as modified by any accompanying regulatory text, establish the boundaries of the critical habitat designation. The coordinates or plot points or both on which the map is based are available to the public at the field office Internet site (http:// www.fws.gov/wafwo/HanfordPlants/ FLFCH.html), http:// www.regulations.gov at Docket No. FWS–R1–ES–2013–0012, and at the Service's Washington Fish and Wildlife Office. You may obtain field office location information by contacting one of the Service regional offices, the addresses of which are listed at 50 CFR 2.2.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Eriogonum codium critical habitat consists of five components (78 FR 76995-77005; 78 FR 24008-24032):

(i) North- to northeast-facing, weathered basalt cliffs of the Wanapum Formation at the eastern end of Umtanum Ridge in Benton County that contain outcrops, cliff breaks, slopes, and flat or gently sloping cliff tops with exposed pebble and gravel soils.

(ii) Pebbly lithosol talus soils derived from surface weathering of the top of the Lolo Flow of the Priest Rapids Member of the Wanapum Formation.

(iii) Sparsely vegetated habitat (less than 10 percent total cover), containing low amounts of nonnative or invasive plant species (less than 1 percent cover).

(iv) The presence of insect pollinator species.

(v) The presence of native shrub steppe habitat within the effective pollinator distance (300 m (approximately 980 ft)) around the population.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and that may require special management considerations or protection. All areas designated as critical habitat as described below may require some level of management to address the current and future threats to the physical and biological features essential to the conservation of Umtanum desert buckwheat. In all of the described units, special management may be required to ensure that the habitat is able to provide for the biological needs of the species. Further studies leading to an enhancement or reintroduction plan may be necessary to increase population size and prepare for recovery postwildfire. More research is needed to determine habitats most suitable for expansion of the current population. In summary, special management considerations or protections should address activities that would be most likely to result in the loss of Umtanum desert buckwheat plants or the disturbance, compaction, or other negative impacts to the species' habitat. These activities could include, but are not limited to, recreational activities and associated infrastructure, off-road vehicle activity, dispersed recreation, wildfire, and wildfire suppression activities. Special management considerations or protection will conserve the primary constituent elements for the species. Management activities that could ameliorate these threats include, but are not limited to, the fire management plan that has been completed for the Hanford installation (DOE 2011, p. 93) and recently revised to incorporate more detailed management objectives and standards. Though not intended to specifically address Umtanum desert buckwheat, implementation of this plan will contribute to the protection of the primary constituent elements (and physical or biological features) by: (1) Using a map of ''sensitive resources'' on the site during implementation, including the location of Umtanum desert buckwheat habitat; (2) requiring a biologist to assist the command staff in protecting these environments during wildfire suppression efforts; and (3) restricting public access to the entire Umtanum desert buckwheat site, including the pollinator use area. Public access without security clearance is currently prohibited at the Umtanum desert buckwheat site, reducing the risk of trampling or crushing the plants by ORV use. Special management to protect the designated critical habitat areas and the features essential to the conservation of Umtanum desert buckwheat from the effects of the current wildfire regime may include preventing or restricting the establishment of invasive, nonnative plant species, post-wildfire restoration with native plant species, and reducing the likelihood of wildfires affecting the population and nearby plant community components. These actions may be achieved by detailed fire management planning by the DOE, including rapid response and mutual support agreements between the DOE, the Monument, the U.S. Department of the Army, Bureau of Land Management, and the Washington Department of Fish and Wildlife for wildfire control. These agreements should contain sufficient detail to identify actions by all partners necessary to protect habitat for Umtanum desert buckwheat from fire escaping from other ownerships.

***Life History***

**Food/Nutrient Resources**

**Food/Nutrient Narrative**

Adult: Growth rates are also extremely slow, with stem diameters increasing an average of only 0.17 millimeters (mm) (0.007 in) per year (The Nature Conservancy (TNC) 1998, p. 9; Dunwiddie et al. 2001, p. 62) (USFWS, 2013).

**Reproductive Strategy**

Adult: Sexual: self-pollination, cross-pollination (USFWS, 2013)

**Lifespan**

Adult: 100+ years (USFWS, 2013)

**Key Resources Needed for Breeding**

Adult: Insect pollinators (USFWS, 2013)

**Reproduction Narrative**

Adult: Individual plants may exceed 100 years of age, based on counts of annual growth rings on cross sections of the main stems of recently dead plants. Preliminary counts indicate that seed set occurs in approximately 10 percent of flowers observed, potentially limiting reproductive capacity. Based on a pollinator exclusion study (Beck 1999, pp. 25–27), the species is probably capable of at least limited amounts of self-pollination, although the percentage of seed set in the absence of pollinators appears to be low. A variety of insect pollinators were observed on Umtanum desert buckwheat flowers, including ants, beetles, flies, spiders, moths and butterflies (TNC 1998, p. 8). Wasps from the families Vespidae and Typhiidae and a wasp from the species Criosciolia have been observed in the vicinity of Umtanum desert buckwheat, but not on the plant itself. A bumble bee, Bombus centralis, has been observed by Washington Department of Natural Resources (WDNR) specialists utilizing flowers of Umtanum desert buckwheat plants (Arnett 2011b, pers. comm.) (USFWS, 2013).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Cliff, grassland/herbaceous (NatureServe, 2015); scarp, scree (USFWS, 2013)

**Geographic or Habitat Restraints or Barriers**

Adult: Found at elevations between 335 and 390 meters (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow. Specialist or community with key requirements common. (NatureServe, 2015)

**Habitat Narrative**

Adult: Eriogonum codium is restricted to a particular basalt flow, growing on flat or gently sloping areas near the top of the steep basalt cliffs. This species is found at elevations between 335 and 390 meters (Washington Natural Heritage 2002). (NatureServe, 2015) As the basalt of the Lolo Flow weathers, a rocky soil type is formed that is classified as lithosol, a term describing the well-drained, shallow, generally stony soils over bedrock (Franklin and Dyrness 1973, p. 347), and talus slopes associated with eroding outcrops and cliffs. These cliffs (scarps) and loose rock at the base of cliffs or on slopes (defined as scree) are found along the crests and slopes of local hills and ridges, including east Umtanum Ridge, where Umtanum desert buckwheat occurs (USFWS, 2013).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available.

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2021)

**Population Growth Rate:**

Stable (NatureServe, 2015)

**Number of Populations:**

1 (3 sub-populations) (USFWS, 2022)

**Population Size:**

3,016 (USFWS, 2021)

**Additional Population-level Information:**

Estimates for the population reflect the number of vegetative and flowering plants. When monitoring began, five subpopulations were delineated by breaks in substrate exposure (Dunwiddie et al. 2000, p. 60). Due to additional plants being discovered, the five subpopulations were redefined as three separate subpopulations: East, Middle, and West. Monitoring methods have been inconsistent over the years, and it is widely accepted that the monitoring efforts from 1995 to 2011 did not include all of the outlying plant clusters. In fact, the larger counts in 1997, 2011, and 2019 are attributed to either refined counting techniques or the discovery of previously unknown plants and clusters (USFWS, 2022).

**Population Narrative:**

The single Umtanum desert buckwheat population is small and declining. The population has declined from a high of 5,228 plants in 1997 to a low of 3,016 plants in 2019. The Population Viability Analysis (PVA) model for Umtanum desert buckwheat reported an annual population growth rate of 0.9935 with low recruitment indicating that there are greater numbers of plant mortalities occurring than individuals being recruited into the population (Caplow et al. 2007). Therefore, there is a slow decline of less than 1 percent annually without accounting for stochastic events. The population size after stochastic events exhibited sharp declines of 17.7 percent in 1996 and 51.2 percent in 2017. Because the population is small and in decline, it is possible that a single catastrophic event could cause the extinction of the species. (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Climate change (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** climate change represents a potential ongoing threat based on the best available information, more thorough investigations are needed to better understand the potential impacts of climate change to this species.

**Stressor:** Habitat destruction and modification (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Factors adversely affecting habitat of Umtanum Desert buckwheat include wildfire and associated firefighting activities, nonnative plant fuel sources that increase the availability of wildfire fues sources, and potentially wildfire suppression activities. Unauthorized livestock trespassing, prospecting, and off-road vehicle use represent potential threats, which appear to be presently reduced because of improved boundary integrity, access controls, fencing, and enforcement (USFWS, 2013).

**Stressor:** Predation (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Predation of seeds by ants and removal of flower heads by an unknown species has been observed by researchers during demographic monitoring trips. No Umtanum desert buckwheat seedlings have been observed successfully germinating or becoming established near ant colonies. Because seed predation and the removal of flowering structures could significantly reduce the reproductive potential of the species, which is already in gradual decline based on the results of the PVA, these activities are considered to be ongoing threats to Umtanum desert buckwheat (USFWS, 2013).

**Stressor:** Small population size and low recruitment (USFWS, 2013)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Umtanum desert buckwheat has a small population size and distribution, and suffers from low recruitment. These features make it particularly susceptible to potentially changing climate conditions. The lack of establishment and survival of seedlings is a threat, as few plants are becoming established as replacements for plants that die (USFWS, 2013).

***Recovery***

**Reclassification Criteria:**
Recovery priority number of 5

**Delisting Criteria:**
Draft desliting requirement 1. Six Umtanum desert buckwheat populations (USFWS, 2022)

Draft desliting requirement 2. Self-sustaining populations with an average size of 1,200 individuals for at least 15 years (USFWS, 2022)

Draft desliting requirement 3. Populations are in a matrix of native shrubsteppe habitat within effective pollinator distance of 300 meters and threats managed by partners with long-term management commitments (USFWS, 2022).

Draft desliting requirement 4. Populations are adequately protected from wildfire (USFWS, 2022)

Draft desliting requirement 5. Seed collections are established, stored, and maintained at seed banks (USFWS, 2022)

**Recovery Actions:**
- Not available.

***Conservation Measures and Best Management Practices:***
- RECOMMENDATIONS FOR FUTURE ACTIONS • Recovery Action 1: Protect the extant population and reduce the risk from wildfire. Improve access to Umtanum Ridge for emergency activities and recovery actions. Implement habitat restoration activities within and adjacent to occupied habitat to reduce wildfire risk due to abundant invasive plants. • Recovery Action 2: Preserve and augment the extant population by connecting subpopulations and isolated individuals to increase reproductive rates. • Recovery Action 3: Identify potentially suitable habitat sites and survey for additional Umtanum desert buckwheat populations. • Recovery Action 4: In areas of suitable habitat, establish and/or identify at least five additional populations to increase the species' redundancy, representation, and resiliency. • Recovery Action 5: Monitor the rangewide population, track trends, and assess threats. Implement a rangewide monitoring protocol and determine population trends. Develop and implement a detailed monitoring plan to assess known threats and identify potential new threats to the species and its habitat. • Recovery Action 6: Study the species ecology and breeding system, factors limiting reproductive success, the effect of climate change, and the response to management actions to guide conservation efforts. • Recovery Action 7: Promote awareness and conservation of Umtanum desert buckwheat throughout its geographic range.

# SPECIES ACCOUNT: *Eriogonum gypsophilum* (Gypsum wild-buckwheat)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 02/19/1981; Southwest Region (R2) . Proposed for Delisting (USFWS, 2017).

**Physical Description**

This plant is a woody stemmed perennial that grows in dense clumps and is approximately 20 cm high. The leaves are dark green, thick, mainly hairless, 1.5 - 2.5 cm wide and often wider than long, attached at the base, and have an outline like a hen's egg or a kidney. In the. fall the leaves turn bright red. The yellow flowers, 1-2 mm long, and in a broad dense cluster, appear from May to July. (USFWS, 1984)

**Taxonomy**

This species was first collected by E. O. Wooton on August 6, 1909, and described by Wooton and Standley in 1913. There are many species in this genus but Eriogonum gypsophilum is not closely related to any other western species (Wooton and Standley 1913). (USFWS, 1984) Gypsum wild-buckwheat is a distinct species without synonyms or taxonomic controversy. (USFWS, 2016)

**Historical Range**

See Current Range.

**Current Range**

In Eddy County, New Mexico. (USFWS, 2016). Gypsum wild buckwheat is represented by populations at Seven Rivers Hills, Black River, Ben Slaughter Draw, and Hay Hollow, which comprise the species' 60.8 kilometer (km) (37.8 miles (mi)) range (USFWS, 2022).

**Critical Habitat Designated**

Yes; 2/18/1981.

**Legal Description**

On January 19, 1981, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective February 18, 1981) for Eriogonum gypsophilum (Gypsum wild-buckwheat) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in New Mexico (46 FR 5730-5733).

**Critical Habitat Designation**

The critical habitat designation for Eriogonum gypsophilum includes one CHU in Eddy County, New Mexico. This species critical habitat encompasses approximately 130 acres. A map is included in the Final Rule (USFWS, 1981; USFWS, 1984).

New Mexico: Eddy County; T20S. R25E. Section 19: N½, N½ NE¼ SE¼, N½ NW¼ SE¼; and T20S, R24E. Section 24: N½ NE¼, N½ S½ NE¼, NE¼ NW¼, N½ SE¼ NW¼; gypsum soils.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Eriogonum gypsophilum critical habitat are not listed but are thought to be the following (46 FR 5730-5733):

Gypsum soils.

**Special Management Considerations or Protections**

Any activity which would result in disturbance of the area where Eriogonum gypsophilum occurs would probably adversely modify the Critical Habitat. The long-term solution on how to best protect Eriogonum gypsophilum may be to develop a protection plan for the species, which would address and remove present threats. In this respect, Critical Habitat designation may affect Federal activities. The Water and Power Resources Service should include in their planning process for the Brantley Dam Project ways to insure the continued existence of Eriogonum gJpsophilum. These plans should address the problems of slumping of the gypsurm soils and ways to protect the habitat of the Eriogonum gypsophilum so that it is not used for any activity which would not be compatible with the plant's continued existence. The Bureau of Land Management may need to limit future stocking rates of cattle and offroad vehicle use in the small area where the Eriogonum gypsophiIum occurs. This increased planning and the steps required by these agencies should not constitute a large impact or hardship on either agency. (USFWS, 1981)

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual, asexual: vegetative (USFWS, 2007)

**Lifespan**

Adult: 2+ (inferred from USFWS, 2007)

**Breeding Season**

Adult: May - July (USFWS, 1984)

**Reproduction Narrative**

Adult: Gypsum wild buckwheat is a perennial species that reproduces both by producing seed and also asexually by producing clone rosettes from rhizomes or rootsprouts (USFWS, 2007). Flowers appear from May to July (USFWS, 1984).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Grama grassland, creosote bush communities (NatureServe, 2015); Chihuahuan desert scrub (USFWS, 1984)

**Geographic or Habitat Restraints or Barriers**

Adult: 900 - 1,500 m elevation (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Patchy and linear (USFWS, 2007)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015 and USFWS, 2007)

**Habitat Narrative**

Adult: Inhabits open, gypsum in grama grassland, at about 1,500 m; semi-arid. Eroded gypsum clay hills and fans, creosote bush communities, 900-1,100 m (Flora of North America Editorial Committee 2005) (NatureServe, 2015). It occupies gypsum soils and gypsum outcrops of the Permian-age Castile Formation. Distribution of gypsum wild buckwheat plants within its populations is patchy and follows geographic patterns of suitable gypsum outcrops, which are generally elongate and narrow (USFWS, 2007). It occurs in the Chihuahuan region of the Desert Scrub Formation (Donart et al. 1978) (USFWS, 1984).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Number of Populations:**

4 (USFWS, 2022)

**Population Size:**

Estimated to be 50,548 individuals (USFWS, 2016)

**Additional Population-level Information:**

Distribution of gypsum wild-buckwheat plants within its populations is patchy and follows geographic patterns of suitable gypsum outcrops, which are generally elongate and narrow. The lengths of these occupied outcrops are approximately 2.7 kilometers (km) (1.7 miles (mi)) long for the Seven Rivers Hills population, 1.6 km (1 mi) long for the Black River population, and 3.5 km (2.2 mi) long for the Ben Slaughter Draw population. Patches of gypsum wild-buckwheat within populations are also relatively small. The area of occupied habitat is only 16.3 hectares (ha) (40.3 acres (ac)) at Seven Rivers Hills, little more than 11.9 ha (29.5 ac) at Black River, and 66.4 ha (164.1 acres) at Ben Slaughter Draw (including Hay Hollow) for a total range-wide extent of approximately 94.7 ha (233.9 ac) of habitat occupied by this species (Tonne 2005, Sivinski 2013). (USFWS, 2016)

**Population Narrative:**

Estimated numbers of individual plants are the three known locations are as follows: Seven Rivers Hills: 14,168; Black River: 16,660; Ben Slaughter Draw (including Hay Hollow): 19,720. Refined mapping techniques resulted in the delineation of 16.3 ha (40.3 ac) actually occupied by gypsum wild-buckwheat. This is a significant reduction from the approximately 44 ha (109 ac) of occupied habitat identified previously by Spellenberg (1977) and Knight (1993). It appears BLM and Knight used the approximately 109 acres of occupied habitat as the multiplier for an average density estimate, thereby overestimating this population. This original acreage estimate was the basis for the recovery criteria to maintain a population of 10,000 plants at Seven Rivers Hills designated critical habitat area. The Black River and Ben Slaughter Draw populations of gypsum wildbuckwheat also occur as discontinuous patches of plants on the gypsum outcrops. Knight (1993) used belt transects to determine average density of plants within the Black River habitat. He estimated 32 ha (80 ac) of occupied habitat to arrive at a population estimate of 45,280 plants (rosettes). Subsequent GPS mapping (Tonne 2005) of this population significantly reduced the area of occupied habitat on BLM and state- owned lands within this population (the private land portion of this population was not mapped by Tonne). The discrepancies between the population boundaries in Knight's 1993 map and Tonne's 2005 map are more likely the result of the more accurate methods (e.g., use of a Global Positioning System) employed by Tonne than an actual reduction of population coverage between 1993 and 2005. A combination of Knight's (1993) average density estimate of 0.14 plants per m2 (0.01 per ft2) and Tonne's map showing 11.9 ha (29.5 ac) of occupied habitat results in a minimum population number of 16,660 plants at Black River. This estimate may increase when the area of occupied habitat on the private land portion of this population is known. The largest population of gypsum wild-buckwheat occurs at Ben Slaughter Draw. Knight (1993) also sampled this population with belt transects to determine an average density of 0.03 plants per m2 (0.002 per feet2) within occupied habitat. He arrived at a population estimate of 47,233 plants (rosettes) on 117 ha (288 ac). Subsequent GPS mapping of this population conforms to the general population boundaries of Knight's 1993 map, but significantly decreased the occupied habitat area to a more precise 62.4 ha (154.1 acres) (Tonne 2005). A total population estimate of 18,720 plants is obtained by using Knight's 1993 average density estimate and Tonne's 2005 mapped area of occupied habitat. These calculations for Ben Slaughter Draw do not include the 2013 rediscovery of the Hay Hollow portion of the population that he estimated 1,000-1,500 plants across less than 4.0 ha (10.0 ac) (Sivinski 2013). (USFWS, 2016).  Gypsum wild buckwheat remains represented by few (4), small (1–21 ha (3–52 ac)), isolated (by 4.0–71.3 km (2.5–45.3 mi)) populations (see Table 2.1) (Service 2022, pp. 22, 42). These populations are not securely stable (they have average population growth rates below 1.00, and only Seven Rivers Hills currently has good viability) and are unable to rescue one another in the event of catastrophic decline (Service 2022, pp. 50, 103). Note, however, that current population growth rate results are from only two transition-year sets while ten or more consecutive transition year sets may be needed to draw inferences about population growth rates for species with pulsed recruitment (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Mineral extraction and development (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** All gypsum wild-buckwheat habitats are within areas with high potential for fluid minerals leasing and extraction. Oil and gas well pads, roads, and pipelines are proliferating in this region of New Mexico. The BLM SMA on the designated critical habitat of the Seven Rivers Hills population presently eliminates this threat through the requirement of "no surface occupancy" for mineral leases within the designated critical habitat. Roads and pipelines associated with mineral development also must avoid this area. The Seven Rivers Hills SMA protects about 95 percent of the occupied habitat from this land use. SMAs with "no surface

occupancy" stipulations for oil and gas leases were also administratively placed on BLM jurisdictions containing gypsum wild-buckwheat habitats at the Black River and Ben Slaughter Draw populations in 1997 (BLM 1988, BLM 1997). These SMAs protect approximately 50 percent of the total habitat at Black River and Ben Slaughter Draw from oil and gas development (Tonne 2005). Approximately 65 percent of total habitat area in all three gypsum wild-buckwheat populations is presently protected from surface impacts associated with oil and gas development. Knight (1993) concluded that mineral development for oil and gas, and possibly gypsum, was the only serious potential threat to gypsum wild-buckwheat. At this time, surface disturbance associated with federal mineral development is very unlikely to occur on gypsum wild-buckwheat habitats within the BLM SMAs. Mineral development could potentially affect nearly 50 percent of the Black River population. The private land portion of the Black River population could also be impacted by future minerals development. However, about 50 percent of the Black River habitat, about 95 percent of the Seven Rivers Hills habitat, and approximately 50 percent of Ben Slaughter Draw habitats have been protected by the "no surface occupancy" stipulation of the BLM SMAs (Tonne 2005). Oil and gas may be leased on these lands, but must be extracted by directional drilling from outside the SMAs. Directional drilling allows a company to develop fluid minerals without needing to be directly above (vertical of) the target, meaning this technology may afford greater avoidance options for conserving sensitive habitats. Rights-of-ways for the roads and pipelines associated with oil and gas development must also avoid disturbance of the SMAs. The Seven Rivers Hills and Ben Slaughter Draw SMAs also requires the withdrawal of minerals, such as gypsum, sulfur and salts, from claim and mine development. Mineral claims are not specifically withdrawn from the Black River SMA. The chemical analysis found the gypsum of the Castile Formation to be 85 percent hydric gypsum, which is a suitable quality for mining (Weber and Kottlowski 1959, Knight 1993). Potential for gypsum mining of the Castile formation however, is low at this time because of large deposits of higher quality gypsum presently being mined elsewhere in New Mexico (Knight 1993). (USFWS, 2016)

**Stressor:** Reservoir Development and Flooding (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The threat of flooding from Brantley Reservoir has not been fully realized, primarily due to the use of a spillway in the central section of the main dam (BOR 2009). The elevation of the spillway is 993.5 m (3,259.5 ft) mean sea level and the maximum water surface elevation of the reservoir is 1,006.9 m (3,303.5 ft) mean sea level. Water level peaked on March 29, 2015 (U.S. Geological Survey 2016) at approximately 4.0 m (13 ft) above the spillway at 997.5 m (3272.5 ft) elevation. Even at this highest level, the pool remained to the east of U.S. Highway 285 and the gypsum wild-buckwheat population. Knight (1993) analyzed the potential impacts from Brantley Reservoir reaching the maximum flood pool with the assumption that the water level would rise similarly across U.S. Highway 285. Under this assumption, the maximum flood event pool in Brantley Reservoir could temporarily flood a few hectares of gypsum wildbuckwheat habitat. He found eight gypsum wild-buckwheat plants at or below the 1,002.8 m (3,290 ft) level on the west side of U.S. Highway 285. The soils in this area would become saturated for a time after a flood and could potentially be invaded by saltcedar (Tamarix spp.), an invasive tree that often lines the banks of reservoirs. Knight surveyed another 6 m (20 ft) vertical up to the 1,009 m (3,310 ft) level where saltcedar might become established and located an additional 44 gypsum wild-buckwheat plants. In 1993, there were 52 plants in the hypothetical zone of maximum flood impact. A flood event could potentially impact about 100 plants in this

population of several thousand plants. However, at the highest water level recorded in 2015, the water did not reach U.S. Highway 285 and the gypsum wild-buckwheat was not impacted. Therefore, Brantley Reservoir is not a significant threat to gypsum wild-buckwheat. The populations at Black River and Ben Slaughter Draw are not near any existing or proposed reservoirs and therefore, are not threatened by flooding. The Seven Rivers Hills population is the only known population that could be affected by flooding. (USFWS, 2016)

**Stressor:** Drought (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Inadequate seasonally appropriate soil moisture is typically caused by drought and may be exacerbated by hydrological alteration (Factors A and E). Climate change projections for gypsum wild buckwheat's range predict increased temperatures (+2–5 °C (+4–9 °F)), and relatively unchanged precipitation (+3.8 to -6.6 millimeters (mm) (+0.15 to -0.26 inches (in))) through 2099 under representative concentration pathway RCP) scenarios 4.5 and 8.5, respectively. These changes would increase evaporation and drought, adversely affecting survival and recruitment of gypsum wild buckwheat plants. Gypsum wild buckwheat's tolerance of desiccation and ability to go dormant in response to soil moisture stress provides some resilience to climate change, but increases in the intensity, frequency, and/or duration of drought would likely stress this adaptive capacity. Increased drought may also lead to increased predation (Factor C) resulting from reduced availability of alternative preferred forage for herbivores. It is unknown if gypsum wild buckwheat's ability to obtain scarce nutrients and its strategies for surviving drought and herbivory can support self-sustaining wild populations through climate change (USFWS, 2022).

***Recovery***

**Reclassification Criteria:**
Not applicable.

Recovery Priority Number: 14

**Delisting Criteria:**
The criteria for delisting are based upon the designation of the critical habitat as a Bureau of Land Management (BLM) Area of Critical Environmental Concern (ACEC) to maintain the population of 10,000 individuals. Some other special use designation which would secure the area from degradation due to human activities would be acceptable. (USFWS, 1984)

**Recovery Actions:**
- Prevent further impacts by designating the critical habitat area as an ACEC; develop a management plan; manage livestock grazing and study its effects; regulate recreational use, including Off-Road Vehicle (ORV) traffic, in the habitat; and monitor the effects of raised water level in Brantley Reservoir (USFWS, 2016).
- Maintain healthy populations by studying gypsum wild buckwheat biology and habitat characteristics (USFWS, 2016).
- Inventory suitable habitats for new populations (USFWS, 2016).
- Develop public appreciation and support for gypsum wild buckwheat. (USFWS, 2016)

- Recommendation for Future Action from 2016 5-Year Review: Through Section 4 of the ESA, the Service is required to conduct a 12-month finding to review the petition request to delist the gypsum wild-buckwheat and concurrently propose to delist. A post-delisting monitoring plan will be developed and made available for public review and comment prior to a final rulemaking. (USFWS, 2016)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Direct Conservation Actions • Maintain and extend barricades that block motor vehicle access to occupied areas. Close vehicle access to populations and to linear features intersecting populations. • Increase avoidance distances to 300 m for all potentially adverse land use or treatment activities. Maintain avoidance distances over time and across land jurisdictions. • Expand the Hay Hollow population to increase occupied extent and area. For example, establish subpopulations of plants from at least 50 Hay Hollow-sourced maternal lines in suitable soils on the adjacent escarpments north and south of the current Hay Hollow population. • Discover and/or introduce populations that increase gypsum wild buckwheat's range extent and diversity of associated vegetation types, geological units, and climate zones. Research and Monitoring • Expand long-term demographic monitoring across land jurisdictions. Maintain monitoring plots and continue demographic studies until the average transition matrix from 10–15 consecutive years of data demonstrates a stable or increasing population growth rate. • Identify and document gypsum wild buckwheat seed germination and seedling establishment requirements. • Identify and document specifications for suitable gypsum wild buckwheat soils (e.g., soil testing for percent gypsum, other nutrients, and soil microorganisms; soil depth probing; etc.). • Proactively model, survey, and map suitable gypsum wild buckwheat soils. • Identify and document techniques for restoring the gypsum wild buckwheat suitability of compacted, hypergypsic soils. Building Community Support • Install and maintain signs that support education about, and enforcement of, current and existing protective land use designations. Stay ahead of emerging adverse recreational use trends. • Recruit and retain botanical expertise amongst agency environmental review and project management staff (USFWS, 2022).
- Discretionary conservation measures (including project clearance surveys, environmental review of potential impacts, and avoidance distances for surface disturbing activities) currently account for a significant proportion of gypsum wild buckwheat protections (77% of population areas are protected by discretionary conservation measures versus 40% of population areas by special land use designations). Since federal listing under the Act, gypsum wild buckwheat populations have been managed for conservation and expansion primarily through local stakeholder initiative and discretionary programs, practices, and funding. The comprehensive suite of discretionary conservation actions has been effective at minimizing risks from threats and maintaining the status of this species. However, discretionary conservation is vulnerable to rollbacks as budgets and/or administrative priorities change. They are also vulnerable to staff attrition and turn-over. If the species were delisted, continuation of these conservation actions would be uncertain in the absence of formalized administrative direction to retain them (USFWS, 2022).

# SPECIES ACCOUNT: *Eriogonum longifolium var. gnaphalifolium* (Scrub buckwheat)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 5/27/1993; Southeast Region (R4)

**Physical Description**

Eriogonum longifolium var. gnaphalifolium is a perennial herb. It has a taproot and one to three above-ground stems up to 1 m tall, but upwards of 10 stems have been observed in vigorous specimens, especially post-fire. It has a basal rosette of leaves that are 15 to 20 cm long, narrow, and white-woolly on the underside. The stem leaves are smaller than the rosette leaves. The stem terminates in a corymb, with each branch of the corymb ending in a cup-shaped involucre that holds a cluster of 15 to 20 small flowers, with each flower hanging on its stalk down below the involucre. The involucre is silvery, silky-pubescent, and the flowers are green with pink anthers (Rickett 1967) (USFWS, 1999)

**Taxonomy**

The genus Eriogonum includes about 150 species, most of them in western North America. Florida has only two species, both native to high pineland. Eriogonum tomentosum is common throughout the northern part of the state, as far south as Highlands County. The second species, scrub buckwheat, was named Eriogonum floridanum by J.K. Small (1903). Subsequent publications on Florida?s flora consistently adopted Small?s treatment of E. floridanum as a full species (Small 1933, Kral 1983, Ward 1979, Wunderlin 1982), but James Reveal (1968), an expert on the genus, treats the Florida plants as a variety of Eriogonum longifolium, a widespread species of the Great Plains that is represented east of the Mississippi by var. harperi in northern Alabama, Tennessee, and Kentucky (Kral 1983), and by var. gnaphalifolium in Florida (USFWS, 1999).

**Historical Range**

In Florida, in the following counties: Highlands, Hillsborough, Lake, Orange, Osceola, Marion, Pasco, Polk, and Sumter (USFWS, 1996)

**Current Range**

In Florida, in the following counties: Highlands, Hillsborough, Lake, Orange, Osceola, Marion, Pasco, and Polk (USFWS, 1996; USFWS, 2018)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (NatureServe, 2015)

**Lifespan**

Adult: Unknown (NatureServe, 2015)

**Breeding Season**

Adult: January to November (NatureServe, 2015); May - October (USFWS, 1999)

**Key Resources Needed for Breeding**

Adult: Disturbance or fire; hunting wasps and bees (NatureServe, 2015); open sand, moist soils (USFWS, 1999)

**Reproduction Narrative**

Adult: Eriogonum longifolium var. gnaphifolium is an herbaceous perennial that presumably is long-lived and slowly growing. It flowers and reproduces primarily after fires or other disturbances (e.g. logging, mowing) that increase light availability. Although it readily resprouts after fires or other disturbances such as mowing, it does not reproduce vegetatively. Flowering can occur from January to November, but is usually synchronized with fire or other disturbance; most flowering occurs within the first year after a fire. Although a plant is usually in flower for two to three months, the individual flowers are short-lived and open asyncronously. Typically, a maximum of one to two flowers per involucre are open at any one time. The flowers, although inconspicuous, must be insect-pollinated for seed set to occur. Several types of hunting wasps (families Vespidae, Eumenidae, Sphecoidea, Pompilidae) and a few bee species (Halictidae) visit the flowers. These insects, all with an excellent locational sense, may be "traplining" the plants daily for their nectar. Although the flowers provide a dependable source of nectar, it is thought that these insects are the only potential pollinators able to repeatedly located the scattered, inconspicuous flowers (Deyrup pers. communication). Seeds have no dormancy, but germinate only in microsites with little or no litter and sufficient moisture (Carrington unpubl. data). Virtually all seedling establishment, therefore, must occur within the first year after a fire; litter buildup is prohibitive afterwards. Seedling establishment tends to be rare, however, probably because moisture conditions are usually not optimal due to high soil surface temperatures and evaporation rates following growing season fires. Most seedling establishment probably occurs in very wet periods after fires. In the low-light conditions of long-undisturbed communities, Eriogonum longifolium var. gnaphifolium individuals are present as inconspicuous basal rosettes; flowering individuals are rare, and occur only in openings or on edges such as road shoulders or fire breaks (pers. obs.). Plants may be capable of surviving without leaves in undisturbed communities by subsisting on stored carbohydrates in their large roots; this possibility is suggested by the "sudden appearance" of previously undetected adult plants in populations monitored for several years (Menges pers. communication). Longevity of individuals is unknown, but since establishment from seed is extremely rare in long-unburned communities, populations may decline or vanish in sites unburned for several decades. Drought tolerance assumed from habitat. Reproduction is sexual (NatureServe, 2015). Although little information on the reproduction of this species is available, plants in the Ocala NF have been observed with immature flower stalks between April and mid-July and bloom from May to mid-October. Seedlings germinate in summer in open sand (R. Yahr, Archbold Biological Station, personal communication 1998) (USFWS, 1999).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: oak-hickory scrub, turkey oak barrens, and sandhill vegetation communitied on the Lake Wales Ridge (USFWS, 2018)

**Dependencies on Specific Environmental Elements**

Adult: 5 - 20 year fire intervals (USFWS, 2018)

**Environmental Specificity**

Adult: Moderate (inferred from USFWS, 2018)

**Habitat Narrative**

Adult: Scrub buckwheat occurs in oak-hickory scrub, turkey oak barrens, and sandhill vegetation communities on the Lake Wales Ridge from Highlands County north to Lake County. It is also found to a limited extent on the Mount Dora Ridge in the ONF in Marion County and on two parcels of private property in Orange County. Each of the vegetation communities where scrub buckwheat occurs evolved with periodic fire. Demographic modeling suggests population viability is highest when fire return intervals are 5 - 20 years (Satterthwaite et al. 2002) . Scrub buckwheat occurs in several xeric plant communities that may be burned at intervals of 1-8 years for sandhill to 5-12 years for oak-hickory scrub. On the ONF, scrub buckwheat occurs within actively harvested timber stands and habitats that are not managed specifically for timber production. (USFWS, 2018).

***Dispersal/Migration***

**Dispersal**

Adult: Low (inferred from NatureServe, 2015)

**Dispersal/Migration Narrative**

Adult: Seeds have no obvious dispersal mechanism, and usually drop beneath the parent plant; some may be carried a short distance in runoff during a rain (NatureServe, 2015).

***Population Information and Trends***

**Population Trends:**

Not available

**Species Trends:**

Unknown (USFWS, 2018)

**Number of Populations:**

67 extant (USFWS, 2023)

**Additional Population-level Information:**

A total of 93 E. longifolium var. gnaphalifolium EO records have been reported to FNAI since 1961. Based on FNAI’s most recent EO database (2022), there are 67 extant populations with over two-thirds occurring on conservation lands (USFWS, 2023).

**Population Narrative:**

The spatial distribution of scrub buckwheat has not changed from that reported in the 1996 recovery plan. However, additional populations have been located on properties that have been subsequently acquired for conservation purposes within the historic range. Turner et- al. (2006) indicated that there are 27 populations of scrub buckwheat on protected public and private lands and 21 populations on unprotected private lands. Scrub buckwheat populations that are located on unprotected lands are susceptible to extirpation because of land use changes. However, periodic censuses are not conducted and it is not possible to quantify the number or location of extirpations that have occurred due to habitat destruction. The Service is aware of two populations, both in Lake County, that have been extirpated due to issuance of incidental take permits under section 10 of the Endangered Species Act. (USFWS, 2018)

***Threats and Stressors***

**Stressor:** Habitat destruction and degradation (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Twenty-seven of the 48 known scrub buckwheat localities occur on private, local, State, or Federal lands that are protected. This number of sites is substantially higher than the nine protected sites specified in recovery criterion number 1. Habitat loss or modification due to land use changes is not anticipated at these 27 sites because most were acquired for conservation purposes. Nonetheless, simply protecting scrub buckwheat habitat is insufficient to ensure long-term persistence because, as discussed above, this species requires periodic habitat management actions. Except for those properties described above, we do not currently have information about the type or frequency of land management activities on public lands where scrub buckwheat occurs. However, in general, it is widely documented that most public land managing agencies have not been able to burn as many acres as are targeted in their management plans. Consequently, most agencies are backlogged in prescribed burning (R. Mulholland, Florida Department of Environmental Protection, personal communication, 2008). Even though we know managing agencies are faced with difficulties in use of prescribed fire in general, we do not know whether specific areas that contain scrub buckwheat habitat on public lands are threatened with modification due to lack of management. - The 21 scrub buckwheat populations occurring on unprotected private lands are susceptible to degradation of habitat due to lack of management and destruction due to land use changes. Habitat degradation will likely continue on these lands because private landowners have no incentives to manage their properties for scrub buckwheat. Even though scrub buckwheat can persist for long periods in fire suppressed conditions, a reduction in flowering and seedling recruitment can be expected in long-unburned habitats (McConnell and Menges 2002, Satterthwaite et al. 2002, Menges 2007). These adverse effects are expected to continue into the future on unprotected and unmanaged parcels. In addition, urban development is projected to increase in Florida in the coming decades (Zwick and Carr 2006), and we expect a commensurate decline in native vegetation communities. Such assessments, however, cannot project absolute risks of habitat destruction, on a parcel-by-parcel basis. Consequently, while we acknowledge the future risks of destruction of unprotected scrub buckwheat populations, we do not know which, if any, of the 20 populations are imminently at risk. - As a result of land acquisition efforts over the past several decades by private entities and local, State, and Federal governments, 27 scrub buckwheat populations have been protected from habitat destruction and this level of conservation has exceeded recovery criterion 1 in the recovery plan, Even though 21 of the known populations of scrub buckwheat

are not secure and are vulnerable to destruction or decline, we believe the 77 protected populations represent an adequate number of conserved populations to ensure long-term persistence of this species if protected populations benefit from periodic management activities that create and maintain suitable scrub buckwheat habitat (see Recommendations for Future Actions). While each of the public lands containing scrub buckwheat may undertake management activities, we do not currently have information about what types of management or how frequently management occurs on most public lands. Consequently, scrub buckwheat may still be at risk from habitat modification due to lack of management, but we will not know the extent of this risk until we evaluate more thoroughly the historic and ongoing management actions on public lands (see Recommendations for Future Actions). (USFWS, 2018)

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 15 (USFWS, 2023)

**Delisting Criteria:**
1. Complete planned land acquisitions (USFWS, 1996)

2. Protect at least one more site in Lake and/or Pasco counties (one site is protected in Pasco). Demographic monitoring in conjunction with habitat manipulation (prescribed fire or other measures) appears essential, so monitoring is needed for at least five years. (USFWS, 1996)

**Recovery Actions:**

- 1. Determine current distribution of E. longifolium var. gnaphalifolium. A survey has not been made of the Lake Wales Ridge for this species, making defining a complete distribution in South Florida difficult. (USFWS, 1999)
- 2. Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties has been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases is isolated. (USFWS, 1999).
- 3. Continue research on life history characteristics of E. longifolium var. gnaphalifolium. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species more specific biological information is needed. (USFWS, 1999)
- 4. Continue monitoring the existing populations of E. longifolium var. gnaphalifolium. Evaluate the effectiveness of the monitoring protocol used to assess population trends for E. longifolium var. gnaphalifolium. Monitor and detect changes in demographic characteristics, such as growth, survival, mortality. Monitor the effects of various land management actions on E. longifolium var. gnaphalifolium. Continue to work with private landowners. Monitor introduced plants. Monitoring of reintroduced plants will be essential for assessing the status of new plants and their contribution to the population as a whole. (USFWS, 1999).
- It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed. Public outreach efforts must also continue to address the increasing concern that horticultural demand for rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial

production and horticultural uses of endangered species provide little benefit to species, since the recovery of E. longifolium var. gnaphalifolium and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999).

- Revise the recovery criteria to establish measurable goals for demographic monitoring, including but not limited to: the number of populations that should be monitored, the demographic parameters that should be measured, and the demographic performance levels/rates that should be met (USFWS, 2018).
- Monitoring of scrub buckwheat populations should be initiated on the ONF to evaluate the response of scrub buckwheat to soil disturbances associated with timber harvesting/site preparation activities and to determine the status of the species on the ONF (USFWS, 2018).
- The demographic status of scrub buckwheat populations may be inferred with minimal additional information. We believe that information regarding the number of individual plants and land management history can allow for a reasonable estimation of the current demographic status of extant scrub buckwheat populations. In this regard, we do not currently know how many plants exist on 23 of the 27 public lands where records indicate scrub buckwheat occurs. Consequently we recommend that surveys be conducted on public lands where no count data are available. Surveys initiated soon after fire would be valuable in assessing post-fire response of scrub buckwheat. We also suggest that a synthesis be conducted of historic and ongoing management actions on the same parcels for which counts are conducted. Knowing the historic and ongoing management strategy will provide information about whether land management strategies are conducive to long-term persistence of scrub buckwheat. (USFWS, 2018)
- The use of temporally and spatially appropriate management actions (e.g., prescribed fire or other disturbance regime) in areas containing scrub buckwheat should be encouraged on all public lands (USFWS, 2018).

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES • Conduct surveys on all conservation lands where the species is known to occur. Surveys should include locations of plants, estimate number of individuals, and general habitat conditions (i.e. recent habitat management, time since fire). Current survey information for populations are critical for future evaluations. • Establish a standardized monitoring protocol for consistency among populations and conservation lands (USFWS, 2023).

# SPECIES ACCOUNT: *Eriogonum ovalifolium var. williamsiae* (Steamboat buckwheat)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 8/7/1986; Pacific Southwest (R8)

**Physical Description**

Steamboat buckwheat (Figure 2) is a low, densely matted, compact perennial herb, 0.5-4.5 dm across, with numerous, densely-leaved, woody branches. The above-ground portions of the plant arise from a shallow but stout, woody, reddish brown taproot (usually in older plants), or a shallow, fibrous, rhizomatous root system (in younger plants). Each plant bears numerous oval to reniform leaves congested in tight rosettes. Leaf blades are generally 3-8 mm, 5-10 mm wide, and are densely covered with greenish-white to tannish-white hairs. Some leaves exhibit a faint brown margin at maturity. Petioles are generally 3-6 mm long, woolly, and often wavy or curled. Inflorescences are borne on erect, partly woolly stems, up to 2.5 dm (10 in) long, and are enclosed in cone shaped involucres covered with densely-matted, woolly hairs. Five to eight involucres are clustered in a head at the top of each stem. Flowers are generally white with a central greenish-brown rib, turning pinkish-tan with age (Reveal 1981; Williams 1982). Blooms May-early June. (USFWS, 1995)

**Taxonomy**

Named for Margaret Williams (1917-2000). Genetic analysis by Archibald et al. (2001) revealed var. williamsiae has high genetic variability, with levels of variation similar to that typical of a widespread species rather than a narrow endemic; and that all six varieties (note: var. depressum, var. monarchense, var. ochroleucum, var. pansum, and var. vineum were not sampled for the study) are very similar allozymically with var. williamsiae being the most similar to the widespread var. ovalifolium. Also, although var. williamsiae and var. ovalifolium are morphologically distinct, their genetic similarity warrants further study to determine whether or not they should be treated as separate taxa. Further, evidence of male sterility in var. williamsiae plus other data led Archibald et al. (2001) to hypothesize that this taxon might be either a hybrid or undergoing cytoplasmic introgression. (NatureServe, 2015)

**Historical Range**

See Current Range.

**Current Range**

This species is known from a single population in Washoe County, Nevada, located approximately 10 miles south of Reno. (USFWS, 2019)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual and asexual (NatureServe, 2015)

**Dependency on Other Individuals or Species**

Adult: Flowers are visited by a diverse group of smallish insects including bees, wasps, flies, and butterflies (Archibald et al., 2001). Some observers have suggested that butterflies pollinate them and that ants disperse the seeds (Soper, 1987). (NatureServe, 2015)

**Breeding Season**

Adult: May to June (NatureServe, 2015)

**Reproduction Narrative**

Adult: The plant reproduces by seed and vegetative spread. Clonal propagation may be the primary mode of reproduction in Steamboat buckwheat, coupled with occasional occurrences of seed production through sexual recombination (Ten Knight, TNC and Jim Morefield, NNHP, pers. comm., May 19, 1994). Flowers are visited by a diverse group of smallish insects including bees, wasps, flies, and butterflies (Archibald et al., 2001). Some observers have suggested that butterflies pollinate them and that ants disperse the seeds (Soper, 1987). The plant can spread clonally by rhizomes, so individual genets are difficult to distinguish (Knight, 1993). It is gynodioecious and males are sterile, or female plants produce flowers whose stamens bear anthers that are either small, poorly developed and knob-like, or larger but flattened; neither type produces pollen. The flowers of hermaphroditic plants produce normal, plump anthers that produce pollen. These flowers are self-compatible, but require a pollinator (Archibald et al., 2001). Genotype frequencies indicate mating is random and cloning has been documented but the frequency of this occurrence is not known (Archibald et al., 2001). Individuals were transplanted to containers at the Nevada Division of Forestry nursery and produced seed successfully, suggesting that this species does not depend on the pollination services of a highly specific pollinator. (NatureServe, 2015)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Playa, salt flat (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: The species colonizes the deposits only after precipitation has leached high concentrations of sodium, potassium, and other soluble chemicals from the substrates. Moisture is derived from precipitation rather than spring sources. (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Largely restricted to moderately deep, siliceous hot springs deposits known as sinter. Over time, as soils accumulate and develop on the deposits, other species invade and eventually out-compete the buckwheat (USFWS, 1995). (NatureServe, 2015)

**Environmental Specificity**

Adult: Very narrow. Specialist or community with key requirements scarce. (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Moderate (NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Open areas on the slopes of deep (approximately 25 m), dome-shaped, siliceous hot springs deposits in an area that has been intermittently geothermally active for the past 2.5 million years. It is largely restricted to moderately deep, siliceous hot springs deposits known as sinter which originated from the discharge of hot-spring waters and thermal ground water saturated with amorphous silica (USFWS, 1995). The species colonizes the deposits only after precipitation has leached high concentrations of sodium, potassium, and other soluble chemicals from the substrates. Moisture is derived from precipitation rather than spring sources. Over time, as soils accumulate and develop on the deposits, other species invade and eventually out-compete the buckwheat (USFWS, 1995). (NatureServe, 2015)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Williams (1982) suggested that the seeds of Steamboat buckwheat are disseminated by wind. Viability of seeds may be quite low. (USFWS, 1995)

***Population Information and Trends***

**Population Trends:**

Uncertain (USFWS, 2019)

**Number of Populations:**

1 (USFWS, 2019)

**Population Size:**

See narrative; difficult to estimate (USFWS, 2019)

**Population Narrative:**

Various estimates of the abundance of Eriogonum ovalifolium var. williamsiae have been made over the 32 years since the plant was listed. These estimates have ranged from 10,000 to 15,000 individual plants in the final rule listing the species (Service 1986) to 85,000 plants by Knight (1997), to 200,000 plants by Morefield (2001). Knight 1993 noted that a precise enumeration of individual plants is infeasible because the species is rhizomatous and propagates primarily by vegetative runners. (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Development (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** A substantial portion of the Steamboat buckwheat occurs on a private parcel adjacent to U.S. Highway 395, giving it high potential for commercial development. About 60 percent of this 12 ac (4.9 ha) parcel, labeled Moana Lane Nursery in Figure 1, is occupied habitat comprising an estimated 15 percent of the total occupied habitat for the Steamboat buckwheat and over 20 percent of the two-thirds of the entire population that occurs on private land; moreover, the habitat on this property is believed to support dense concentrations of the buckwheat based on observations of similar habitat on adjacent Ormat-leased lands. For these reasons, conservation of this habitat is considered integral to the recovery of the Steamboat buckwheat. The landowner has repeatedly expressed interest in protecting the property either through fee title acquisition or through a conservation easement. The Nevada Department of State Lands has indicated a willingness to accept the property and the NDF has agreed to manage it, but to date no funding has been available to secure this part of the population. Although this private property remains subject to the permitting requirements of NDF (see Factor D, Section II.C.2.d), the development of this property remains a potential threat. (USFWS, 2009)

**Stressor:** Cessation of hot spring activity (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** As noted in the biological discussion above (Section II.C.1.e.), hot spring activity on the site has ceased, and while the complex geothermal system is still not well understood, the cause is likely related to numerous factors including geothermal production, drawdown of the regional groundwater table resulting from increased domestic and municipal use, and possible lack of recharge due to drought (BLM 1993). It should be noted, however, that surface flow has not reappeared despite several wet/dry climatic cycles since the latter conjecture was made. Nevertheless, there is currently adequate habitat to support a robust population of the Steamboat buckwheat, and while the cessation of sinter creation may pose a long-term threat to its persistence, the species' survival does not appear at current risk due to the cessation of hot spring activity. (USFWS, 2009)

**Stressor:** Mining (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** An active mining claim exists on a portion of the population on BLM land, but seems unlikely to be developed while the surrounding private lands are in geothermal production. Therefore, mining does not appear to be a significant threat at this time and is unlikely to become significant while the geothermal plant remains in operation. (USFWS, 2009)

**Stressor:** Off-road vehicles (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Off-road vehicle use has been substantially reduced due to fencing of the industrial areas, vigilance of the geothermal facility staff, and the installation of a right-of-way fence along U.S. Highway 395 by NDOT. The geothermal facility has recently installed a locked gate along their main access road which limits unauthorized access from this point. Occasional off-road vehicle use, usually by motorcycle, still occurs via other access points, but does not constitute a

significant threat to the species. There is no evidence of recent refuse dumping in the area so this activity is no longer considered to be a significant threat. (USFWS, 2009)

**Stressor:** Moisture availability (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Changes in moisture availability were cited in the final rule based on observations that plants have been observed to die when more than normal moisture, presumably precipitation, is received. This led to speculation that off-road vehicle use and refuse dumping might alter moisture patterns, thereby affecting plants. As noted above, both off-road vehicle use and refuse dumping no longer pose a significant threat to the species. The possibility that geothermal test wells might contribute to changes in water regimes has been discussed above. Some alteration in water flow patterns may have resulted from road and/or facility construction, but their effects are unknown and unlikely to be significant because of their limited extent. (USFWS, 2009)

**Stressor:** Human activities (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Minor impacts continue to affect small numbers of individuals, usually in peripheral areas adjacent to the highway or industrial sites. For example, in 2002 the NDF reported that a Nevada Department of Transportation (NDOT) project resulted in the loss of one plant. In 2004, NDF reported the transplantation of four plants to avoid loss during construction of a pipeline and geothermal facility, the loss of one plant hit by a snow plow during a storm, and the killing of an estimated 15 plants which were driven over by a crew servicing a billboard. In 2005, NDF reported that NDOT had killed one plant during construction of a right-of-way fence. In 2006, NDF reported that a spill of drilling mud had impacted 107 plants, all of which survived. These impacts, individually or collectively, do not constitute a significant loss of habitat for this variety and are far below a level that would jeopardize its existence. The current transportation plan for the area developed by Washoe County proposes a road that would likely impact occupied habitat, but this action would be subject to permitting by NDF. (USFWS, 2009)

**Stressor:** Predation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Some of the poor seed production observed in this variety has been attributed to high seed predation by larvae of a lycaenid butterfly species in the genus Euphilotes (Tepedino et al. 2000, p. 9). However, seed tested by the Berry Botanical Garden has shown seed viability of less than 1 percent, which strongly suggests that other factors, including genetic incompatibility factors, may be more significant in limiting sexual reproduction (see, however, the results of seedling monitoring during 2006 discussed in II.C.1.a. above). At this time, there is no evidence that disease or seed predation are significant threats to the species. (USFWS, 2009)

**Stressor:** Narrow distribution and small population size (USFWS, 2009)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** The final rule listing the Steamboat buckwheat indicated that the narrow distribution and small population size of the Steamboat buckwheat may make it vulnerable to fire or other disturbance in its habitat, and that a loss of individuals may have adverse effects on the reproductive capacity and survival of the species. The vulnerability of the habitat to fire has been addressed above in Section II.C.1.e. in our discussion of weeds. While it appears that the sexual reproductive capacity of the plant is limited, the Steamboat buckwheat does appear to have increased slightly in total area and perhaps numbers due to the control of disturbances caused by public access. No long-term monitoring data are available to precisely evaluate the status of the species, but anecdotal evidence suggests that it has successfully established in disturbed areas where it previously was not present. In addition, areas in which ramets (a unit of clonal growth) were transplanted as mitigation for the original loss of habitat from the cooling tower facility appear to be self-maintaining. Either those ramets have been successful in maintaining individuals through asexual reproduction, or they are successfully reproducing seedlings, or both, in the mitigation areas. (USFWS, 2009)

**Stressor:** sinter deposition (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** We are also concerned about the long-term sustainability of Steamboat buckwheat habitat because sinter deposition associated with hot spring waters has temporarily or permanently ceased. This is likely due to numerous factors including geothermal production nearby, drawdown of the regional groundwater table resulting from increased domestic and municipal use, and possible lack of recharge due to drought (USFWS, 2022)

***Recovery***

**Reclassification Criteria:**
Downlisting for Eriogonum ovalifolium var. williamsiae can be considered when: (USFWS, 1995)

1. Protective conservation easements or fee acquisitions secure approximately 185 acres of occupied habitat currently in private ownership; (USFWS, 1995)

2. Cooperative agreements are established for approximately 80 acres of occupied public lands and approximately 37 acres of occupied State lands within a highway easement; (USFWS, 1995)

3. Comprehensive management plans have been developed and implemented on all occupied habitat. (USFWS, 1995)

Recovery Priority Number: 3

**Delisting Criteria:**
Delisting Recovery Criteria (amended recovery criteria) Delisting may be warranted when the current downlisting criteria have been met and the species exhibits sufficient resiliency, redundancy, and representation to support long-term viability.

1. Threats are reduced or eliminated so that the species is capable of persisting without substantial human intervention or perpetual endowments are secured for management necessary to maintain the continued existence of the species. Outstanding management needs include: a) implementing the monitoring protocol, b) updating and renewing the Steamboat Buckwheat Management Plan (Knight 1997), c) controlling competition with nonnative weeds, and d) exploring potential methods of restoration of geothermal processes that maintain and create habitat. (USFWS, 2019)

2. All size classes are represented, the population is increasing or stable, and management objectives identified in the monitoring protocol are achieved (Pavlik 2002, Pavlik and Stanton 2003). Monitoring objectives were developed to detect and document 1) trends in the numbers of Eriogonum ovalifolium var. williamsiae plants in characteristic habitats, 2) the frequency and contribution of episodic reproduction to population stability, and 3) successional changes in common species that comprise the plant community of Steamboat Hills. Monitoring objectives are as follows: (a) Eriogonum ovalifolium var. williamsiae in the Main Terrace and Central Drainage habitats are within ± 15% of their 2003 baseline levels after five and ten consecutive years of monitoring with a 95% level of confidence. (b) Eriogonum ovalifolium var. williamsiae in the Main Terrace and Central Drainage habitats each produce a significant cohort of seedlings (20% of the mean density in a given subpopulation in a given year is contributed by "seedlings") at least once during five consecutive years of monitoring (or twice in ten years) with a 95% level of confidence. (c) Total live absolute cover by subpopulations of common shrubs [e.g. Artemisia tridentata (sagebrush), Atriplex confertifolia (shadscale), Chrysothamnus nauseosus (rabbitbrush), Purshia tridentata (bitterbrush)], perennial grasses [e.g. Poa secunda (bluegrass), Leymus cinereus (Great Basin wildrye)], and weeds [e.g. Bromus tectorum (cheatgrass)], as well as E. ovalifolium var. williamsiae are within ± 15% of their 2003 baseline levels after five and ten consecutive years of monitoring with a 95% level of confidence. (USFWS, 2019)

3. The ex situ seedbank is maintained through the collection of fresh seed from Eriogonum ovalifolium var. williamsiae plants every 10 years. Collections that are spread over time produce lower extinction risk to wild populations, while maintaining a species' genetic variation within an ex situ seedbank (Menges et al. 2004). The ex situ seedbank is currently maintained with Center for Plant Conservation-affiliated botanic garden, the Rae Selling Berry Seed Bank and Plant Conservation Program at Portland State University (formally the Berry Botanic Garden). Currently, the ex situ seedbank holds approximately 23,000 viable seeds from collections made from 1992-1995 in long-term storage (i.e. freezer). In 1999, a germination trial on a sample of these seeds found greater than 70% germination (E. Guerrant, Rae Selling Berry Seed Bank, pers. comm. 2018a, E. Guerrant, unpubl. data, 2018b). (USFWS, 2019)

**Recovery Actions:**
- Protect Steamboat buckwheat habitats from adverse ohysical and biological modifications. The entire population of Steamboat buckwheat is restricted to approximately 100-1 50 ha (250-375 ac) of private and federally managed lands. Comprehensive management of Steamboat buckwheat will require development of a range-wide protection strategy in cooperation with the property owners, the BLM, FHWA, NDOT, and other concerned or knowledgeable entities such as NDF, NNHP, and TNC. (USFWS, 1995)
- Determine Steamboat buckwheat biology and habitat requirements. Maintenance of a viable, self-sustaining population of Steamboat buckwheat well into the future will require: 1) Implementation of a monitoring program for gauging population trends and habitat

conditions; and 2) new research on various aspects of the taxon's biology and habitat requirements. (USFWS, 1995)

- Provide public information and education. Recovery of Steamboat buckwheat will be dependent, in part, on the interest and willing cooperation of the private property owners and other members of the local community. An effective outreach program would help to deter negative sentiment for the recovery process and create an avenue for involvement and support among property owners, other members of the public, and the resource management agencies. (USFWS, 1995)
- Recommendation for Future Action from 2009 5-Year Review: The highest priority should be given to recovery criterion 1, i.e., securing conservation easements or fee acquisition of the estimated 66 percent of the habitat which occurs on private lands. Given the generally industrial nature of the private lands leased by the geothermal company from the Dorothy Towne Trust, the purchase of a conservation easement to secure these populations is likely to be the best option for these lands. The only other parcel of private land, roughly 12 ac (4.9 ha) in size with an estimated 7 ac (2.8 ha) of habitat, would most likely be best acquired in fee title and transferred to either Nevada Division of State Lands or the BLM, with a subsequent recovery management agreement for the entire population to be developed with the NDF or other interested entity. Once the recovery management agreement, with adequate provisions for adaptive management, is in place, the species could be proposed for delisting. (USFWS, 2009)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: (optional, but may be helpful to identify priorities for management actions and information needs for next 5-year review) We updated the Recovery Plan for Steamboat buckwheat through a Recovery Plan Amendment in 2019. In the Recovery Plan Amendment, we synthesized the adequacy of the existing recovery criteria, outlined amended recovery criteria, the rationale supporting the recovery plan modification, and analyses of the most recent monitoring data. Future actions for this species should focus on downlisting and delisting recovery criteria such as: protective conservation easements or fee acquisition of occupied habitat in private ownership, updating or developing conservation or management plans and/or cooperative agreements, and reducing threats such as nonnative, invasive species (USFWS, 2022).

# SPECIES ACCOUNT: *Eriogonum pelinophilum* (Clay-Loving wild buckwheat)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 07/13/1984; Mountain- Prairie Region (R6) (USFWS, 2015)

**Physical Description**

A low, stout, perennial herb, 5-10 cm high, with narrow, inrolled leaves that look like green scrolls. Clusters of white or cream-colored flowers with a rounded greenish-red to brownish-red perianth borne at the ends of the branches (NatureServe, 2015).

**Taxonomy**

The species was first recognized as its own taxon in 1969, and officially described by James Reveal in 1973 (Reveal 1969, pp. 75-76; 1973, pp. 120-122). The Eriogonum genus has undergone rapid evolution in the arid regions of the West, with roughly 250 species. This native North American genus is second only to Penstemon (beardtongue) in number of species (Reveal 2005a, p. 1) (USFWS, 2009).

**Historical Range**

Eriogonum pelinophilum was first collected near Hotchkiss, Colorado, in Delta County in 1958. Eriogonum pelinophilum is endemic to the rolling clay (adobe) hills and flats immediately adjacent to the communities of Delta and Montrose, Colorado (USFWS, 2009).

**Current Range**

Estimated range is 420 square kilometers, calculated in GIS by drawing a minimum convex polygon around the known occurrences. Imprecisely reported occurrences are not included (NatureServe, 2015). The plants extend from near Lazear, east of Delta on the northern end of the species' range, to the southeastern edge of Montrose in Delta and Montrose Counties, Colorado (USFWS, 2009). Clay-loving wild buckwheat extends from just west of Lazear, Colorado on the northern end of the species' range, to the southeastern edge of Montrose on the southern end of the species' range (USFWS, 2022)

**Critical Habitat Designated**

Yes; 7/13/1984.

**Legal Description**

On July 13, 1984, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Eriogonum pelinophilum (Clay-Loving wild buckwheat) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in Colorado (49 FR 28562-28565).

**Critical Habitat Designation**

The critical habitat designation for Eriogonum pelinophilum includes one CHU in Delta County, Colorado. This species critical habitat encompasses approximately 119.8 acres (49 FR 28562-28565).

Colorado, Delta County. About 3 miles east of Austin near Highway 92. T14S, R94W 6th P.M. Section 26-west 225 feet of Section 26 lying south of State Highway 92 (5.6 acres). Section 27-that part of the SE¼ SE¼ lying south of State Highway 92 (35.6 acres]. Section 34-an area bounded by a line beginning at the northeast comer of Section 34, thence south along the section line 200 feet to a point; thence southwesterly to a point 1050 feet south and 550 feet west of the northeast comer of Section 34; thence southwesterly to a point 700 feet north and 900 feet east of center ¼ corner of Section 34; thence westerly 900 feet to the north-south ¼ line; thence northerly 600 feet along the ¼ line to a point; thence northeasterly to a point of the east 1/16 line; thence northerly along the 1/16 line 300 feet to the north section line of Section 34; thence easterly along the north section line to the point of beginning (65.0 acres). Section 35-north 200 feet of the west 225 feet (1.0 acres]. Section 27-west 200 feet of Section 27 lying south of State Highway 92 (4.3 acres]. Section 28-east 400 feet of Section 28 lying south of State Highway 92 (8.3 acres). Total 119.8 acres.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Eriogonum pelinophilum critical habitat are not specified but are thought to be the following (49 FR 28562-28565):

The primary constituent elements include those factors associated with the whitish alkaline clay soils within the sparsely vegetated badlands of Mancos shale.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: cross-pollination, self-pollination (NatureServe, 2015)

**Lifespan**

Adult: 50+ years (inferred from NatureServe, 2015)

**Breeding Season**

Adult: May - September (USFWS, 2009)

**Key Resources Needed for Breeding**

Adult: Insect pollinators (USFWS, 2022)

**Reproduction Narrative**

Adult: E. pelinophilum requires an insect pollinator in order to set seed (Bowlin et al. 1993). Experimental study showed that the species is self-compatible (sets viable seed when pollen is transferred between flowers on the same plant); the authors believe that "pollinators moving from male-stage to female-stage flowers on the same plant will occasionally effect pollination" (Bowlin et al. 1993). Pollinators also frequently move between plants, resulting in a mixed breeding system with some pollination from other flowers on the same plant and some from flowers on different plants (Bowlin et al. 1993). A wide variety of insects visit and probably pollinate the flowers. Both ants and flying insects appear to be effective pollinators, with a field experiment showing no significant difference in seed set among flowers visited only by ants, only by flying insects, or by both groups (Bowlin et al. 1993). Results from the Colorado Natural Areas Program (CNAP) monitoring program on E. pelinophilum (1987, 1988) indicate that E. pelinophilum is a long-lived perennial with a probable population turnover rate of approximately 20-50 years. All Eriogonum species studied thus far have seeds that require a cold period to break dormancy (not necessarily a freeze). Mixed selfing and outcrossing occurs (NatureServe, 2015). Flowering typically occurs from late May to early September with individual flowers lasting fewer than 3 days (Bowlin et al.1992, p. 298) (USFWS, 2009). Over 50 species of insects visit clay-loving wild buckwheat flowers (Bowlin et al. 1992, p. 300; Tepedino et al. 2011, p. 60). Roughly half of these species are native bees, and 18 species are native ants. Seed set is similar between plants pollinated by ants and plants pollinated by flying pollinators, which suggests that ants are important pollinators of the species (Bowlin et al. 1992, p. 298). Some fruits are removed by harvester ants, but no information suggests this is a major dispersal mechanism. (USFWS, 2022)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Salt desert shrubland (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 1580 - 1950 m elevation (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: 75 - 500 individuals per acre (NatureServe, 2015)

**Environmental Specificity**

Adult: Very narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Eriogonum pelinophilum is found in substrates derived from the Mancos Formation shales. Inhabits whitish, alkaline clay soils on Mancos shale. Vegetation is a sparse salt desert shrub community. Occurs at 1580 - 1950 m elevation. The entire area is typified by rolling adobe (clay) hills and flats. Generally, the plants are found in a sharply defined soil microhabitat with shadscale (Atriplex confertifolia), on mid to lower slopes of the hills. The soil types are part of the Billings Series, known for its fine texture and weak and unstable structure. These soils are calcareous throughout and in some places have visible accumulations of calcium carbonate or calcium sulfate (Cline et al. 1967). Because of the low moisture availability, communities in which E. pelinophilum occur are characterized by low species diversity, low productivity and minimal canopy cover. Eriogonum pelinophilum is codominant with other xerophytic shrubs or subshrubs such as shadscale, the rare Penstemon retrorsus, Castle Valley clover (Atriplex cuneata), mat saltbush, black sagebrush (Artemesia nova) and Xylorhiza venusta (Neely 1985, O'Kane 1985). The communities are apparently stable, climax associations, judging from the lack of invading species capable of dominating the sites. Densities range from 75 - 500 individuals per acre (180 per acre average) (NatureServe, 2015). Eriogonum pelinophilum plants are generally found within swales or drainages that are moister than surrounding areas (USFWS, 2009). Clay-loving wild buckwheat extends from just west of Lazear, Colorado on the northern end of the species’ range, to the southeastern edge of Montrose on the southern end of the species' range (Figure 3). The plant occurs at elevations of 5,180 to 6,350 feet (ft) (1,580 to 1,940 meters [m]). (USFWS, 2022)

***Dispersal/Migration***

**Dispersal**

Adult: Low (NatureServe, 2015)

**Dispersal/Migration Narrative**

Adult: Most seed is dispersed locally (Bowlin et al. 1993). Seed dispersal is usually passive, either being consumed or carried by animals, windblown, or moved by gravity or water (NatureServe, 2015). Some fruits are removed by harvester ants (Bowlin et al. 1992, p. 299); however, no information is available for the species on seed dispersal mechanisms (USFWS, 2009).

***Population Information and Trends***

**Population Trends:**

Unknown (NatureServe, 2015)

**Species Trends:**

Relatively stable (NatureServe, 2015)

**Number of Populations:**

15 (USFWS, 2022)

**Population Size:**

~278,000 (USFWS, 2009)

**Adaptability:**

High (inferred from NatureServe, 2015)

**Population Narrative:**

Appears to be susceptible to impacts from grazing. Eriogonum pelinophilum appears to be a long-lived plant, with a calculated half-life of nearly 200 years (Carpenter and Schultz 1994). However, it is facing extreme pressure from residential and agricultural development, and occurrences have been extirpated. The long term population trend is unknown. The short term trend is relatively stable. The total area occupied by the mapped occurrences is 959 acres (calculated by the Colorado Natural Heritage Program in 2012). There are 9 occurrences with good or excellent viability (NatureServe, 2015). Today, the species is known from 12 existing (extant) Eos 2 additional populations. The most recent rangewide population estimate for all A through D ranked Eriogonum pelinophilum EOs is very roughly 278,000 individuals across 582 occupied ac (233 ha). Genetic variation has not been studied and, therefore, is unknown. When a rectangle is drawn around all known occurrences, it measures roughly 11.5 mi (18.5 km) from east to west and 28.5 mi (46 km) from north to south (CNHP 2009, spatial data) (USFWS, 2009). When clay-loving wild buckwheat was first listed, the species was known from only one site with roughly 10,000 individuals at the northern end of the species' currently known range (49 FR 28562; Figure 1). Since the species' listing, increases in survey effort have discovered more occurrences of the plant. Clay-loving wild buckwheat is now known to exist across 15 occurrences (Figure 2) and potentially exists at six additional historical occurrences. Despite the discovery of new occurrences, annual monitoring efforts by the Bureau of Land Management (BLM) have documented declines in plant density across the species' range (BLM 2021, entire), particularly over the last five years. Some occurrences experienced declines greater than 70 percent when compared to estimated densities from 2013 (BLM 2021, p. 5). (USFWS, 2022)

***Threats and Stressors***

**Stressor:** Agricultural, urban, and residential development (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The growing human population means more houses, more subdivisions, more industrial development, and increased utility and transportation needs that could impact Eriogonum pelinophilum occurrences as well as its suitable habitat. All EOs near Olathe and Montrose (EOs 004, 006, 011, 012, 013, 016, 018, 021, 022, 024, and 041) have agricultural fields or development immediately adjacent suggesting that some habitat and plants were lost when these areas were developed. The North Selig, Selig, Peach Valley, East, South, and Loutzenhizer Canals are all large canals that run along the eastern side of the Uncompahgre Valley and through Eriogonum pelinophilum habitat. Because of their proximity to E. pelinophilum EOs, suitable habitat and plants were likely lost during the construction of these canals. All canals and laterals have roads on at least one side, and most have roads running along both sides. These canals and associated roads support nonnative invasive plants and provide conduits for their spread. To reduce salt loading, a salinity control program was initiated in 1990. This program first eliminated flow through the canals during the winter and is now working to line laterals (Bureau of Reclamation 1994, summary). Because many of the E. pelinophilum EOs are located along laterals that are prioritized for lining, further impact to the species from these activities is a possibility. Increasing development continues to fragment and impact Eriogonum pelinophilum and its habitat. This development includes residential and industrial buildings, agricultural fields, power lines, canals, and roads (USFWS, 2009).

**Stressor:** Off-road vehicle use (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Aside from the direct loss of Eriogonum pelinophilum individuals, cars, motorcycles, and ORVs (collectively ORVs) may impact E. pelinophilum habitat in several ways. One common effect is soil compaction, which diminishes water infiltration, destroys soil stabilizers, and increases erosion from water and wind (ORV effects summarized in Ouren et al. 2007, pp. 1-225). Because of decreased soil moisture and increased compaction, plant size is generally reduced. Soil compaction also increases the potential for invasive, nonnative annuals and other early successional plants to establish rapidly in ORV routes. Other impacts such as edge effects, fragmentation, and dust impacts occur from ORV use. The Mancos shale soils are vulnerable to ORV impacts because the clay is especially vulnerable to compaction and because there are no rocks and little vegetation to resist erosion (USFWS, 2009).

**Stressor:** Nonnative invasive plants (USFWS, 2009)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Nonnative species documented within or adjacent to Eriogonum pelinophilum EOs include: Acroptilon repens (Russian knapweed), Alyssum parviflorum or A. simplex (alyssum), Bromus inermis (smooth brome), Bromus tectorum (cheatgrass), Cardaria draba (whitetop or hoary cress), Cardaria pubescens (hairy whitetop), Ceratocephala testiculata (bur buttercup, hornhead, or curveseed butterwort), Chorispora tenella (blue mustard or crossflower), Cirsium arvense (Canada thistle), Descurainia sp. (tansy mustard), Elaeagnus angustifolia (Russian olive), Erodium cicutarium (storksbill or redstem filaree), Erysimum repandum (spreading wallflower), Halogeton glomeratus (halogeton or saltlover), Lactuca serriola (prickly lettuce), Lepidium perfoliatum (clasping pepperweed), Melilotus officinale (yellow sweetclover), Salsola tragus (prickly Russian thistle), Sisymbrium altissimum (tall tumble mustard), Traxacum officinale (common dandelion) (CNHP 2009, pp. 1-81; USFWS 2009a). Because Eriogonum pelinophilum is a long-lived perennial and was established before many of the nonnatives were introduced, impacts may not be immediate and would require longer term monitoring to quantify. However, nonnatives occur at all EOs (USFWS, 2009).

**Stressor:** Livestock use (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Threats related to livestock use include the eating of individual plants, physical effects of trampling of plants, and the indirect effects of habitat degradation. During the most extensive survey for the Eriogonum pelinophilum within the most numerous EO (018), minor impacts from livestock, especially from trampling near sheep bed grounds, were documented (Ferguson 2007, p. 2). At one location near sheep bedding grounds, Eriogonum pelinophilum plants were found on root pedestals, apparently due to the increased erosion in the area (Ferguson 2007, p. 8). During 2009, significant livestock impacts occurred within EO 018, the largest Eriogonum pelinophilum site containing over two thirds of the known individuals (USFWS, 2009).

**Stressor:** Herbicide Use (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The proximity of E. pelinophilum to agricultural fields and nonnative species makes the species vulnerable to this impact (USFWS, 2009).

**Stressor:** Herbivory (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Tent caterpillar impacts to E. pelinophilum were noted in 2007 (Ferguson 2007, p. 6). Herbivory where several plants were heavily browsed has been documented in two instances, but the herbivore is unknown and the number of individuals impacted was low (Ferguson 2007, p. 7). Herbivory of numerous individuals was documented associated with livestock use in 2009; although, this use has not yet been well quantified (Sharp, in litt. 2009) (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2009)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Future projections for the southwest predict increased temperatures, more intense and longer-lasting heat waves, an increased probability of drought that are worsened by higher temperatures, heavier downpours, increased flooding, and increased erosion (Karl et al. 2009, pp. 129-134). These changes will affect fire frequency, community assemblages, and the ability of nonnative species to succeed. The Mancos shale is limited in distribution and the plant is a long-lived perennial, both factors will limit E. pelinophilum's ability to migrate with a changing climate. Climate change likely is and will affect all Eriogonum pelinophilum populations (USFWS, 2009).

***Recovery***

**Reclassification Criteria:**
Ten healthy populations are secured in their natural habitat (USFWS, 1988).

Recovery Priority Number: 8C

**Delisting Criteria:**
Twenty healthy populations are secured in their natural habitat (USFWS, 1988).

**Recovery Actions:**
- Initiate scientific research on known and potential habitat and the biology of the species (USFWS, 1988).
- Remove threats to the clay-loving wild-buckwheat and secure populations and tier ecosystems (USFWS ,1988).
- Develop public awareness and appreciation for the "adobes" habitat on which the clay-loving wild-buckwheat grows (USFWS, 1988).
- Permanently protect all occupied habitat. On public lands, add additional and expand existing ACECs, remove threats (especially ORV activity and negative impacts from livestock use), and provide more stringent protection within RMPs. On private land, pursue conservation easements, appropriate zoning incentives, and land acquisitions to protect populations (USFWS, 2009).
- Coordinate with local governments to better protect Eriogonum pelinophilum. Consider lower densities for new developments, open space, avoidance measures, and other actions to conserve the species. Integrate these actions into county and city land use planning designations (USFWS, 2009).
- Conduct education and outreach efforts for the public. The intent of these efforts will be to secure more Eriogonum pelinophilum sites for conservation. Develop and implement permanent conservation agreements and easements for populations on private lands. Provide technical and financial support for conservations actions on private lands (USFWS, 2009).
- Work with all parties to prevent ORV use within Eriogonum pelinophilum habitat (USFWS, 2009).
- Consider removing livestock from all Eriogonum pelinophilum sites. If livestock use continues, careful monitoring of the species and the livestock use should occur. Research (see below) assessing the effects of livestock use should be conducted (USFWS, 2009).

- Conduct nonnative invasive plant control activities where needed to conserve Eriogonum pelinophilum. Control should be conducted with extreme care to reduce impacts to E. pelinophilum (USFWS, 2009).
- Recommend at least a 200 m/656 ft. buffer between occupied or suitable habitat and ground disturbance or other activities that may affect Eriogonum pelinophilum or its habitat (USFWS, 2009).
- Revise the recovery plan for Eriogonum pelinophilum so that it reflects the best scientific and commercial information available. The revised recovery plan should include objective, measurable criteria which, when met, will result in a determination that the species be removed from the Federal List of Endangered and Threatened Plants. Recovery criteria should address all threats impacting the species. The recovery plan also should estimate the time required and the cost to carry out those measures needed to achieve the goal for recovery and delisting (USFWS, 2009).
- Revise critical habitat for Eriogonum pelinophilum. “Critical habitat” is defined as: (1) specific areas within the geographical area occupied by the species at the time of listing, if they contain physical or biological features essential to conservation, and those features may require special management considerations or protection; and (2) specific areas outside the geographical area occupied by the species if the agency determines that the area itself is essential for conservation (USFWS, 2009).
- Develop and implement consistent conservation measures in the Uncompahgre Field Office’s RMP revision that will avoid and minimize impacts to Eriogonum pelinophilum from all development, ORV, and grazing activities. Include protection for all occupied and suitable habitat in the conservation measures (USFWS, 2009).
- Expand existing ACECs to include contiguous occupied and suitable habitat for the plant and its pollinators. Revise ACEC management guidelines to better protect Eriogonum pelinophilum. Consider creating new ACECs to conserve the species, especially in the northern portion of the species’ range near the Selig Canal sites (EOs 014 and 025) and unsurveyed land in the area (USFWS, 2009).
- Inventory potential habitat for Eriogonum pelinophilum on public and private lands. Report results to CNHP, BLM, and the Service. These surveys will provide better information to guide recovery and conservation actions as well as project planning (USFWS, 2009).
- Initiate range-wide trend monitoring to track the health of Eriogonum pelinophilum. Include a component to analyze potential effects from disturbances, nonnatives, and climate change (USFWS, 2009).
- Monitor the effects of development activities located within 200 m/656 ft. of plant populations on plants, pollinators, and habitat. Change buffers as determined by monitoring results (USFWS, 2009).
- Conduct demographic monitoring that determines critical life history stages that will enhance management of the species (USFWS, 2009).
- Conduct research studying demographic parameters that identifies critical life history stages (USFWS, 2009).
- Conduct research studying genetic diversity and taxonomic relations of Eriogonum pelinophilum. This research should address what populations are most important to conserve and investigate if genetic diversity is a problem for small isolated populations (USFWS, 2009).
- Conduct research investigating the effects of various threats. For example, impacts of various levels of livestock use, the impacts of ORVs, the impacts of nonnative species, and

the effects of various disturbance levels (USFWS, 2009).

- Incorporate demographic, genetic diversity, and threat research into a population viability analysis that addresses minimum population size, and trajectories factoring in effects of threats (USFWS, 2009).

# SPECIES ACCOUNT: *Eriogonum tiehmii* (Tiehm's buckwheat)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered

**Physical Description**

Eriogonum tiehmii is a member of the Polygonaceae (buckwheat family). It is a low growing perennial herb forming a dense compact mat up to 10.8 inches (in; 30 centimeters (cm)) across and 6 in (16 cm) high. Leaves are only at the base of the plant, blueish gray in color, elliptic, and gray tomentose, or hairy, on both surfaces. Tight balls of flowers arise from a leafless, hairy stem (i.e. the inflorescence or flowering stalk). The tepals (i.e., components of the flower that are similar looking and cannot be distinguished into sepals and petals) are light yellow to cream, aging lighter and/or turning red with age. Eriogonum tiehmii is the only buckwheat in the subgenus Eucycla known to have well defined stalked glands on the outer surfaces of its tepals (Figure 2; Reveal 1985, pp. 277–278; Morefield 1995, pp. 6–7). (USFWS, 2021)

**Taxonomy**

Eriogonum tiehmii was discovered in 1983 by Arnold Tiehm (Morefield 1995, p. 5) and described by James Reveal in 1985 (pp. 277–278). Within the genus, E. tiehmii is placed in the subgenus Eucycla (Morefield 1995, p 8; Reveal 2012, pp. 256–261). In Nevada, E. tiehmii is morphologically most similar to E. anemophilum (West Humboldt buckwheat) and the creamcolored phase of E. beatleyae (Beatley's buckwheat). However, the stems of the latter are glandular, not hairy as in E. tiehmii, and the involucre (or bracts subtending the flower) of both species are smaller than on E. tiehmii. (USFWS, 2021)

**Current Range**

As described above, Eriogonum tiehmii was first discovered in 1983. As of 1994, E. tiehmii was only known from its type locality, so field surveys were undertaken to relocate the historical location and find any additional locations of the species. Field surveys located five new locations on approximately 9 acres (ac; 3.6 hectares (ha)), all within 1 mile of the type locality (Morefield 1995, p.1). Population boundaries of E. tiehmii were last mapped by Nevada Division of Natural Heritage in 2008–2010, with the most recent surveys for the species conducted in 2019 (Morefield 2008 entire; Morefield 2010, entire; Kuyper 2019, entire). From the 2019 survey effort, the estimated area occupied by the species increased by approximately 14 percent, however, it is unclear if this indicates a true increase in the amount of area occupied by E. tiehmii, because observers and mapping tools used have not been the same among years (Table 1). In 1994, to fully understand the extent of occupied habitat, thirty-three additional sites covering 301 ac (121.8 ha) that met habitat requirements described above were surveyed without encountering Eriogonum tiehmii (Morefield 1995, pp 8–9). Morefield surveyed other areas sporadically between 1995 and 2018 looking for E. tiehmii and had similar results (Ioneer 2020b, p. 12). In 2018, a contractor for Ioneer USA Corporation (Ioneer) developed a habitat suitability model to identify potential habitat for E. tiehmii within a ten-mile radius of the known population utilizing ArcGIS and remote sensing data (Ioneer 2020b, p.12). The habitat suitability model identified 20 sites, totaling 1,126 ac (455.7 ha), as potential habitat based on soil and geology and an additional 24 sites were identified based on professional knowledge of geology, geomorphology, and soils in the surrounding area (Ioneer 2020b, p.12). Surveys of potential habitat by EM Strategies led to the discovery of two additional small subpopulations, subpopulation 7 and 8, near the already known subpopulations. No new populations of E. tiehmii were found within the ten-mile radius of the existing population (Ioneer 2020b, p. 12). (USFWS, 2021)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 2021)

**Dependency on Other Individuals or Species**

Adult: Insect pollinated (USFWS, 2021)

**Reproduction Narrative**

Adult: Eriogonum, in general, are sexual reproducers and insects are the most common pollinators (Gucker and Shaw 2019a, pp. 5–6). Some studies have shown that Eriogonum flowers can be pollinated by everything from beeflies and closely related spider predators (the Acroceridea (Cyrtidae)) to specialist pollinators, while other Eriogonum species are capable of selfpollination (Moldenke 1976, pp. 20–25). For example, Eriogonum ovalifolium var. vineum (Cushenbury buckwheat), an endangered buckwheat, is pollinated by flies, as well as sweat bees (Neel and Ellstrand 2003, p. 339). Another endangered buckwheat, E. ovalifolum var. williamsiae (steamboat buckwheat), is self-compatible, but requires a pollinator to transfer pollen from its stamens to its stigma and is visited by a diverse group of bees, wasps, flies, and butterflies (Archibald et al. 2001, p. 612). Primary pollinator visitors to Eriogonum tiehmii include wasps, beetles, and flies (McClinton et al. 2020, p. 18). To test if E. tiehmii is capable of self-pollination, mesh bags were placed over unopened inflorescences to preclude insect visitors in the beginning of the flowering season in May 2020. In early June 2020, additional bags were placed over previously opened, marked flowers that had the opportunity to be visited by pollinators to compare seed production between open-pollinated and bagged flowers (McClinton et al. 2020, p. 22). Results indicate that E. tiehmii plants may be able to produce some seed when pollinators are excluded (through wind pollination or selfing), but open pollination significantly increased seed production, averaging 7.3 times as many seeds as bagged inflorescences (McClinton et al. 2020, p. 22). Therefore, E. tiehmii benefits from pollinator services and needs pollinators to increase seed production. (USFWS, 2021)

**Habitat Type**

Adult: Dry Uplands

**Dependencies on Specific Environmental Elements**

Adult: occurs between 5,906 and 6,234 feet (ft; 1800 and 1900 meters (m)) in elevation (USFWS, 2022)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2022). Inferred due to elevational limitations

**Habitat Narrative**

Adult: Eriogonum tiehmii occurs between 5,906 and 6,234 feet (ft; 1800 and 1900 meters (m)) in elevation and on all aspects with slopes ranging from 0-50 degrees (Ioneer 2020b, p. 5; Morefield 1995, p. 11). The species occurs on dry, upland sites, subject only to occasional saturation by rain and snow and is not found in association with free surface or subsurface waters (Morefield 1995, p. 11). Although there is no information on E. tiehmii's specific water needs during its various life stages (i.e., dormant seed, seedling, juvenile, adult), it appears to be primarily dependent on occasional precipitation for its moisture supply (Morefield 1995, p. 11). From 1980–2017, long-term average annual precipitation during the growing season (October to September) at Dyer, Nevada (the closest climate center to E. tiehmii) was 5.13 in (13.0 cm), with the majority of precipitation received in January and February (Western Regional Climate Center (WRCC) 2020). Thus, we assume that E. tiehmii requires annual precipitation that is at or above the 1980–2017 average. There is also no information on the specific temperature tolerances of E. tiehmii. However, the species experiences warm, dry summers (average daily maximum 85–95°F (29.4–35 °C)) and cold moist winters (average daily minimum 15–25°F (-9.4– -3.9 °C)); WRCC 2020; Morefield 1995, p. 10), which allows us to assume that it adapted to seasonal temperature changes within these ranges. (USFWS, 2021)

***Dispersal/Migration***

**Dispersal**

Adult: Unknown. Likely gravity, wind, and water (USFWS, 2022).

***Population Information and Trends***

**Population Trends:**

Unknown

**Number of Populations:**

1 population, 8 subpopulations ((USFWS, 2021)

**Population Size:**

~43,921 total for all populations (USFWS, 2021)

**Population Narrative:**

Initial surveys for Eriogonum tiehmii documented six subpopulations with an estimated total of 17,015 individuals (Table 1; Morefield 1995, p.14, Appendix 1). The Nevada Natural Heritage Program conducted additional surveys for E. tiehmii from 2008–2010. Again, no new subpopulations were found, but the extent of the six known subpopulations were refined, remapped, and estimated as 36,540 individuals (Table 1; Morefield 2008, entire; Morefield 2010, entire; Kuyper 2019, p.2). A 2019 survey documented eight subpopulations. Two subpopulations were completely surveyed (subpopulations 5, 7) and five subpopulations (subpopulation 1, 2, 3, 4, 6) were sampled with belt transects so that data collection can be repeatable for direct comparisons in the future (Table 1; Kuyper 2019, p. 2; Ioneer 2020b, p. 7). Subpopulation 8 is a single E. tiehmii plant (Kuyper 2019, p. 2). Two additional small subpopulations (7 and 8) were found near the already known subpopulations with the total number of plants estimated as 43,921 individuals. While we have confidence in the 2019 estimates of abundance, the survey methods used are too variable to infer population trends over time. In addition to abundance estimates, the 2019 survey categorized a subsample (1,813 individuals) of Eriogonum tiehmii by size based on plant length and width (Table 2; Kuyper 2019, p. 3; Ioneer 2020b, pp. 7–8). Subpopulation 6 had the most individuals in the smallest size class (seedlings, 0-5 cm2 ) indicating that this subpopulation is likely experiencing the most recruitment (Table 2; Kuyper 2019, p. 3; Ioneer 2020b, pp. 7–8). These data also indicate that overall, most plants in the population are young (5-80 cm2 ), but certain subpopulations —1, 2, and 6 — have the majority of older and larger plants (325-725 cm2 , 725-1260 cm2 , 1260-2000 cm2 , 2000-3000 cm2 , 3000+ cm2 ). (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Habitat modification (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This broad category includes threats that can physically disturb, damage, or kill Eriogonum tiehmii plants or degrade or destroy the habitat required by the species. While most of the threats identified here are associated with human activities, some natural processes such as herbivory (causing damage to or killing individual plants) may also impact the species and is discussed in Section 3.1.2. The habitat modification category also includes several threats that increase the potential for invasive, non-native plant species to be introduced into E. tiehmii habitat, thereby increasing competition for resources. While there is evidence of past and on-going habitat modification within the E. tiehmii population, there have been no studies of the species' response to these threats at the individual, subpopulation, and/or population level.

**Stressor:** Herbivory (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbivory on University of Nevada, Reno (UNR) Seedling Transplant Experiment In 2020, researchers from UNR, under contract with Ioneer, conducted an Eriogonum tiehmii transplant study (see Section 2.4 for further discussion of soil properties related to this study). A total of 3,276 seeds were planted in pots at the UNR greenhouse. Overall, 32 percent emerged (1,057 seeds) and of those, 958 were mature enough (>2 leaves) to be transplanted into the wild on April 27–29, 2020. Three unoccupied sites based on habitat suitability models (see Section 2.5) were chosen for transplanting greenhouse grown E. tiehmii seedlings. Experiment installation and monitoring are described in greater detail in McClinton et al. 2020 (pp. 38–47). After two months of growth in the wild, 62.2 percent (596 plants) of all Eriogonum tiehmii seedlings planted were still present and green. However, monitoring between June 22 and July 6, 2020, detected a major herbivory event in which seedlings were totally excavated or their stems severed, resulting in the loss of almost all transplants (585 plants) (McClinton et al. 2020, p. 43). To gain information about herbivore size, test ways to exclude herbivores, and protect the 1 percent of surviving transplants, different sized exclosures were installed on the remaining plants. These exclosures included hamster cages with bars >2.5 cm apart, open-topped metal cones made of 0.6cm mesh, large fine-meshed metal strainers (20cm diameter), small finemeshed metal strainers (15.9cm diameter), and small fine-meshed plastic strainers (13.3cm diameter) (McClinton et al. 2020, p. 40). All plants left uncovered did not survive. Of the plants

that had an exclosure installed, 59 percent survived until July 21, 2020, which was the last day of monitoring (McClinton et al. 2020, p. 42). Game cameras were installed in July 2020 and deer mice were the most likely culprits of seedling depredation (Service 2020b, entire). Researchers did not expect depredated seedlings to re-sprout (USFWS, 2022)

**Stressor:** Climate Change (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The terms “climate” and “climate change” are defined by the Intergovernmental Panel on Climate Change (IPCC). The term “climate change” thus refers to a change in the mean or variability of one or more measures of climate (for example, temperature or precipitation) that persists for an extended period of time, whether the change is due to natural variability or human activity (IPCC 2014, pp. 119–120). Results of scientific analyses presented by the IPCC show that anthropogenic greenhouse gas emissions have increased since the pre-industrial era as a result of human activities and are now higher than ever. This has led to unprecedented atmospheric concentrations of greenhouse gases and are “extremely likely” (defined by the IPCC as 95–100 percent likelihood) to be the dominant cause of the observed warming since the mid20th century (USFWS, 2022)

# SPECIES ACCOUNT: *Eriophyllum latilobum* (San Mateo woolly sunflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 03/06/1995; Pacific Southwest (R8)

**Physical Description**

An herbaceous (nonwoody) perennial of the aster family (Asteraceae) with leafy stems 30 to 60, exceptionally 90, centimeters (12 to 16 inches) high (J. Mooring, in !itt., 1998). The upper surfaces of the deeply cleft leaves are a smooth dark green and the lower surfaces are covered with densely interwoven white hairs. The golden flower heads are borne in loose clusters (Munz and Keck 1959, McGuire and Morey 1992). Eriophy!lum latilobum differs from Eriophyllum confert~florum (golden yarrow) in having seven to eight ray flowers (the flowers usually located on the edge of the head of members of the aster family) rather than five ray flowers, and a more open inflorescence (Abrams and Ferris 1960, J. Mooring, in litt., 1998). Eriophyllum lanatum var. arachnoideum (common woolly sunflower) differs from the other two species in having 13 ray flowers and shallowly cleft leaves (Abrams and Ferris 1960, Hickman 1993). San Mateo woolly sunflower can be mistaken for plants from several populations that seem to be of hybrid origin between Eriophyllum lanatum and Eriophyllum conferflorum. Plants of these populations have either four or six sets of chromosomes and are located near Black Mountain and Montebello Ridge (Mooring 1994, J. Mooring, in litt., 1996, 1998). (USFWS, 1998)

**Taxonomy**

Eriophyllum latilobum is a tetraploid (having four sets of chromosomes) (Carlquist 1956, Mooring 1973) and is believed to have originated as a hybrid between Eriophyllum confertiflorum var. confertiflorum and Eriophyllum lanatum var. arachnoideum (Constance 1937, Munz and Keck 1959, Hickman 1993, Mooring 1994) (USFWS, 2011). A member of the aster family (Asteraceae) (USFWS, 1998).

**Historical Range**

San Mateo County, California. (USFWS, 2011)

**Current Range**

San Mateo County, California. (USFWS, 2011)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (inferred from USFWS, 2011)

**Breeding Season**

Adult: April - June (USFWS, 2011)

**Key Resources Needed for Breeding**

Adult: Insect pollinators (USFWS, 2012)

**Reproduction Narrative**

Adult: Blooms from April to June. Its pollinators include syrphid flies and bees. Eriophyllum latilobum is not a vigorous reproducer; low germination rates and low seedling survival have been observed under greenhouse conditions (John Mooring, in litt., 1992; McGuire and Morey 1992) (USFWS, 2011).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Cismontane woodland, Gen oak woodland (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 45 - 150 m elevation (NatureServe, 2015)

**Environmental Specificity**

Adult: Very narrow (NatureServe, 2015)

**Dependency on Other Individuals or Species for Habitat**

Adult: Quercus agrifolia (USFWS, 2011)

**Habitat Narrative**

Adult: Inhabits moist, steep slopes of serpentine-influenced rocky soil, mostly in shaded spots. Inhabits cismontane woodland (serpentinite, often on roadcuts) at elevations of 45 - 150m (California Native Plant Society 2001) and Gen oak woodland at elevations of 100 - 150m (Hickman 1993). The environmental specificity is very narrow; it is only known from a few sites on serpentine in San Mateo County, California (NatureServe, 2015). Eriophyllum latilobum is restricted to shaded moist sites on steep grassy or sparsely wooded slopes. It apparently grows best under or very near coast live oak (Quercus agrifolia) (J. Mooring, in litt., 1998) (USFWS, 2011).

***Dispersal/Migration***

**Dispersal**

Adult: Low (USFWS, 2012)

**Dispersal/Migration Narrative**

Adult: Seed dispersal is by gravity, so most seeds fall close to the parent plant (J. Mooring, pers. comm. as cited in McGuire and Morey 1992) (USFWS, 2011).

***Population Information and Trends***

**Population Trends:**

Decline of 30-50% (NatureServe, 2015)

**Species Trends:**
Additional occurrences discovered since listing (inferred from USFWS, 2011)

**Number of Populations:**
4 (USFWS, 2011)

**Population Size:**
250 - 1000 individuals (NatureServe, 2015); variable from year to year (USFWS, 2011)

**Adaptability:**
Low (inferred from NatureServe, 2015)

**Population Narrative:**
Apparently highly vulnerable though the exact biological reasons are unknown. This species has experienced a long-term decline of 30-50%. The main population near Crystal Springs, San Mateo County, has declined from many plants to a few hundred after an unfortunate mowing incident in 2001 (?). However there were about 200 seen in the latest survey. An additional 200 seen at Montara Mtn site in 2004. 3 and possibly a couple more sites known. Only two are currently mapped at CNDDB; backlog contains a few more. 1 from La Honda is historical. The estimated population size is 250 - 1,000 plants (NatureServe, 2015). Some years the number of plants in some subpopulations ranges from zero to less than five; other years the same subpopulations contain 500 percent more plants. At the time of listing, there was only one known population on Crystal Springs Road. Since then, there have been three additional occurrences discovered (USFWS, 2011).

***Threats and Stressors***

**Stressor:** Habitat degradation (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The steep slopes along Crystal Springs Road provide a very unstable habitat for E. latilobum. The slopes are subject to erosion and soil slippage. After soil slippage occurs, road maintenance crews remove the slumped soil, which may contain mature individuals, seedlings, and/or seeds of E. latilobum. The road cut is then reshaped, which may damage plants remaining on the banks. Dumping of garden debris and downhill seepage of pesticides from homeowners living above the population may have negative impacts on Eriophyllum latilobum habitat (USFWS, 2011).

**Stressor:** Nonnative vegetation (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The plant is threatened by competition with nonnative plants; its habitat is more densely populated with Carduus sp. and Bromus sp. than it was 10 years ago (John Mooring, pers. comm., 1992). In a 2009 report prepared by Nomad Ecology for San Francisco Public

Utilities Commission and M&E/WRE Joint Venture, the non-native invasive plants considered a threat to habitat along Crystal Springs Road included fennel, French broom, and jubata grass. Other non-native invasive plants teasel, poison hemlock, bull thistle, and milk thistle were also present in this area (Nomad 2009). In the natural population, competing species such as plumeless thistle (Carduus sp.) may affect germination and seedling establishment (J. Mooring, in litt., 1998). (USFWS, 2011)

**Stressor:** Low reproductive output (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Germination rates for E. latilobum are lower than for any other sunflower, less than 10% (CDFG 1997). In the 2009 seed bank collection report from Rancho Santa Ana Botanic Garden, seed collected from CNDDB #4 had a germination rate of 28% (USFWS, 2011).

**Stressor:** Stochastic events (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The small number of populations and low numbers of individual plants are also a factor. Because of the existence of few populations exhibiting low viability and located in an unstable habitat, this species is extremely vulnerable to extinction from random catastrophic events (Menges 1991, Primack 1993, Meffe and Carroll 1994) (USFWS, 2011).

**Stressor:** Climate change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A modeling study completed by Loarie et al. (2008) provides an evaluation of potential trends to California's floristic communities under climate change scenarios. In general, plant diversity will shift in two divergent directions: along the coast and northwards at higher elevations; and southwards at higher elevations of the Sierra Nevada. The models suggest that climate change has the potential to break up local floras, resulting in new species combinations, with new patterns of competition and biotic interactions (Loarie et al. 2008). Based on these models, Eriophyllum latilobum plants would likely be unable to shift their range because of their dependence on a rare soil type and their supposed limited ability for seed dispersal (USFWS, 2011).

***Recovery***

**Reclassification Criteria:**
A/1: A minimum of five colonies1 of San Mateo woolly sunflower are fully protected and managed with the primary intention of preserving the occurrences in perpetuity. Each protected colony includes occupied habitat along with adjacent unoccupied habitat and a 150-meter (500-foot) buffer at the known site. If genetic research confirms that additional historical and/or extant Eriophyllum populations in San Mateo County were/are San Mateo woolly sunflower, these sites are also protected and managed as described above. If additional individuals, sub-populations, or populations are discovered on private lands, they are secured through land

acquisitions, conservation easements, or other means and protected as described above. (USFWS, 2019)

A/2: Management plan(s), approved by the Service, are implemented for the colonies described in A/1 and any occupied or unoccupied habitat identified as essential to survival. The plans include provisions for standardized annual monitoring of populations and provisions for the collection and preservation of viable genetic material that might otherwise be lost because of planned habitat destruction or modification. (USFWS, 2019)

E/1: Each colony described in A/1 contains a minimum of 150 (but preferably more) individuals each year for a minimum of 20 years. (USFWS, 2019)

E/2: Each colony described in A/1 has numbers of individuals that exhibit a stable or increasing trend over a period of 20 years that includes two normal precipitation cycles (or longer if suggested by the results of demographic monitoring). (USFWS, 2019)

E/3: Impacts from competition with native and nonnative species are managed so they do not pose a threat to the persistence of any of the San Mateo woolly sunflower colonies described in A/1. (USFWS, 2019)

E/4: Seeds, representative of the breadth of the species' genetic diversity, are stored in at least two Center for Plant Conservation certified facilities and reliable seed germination and propagation techniques are understood. Unless storage techniques and/or research show otherwise, stored seeds are replenished every 5 years in order to ensure seed viability. (USFWS, 2019)

E/5: If genetic research confirms that CNDDB occurrences #2 and #3 contained populations of San Mateo woolly sunflower that have since been extirpated, these occurrences are reestablished using appropriate habitat restoration and plant propagation techniques. These additional occurrences are important due to the limited availability of the appropriate habitat. (USFWS, 2019)

Recovery Priority Number: 11

**Delisting Criteria:**
A/1: A minimum of 20 self-sustaining colonies of San Mateo woolly sunflower are established on suitable habitat within or near the plant's known historical range, and are fully protected and managed with the primary intention of preserving the populations in perpetuity. Each protected area includes occupied habitat with adjacent unoccupied habitat and a 150-meter (500-foot) buffer, where possible. If historical and/or extant Eriophyllum colonies (outside of the San Mateo Creek Watershed) are determined to be San Mateo woolly sunflower, a minimum of 40 self-sustaining colonies are protected and managed as described above. Additional colonies are protected if indicated by modeling or research. (USFWS, 2019)

A/2: All lands upslope from the colonies described in A/1 are protected from incompatible uses.

A/3: Potential negative effects to San Mateo woolly sunflower habitat from sudden oak death infestations are absent or below a level that threatens colony health and/or persistence.

(USFWS, 2019)

E/1: For a minimum of 20 consecutive years that include two normal precipitation cycles each colony described in A/1 exhibits a stable or increasing population trend with a rolling average of at least 300 individuals. During low density years (presumably from natural population fluctuations), each colony described in A/1 contains a minimum of 150 individuals. (USFWS, 2019)

E/4: Impacts from competition with native and nonnative species are managed so they do not pose a threat to the persistence of any of the San Mateo woolly sunflower colonies described in A/1. (USFWS, 2019)

E/5: Long-term management of San Mateo woolly sunflower habitat is both practically and financially sustainable. Financial resources for long-term habitat management are secured. (USFWS, 2019)

**Recovery Actions:**

- 1. Protect San Mateo woolly sunflower colonies and identify or establish additional colonies. 1.1. Ensure that all road and utility maintenance personnel are aware of San Mateo woolly sunflower along Crystal Springs Road and mark colonies with permanent signs/markers. Implement other protection measures as needed. (Priority 1). 1.2. Secure colonies through land acquisitions, conservation easements, or other means. (Priority 1). 1.3. Identify and protect potential introduction sites. (Priority 1). 1.4. Search for additional colonies on private and city land. Secure additional colonies through land acquisitions, conservation easements, or other means. (Priority 2). 1.5. Implement a seed increase and/or propagation program that may be used to establish new colonies and supplement existing colonies when necessary. (Priority 2). 1.6. Establish new colonies, to the extent described in the recovery criteria, within or near the species' known historical range. Colonies should be established in suitable habitats that exhibit a range of natural environmental conditions. Numerous introductions may be necessary to achieve adequate success rates and determine the range of habitat conditions under which successful establishment can be achieved. (Priority 2). (USFWS, 2019)
- 2. Research San Mateo woolly sunflower life history and conservation strategies. 2.1. Conduct genetic research on existing colonies to determine the species' genetic structure and genetic diversity. (Priority 1). 2.2. Study the historical and extant Eriophyllum occurrences that have been classified as San Mateo woolly sunflower to determine accurate species identities. Delineate the actual and historical range of San Mateo woolly sunflower. (Priority 1). 2.3. Research and develop reliable seed germination and propagation techniques. (Priority 1). 2.4. Determine the most effective and efficient habitat management practices to enhance colony health and reduce impacts from competing species and erosion. Experimentally test fire disturbance104 as a management tool. (Priority 1). 2.5. Research optimal habitat characteristics, factors influencing seed germination, mechanisms of dispersal, impacts of seed predation, and potential impacts from climate change. (Priority 2). 2.6. Study the demography (including seedling survivorship). , reproductive biology, and phenotypic plasticity (the capacity for marked variation in observable structural and functional properties of an organism because of environmental influences during development). of colonies. (Priority 3). (USFWS, 2019)

- 3. Monitor and manage San Mateo woolly sunflower colonies. 3.1. Implement site-specific management plans. Manage habitat in occupied areas and in surrounding areas that affect, or could affect, conditions in occupied areas (e.g. weedy species invade from adjacent areas). . Best habitat management and restoration practices may include complete eradication of nonnative species, planting coast live oak trees, and/or treating sudden oak death infestations. (Priority 1). 3.2. Implement a standardized annual monitoring program with the power to detect population trends. (Priority 2). 3.3. Store seeds in at least two Center for Plant Conservation certified facilities. Unless storage techniques and/or research show otherwise, replenish seed stock every 5 years to ensure seed viability. (Priority 2). 3.4. Establish a Service-approved monitoring plan to cover a minimum of 5 years post-delisting. The plan will be ready for implementation at the time of delisting to ensure the ongoing conservation of the species and the continued effectiveness of management actions. Adequate funding must be dedicated in order to implement the delisting management plan. (Priority 3). (USFWS, 2019)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: The following recommendations for future actions are from the 2011 5-year review, 2019 Recovery Plan Amendment (Service 2019), scientific literature, and as a result of discussions with species experts. 1. Protect San Mateo woolly sunflower colonies and identify or establish additional colonies. Ensure that all road and utility maintenance personnel are aware of San Mateo woolly sunflower along Crystal Springs Road. 2. Monitor and manage San Mateo woolly sunflower colonies. Conduct regular protocol surveys and implement site-specific management plans. Establish an encroachment threshold for invasive plants that triggers management action. 3. Research San Mateo woolly sunflower life history and increase understanding of its germination and propagation to determine the potential for reintroduction success. (USFWS, 2021)

# SPECIES ACCOUNT: *Eryngium aristulatum var. parishii* (San Diego button-celery)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 08/03/1993; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A perennial or biennial herb arising from a taproot. The flowers occur on stems and have rigid spiny bracts (NatureServe, 2015).

**Taxonomy**

A member of the Apiaceae (parsley/carrot family). Eryngium aristulatum var. parishii is one of three varieties of Eryngium aristulatum (Constance 1993, p. 147). Eryngium aristulatum var. parishii is separated from Eryngium aristulatum var. aristulatum (common) by having styles in fruit that are about the same length as the calyx (outer whorl of protective structures around the flower) and is separated from Eryngium aristulatum var. hooveri (Hoover's button-celery) by having bractlets (modified leaves) without callused margins (Constance 1993, pp. 147–148) (USFWS, 2010).

**Historical Range**

At the time of listing, Eryngium aristulatum var. parishii was considered extant in Riverside County at Santa Rosa Plateau, in San Diego County at Otay Mesa, Kearny Mesa, Del Mar Mesa, Marine Corps Air Station (MCAS) Miramar, and Marine Corps Base (MCB) Camp Pendleton, and in northern Baja California, Mexico (USFWS 1993, p. 41385). The historical distribution of Eryngium aristulatum var. parishii habitat included a coastal swath from Mesa de Colonet and San Quintin in Baja California, Mexico, north to Los Angeles County, California in the United States (USFWS, 2010).

**Current Range**

Eryngium aristulatum var. parishii currently occurs in 14 geographic areas in Riverside and San Diego Counties (USFWS, 2010). Occurs in the Santa Rosa Plateau in Riverside Co. and San Diego Co. California, and Baja California, Mexico. This species occurs in a small portion of the southwest portion of Riverside Co., and from San Diego Co. from Camp Pendelton Marine Base south into Baja California, Mexico to Ensenada (USFWS 1998) (NatureServe, 2015).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: cross-pollination (USFWS, 2010)

**Lifespan**

Adult: 2+ years (inferred from USFWS, 2010)

**Breeding Season**
Adult: April - June (USFWS, 2010)

**Key Resources Needed for Breeding**
Adult: Ephemerally wet conditions; insect pollinators, based on closely related species (USFWS, 2010)

**Reproduction Narrative**
Adult: Relies on ephemerally wet conditions to reproduce; blooming from April to June. It is an outcrossing taxon that reproduces exclusively by seeds. E. a. var. parishii is presumably insect-pollinated (Zedler 1987, pp. 61–64), potentially by bee flies (Bombyliids) (Schiller et al. 2000, pp. 386–396) and solitary bees (Apoidea), as are many vernal pool species (Thorpe 2007, pp. 51–57) (USFWS, 2010).

**Habitat Type**
Adult: Wetland (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**
Adult: Vernal pool (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**
Adult: Disturbance regime (USFWS, 2010)

**Geographic or Habitat Restraints or Barriers**
Adult: Succession (inferred from USFWS, 2010)

**Environmental Specificity**
Adult: Very narrow (inferred from USFWS, 2010)

**Tolerance Ranges/Thresholds**
Adult: Moderate (inferred from USFWS, 2010)

**Habitat Narrative**
Adult: Grows in vernal pools (Smith and Berg, 1988) (NatureServe, 2015). It is a clay soil, surface and non-surface hard pan, vernal pool obligate. Eryngium aristulatum var. parishii seems more tolerant of peripheral vernal pool habitat than most obligate vernal pool species. It is specifically adapted to surviving in vernally wet conditions due to the presence of aerenchyma tissue (air channels in the roots) that facilitates necessary gas exchange in submerged plants (Keeley 1998, pp. 121–175). Habitat occupied by Eryngium aristulatum var. parishii is dependent upon some form of disturbance to set back succession (e.g., periodic fire and annual inundation) (USFWS, 2010).

***Dispersal/Migration***

**Dispersal/Migration Narrative**
Adult: Not available

***Population Information and Trends***

**Population Trends:**

95 - 97% decline in habitat (USFWS, 2010)

**Number of Populations:**

~98 U.S. locations presumed extant or extant (USFWS, 2023)

**Population Narrative:**

It is restricted to southern coastal California, with few occurrences in northern Baja California, Mexico. Eryngium aristulatum var. parishii can be locally abundant in remnant vernal pools; however, the distribution of this variety has been dramatically reduced due to loss of most (95 to 97 percent) of the vernal pool habitat in San Diego County (USFWS 1998, p. iii) (USFWS, 2010). In summary, the species is extant or presumed extant at approximately 98 locations within the Unites States. At least 26 locations in the United States are considered extirpated or possibly extirpated. There are likely many more extirpated locations that were not recorded prior to development, because by 1978, 90 percent of vernal pool habitat in San Diego County was already lost (Beauchamp 1979, p. 1). The isolated populations newly documented in Orange County and 100 miles farther south in Baja California, Mexico, appear to be outliers, and the core distribution in Riverside and San Diego counties remains mostly unchanged. Therefore, this information does not substantially alter our understanding of the distribution of Eryngium parishii var. aristulatum (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Urbanization and agricultural development (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Loss of habitat from development is considered a primary contributor to vernal pool loss throughout California (Holland 1988, p. 1013; Barbour et al. 2007, p. 7), and specifically to vernal pools in southern California (Bauder 1986, p. 9-4; Bauder 1987, pp. 209–213). There is no certainty nor is there any likelihood that pools or pool complexes that fall outside the Multiple Habitat Planning Area (MHPA) will ultimately be conserved; these areas are still subject to development pressures. What was once a large, relatively unbroken expanse of patchy but interconnected pool habitat, has become remnant “islands” of vernal pools within an expanse of varying levels of anthropogenic disturbance, and permanently altered landscape (e.g., pools at N 8 General Dynamics site on Kerney Mesa, I 6C Bob Baker 2 on Mira Mesa, and C17– 18 on Mira Mesa; see Appendix 1) (USFWS, 2010).

**Stressor:** Off-highway vehicle (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Damage can be caused by motorcycles, quads, mountain bicycles, and four-wheel drive vehicles. Bauder (1987, p. 209) indicated that some impacts from OHVs were considered vandalism, while other damage occurred in the course of legitimate activities including fire

fighting, security patrols, and military maneuvers. Altered pool hydrology may favor invasion of nonnative plants by allowing nonnatives to encroach in areas where the hydrological conditions had been altered by OHVs; vehicles can also break through the clay hard pan, causing hydrological damage that may not be repaired. The use of OHVs causes fragmentation, degradation, and destruction of vernal pools (Hilty et al. 2006, p. 157; Forman et al. 2003, pp. 113–138; Wilcove et al. 1998, pp. 607–615). Transportation corridors have the potential to spread disease, drain or damage pools, and facilitate the invasion of nonnative species (Hilty et al. 2006, p. 157) as well as mixing of otherwise naturally separated native species and genotypes (e.g., fairy shrimp lineages). It is likely that OHV use continues to be a nearly rangewide threat to Eryngium aristulatum var. parishii and its habitat (USFWS, 2010).

**Stressor:** Trampling (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat destruction associated with livestock and human access was considered to be a threat to Eryngium aristulatum var. parishii at listing (USFWS 1993, p. 41388) and in the Recovery Plan (USFWS 1998, p. 47). Impacts from this threat include soil compaction and erosion, though this is not a predominant threat. Destruction of E. a. var. parishii habitat from cattle is dramatically reduced, though some vernal pools continue to be impacted by livestock, such as horses in the J26 vernal pool complex in Otay Mesa (Wynn, pers. comm. 2010) (USFWS, 2010).

**Stressor:** Mowing and plowing (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Mowing and plowing/discing of habitat has been used to reduce fire hazards and to shorten vegetative cover for birds to reduce bird air-strike hazards and bird air mortality hazards (U.S. Marine Corps 2006, pp. 7-1–7-36; U.S. Marine Corps 2007, pp. F-47–F-49). Restrictions of these activities where there is a Federal or State nexus via INRMP site management plans and overarching MSHCPs have reduced the loss of habitat due to mowing or plowing; however, impacts from this threat have yet to be quantified (USFWS, 2010).

**Stressor:** Highway construction (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Road development and inter-related actions were classified as a threat to Eryngium aristulatum var. parishii when it was listed. Roads are closely associated to habitat fragmentation (loss) due to urban and agricultural development. Vernal pools and associated habitat proximal to basins have been eliminated by road and highway construction. Mitigation for roadway development has included the restoration of vernal pool habitat and introduction of key vernal pool species. Restoration of vernal pools has had some degree of success in the short term; however, the long term effectiveness of this mitigation approach is still being studied (Black and Zedler 1998, pp. 195–205). Road development and related construction activities are still a primary threat to the variety (USFWS, 2010).

**Stressor:** Altered hydrology (USFWS, 2010)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Seasonality (phenology) of vernal pools requires annual hydrologic input during the spring months to moisten and fill pools and basins. Due to urbanization, hydrologic cycles have been affected near vernal pool complexes (Bauder 1987, pp. 209–213). However, impacts from this threat to Eryngium aristulatum var. parishii appear to have decreased since the time of listing due to development standards that are intended to prevent runoff from entering vernal pool basins (Wynn, pers. obs. 2009) (USFWS, 2010).

**Stressor:** Military activities (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Impacts to vernal pool sites resulted from large equipment (e.g., tanks) and civilian use on base (USFWS 1993 p. 41388). Training activities near and adjacent to vernal pool habitat have resulted in site-specific impacts to vernal pool species, such as rutting of pools. Approximately 70 percent of the remaining vernal pool complexes occur on lands within military jurisdiction (USFWS 2008, p. 16). Since listing, conservation efforts on military lands have been in place due to implementation of the Sikes Act and the Sikes Act Improvement Act described below under Factor D, which require military installations to develop INRMPs (USFWS, 2010).

**Stressor:** Insect herbivory (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Predation was not identified as a threat at listing, but insect herbivory of E. a. var. parishii was later considered a disturbance concern in the recovery plan and remains a potential threat to the taxon (USFWS 1993, p. 41388; USFWS 1998, p. 67). This can have considerable effects on plant population dynamics, and may include: (1) Damage to roots, leaves, flowers, and developing seeds; and (2) ultimately reduce living plant fitness and reproductive success in the presence of native and nonnative competitors (Louda 1994, pp. 118–138) (USFWS, 2010).

**Stressor:** Nonnative plants (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** San Diego County and the range of Eryngium aristulatum var. parishii are in a mild, Mediterranean climate zone that makes the potential and rate for nonnative species incursion high. Nonnative plants are documented to alter natural landscapes and available habitat in San Diego County (Bauder 1987, pp. 209–213). Invasive, nonnative plants have long been considered a concern in vernal pool habitat (Holland 1988, p. 1014). Some of these biological impacts include competition with E. a. var. parishii for water, soil nutrients, space above and below ground, and displacement of natural pollinators. Bauder (2005, p. 2133) states that Agrostis avenaca (Pacific bentgrass) and Polypogon monspeliensis (rabbitsfoot grass) are present in San Diego County vernal pools, and that research in the field and under controlled conditions indicates “both grasses negatively affect native pool species in a variety of ways, ranging from survivorship to reproductive success.” (USFWS, 2010).

**Stressor:** Altered fire regime (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire is a natural component for regeneration and maintenance in E. a. var. parishii habitat (Bauder 1996, p. 2). However, the taxon faces two seemingly diametrically opposed forces: lack of fire, and re-introduction of fire (accidental and purposeful) to an altered landscape. Fire in areas where Eryngium aristulatum var. parishii exist can remove vegetation cover that would otherwise aid in controlling erosion post fire. This may in turn result in local sedimentation of the pools or otherwise disrupt vernal pool ecology. Although habitat occupied by Eryngium aristulatum var. parishii is dependent upon some form of disturbance to set back succession (e.g., periodic fire and annual inundation), fires at critical times can eliminate populations of E. a. var. parishii by killing individual plants or seed banks through intense heat, or overheating soil to create hydrophobic conditions (Agee 1993, pp. 1– 493; Keane et al. 2002, pp. 3–11; Keeley 2001, pp. 81–94; Arno and Fiedler 2005, pp. 7–38) (USFWS, 2010).

**Stressor:** Small population size (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Eryngium aristulatum var. parishii is limited by its inherent ecological tolerances and by past and current anthropogenic activities that occur within a vernal pool, in proximity to vernal pool complexes, or within a watershed of a vernal pool or complex. Events outside the range of natural influence or frequency variability, such as floods, fires, contamination, or drought, can substantially reduce or eliminate small populations and increase the likelihood of extinction (Lande 1993, p. 912). Small populations are more vulnerable to natural catastrophes and stochastic demographic, genetic, and environmental events (Barrett and Kohn 1991, pp. 3–30). Genetic effects may further influence population demography via inbreeding depression and genetic drift (Barrett and Kohn 1991, pp. 3–30; Menges 1991, pp. 58–61) (USFWS, 2010).

**Stressor:** Loss of pollinators (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Cumulative effects of habitat loss, drought, and urbanization on native pollinators contribute to an extant and future threat to Eryngium aristulatum var. parishii. The National Research Council of the National Academies (2007, pp. 73–74) indicated that “some pollinators in North America representing a diversity of taxa are, in fact, in decline.” When native pollinators are diminished, redundancies in pollinator systems may be disrupted thus impacting the reproductive output of the variety (USFWS, 2010).

**Stressor:** Climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Drought was noted as a threat to Eryngium aristulatum var. parishii at the time of listing; however, its relationship to climate change has been derived since listing. The effects of

an unpredictable precipitation regime on vernal pools, and on vernal pool species will have consequential effects on short and long term persistence of most if not all pools within basins (Bauder 2005, pp. 2129–2135). Ecosystem communities in California are expected to be ‘reshuffled’ due to climate disruption (Stralberg et al. 2009, pp. 1–8). The Service recognizes that climate change is an important issue with potential effects to listed species and their habitats; however, information to make precise oceanographic and atmospheric predictions regarding its immediate effects to vernal pool species, including Eryngium aristulatum var. parishii and its habitat, is lacking (USFWS, 2010).

***Recovery***

**Reclassification Criteria:**
1. Existing vernal pools and their associated watersheds that contain Eryngium aristulatum var. parishii should be secured from further loss and degradation in a configuration that maintains habitat functions and species viability (USFWS, 1998).

2. The existing vernal pools and their associated watersheds contained within the complexes identified in Table 5 are secured in a configuration that maintains habitat function and species viability (as determined by recommended research) (USFWS, 1998).

3. Secured vernal pools are enhanced or restored such that population levels of existing species are stabilized or increased (USFWS, 1998).

4. Population trends must be shown to be stable or increasing for a minimum of 10 consecutive years prior to consideration for reclassification. Monitoring should continue for a period of at least 10 years following reclassification to ensure population stability (USFWS, 1998).

Recovery Priority Number: 9C (USFWS, 2023)

**Delisting Criteria:**
Delisting of the species is conditional on the downlisting criteria shown above, improvement (stabilized or increasing population trends) at all currently known sites; restoration, protection, and management of the minimum habitat area and configuration needed to ensure long-term viability; and establishing historic but locally extirpated species populations when needed to ensure viability (USFWS, 1998).

In the interest of ensuring these criteria are clearly articulated, we are amending the following clarification to the existing recovery plan. This amendment does not represent a revision of the delisting criteria, it simply provides more specific terminology. Delisting for the species covered by the 1998 recovery plan may be considered when the downlisting criteria have been met and: 1. All 74 geographic areas and associated vernal pool complexes as identified in Appendices F and G of the 1998 Recovery Plan under each of the specific management areas are protected and managed to ensure long-term viability. 2. The U.S. Fish and Wildlife Service must determine that the following factors are no longer present, or continue to adversely affect, Eryngium aristulatum var. parishii, Pogogyne abramsii, Pogogyne nudiuscula, Orcuttia californica, and the Riverside and San Diego fairy shrimp: ( 1) the present or threatened destruction, modification, or curtailment of their habitat range; (2) over utilization for commercial, recreational, scientific, or educational purposes; (3) disease or predation; (4) the inadequacy of existing regulatory mechanisms; and ( 5) other natural and manmade factors affecting their continued existence (50 CFR 424.11). 3. Population trends for all seven taxa continue to be stable or increasing for 10 consecutive years after threats have been sufficiently ameliorated or managed ( completion of delisting criterion 2) prior to consideration for delisting. (USFWS, 2019)

**Recovery Actions:**

- Conduct surveys and research essential to the conservation of the species (USFWS, 1998).
- Secure the existing vernal pools and their associated watersheds (USFWS, 1998).
- Where necessary reestablish vernal pool habitat to the historical structure (USFWS, 1998).
- Manage and monitor habitat and listed species (USFWS, 1998).
- Conduct rangewide monitoring using species-specific protocol to ascertain distribution and abundance; assimilate monitoring data into a standardized database available to all cooperators, researchers, public, and regulators. Publish results in peer reviewed journal(s) (USFWS, 2010).
- Develop a coordinated interagency invasive species prevention and eradication program for all vernal pool habitat where Eryngium aristulatum var. parishii is extant (USFWS, 2010).
- Identify Eryngium aristulatum var. parishii pollinators, their required habitat, and implement measures to ensure their maintenance throughout the range of E. a. var. parishii (USFWS, 2010).
- Conduct hydrological monitoring and modeling to ascertain vulnerability of pools and complexes to likely altered hydrological conditions associated with climate change (USFWS, 2010).
- Determine the utility of enhanced and artificially created vernal pools to the conservation of the species and standardize methods of site selection, selection of propagation materials, outplanting protocols, success criteria, and remediation methods (USFWS, 2010).
- Coordinate with partners, such as MCAS Miramar and MCB Camp Pendleton, to help manage and protect vernal pool habitat (USFWS, 2010).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The actions are intended to reduce threats to Eryngium aristulatum var. parishii and provide information to better understand the biological and physical factors limiting the population growth and distribution. We recognize that conservation of E. a. var. parishii will require cooperation and coordination with partners to minimize impacts from current threats, aid future restoration, and maximize effectiveness of limited funding. 1. Work with partners to identify opportunities for conservation of Eryngium aristulatum var. parishii occurrences on private lands. Support land acquisition to meet Habitat Conservation Plan goals. Work with local, State, and Federal partners to identify and leverage funding (i.e., section 6) to acquire E. a. var. parishii habitat. 2. Adaptively manage E. a. var. parishii occurrences to maintain, enhance, or restore habitat and reduce threats. a. Manage nonnative species in vernal pool habitat. b. Coordinate with partners to develop a nonnative species prevention and eradication program for all vernal pool habitat where E. a. var. parishii is extant. c. Ensure the correct species pallet from a nearby source is being selected for areas during restoration projects inside and outside of the known range for E. a. var. parishii. 3. Monitor occurrences to assess management effectiveness. a. Conserve E. a. var. parishii seed in an off-site seed bank. b. Work with partners in Baja California, Mexico to survey additional areas for E. a. var. parishii and identify conservation opportunities. 4. Maintain or enhance E. a. var. parishii genetic diversity. a. Conduct a population genetics study to characterize genetic variation and structure. Based on study results, develop best management practices to maintain genetic diversity within the species. b. Further investigate the taxonomy and genetic relationships between of E. aristulatum, E. vaseyi, E. aristulatum var. hooveri, E. pendletonense, and other similar Eryngium species; especially those occurring at MCB Camp Pendleton, Costa Mesa, Santa Rosa Plateau, and Baja California, Mexico, and compare to E. a. var. parishii. c. Investigate/monitor the potential for hybridization between E. a. var. parishii and E. pendletonense at Bluff Las Flores [EO 53]. 5. Model species' response to climate change and assess options to translocate the species into projected suitable habitat. a. Develop hydrological monitoring and modeling to determine characteristics and identification of pools and complexes likely to be impacted by prolonged drought, and lack of seasonal rainfall caused by climate change effects to El Niño/Southern Oscillation (USFWS, 2023).

# SPECIES ACCOUNT: *Eryngium constancei* (Loch Lomond coyote thistle)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 08/01/1985; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

Loch Lomond button-celery is a perennial herb. Decumbent. Several flowered inflorescence with spiny bracts (NatureServe, 2015).

**Taxonomy**

Problematic genus, but E. constancei seems generally agreed upon as an entity (Bittman 1998) (NatureServe, 2015). A member of the carrot family (Apiaceae). Other common names for this species are Loch Lomond button-celery and Constance's coyote-thistle (Smith et al. 1980) (USFWS, 2005).

**Historical Range**

For over 5 decades, this species was known only from Loch Lomond, where it was first collected in 1941 (Sheikh 1983). Eryngium constancei has always been restricted to the Lake-Napa Vernal Pool Region (Keeler-Wolf et al. 1998) (USFWS, 2005).

**Current Range**

At the time of listing, the Loch Lomond coyote-thistle was only known to occur within the bed of a 7-acre vernal lake near the mountain community of Loch Lomond in southern Lake County, California (Service 1986, p. 45904). In our previous 5-year review, we described four known occurrences: three in Lake County and one in Sonoma County (Service 2009, p. 10). These occurrences, from north to south include the Dry Lake occurrence south of Clear Lake, the occurrence near Loch Lomond, an occurrence near the town of Cobb, and the Diamond Mountain occurrence near the city of Calistoga in Sonoma County (Service 2009, p. 10). In 2013, a comment reported to the Diversity Database suggested the population in Sonoma County may actually be a pubescent form of Eryngium aristulatum; however, an unpublished occurrence report submitted to the Diversity Database in 2021 confirms the species identification (Diversity Database 2021 unpublished report, p. 1). The current distribution of the Loch Lomond coyotethistle is the same as described in the 2009 5-year review, with all populations currently presumed extant (USFWS, 2023).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: 2+ years (USFWS, 2005)

**Breeding Season**

Adult: June - August (USFWS, 2005)

**Reproduction Narrative**

Adult: Eryngium species are biennial or perennial, with an overwintering rootstock. Eryngium constancei flowers after the water evaporates from the pools, typically between June and August (California Department of Fish and Game 1985, 1994) (USFWS, 2005).

**Habitat Type**

Adult: Terrestrial, wetland (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Northern volcanic ashflow vernal pool, Northern basalt flow vernal pools (USFWS, 2009)

**Geographic or Habitat Restraints or Barriers**

Adult: ~463 - 853 m elevation (NatureServe, 2015; USFWS, 2009)

**Environmental Specificity**

Adult: Very narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Eryngium constancei grows abundantly within the borders of the meadow-like bed of the Loch Lomond lake at an elevation of 853 m. Rain fills the lake bed in winter, but the water evaporates in spring and early summer, leaving a seasonal meadow-like area in which Eryngium constancei and other plants germinate, flower, and set seed. The volcanic soils of the lake basin, together with its particular hydrological characteristics and the surrounding topography, may account for the unique presence of this species. It lives in fragile vernal pool habitat. The environmental specificity is very narrow (NatureServe, 2015). Loch Lomond is a small, intermittent lake with a surface area of about 3.2 hectares (7 acres) at maximum inundation (U.S. Fish and Wildlife Service 1985). This wetland is classified as a Northern Volcanic Ashflow Vernal Pool (Sawyer and Keeler-Wolf 1995; CNDDB 2007) and is on Collayomi-Aiken-Whispering complex soils. The surrounding area is mountainous and supports a mixed forest. On Diamond Mountain, the pools where Eryngium constancei grows are shallow and spring-fed (CNDDB 2007); they are classified as Northern Basalt Flow Vernal Pools (Sawyer and Keeler-Wolf 1995; CNDDB 2007). The Dry Lake pool is at an elevation of 463 meters (1,520 feet) and is surrounded by Quercus douglasii (blue oak) woodland. (USFWS, 2009). Soils underlying Dry Lake are in the Sobrante-Guenoc-Hambright complex (USFWS, 2005).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Unknown; presumed decline of < 30% (NatureServe, 2015)

**Species Trends:**

3 additional occurrences found since listing (USFWS, 2009); stable (NatureServe, 2015)

**Number of Populations:**

3 (USFWS, 2023)

**Population Size:**

Millions (total) (USFWS, 2023)

**Adaptability:**

Low (inferred from NatureServe, 2015)

**Additional Population-level Information:**

At the time of listing, abundance estimates were not available for the one population at Loch Lomond, but it was described as abundant (Service 1986, p. 45904). The previous 5-year review reported population abundances of millions for the Loch Lomond population, 50,000 for the Diamond Mountain population, and 25,000 for the Dry Lake population. However, these estimates were from 1991, 1996, and 1997, respectively. There was no abundance estimate reported for the Cobb population (Service 2009, p. 9). Current abundances are similar to what was reported in the previous 5-year review (Diversity Database 2023); however, the unpublished report submitted to the Diversity Database in 2021 reported the Diamond Mountain population had declined to approximately 20,000 plants (Diversity Database 2021 unpublished report, p. 1). As described in the Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (Recovery Plan) (Service 2005), which includes the Loch Lomond coyote-thistle, we would not expect the population to vary substantially among years because the species is a perennial (USFWS, 2023).

**Population Narrative:**

This vernal pool plant is vulnerable, though the biological reasons for it are unknown. The long term trend is not known, but is assumed to have been a slight decline (< 30%). The estimated population size is millions of individuals each year (Bittman 1998). The population trend has been stable for the past 10 years (NatureServe, 2015). Since listing in 1986 and proposed downlisting in 1993, three additional occurrences of Eryngium constancei were found. There are four extant occurrences (USFWS, 2009). The Dry Lake and Sonoma County populations numbered in the tens of thousands in both 1996 and 1997. However, in 1996, the Loch Lomond population was at least two orders of magnitude larger than in 1997 (California Natural Diversity Data Base 2003). The size of the fourth population has not been reported (USFWS, 2005).

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Currently, routine highway maintenance, trash dumping and, to a smaller degree, occasional fence vandalism, vehicle trespass, and trampling still threaten E. constancei at the Loch Lomond site. Specific threats to two of the four extant populations are that at least one of the occupied pools at Diamond Mountain may be converted to a vineyard, and the owner of Dry Lake has proposed excavating the pool for a reservoir (CNDDB 2007). Changes in hydrology threaten three of the four occurrences. In addition, runoff from adjacent roads and swimming pools creates excess water flow, whereas drainage ditches, culverts, and diversion of a natural spring are reducing the flow of water to E. constancei habitat (Hrusa and Buckmann 2000; CNDDB 2007). Existing and potential sources of changes to the hydrology at two sites include

adjacent roads, drainage ditches in and adjacent to Loch Lomond, development south of the lake (CNDDB 2007), and a culvert alongside one of the Diamond Mountain pools. Larger-scale hydrological alterations, including commercial development and timber harvesting, are also occurring in all the watersheds where Eryngium constancei grows, thus posing added hydrological threats (U.S. Fish and Wildlife Service 1986, 1993; CDFG 1994; K. Aasen in litt. 1995; B. Hunter in litt. 1996; CNDDB 2007). Not only does removal of trees and construction of logging roads alter the flow of water, but it also causes erosion, which can bury the plants and affect the hydrology (U.S. Fish and Wildlife Service 1985, U.S. Fish and Wildlife Service 1986, U.S. Fish and Wildlife Service 1993; California Department of Fish and Game 1994; Aasen in litt. 1995; B. Hunter in litt. 1996). The Loch Lomond and Diamond Mountain occurrences are threatened by hydrological alterations within their watersheds. By affecting the amount of runoff entering the pools or the rate at which the pools dry, the depth and duration of inundation can increase or decrease, creating conditions unsuitable for the survival of Loch Lomond coyote thistle. The Dry Lake occurrence is threatened by trash dumping and erosion into the pool; the surrounding slopes have been stripped of vegetation and are eroding (CNDDB 2007). The Loch Lomond occurrence is also threatened by occasional fence vandalism and vehicle trespass (S. Zalusky, pers. comm. 2008) (USFWS, 2009).

**Stressor:** Trampling/grazing (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Currently, the occurrence at Dry Lake is heavily impacted by horse padocking (S. Zalusky, pers. comm. 2008) (USFWS, 2009).

**Stressor:** Stochastic events (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The extremely restricted distribution of Eryngium constancei is a threat to its long-term viability. Although the individual populations are sufficiently large that intrinsic problems such as genetic drift are not a concern, other random events could cause the species to go extinct. Catastrophic weather events, climate change, or other unforeseen circumstances potentially could eliminate all of the populations. In particular, small numbers of localities makes it difficult for this species to persist while sustaining the impacts from adjacent development, drought, or other unknown factors. Such populations may be highly susceptible to extirpation due to chance events or additional environmental disturbance (Goodman 1987; Gilpin and Soule 1988). If a locality of E. constancei has several consecutive years of poor rainfall, or changes in hydrology from adjacent development, it is possible that all individuals within the locality will become extirpated (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Drought or flood conditions will place additional strains on the vernal pool ecosystem supporting E. constancei occurrences, some of which are already fragmented or reduced by habitat conversion to wineries and development. Where occurrences persist on only marginal

habitat, the addition of extreme drought conditions is likely to result in higher rates of mortality in the short term with the effects of low reproductive output and survivorship persisting after the drought has ceased. The predicted impacts on California's ecosystems projected with a high certainty include (1) higher sea level; (2) decreased suitable habitat for many terrestrial species as climate change intensifies human impacts [for example, isolated patches of vernal pools can be so poorly connected with other patches that migrations required by climate change may be difficult or impossible without human intervention (Field et al. 1999)]; and (3) increased competition among urban, agricultural, and natural ecosystem uses due to decreased precipitation. Although the specific effects of climate change on Eryngium constancei are unknown, the effects of increased winter flooding and drought conditions in the spring and summer have the potential to adversely affect this species (USFWS, 2009).

***Recovery***

**Reclassification Criteria:**
recommend the recovery priority number be changed from 14 to 8C (USFWS, 2023).

**Delisting Criteria:**
1. Suitable vernal pool habitat within each prioritized core area for the species is protected (USFWS, 2009).

2. Species occurrences distributed across the species geographic range and genetic range are protected. Protection of extreme edges of populations protects the genetic differences that occur there (USFWS, 2009).

3. Reintroductions must be carried out and meet success criteria established in the recovery plan (USFWS, 2009).

4. Additional occurrences identified through future site assessments, GIS and other analyses, and status surveys that are determined essential to recovery are protected. Any newly found occurrences may count towards recovery goals if the occurrences are permanently protected as described in the recovery plan (USFWS, 2009).

5. Habitat protection results in protection of hydrology essential to vernal pool ecosystem function, and monitoring indicates that hydrology that contributes to population viability has been maintained through at least one multi-year period that includes above average, average, and below average local rainfall as defined above, a multi-year drought, and a minimum of 5 years of post-drought monitoring (USFWS, 2009).

6. Habitat management and monitoring plans that facilitate maintenance of vernal pool ecosystem function and population viability have been developed and implemented for all habitat protected, as previously discussed in sections 1A-E (USFWS, 2009).

7. Mechanisms are in place to provide for management in perpetuity and long-term monitoring of 1A-E, as previously discussed (funding, personnel, etc) (USFWS, 2009).

8. Monitoring indicates that ecosystem function has been maintained in the areas protected under 1A-D for at least one multi-year period that includes above average, average, and below

average local rainfall, a multi-year drought, and a minimum of 5 years of post-drought monitoring (USFWS, 2009).

9. Seed banking actions have been completed for species that would require it as insurance against risk of stochastic extirpations or that will require reintroductions or introductions to contribute to meeting recovery criteria (USFWS, 2009).

10. Status surveys, 5-year status reviews, and population monitoring show populations within each vernal pool region where the species occur are viable (e.g., evidence of reproduction and recruitment) and have been maintained (stable or increasing) for at least one multi-year period that includes above average, average, and below average local rainfall, a multi-year drought, and a minimum of 5 years of post-drought monitoring (USFWS, 2009).

11. Status surveys, status reviews, and habitat monitoring show that threats identified during and since the listing process have been ameliorated or eliminated. Site-specific threats identified through standardized site assessments and habitat management planning also must be ameliorated or eliminated (USFWS, 2009).

12. Research actions necessary for recovery and conservation of the covered species have been identified (these are research actions that have not been specifically identified in the recovery actions but for which a process to develop them has been identified). Research actions (both specifically identified in the recovery actions and determined through the process) on species biology and ecology, habitat management and restoration, and methods to eliminate or ameliorate threats have been completed and incorporated into habitat protection, habitat management and monitoring, and species monitoring plans, and refinement of recovery criteria and actions (USFWS, 2009).

13. Research on genetic structure has been completed (for species where necessary – for reintroduction and introduction, seed banking) and results incorporated into habitat (USFWS, 2009). protection plans to ensure that within and among population genetic variation is fully representative by populations protected in the Habitat Protection section of this document, described previously in sections 1A-E

14. Research necessary to determine appropriate parameters to measure population viability for each species have been completed (USFWS, 2009).

15. Recovery Implementation Team is established and functioning to oversee rangewide recovery efforts (USFWS, 2009).

16. Vernal pool regional working groups are established and functioning to oversee regional recovery efforts (USFWS, 2009).

17. Participation plans for each vernal pool region have been completed and implemented (USFWS, 2009).

18. Vernal pool region working groups have developed and implemented outreach and incentive programs that develop partnerships contributing to achieving recovery criteria 1-4 (USFWS, 2009).

**Recovery Actions:**

- Habitat protection (USFWS, 2005).
- Adaptive habitat management and monitoring (USFWS, 2005).
- Status surveys (USFWS, 2005).
- Research (USFWs, 2005).
- Public participation and outreach (USFWS, 2005).
- Protect vernal pool habitat from being destroyed or modified by development, agriculture, or other activities. Acquire conservation easements or fee title to habitat lands to help guarantee protection of the species in perpetuity (USFWS, 2009).
- Develop and implement standardized population trend survey protocols to complete updated status surveys at all four occurrences (USFWS, 2009).
- Create and convene regional vernal pool working groups in the Lake-Napa Region where Eryngium constancei occurs. Regional vernal pool working groups will be important for the tracking the progress of recovery efforts, including the amount of suitable habitat protected for each of the species in the core areas (USFWS, 2009).
- Collect seeds from populations from which it has not yet been collected following the Center for Plant Conservation Guidelines (1991). Seed collections should be stored in at least two sites, including the National Center for Genetic Resources in Fort Collins, Colorado, and a facility certified by the Center for Plant Conservation (USFWS, 2009).
- Withdraw the proposal to reclassify Eryngium constancei from endangered to threatened (USFWS, 2009).
- Consider modifying the Boggs Lake-Clear Lake core area to incorporate the entire Loch Lomond Vernal Pool Ecological Reserve and adjacent watershed (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of Loch Lomond coyote-thistle. Some of these recommendations have already been discussed in the previous 5-year review (Service 2009, pp. 17–18) and remain valid. 1. Protect vernal pool habitat from being destroyed or modified by development, agriculture, or other activities. Acquire habitat through conservation easements or fee title to help guarantee protection of the species in perpetuity. 2. Develop and implement standardized population trend survey protocols to complete updated status surveys at all four occurrences. 3. Create and convene regional vernal pool working groups in the Lake-Napa Region where Loch Lomond coyote-thistle occurs. Regional vernal pool working groups will be important for the tracking the progress of recovery efforts, including the amount of suitable habitat protected for the Loch Lomond coyote-thistle. 4. Collect seeds from populations from which it has not yet been collected following the latest Center for Plant Conservation Guidelines. Seed collections should be stored in at least two sites, including the National Center for Genetic Resources in Fort Collins, Colorado, and a facility certified by the Center for Plant Conservation. 5. The Recovery Plan describes both down- and de-listing criteria as preliminary that will need periodic reassessment because data were lacking at the time the Recovery Plan was developed. Therefore, reassess and refine both down- and de-listing criteria for the Loch Lomond coyote thistle, if appropriate, to better reflect the species' life history and narrow range (USFWS, 2023).

# SPECIES ACCOUNT: *Eryngium cuneifolium* (Snakeroot)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 2/20/1987; Southeast Region (R4)

**Physical Description**

Eryngium cuneifolium is an aromatic perennial herb with a long, woody taproot, and persistent rosette of dark green. It usually has several erect, branching, flowering stems. It ranges from 0.25 to 0.5 m in height, rarely reaching as high as 0.9 m. The leaves are clustered at the base of the plant. The basal leaves are long, stalked, and shaped like narrow wedges, with 3 to 5 bristle-tipped teeth at the apex. Stem leaves are smaller and lack leaf stalks. The flowers are small, with white petals, filaments, styles and stigmas but powdery blue anthers form small heads, with bristly bracts. The sepals and petals are each about 1.5 to 2 mm long. The inferior ovary develops into a fruit about 1.5 to 2 mm long. The flowers and bristle bracts form heads 4 to 8 mm in diameter (Bell 1963, Wunderlin et al. 1981). Sterile plants are easily recognized in the field by their basal rosettes (Wunderlin et al. 1981). Flowering is from August to October (other Eryngium species, including E. aromaticum and E. baldwinii have blue flowers). (USFWS, 1999)

**Taxonomy**

Eryngium cuneifolium, a member of the parsley family (Apiaceae or Umbelliferae), is most closely related to E. aromaticum (Bell 1963, Wunderlin et al. 1981). It was described by J.K. Small (1933) and its status as a species was upheld by O.R. Bell's (1963) review of the genus. Preparers of status reports (Wunderlin et al. 1981, Kral 1983) have also concurred that this is a distinct species. There are no synonyms in the botanical literature (Bell 1963, Wunderlin et al. 1981). Other common names for this species include wedged-leaved button-snakeroot (Wunderlin et al. 1981) and semantic variations thereof. (USFWS, 1999)

**Historical Range**

This species was first collected in 1927 near Sebring. Highlands County, Florida. (USFWS, 1999)

**Current Range**

Southern Highlands County, Florida, near the town of Lake Placid. It occurs only on the southern Lake Wales Ridge. (USFWS, 1999)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 1999)

**Lifespan**

Adult: short-lived (less than 10 years ) (USFWS, 2019)

**Reproduction Narrative**

Adult: Reproduction in E. cuneifolium is sexual. The species can reproduce readily by seed. There seems to be no special seed-dispersal mechanism (other than gravity) and pollination is likely to be similar to that of other members of Apiaceae, most likely by generalist insects (Wunderlin et al. 1981, Kral 1983). Germination and leafing dates are unknown. Budding is believed to occur in July. The plant flowers vigorously from September through October. Anthesis occurs from August to October . Fruiting and seed dispersal is believed to occur between October and January . Seeds are mature in November. Specimens have been collected in late November and December. (USFWS, 1999)

**Habitat Type**

Adult: Scrub vegetation

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 1999)

**Habitat Narrative**

Adult: Snakeroot is found in open sand gaps in rosemary habitats within the Lake Wales Ridge in Highlands County. Nearly every aspect of snakeroot's demography is affected by time-since-fire. The beneficial effects of fire are largely indirect, though removal of litter, competing vegetation, and ground lichens. Snakeroot is sensitive to shrub cover and is dependent on the gaps created between rosemary shrubs immediately after fires. (USFWS, 2019)

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Declining (inferred) (USFWS, 2019)

**Number of Populations:**

13 occurrences (USFWS, 2019)

**Population Narrative:**

In the last FNAI Element Tracking Summary (FNAI 2015) there were 13 known occurrences, 10 of which were on 5 managed areas. This was a significant decline (approximately 32 percent) from the 19 reported occurrences in the previous 5-year status review (2010c) (USFWS, 2019). Population sizes of snakeroot tend to vary widely with time since fire occurrence (Menges and Quintana-Ascencio 2004). Most EORs do not have regular population size estimates, although some have been reported previously (Service 2010). Population sizes reported by FNAI ranged from 10 to 10,000+ individual plants, but some EORs do not have population sizes indicated (FNAI 2020, Table 1). At ABS, the number of plants in study populations between 2014 and 2019 has ranged from 1,300 to 2,700 individuals, with several hundred additional plants outside of study areas (Menges, unpublished data). At Royce Ranch, plants in plots have varied from about 300 to 500 during the past few years, but there are probably thousands of additional plants at the site (Menges, unpublished data). (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species is restricted to xeric scrub habitats in one or more of the interior Central Florida counties of Polk, Highlands, Hendry, Osceola, and Lake, where habitat destruction from development continues to occur and development pressure remains high. Areal extent of post-Columbian xeric upland habitat loss on the Lake Wales Ridge is estimated to exceed 85 percent (Weekley et al. 2008a). Increasing pressure from population growth is likely to result in further loss of these habitats going forward. Carr and Zwick (2016) analyzed existing land use and landscape patterns to identify areas (including central Florida) most likely for development to accommodate a growing human population. They suggests that Florida's 2070 population will be early 15 millionpersons greater than in 2010, for an estimated total of 33,721,828. Using these figures, they estimated relative losses to agriculture, open space, and conservation to other land uses. If trends continue, they estimate 34 percent of land will be developed by 2070, up from 19 percent in 2010. At the same time, conservation lands will increase less than 1 percent (from 9,269,000 acres in 2010 to 9,525,000 acres by 2070). Overall, loss of habitat to development, primarily on private lands, will likely continue in Central Florida, eliminating populations and reducing the area of suitable habitat for these species. Therefore, habitat on protected lands are critical for the recovery of this scrub plants. (USFWS, 2019)

**Stressor:** Lack of adequate fire management
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire is necessary to maintain the scrub habitats upon which this species depends. Historically, lightning-induced fires were a vital component in maintaining native vegetation within the scrub community. Fire suppression started on a regional scale on the Central Florida ridges about 80 years ago. Due to the extent of residential and agricultural development throughout Central Florida, fire has all but disappeared from the region as a widespread, natural phenomenon. Prescribed fire is a crucial management component for maintenance of all scrub habitats. Because of the difficulties of applying prescribed fire on an ever-increasing urban landscape, imperiled species on unmanaged sites will almost certainly disappear over time (Turner et al. 2006). In managed areas, prescribed fire is essential to manage habitats and restore or maintain suitable conditions for scrub species. (USFWS, 2019)

**Stressor:** Limited geographic range
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species occurs occur within a relatively limited geographic range in Central Florida. The limited geographic range in combination with the loss of habitat has resulted in a highly fragmented landscape where the remaining scrub areas and their residing species have become more and more isolated from each other, thereby making resiliency, redundancy, and representation more challenging to achieve. The effects of habitat fragmentation on species richness have been exhaustively studied (MacArthur and Wilson 1967, Diamond 1975, 1978; Simberloff and Abele 1976, 1982; Zimmerman and Bierregaard 1986). For most taxonomic

groups, large habitat patches in close proximity to each other provide for the greatest species diversity and minimize extinction probabilities. On the contrary, small patches that are isolated are less likely to preserve species that would otherwise be common in the mosaic of communities that existed before isolation. Since at least the Pleistocene, Florida scrub has been characterized by an insular, discontinuous distribution, but the degree of habitat fragmentation seen today is unprecedented and certainly will contribute to increases in extinction rates among scrub-dependent plants and animals. (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**

1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations and sites needed to assure 20 to 90 percent probability of persistence for 100 years (USFWS, 1999)

2. When these sites, within its historic range, are adequately protected from further habitat loss, degradation, and fragmentation (USFWS, 1999)

3. When these sites are managed to maintain the rosemary phase of xeric oak scrub communities to support E. cuneifolium (USFWS, 1999)

4. When monitoring programs demonstrate that populations of E. cuneifolium on these sites support the appropriate numbers of self-sustaining populations, and those populations are stable throughout the historic range of the species (USFWS, 1999)

Recovery Priority Number: 2

**Delisting Criteria:**

1. At least 20 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)

2. Populations (as defined in criterion 1) in rosemary scrub habitats are distributed across the known range of the species. (USFWS, 2019)

3. Populations are protected and managed via a conservation mechanism to a degree that enough suitable habitat is present for the species to remain viable for the foreseeable future. (USFWS, 2019)

**Recovery Actions:**

- Determine current distribution of E. cuneifolium. This species has been relatively well surveyed and a distribution has been ascertained. Additional surveys will confirm the species’ distribution and locate new sites. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties has been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)

- Conduct research on life history characteristics of E. cuneifolium. Continue the study of basic biology and ecology of this species. To effectively recover this species, more specific biological information is needed. (USFWS, 1999)
- Monitor existing populations of E. cuneifolium. Develop monitoring protocol to assess population trends for E. cuneifolium. Develop a quantitative description of the population structure of E. cuneifolium. (USFWS, 1999)
- Provide public information about E. cuneifolium. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. Care is needed, though, to avoid revealing specific locality information about E. cuneifolium. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of E. cuneifolium and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)
- Develop delisting criteria. Once reclassification is achieved, research and monitoring results may provide data necessary to develop delisting criteria. (USFWS, 1999)
- Habitat-level Recovery Actions: Prevent degradation of existing habitat. Restore areas to suitable habitat. Continue habitat-level research projects. Monitor habitat/ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • Introduce plants to suitable, managed habitats to increase the number of such populations to 20. • Continue demographic monitoring and expand to additional occurrences, especially those that are protected. Menges et al. (2019) suggest level 3 demographic monitoring as the highest priority. • Advocate and support the application of prescribed fire on managed areas to maintain rosemary scrub habitat for snakeroot. • Ensure representation of snakeroot at the National Center for Genetic Resources Preservation in Fort Collins, Colorado. • Service recovery leads should maintain open lines of communication with State land managers and provide updates as appropriate to ensure proper management of occurrences. • Continue to improve the capacity for planting snakeroot as part of restoration efforts. • Acquire land with existing populations from willing sellers and restore scrub habitat on these sites, including the implementation of prescribed fire. • Utilize outreach and assistance programs to encourage private landowners to protect and manage scrub habitat on private lands. (USFWS, 2021)

# SPECIES ACCOUNT: *Eryngium sparganophyllum* (Arizona eryngo)

***Species Taxonomic and Listing Information***

**Listing Status:** Proposed Endangered

**Physical Description**

Arizona eryngo is an herbaceous perennial dicot that grows to a height of about 1.5 meters (m) (~5 feet [ft]) with long, linear, parallel-veined leaves that emerge from a basal rosette (Stromberg et al. 2019, p. 3, Makings 2013, p. 74) (Figure 2.1). The plant is conspicuous when flowering (Makings 2013, p. 74) in June through September (Stromberg et al. 2019, p. 8; New Mexico Rare Plants 2013, p 1). The flowers are cream-colored and clustered in dense heads at the end of the branching, scapose inflorescences (Stromberg et al. 2019, p. 3; Makings 2013, p. 74). The flower heads are ovoid or ovoid-oblong and are 12-25 millimeters (mm) (0.47-0.98 inch [in]) long and 10-15 mm (0.39-0.59 in) wide, with several ovate or lanceolate basal bracts and similar, but smaller bractlets within the head that barely exceed to the length of the fruits (New Mexico Rare Plants 2013, p 1). The fruit, a schizocarp splitting into two mericarps, is ovoid and 3-4 mm (0.12-0.16 in) long (Stromberg et al. 2019, p. 8; New Mexico Rare Plants 2013, p 1). Root depth is uncertain, but roots grow to at least 20 cm and likely beyond (Li personal communication December 11, 2019) (USFWS, 2020).

**Taxonomy**

Eryngium sparganophyllum is an herbaceous perennial flowering plant in the Apiaceae, or carrot family (Wooton and Standley 1915, 475-478; Hooker 1897, p. 42). Arizona eryngo is one of about 250 species in the genus worldwide (Calviño et al. 2008, p. 1130); it is one of 30 Eryngium species native to the U.S. (with an additional two in the U.S. that are naturalized), and one of five known from Arizona, although one (E. phyteumae) has not been seen since 1882 (Calviño personal communication April 5, 2020). Arizona eryngo was first described by botanist William Hemsley and illustrated by Matilda Smith in Hooker's Icones Plantarum (Hooker 1897, p. 42) from the specimens collected by Charles Wright at Las Playas, New Mexico (the type locality) in 1851 (Stromberg et al. 2019, p. 4; Wooton and Standley 1915, p. 478; Hooker 1897, p. 42) (USFWS, 2020). Hemsley and illustrated by Matilda Smith in Hooker's Icones Plantarum (Hooker 1897, p. 42) from the specimens collected by Charles Wright at Las Playas, New Mexico (the type locality) in 1851 (Stromberg et al. 2019, p. 4; Wooton and Standley 1915, p. 478; Hooker 1897, p. 42).

**Historical Range**

Arizona eryngo is known historically from six sites: three sites in Arizona and one in New Mexico in the U.S., and one site in Sonora and one site in Chihuahua in Mexico (Sánchez Escalante et al. 2019, pp. 16-17; Stromberg et al. 2019, pp. 3-8) (USFWS, 2020).

**Critical Habitat Designated**

Yes; 7/11/2022.

**Legal Description**

We, the U.S. Fish and Wildlife Service (Service), determine endangered species status under the Endangered Species Act of 1973 (Act), as amended, for the Arizona eryngo (Eryngium sparganophyllum), a plant species native to Arizona and New Mexico in the United States, and to Sonora and Chihuahua in Mexico. We also designate critical habitat for the Arizona eryngo. In total, approximately 12.7 acres (5.1 hectares) in Pima and Cochise Counties, Arizona, fall within the boundaries of the critical habitat designation. This rule extends the protections of the Act to this species and its designated critical habitat.

**Critical Habitat Designation**

Critical habitat units are depicted for Pima and Cochise Counties, Arizona

**Primary Constituent Elements/Physical or Biological Features**

Within these areas, the physical or biological features essential to the conservation of Arizona eryngo consist of the following components:

(i) Cienegas within the Chihuahuan and Sonoran Deserts: (A) That contain permanently moist to saturated, organic, alkaline soils with some standing water in winter and that are moist at or just below the surface in summer; and (B) That have functional hydrological processes and are sustained by springflow via discharge of groundwater.

(ii) Areas of open canopy throughout the cienega.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features which are essential to the conservation of the species and which may require special management considerations or protection. The features essential to the conservation of this species may require special management considerations or protection to reduce the following threats: physical alteration of cienegas, water loss, and changes in co-occurring vegetation. Management activities that could ameliorate these threats include, but are not limited to: Use best management practices (BMPs) to minimize erosion and sedimentation; remove and control invasive, nonnative species (e.g., Johnsongrass) that encroach on critical habitat; selectively manage woody vegetation that encroaches on critical habitat; exclude livestock, or in some instances where such management would further the conservation of cienega habitat and the species, use highly managed grazing; avoid or minimize groundwater withdrawal to maintain adequate springflow to maintain cienegas; and avoid springflow diversion and springhead modification to maintain springflow to cienegas.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Cross pollination (USFWS, 2020)

**Reproduction Narrative**

Adult: Arizona eryngo grown in nurseries can flower in their first year. At natural sites, plants flower from June to September (Stromberg et al. 2019, p. 8; New Mexico Rare Plants 2013, p 1). Dry fruits ripen in September and October (Li 2020, p. 2; AGFD 2019, p. 2; Stromberg et al. 2019, p. 8). Stromberg et al. (2019, p. 8) studied plants at Lewis Springs and found that mature plants in 2018 produced an average of 1.75 flowering stalks, each with an average of 3.4 inflorescences per stalk (up to 12 inflorescences per stalk had been observed in prior years). In 2014, they found that each inflorescence contained an average of 96 flowers and therefore, given the two seeds per fruit, estimated that an individual plant could produce several hundred seeds per season. They reported that the observed number of flowering stalks was considerably lower at Lewis Springs in 2018 than in prior years, as surface soils were subjectively drier, with saturated conditions detected only when excavating several centimeters (cm) into the wetland soils. Li (2019, p. 8), based on his observations of the species at La Cebadilla, also hypothesizes that flowering is determined by soil moisture availability and temperature (i.e., summer warmth) Aboveground, plants dieback partially or completely in the winter months such that almost no green or very little green aboveground structure can be seen (Li 2020, p. 9). While little is known about the reproductive strategy/ecology of Arizona eryngo, it is likely that pollinators are required for cross-pollination in this species. Pollinators do not seem to be lacking and abundant animal activity on the flowers is readily observed (Li, p. 8; J. Simms 2019, p. 1, Stromberg et al. 2019, p. 8). Another Eryngium similar in appearance to Arizona eryngo, E. yuccifolium (rattlesnake master) is xenogamous species (transfer of pollen grains from the anther to the stigma of a different plant) with temporal dioecism (Molano-Flores 2001, p. 5). Temporal dioecism is a synchronized flowering sequence that allows pollen to be shed before any stigma becomes receptive, minimizing geitonogamous pollinations (the fertilization of a flower by pollen from another flower on the same or a genetically identical plant) and maximizing outcrossing (Molano-Flores 2001, p. 5). The patterns of seed dispersal, germination percentages, and the rates of seedling establishment in the wild are not known (AGFD 2019, p. 2; Stromberg et al. 2019, p. 8). Arizona eryngo seeds are large and heavy and therefore are not likely to fall far from the mother plant. The height and the swaying of the inflorescence suggests that seeds may be dispersed by wind, but only short distances. Barbs around the seeds, however, likely function as hooks that may enable dispersal via attachment to mammals and birds (Blackwell et al. personal communication May 8-11, 2020). (USFWS, 2020).

**Habitat Type**

Adult: Spring-fed cienegas (USFWS, 2020)

**Habitat Narrative**

Adult: Arizona eryngo requires perennially moist, organic alkali soils found in spring-fed cienegas supported by adequate groundwater (Figure 2.3). Plants grow best in full sun in areas with few nonnative plant species, limited woody vegetation, or other vegetation that may shade or otherwise outcompete them. While the species reproduces asexually, pollinators are likely needed for sexual reproduction necessary to maintain genetic diversity (USFWS, 2020). The species is a habitat specialist and occurs in open, sunny, spring-fed cienega wetlands where soils are organic, alkali, and perennially moist. Plants grow best in full sun in areas with few nonnative plant species, limited woody vegetation, and other vegetation that may shade or otherwise outcompete them. (USFWS, 2024)

***Dispersal/Migration***

**Dispersal**

Adult: Unknown (USFWS, 2020)

**Dispersal/Migration Narrative**

Adult: The patterns of seed dispersal, germination percentages, and the rates of seedling establishment in the wild are not known (AGFD 2019, p. 2; Stromberg et al. 2019, p. 8). Arizona eryngo seeds are large and heavy and therefore are not likely to fall far from the mother plant. The height and the swaying of the inflorescence suggests that seeds may be dispersed by wind, but only short distances. Barbs around the seeds, however, likely function as hooks that may enable dispersal via attachment to mammals and birds (Blackwell et al. personal communication May 8-11, 2020). (USFWS, 2020)

***Population Information and Trends***

**Number of Populations:**

4 population areas (USFWS, 2025)

**Population Size:**

30,422 genets or aggregates with a 95% confidence interval of the population size (USFWS, 2020). The remaining populations are isolated from one another, and as of 2018 to 2020, estimates indicate there is a range of 56 to 31,467 individuals per population (USFWS, 2025)

**Population Narrative:**

The Arizona eryngo population is estimated to be 30,422 genets or aggregates with a 95% confidence interval of the population size, according to the boostrapping estimation, of (19,289, 43,469) genets at Lewis Springs (Li 2020b, p. 1). (Li 2020b, p. 1). As described in section 2.3, each clone has a unique basal stem, and multiple clones can form a clustered aggregate that resembles an individual plant (Li 2020a, p. 2). Li (2020a, p. 2, 2020b, p. 1) refers to such an “individual plant” as a clonal aggregate or genet, which is the basic unit of Arizona eryngo population size. Stromberg et al. (2019, p. 6) estimated Arizona eryngo population size at La Cebadilla in the low thousands (calculated using the estimated spatial extent of 4,494 m2 and assumption of a minimum of one plant per 2 m2 quadrat). Further study indicates that the mean number of individuals per 1m2 (in 30 established study plots) was 6.7, which explains why Stromberg et al.’s (2019) estimate was lower. While this is the largest of the four extant populations, the plants occur in a very confined space and remain tied to the fate of the cienega. The La Cebadilla Cienega occurs within Arizona Upland subdivision of Sonoran Desert Scrub at about 825 m (2,707 ft) in elevation. The climate is semiarid with a mean annual temperature of 20 degrees C and mean annual precipitation of 337 mm (13.27 in) (Stromberg et al. 2019, p 5; Wolkis 2016, p. 35). At this site, Arizona eryngo is primarily associated with Eleocharis palustris, Muhlenbergia asperifolia, Schoenoplectus americanus, and Anemopsis californica. Other associates of Arizona eryngo at La Cebadilla Cienega were Almutaster pauciflorus, Distichlis spicata, Eustoma exaltatum, Juncus balticus and Sisyrinchium demissum (Stromberg et al. 2019, p. 6) (USFWS, 2020). Arizona eryngo is known historically from six sites in Arizona, New Mexico (now extirpated), Sonora, and Chihuahua at elevations ranging from 825 to 1,492 m (Table 1, Figure 1). Four of six of the spring-fed cienegas were/are thermal springs (Agua Caliente, Arizona; Las Playas, New Mexico; Rancho Agua Caliente, Sonora; and Ojo Vareleño, Chihuahua). The species was extirpated from two known sites (one site in Arizona [Agua Caliente] and one site in New Mexico [Las Playas]) but remains extant at the other four sites (two in Arizona [Lewis Springs and La Cebadilla], one in Sonora [Rancho Agua Caliente], and one in Chihuahua [Ojo Vareleño]). The remaining populations are isolated from one another, and as of 2018 to 2020, estimates indicate there is a range of 56 to 31,467 individuals per population (Table 1). In the SSA, we consider a population to have high resiliency if it has more than 1,840 plants, moderate resiliency if it has between 800 and 1,840 plants, and low resiliency if it has between 50 and 799 plants. A population with fewer than 50 plants is considered functionally extirpated. We have defined four representation areas based on river basin boundaries and geographic separation of known historical populations (Figure 1). The four populations and river basins of representation are: 1) the La Cebadilla population in the Santa Cruz River Basin, 2) the Lewis Springs population in the San Pedro River Basin, 3) the Rancho Agua Caliente population in the Rio Bavispe River Basin, and 4) the Ojo Vareleño population in the Rio Casas Grandes (Mimbres) Basin. Recovery criteria are based on populations within these four representation areas. (USFWS, 2024) The species is presumed extirpated from two known sites (one site in Arizona [Agua Caliente] and one site in New Mexico [Las Playas]) but remains extant at the other four sites (two in Arizona [Lewis Springs and La Cebadilla], one in Sonora [Rancho Agua Caliente], and one in Chihuahua [Ojo Vareleño]). The remaining populations are isolated from one another, and as of 2018 to 2020, estimates indicate there is a range of 56 to 31,467 individuals per population (Table 1). In the SSA, we consider a population to have high resiliency if it has more than 1,840 plants, moderate resiliency if it has between 800 and 1,840 plants, and low resiliency if it has between 50 and 799 plants. A population with fewer than 50 plants is considered functionally extirpated. We have defined four representation areas based on river basin boundaries and geographic separation of known historical populations (Figure 1). The four populations and river basins of representation are: 1) the La Cebadilla population in the Santa Cruz River Basin, 2) the Lewis Springs population in the San Pedro River Basin, 3) the Rancho Agua Caliente population in the Rio Bavispe River Basin, and 4) the Ojo Vareleño population in the Rio Casas Grandes (Mimbres) Basin. Recovery criteria are based on populations within these four representation areas. (USFWS, 2025)

***Threats and Stressors***

**Stressor:**
**Exposure:**
**Response:**
**Consequence:**
**Narrative:**

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 5C

1. Fourteen or more populations of Arizona eryngo are viable throughout the species' geographic range in the U.S. and Mexico, including populations in the four representation areas as follows: a. Santa Cruz River Basin: at least four populations, including La Cebadilla and three additional populations that are newly discovered or introduced (these may include Agua Caliente, Canoa, Bar V, and LCNCA). b. San Pedro River Basin: at least two populations, including Lewis Springs and one additional population that is newly discovered or introduced. c. Rio Bavispe River Basin: at least two populations, including Rancho Agua Caliente and one additional population that is newly discovered or introduced, or two populations that are newly discovered or introduced. d. Rio Casas Grandes Basin (Mimbres): at least four populations, including Ojo Vareleño and three additional populations that are newly discovered or introduced, or four populations that are newly discovered or introduced. e. Two additional populations that are

newly discovered or introduced in any existing or new representation area. Introduced populations are created using appropriate genetic stock and are placed in suitable habitat and microhabitat. Of the 14 populations referenced above, at least: a. One population supports more than 30,000 adult individuals (i.e., genets), b. One population supports more than 1,840 adult individuals (i.e., genets), c. Six populations support more than 800 adult individuals (i.e., genets), d. Six populations support more than 100 adult individuals (i.e., genets). The total number of adult individuals may be spatially distributed in subpopulations within a population (i.e., the subpopulations must be close enough to interact via pollination). These population numbers will be maintained (natural recruitment is greater than or equal to documented plant loss) for a total of at least 5 years over the last 10-years of the period prior to downlisting (20 years), as indicated by monitoring every 1 to 3 years, including during the three most recent monitoring events. This allows for some fluctuation in population abundance due to drought or other threats. (USFWS, 2025)

2. A collection of seed representing the geographical, morphological, and genetic diversity of Arizona eryngo is started within 5 years of the finalization of this recovery plan, with regular supplemental collections, and maintained in at least one Center for Plant Conservation partner, or botanical or seed storage institution for conservation purposes. (USFWS, 2025)

3. A living collection of plants representing the geographical, morphological, and genetic diversity of Arizona eryngo is started within 5 years of the finalization of this recovery plan, with needed supplemental collections, and maintained long-term in at least one botanical institution for educational and conservation purposes. (USFWS, 2025)

4. Lands supporting 10 of 14 populations of Arizona eryngo are protected in perpetuity through a conservation easement, habitat conservation plan, or other conservation mechanism appropriate to the land status. (USFWS, 2025)

5. Conservation and management programs and plans address the threats to Arizona eryngo, including cienega habitat loss, drying, and alteration; changes in co-occurring vegetation; and direct harm to Arizona eryngo. The following must be met: a. site-specific plans are developed and at least partially implemented, such that: i. competing native and nonnative vegetation is reduced to a level that ensures Arizona eryngo is not shaded and that the vigor of mature plants and seedlings is not negatively affected (Factor A), ii. a more natural fire or other disturbance regime (e.g., mechanical vegetation removal, prescribed grazing) is promoted (Factor A), iii. natural spring flow supporting cienegas is increased by reducing water loss (from groundwater pumping, etc.) and increasing water conservation and recharge (Factor A), iv. moist soil cienega habitat is increased (Factor A), v. herbivory and trampling are managed to benefit species survival (Factor C), and vi. native plant diversity is maintained or increased, thus promoting native pollinators; and b. data on the conservation and management of Arizona eryngo are collected and shared among landowners, managers, and researchers. (USFWS, 2025)

**Delisting Criteria:**
1. Fourteen or more populations of Arizona eryngo are viable throughout the species' geographic range in the U.S. and Mexico, including populations in the four representation areas as follows: a. Santa Cruz River Basin: at least four populations, including La Cebadilla and three additional populations that are newly discovered or introduced (these may include Agua Caliente, Canoa, Bar V, and LCNCA). b. San Pedro River Basin: at least two populations, including

Lewis Springs and one additional population that is newly discovered or introduced. c. Rio Bavispe River Basin: at least two populations, including Rancho Agua Caliente and one additional population that is newly discovered or introduced, or two populations that are newly discovered or introduced. d. Rio Casas Grandes River Basin: at least four populations, including Ojo Vareleño and three additional populations that are newly discovered or introduced, or four populations that are newly discovered or introduced. e. Two additional populations that are newly discovered or introduced in any existing or new representation area. (USFWS, 2025)

2. A collection of seed representing the geographical, morphological, and genetic diversity of Arizona eryngo is started within 5 years of the finalization of this recovery plan, with regular supplemental collections, and maintained in at least one Center for Plant Conservation partner botanical or seed storage institution for conservation purposes. (USFWS, 2025)

3. A living collection of plants representing the geographical, morphological, and genetic diversity of Arizona eryngo is started within 5 years of the finalization of this recovery plan, with needed supplemental collections, and maintained in long-term in at least one botanical institution for educational and conservation purposes. (USFWS, 2025)

4. Lands supporting 12 of 14 populations of Arizona eryngo are protected in perpetuity through a conservation easement, habitat conservation plan, or other conservation mechanism appropriate to the land status. (USFWS, 2025)

5. Conservation and management programs and plans address the threats to Arizona eryngo, including cienega habitat loss, drying, and alteration; changes in co-occurring vegetation; and direct harm to Arizona eryngo. The following must be met: a. site-specific plans are developed and fully implemented, such that: competing native and nonnative vegetation is reduced to a level that ensures Arizona eryngo is not shaded, and that the vigor of mature plants and seedlings are not negatively affected (Factor A), i. a more natural fire or other disturbance regime is promoted (Factor A), ii. natural spring flow supporting cienegas is increased by reducing water loss (from groundwater pumping, etc.) and increasing water conservation and recharge (Factor A), iii. moist soil cienega habitat is increased (Factor A), iv. herbivory and trampling are minimized (Factor C), and v. native plant diversity is maintained or increased, thus promoting native pollinators; and b. data on the conservation and management of Arizona eryngo are collected and shared among landowners, managers, and researchers. (USFWS, 2025)

**Recovery Actions:**

- Objective 1. Increase the size and number of populations (i.e., improve resiliency and redundancy) through Arizona eryngo augmentation and introduction success. (USFWS, 2025)
- Objective 2. Ensure long-term Arizona eryngo conservation through the establishment of ex-situ plant and seed collections housed at multiple Center for Plant Conservation approved botanical institutions and seed banks. (USFWS, 2025)
- Objective 3. Improve our understanding of the status and conservation needs of Arizona eryngo and its habitat through monitoring and research and practice adaptive management in which recovery is monitored and recovery tasks are revised by the USFWS in coordination with partners as new information becomes available. (USFWS, 2025)
- Objective 4. Reduce threats of loss and alteration of cienegas and water loss from cienegas through the protection, restoration, and proper management of adequate quantity and

quality of functional cienega habitat within existing, newly discovered, and introduced Arizona eryngo populations. (USFWS, 2025)

- Objective 5. Reduce threats from changes in co-occurring vegetation to Arizona eryngo habitat within existing, newly discovered, and introduced Arizona eryngo populations. (USFWS, 2025)
- Objective 6. Identify and reduce other threats (e.g., unsustainable levels or timing of predation or herbivory, trampling, pollinator loss), as needed, to Arizona eryngo growth, reproduction, and recruitment within existing, newly discovered, and introduced Arizona eryngo populations. (USFWS, 2025)
- Objective 7. Ensure long-term Arizona eryngo conservation through adequate funding, public education and outreach, and partnerships. (USFWS, 2025)

# SPECIES ACCOUNT: *Erysimum capitatum var. angustatum* (Contra Costa wallflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 05/27/1978; Pacific Southwest (R8)

**Physical Description**

a short-lived perennial and monocarpic (individuals die after setting seed) (Service 1984). Pollination is by bees that nest in open banks and may also be by a variety of other unspecified insects (Service 2002). A study in 1987 by Pavlik et al (1998a) determined that seed production for E.c. var. angustatum was not a limiting factor and germination of new seeds was considered relatively high, with 40-60% typical, comparable to germination rates in non-endangered relatives. Additional work by Pavlik et al (1988b) determined that, at that time, the growth of E.c. var. angustatum populations was not genetically constrained, but was environmentally constrained due to limited habitat, interspecific vegetation competition, and possibly pollination limitations. Seedling emergence (and presumably, germination) was significantly higher in dune soils than unbroken clay soil, and higher (but not significantly) in dune soil than in broken clay soil (Pavlik et al 1988b). The reproductive phenology encompasses germination in October, leafing from October through December, budding in February, flowering in March (peaking in April or May), and fruiting beginning in April and peaking in July (Service 2008). (USFWS, 2019)

**Taxonomy**

Note that Erysimum asperum var. angustatum is a different plant, treated as a synonym of the typical E. capitatum var. capitatum by Kartesz (1994 checklist), recognized as a full species (E. angustatum) in Kartesz (Feb. 1999 draft data). Reports of the Contra Costa wallflower from Alaska and Canada are presumably due to confusion of these two similar names (NatureServe, 2015). The Contra Costa wallflower is one of the many varieties of the western wallflower (Erysimum capitatum). A member of the Brassicaceae (mustard) family (USFWS 1984) (USFWS, 2008).

**Historical Range**

The Contra Costa wallflower is endemic to the riverine dune habitat found within and immediately adjacent to the Antioch Dunes NWR in Contra Costa County, California. (USFWS, 2008)

**Current Range**

This species is only known known from the Antioch Dunes in Contra Costa County, California. (USFWS, 2008)

**Critical Habitat Designated**

Yes; 8/31/1978.

**Legal Description**

On August 31, 1978, the U.S. Fish and Wildlife Service, designated critical habitat for Erysimum capitatum var. angustatum (Contra Costa wallflower) under the authority of the Endangered Species Act of 1973 (43 FR 39042 - 39044). Critical habitat was designated for one unit in

California.

**Critical Habitat Designation**

One critical habitat unit is designated in California, described as: An area of land, water, and airspace in Contra Costa County with the following components: T. 2 N. R. 2 E. SW 1/4 section 17, E 2/3 of S 1/3 of section 18 (43 FR 39042 - 39044).

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements are not described (43 FR 39042 - 39044).

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (inferred from USFWS, 2008)

**Lifespan**

Adult: 2+ years (USFWS, 2008)

**Breeding Season**

Adult: March - May (USFWS, 2008)

**Key Resources Needed for Breeding**

Adult: Insect pollinators (USFWS, 2008)

**Reproduction Narrative**

Adult: This species is a biennial or short-lived perennial. The reproductive phenology of this species encompasses germination in October, leafing from October through December, budding in February, flowering in March (peaking in April or May), and fruiting in April (peaking in July). Unlike other members of the mustard family, pollination of the Contra Costa wallflower is by a variety of unspecialized insects, including bees nesting along the open banks (USFWS 2002) (USFWS, 2008). According to Harper (1977), it may best be thought of as a monocarpic perennial (USFWS, 1984).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015); riparian (USFWS, 2008)

**Habitat Vegetation or Surface Water Classification**

Adult: Grassland, sand dune, savanna, shrubland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Wind disturbance regime (USFWS, 2008)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs at 3 - 20 m elevation (NatureServe, 2015)

**Environmental Specificity**

Adult: Moderate (inferred from USFWS, 2008)

**Habitat Narrative**

Adult: Inhabits inland dunes at 3 - 20 m elevation (Skinner 1997). More or less consolidated (stabilized) dunes of fine sand and some clay dust, with sparse herbs and shrubs, or less often with pasture grasses, herbs, and scattered Quercus agrifolia (Niehaus 1977) (NatureServe, 2015). The wallflower grows in soil types classified as sand to sandy loam. Precise information about the specific requirements of the Contra Costa wallflower are not well known; however, the plant has been observed growing in steep areas of unstable sand, especially on north-facing slopes adjacent to the river (USFWS 1984, 2002; S. Euing, USFWS, pers. comm. 2007). This plant has also been observed growing in a variety of conditions, including stable dunes of fine sand containing some clay and sparsely vegetated with herbs and shrubs; uneven river front bluff faces and edges; flat terrain in excavated areas; and flat hard pan areas 160 to 660 feet from the river where the hard pan is broken and loose, sandy soil is exposed (USFWS 2002). A natural disturbance regime is caused by the wind shifting the sandy environment in which the Contra Costa wallflower thrives (USFWS, 2008).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seeds are wind-dispersed beginning in mid-May and peaking in September (USFWS, 2008).

***Population Information and Trends***

**Population Trends:**

not considered stable or self-sustaining (USFWS, 2019)

**Species Trends:**

not considered stable or self-sustaining (USFWS, 2019)

**Number of Populations:**

4 (USFWS, 2019)

**Population Size:**

Approximately 9,287 individuals in 2017 (USFWS, 2019)

**Population Narrative:**

According to the CNDDB (2018b), Erysimum capitatum var. angustatum is known from four EOs, all of which are presumed extant (Table 3). Of the four EOs, three are considered natural occurrences and one is considered transplanted outside of native habitat and/or range. The two CNDDB EOs that occur at the ADNWR (EO #1, which includes the Stamm Unit and EO #3, which includes the Sardis Unit) represent the majority of, and possibly the entire, known range-wide natural/native population. Nearly annual plant counts have been conducted in at least some of the subunits of the Stamm and Sardis Units since about 1985. (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Habitat destruction from sand mining, industrial and urban/suburban development, and/or conversion to agriculture (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat for the this species and pollinators, and area available for habitat restoration is threatened by destruction and conversion to other uses. This threat is largely ameliorated on the ADNWR and other properties with protection/management agreements in place, but not on properties without such agreements. (USFWS, 2019)

**Stressor:** Habitat degradation due to loss of natural disturbance regime (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The reduction in sand deposition in Antioch Dunes habitat as a result of water management/use (dams, levees, etc.) in the Sacramento/San Joaquin River Delta system and reduced effectiveness of wind-driven dispersal of sand and disturbance of dunes has and continues to reduce overall size and connectedness of the dune natural community. (USFWS, 2019)

**Stressor:** Habitat degradation due to non-native and native invasive vegetation (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasive vegetation colonizes open sand habitat, reducing available suitable E.c. var. angustatum, and pollinator, habitat. Invasive plants out-compete native species, including E.c. var. angustatum, for sunlight, space, nutrients, and moisture. They also stabilize the sand/soil, eliminating the natural disturbance regime and may cause soils to become more eutrophic (Thomson 2005a, Thomson 2005b, Chin 2012, McNally 2014). The 2008 Five-Year Review notes that the proliferation of non-native invasive plants has been increasing rapidly since 1998 (Service 2008) and these conditions continue (Chin 2012, McNally 2014, Service 2018a, Service 2018b, Service 2018c, Service 2018d). The use of herbicides to control non-native and native invasive vegetation may also present potential threat to E.c. var. angustatum occurring in the same vicinity. Applying herbicides selected for the target species and using appropriate rates and technique should minimize effects to non-target E.c. var. angustatum. These practices have been instituted at the ADNWR, so this threat is considered largely ameliorated there (Service 2008), but it may pose a risk to current and future occurrences of these listed species elsewhere. (USFWS, 2019)

**Stressor:** Habitat degradation due to gypsum dust deposition from neighboring plant (facility) (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The 2008 Five-Year Review reported that gypsum dust building up on plants may reduce exposure to sunlight and decrease photosynthesis. It may also alter soil chemistry due to introduction of calcium and sulphates, which may affect the growth of E.c. var. angustatum and promote colonization by invasive species. Deposition is noted as affecting mostly the Sardis Unit.

The ADNWR staff have met with Georgia-Pacific (G-P) about concerns over the dust and G-P increased efforts to reduce airborne gypsum (beyond the standards for air pollution control) by keeping it wetted down when possible during production activities. At the time of the 2008 Five-Year Review, staff noted a reduction in dust from G-P efforts. The review noted that there was no evidence that gypsum dust was adversely affecting any of the three species (Service 2008). However, it also cited a study that demonstrated that dusts may adversely increase transpiration through the cuticle of insect larvae and cause desiccation and abrasion of the cuticle (Wigglesworth 1945 in Service 2008), which may affect pollinators of O.d. subsp. howellii or E.c. var. angustatum. The ADNWR staff reported an increase in gypsum dust deposition at ADNWR in 2017-2018 (Susan Euing pers. comm. December 12, 2018). In 2018, staff noted that gypsum was being deposited on the refuge at concentrations that coats plants, leading to cancellation of surveys for the Lange’s metalmark in some parts of the refuge (Susan Euing pers. comm. August 17, 2018). In 2019, after several weeks into the Lange’s metalmark survey season, ADNWR staff confirmed that no surveys had been canceled due to concerns about gypsum dust deposition (Louis Terrazas pers. comm. September 10, 2019). The magnitude of this potential stressor requires further investigation and Service partnership with G-P is ongoing. (USFWS, 2019)

**Stressor:** Habitat degradation due to rogue hiking/trails (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This activity may cause direct injury or mortality E.c. var. angustatum from trampling while also increasing potential for accidental introduction of wildfire from hikers. These threats and stressors were significantly reduced when ADNWR was fenced in 1986 and the 2008 Five-Year Review (Service 2008) no longer considered recreational and pedestrian traffic to be a significant threat. However, ADNWR staff note that incidence of trespassing and human encampments at ADNWR has increased in the past several years (Susan Euing pers. comm. December 12, 2018). (USFWS, 2019)

**Stressor:** Overutilization for commercial, recreational, scientific, or educational purposes (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** These activities represent a threat to the Antioch Dunes species from direct mortality of any individual(s) collected and a reduction in annual recruitment by killing or injuring reproductive individuals. (USFWS, 2019)

**Stressor:** Disease or predation (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Three moth taxa are known to prey upon E.c. var. angustatum; a fairy moth (Chalceopla simpliciealla), an egg-eating moth (Calcus spp.), and the diamond back moth (Plutella xylostella) (Service 2008). Pavlik et al (1988b) determined that pre-dispersal predation of seeds significantly impacted reproduction during studies conducted in 1987 and 1988. The magnitude of this stressor requires further investigation. (USFWS, 2019)

**Stressor:** Wildfire (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Wildfire may cause direct mortality of E.c. var. angustatum plants during vulnerable life stages. These stages include the period from germination during the beginning of the wet season in December through the deposition of seeds in mid-summer. However, historical evidence indicates that the native plants may recover rather quickly from a wildfire (Service 2008). Any mortality would also result in reduced annual recruitment by killing or injuring reproductive individuals. The threat extends to pollinators and other pollinator plant species. (USFWS, 2019)

**Stressor:** Fuelbreak discing (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fuelbreak discing may cause direct injury or mortality to E.c. var. angustatum. However, it also creates open, disturbed, sand/soil that may be suitable for colonization by E.c. var. angustatum, as well as invasive vegetation. The net impact of this activity to listed plant resilience is unquantified. (USFWS, 2019)

**Stressor:** Loss of pollinators (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Lange’s metalmark is addressed as a pollinator for this discussion of the potential threat posed by possible insecticide drift from mosquito abatement spraying on neighboring properties (Richmond et al 2015). The Mosquito Abatement District allows for spraying of insecticides to reduce the incidence of West Nile Virus at a wetland adjacent to the Stamm Unit of the ADNWR. The spray could drift on to the refuge and affect pollinators, such as Lange’s metalmark and those that pollinate E.c. var. angustatum. While ADNWR staff have worked with county mosquito control staff to minimize effects from this potential threat, the magnitude of this stressor requires further investigation. As of the 2008 Five-Year Review, there was no evidence that lack or loss of pollinators has negatively impacted or E.c. var. angustatum (Service 2008), but the species requires cross-pollination, so an adequate pollinator population is necessary. Bees are suspected pollinators for both species and hawkmoths may also be pollinators for the primrose; however, actual pollinator taxa are unknown. This potential threat requires investigation. (USFWS, 2019)

**Stressor:** Low population numbers (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** E.c. var. angustatum is threatened by few and small populations that are limited to a small and localized distribution, which increases the risk of extirpation and extinction due to: (1) Reduced resiliency (the ability of a species to withstand stochastic disturbance; resiliency is positively related to population size and growth rate and may be influenced by connectivity among populations); (2) Low redundancy (spreading risk among multiple populations or a large

area to minimize the potential loss of the species from catastrophic events); and (3) Low representation (the breadth of genetic and environmental diversity within and among populations that influences the ability of a species to adapt to changing environmental conditions over time). (USFWS, 2019)

**Stressor:** Climate change (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** E.c. var. angustatum is threatened by multiple environmental effects anticipated with climate change, which may result in loss of habitat, altered temperature and moisture regimes causing direct mortality and/or impaired reproduction, and altered temperature and moisture regimes causing indirect mortality and/or impaired reproduction via phenological mismatches with pollinators and between pollinators and their host and/or other nectar plants (Richmond et al 2015). (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**
Erysimum capitatum var. angustatum will be considered for downlisting when: 1. There are at least five separate self-sustaining (all plants are naturally recruiting) populations of: at least three populations, each with a 15-year moving median of at least 7,000 flowering plants; and least two populations, each with a 15-year moving median of at least 4,000 flowering plants. (a) A distance of at least 1,500 feet and a natural and/or man-made firebreak separates individual populations. (b) Populations should be protected and have in place a long-term management plan for the conservation of E.c. var. angustatum and commitment for implementation of the plan. (USFWS, 2019)

Any flowering individuals counted as naturally recruiting would have to be ≥ two flowering seasons post-outplanting. This would indicate the individual has completed the life cycle in situ. (USFWS, 2019)

**Delisting Criteria:**
Erysimum capitatum var. angustatum will be considered for delisting when: 1. There are at least seven separate self-sustaining (all plants are naturally recruiting) populations of: at least five populations, each with a 15-year moving median of at least 7,000 flowering plants; and at least two populations, each with a 15-year moving median of at least 4,000 flowering plants. OR, population viability analysis determines that E.c. var. angustatum has a range-wide 95% probability of persistence over a 100-year period. (a) A distance of at least 1,500 feet and a natural and/or man-made firebreak separates individual populations. (b) Populations should be protected and have in place a long-term management plan for the conservation of E.c. var. angustatum and commitment for implementation of the plan. (USFWS, 2019)

2. A post-delisting monitoring plan for the species has been developed. (USFWS, 2019)

Any flowering individuals counted as naturally recruiting would have to be ≥ two flowering seasons post-outplanting. This would indicate the individual has completed the life cycle in situ. (USFWS, 2019)

**Recovery Actions:**

- Protect Antioch Dunes ecosystem and essential habitat for the Contra Costa wallflower (USFWS, 1984).
- Restore Antioch Dunes ecosystem, and increase numbers and improve habitat for the Contra Costa wallflower (USFWS, 1984).
- Initiate information and education programs (USFWS, 1984).
- Recommended Actions from 2008 5-Year Review: Continue restoration of riverine dune habitat at Antioch Dunes NWR. - Continue research into life history, habitat requirements, and population studies, including annual population monitoring surveys. - Acquire the McCulloch/Kemwater property abutting the eastern boundary of the Sardis Unit of the Antioch Dunes NWR. - Consider revising the Recovery Plan for the three endangered species endemic to Antioch Dunes, California (USFWS, 2008).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Several areas of future action are suggested over the next five years, which build on the actions articulated in the revised recovery plan (Service 1984) and the riverine dune ecosystem conservation strategies articulated in Service (2019b). These areas include: continuing to restore riverine dune habitat at ADNWR and considering nearby locations for restoration activities; continuing to collect and bank seeds, and propagating and out-planting seedlings; continuing research on habitat requirements, life history, and seed bank dynamics; improving statistical analysis and numerical modeling related to Erysimum capitatum var. angustatum; considering development of a publicly-accessible website for documents, literature, and data related to Erysimum capitatum var. angustatum; and establishing an Antioch Dunes Recovery Implementation Team or recovery working group. Continued research on the habitat requirements and seed bank dynamics of Erysimum capitatum var. angustatum could include identifying areas for possible development of new populations of Erysimum capitatum var. angustatum. For example, the Service's experience with dune restoration at the Refuge provides a strong foundation for expanding dune restoration work over the coming years. This future work could include an analysis of how environmental variables, such as precipitation and temperature patterns, and seeding and out-planting influence population dynamics in currently occupied areas and colonization of newly restored dunes. The status of the assemblage of invertebrate species that pollinate Erysimum capitatum var. angustatum is not currently clear. A study of the current pollinators of wallflower at Antioch Dunes would help add to the Service's understanding of the natural history of this plant and identify which potential pollinators, or groups of pollinators, to monitor to ensure that healthy and diverse pollinator populations continue to occur at and near the Antioch Dunes ecosystem. Statistical and numerical modeling, such as with habitat suitability analysis and population dynamics modeling, can provide insights into possible future locations for development of Erysimum capitatum var. angustatum populations, and future dynamics of these populations. Jones et al. (2019) began developing habitat suitability models for Antioch Dunes eveningprimrose at Antioch Dunes using remote-sensed vegetation metrics (NDVI). It is possible that a continuation of this line of investigation, perhaps including Erysimum capitatum var. angustatum, will lead to improved insights into where and how to develop additional restored sand dunes that will support the recovery of Erysimum capitatum var. angustatum. It may also be useful to consider developing population viability analyses (PVA) that are specifically developed for Erysimum capitatum var. angustatum. For example, it is possible that a stage-structured matrix population model similar to the model developed by Thomson (2005a) for Antioch Dunes evening-primrose could be used to form a foundation for PVA analysis. It is also possible that building and parameterizing such a model, and then projecting this model into various possible futures, including under the influence of changing climate conditions, could help provide insights beyond the PVA's discussed in Service (2019a). As part of efforts to improve statistical analysis and modeling, creating a well-vetted and archived dataset of all Erysimum capitatum var. angustatum surveys, and resolving any discrepancies in counts identified during this review will be critical to progressing on this objective. In late 2019, staff of the Bay-Delta Fish and Wildlife Office met with the staff of the ADNWR and considered convening a recovery implementation team (RIT) for the listed species that occur at the Refuge, including Erysimum capitatum var. angustatum. The primary purpose for convening this group would be to encourage Service biologists, managers and external experts to consider recovery priorities for these species and the Antioch Dunes ecosystem, and continue to stay abreast of emerging research related to Erysimum capitatum var. angustatum and related taxa, riverine dune ecology, and other relevant topics. This group would also help develop a recovery implementation strategy for Antioch Dunes. (USFWS, 2021)

# SPECIES ACCOUNT: *Erysimum menziesii* (Menzies' wallflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 06/22/1992; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A member of the mustard family and a biennial or a short-lived perennial depending on the particular population. Each plant usually has several flowering stems from 0.5 to 1.5 decimeters tall. The flower petals are usually yellow (light or rich yellow), 15-20 mm long. The flowers are grouped into an inflorescence. Fleshy leaves form a basal rosette and are somewhat spoon-shaped, narrowing abruptly to the leaf stalk. Leaf margins are entire, dentate, or lobed. Fruit is a silique, four-sided when green and flattened when dry (Fish and Wildlife Service 1997) (NatureServe, 2015).

**Taxonomy**

Erysimum menziesii is a member of the mustard family (Brassicaceae) (USFWS, 2008). As treated here, following FNA (2010, vol. 7), Erysimum menziesii includes subspecies eurekense, menziesii, and yadonii, but excludes subspecies concinnum. This is the treatment followed by USFWS when the species was listed endangered, Kartesz's 1994 checklist, and the second edition of The Jepson Manual (Baldwin et al. 2012). This treatment is based on Price's 1987 doctoral dissertation. According to FNA, Price's 1993 treatment (followed by Kartesz 1999) accepted four subspecies (concinnum, eurekense, menziesii, and yadonii), three of which were never validly published (NatureServe, 2015).

**Historical Range**

Endemic to California in Monterey, Mendocino, and Humboldt Counties (Fish and Wildlife Service 1997). The range extent is 14,506 sq. km (R. Bittman, pers. comm. 2013) (NatureServe, 2015).

**Current Range**

It is distributed predominately in the nearshore dune community of four disjunct dune systems in northern and central California: Humboldt Bay in Humboldt County, Ten Mile River in Mendocino County, the Marina Dunes at Monterey Bay, and the Monterey Peninsula in Monterey County (Price 1993) (USFWS, 2008).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: self-pollination, cross-pollination (USFWS, 2008)

**Lifespan**

Adult: 8 years (USFWS, 2008)

**Dependency on Other Individuals or Species**

Adult: Erysimum m. ssp. eurekense: Emphoropsis miserabilis (USFWS, 2008)

**Breeding Season**

Adult: February - April (USFWS, 2008)

**Key Resources Needed for Breeding**

Adult: Fall/early winter rains (USFWS, 2008); insect pollinators (USFWS, 1998)

**Reproduction Narrative**

Adult: Its life history is that of a semelparous (monocarpic) perennial, meaning that it flowers and produces fruit only once during its life, after which it dies (E. m. ssp. yadonii reportedly can flower and fruit twice). The wallflower forms a basal rosette of leaves that may persist for up to 8 years before flowering. Blooming typically occurs from March through April, although it may begin as early as late February. The species is self-compatible; therefore, the reproduction of this species involves selfing and facultative outcrossing (able to produce seed either by self-pollination, or pollination by other plants). Erysimum m. ssp. eurekense is pollinated by a solitary bee species (Emphoropsis miserabilis) in Humboldt County (USFWS 1998). The fruits mature by mid-June. Germination follows the first rains in fall or early winter. Fecundity is high, with individual plants producing numerous seeds; however, the wallflower does not have a persistent seed bank in the soil (Carothers 1996), and seedling survivorship is low, with 98.3 percent mortality shown to occur in the first year (Pickart and Sawyer 1998) (USFWS, 2008). The plant's pollinators are thought to be bees, bumblebees, butterflies, and moths (Price 1986) (USFWS, 1998).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Northern foredune or dune mat community, coastal strand (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: High (inferred from NatureServe, 2015 and USFWS, 1998)

**Habitat Narrative**

Adult: The habitats of the Monterey county populations differ from those of the northern California populations. The plants are generally distributed in clusters or patches. In northern California, the species occurs in northern foredune or dune mat community, on the flanks or crests of dunes, open sand areas, sparsely vegetated dunes, and the borders of lupine scrub. The plants can tolerate some sand movement. The associated vegetation community is composed of low-growing suffrutescent perennial and herbaceous native species. Common associates are beach sagewort (Artemisia pycnocephala), dune goldenrod (Solidago spathulata), coast buckwheat (Eriogonum latifolium), sand verbena, beach pea (Lathyrus littoralis) and seashore bluegrass (Poa douglasii). In Monterey County, the species occurs on coastal strand, close to the high tide line, but largely protected from wave action. The species has high exposure to strong wind, salt spray, and occasional wave action from storms and high tides. The substrate is loose sand lacking in organic matter and minerals. Associated species along the Monterey Peninsula include beach primrose (Camissonia cheiranthifolia), beach-bur, sea rocket (Cakile maritima), beach knotweed (Polugonum paronychia), sand verbena and iceplant. Monterey County habitats are relatively free of the invasive Ammophila arenaria (Fish and Wildlife Service 1997) (NatureServe, 2015). These habitats are not spatially fixed, and are subject to cycles of erosion, deposition, and re-establishment of plant communities over decades (USFWS, 1998).

***Dispersal/Migration***

**Dispersal**

Adult: Low to moderate (USFWS, 1998)

**Dispersal/Migration Narrative**

Adult: The seeds remain attached to the fruit walls after dehiscence and disperse over a long period, primarily in conjunction with winter storm events that dislodge the mature inflorescences and scatter them by way of a wind-driven tumbling action (Pickart and Sawyer 1998) (USFWS, 2008). Most seed dispersal is restricted to the immediate vicinity of the parent plants. Long distance dispersal of seed may occur by fragmentation of seed-bearing branches breaking offend tumbling with the prevailing wind. Isolated individuals of E. menziesii occur on slipfaces of bare, active dunes downwind of vegetated dunes at Ten Mile dunes. This indicates that long-distance seed dispersal may occur where the surface roughness of the dune is minimized (USFWS, 1998).

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2008)

**Species Trends:**

30 - 50% decline (NatureServe, 2015)

**Number of Populations:**

16 (USFWS, 2008); 15 (NatureServe, 2015)

**Population Size:**

Unknown (USFWS, 2008); 33,300 (NatureServe, 2015)

**Population Narrative:**

The three subspecies of Erysimum menziesii: ssp. eurekense, ssp. menziesii, and ssp. yadonii, are known from at least 33,300 individuals (Fish and Wildlife Service 1997). Together, the three rare subspecies of Erysimum menziesii, ssp. eurekense, ssp. menziesii, and ssp. yadonii are known from 19 occurrences, 15 of which are presumed to be extant (California Natural Diversity

Database, 2012). Subspecies concinnum is not included here. This species has experienced a short-term decline of 30 - 50% (NatureServe, 2015). Erysimum menziesii is known from at least 16 extant occurrences. With the exception of Erysimum menziesii ssp. eurekense, no statistically valid population estimates have been made of the subspecies of E. menziesii. Therefore, population data are generally inadequate for the purpose of determining trends or assessing response to past management (USFWS, 2008).

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Uncontrolled recreational use, such as hang gliders and hikers, continue to impact some populations (Imper pers. obs. 2006). Threats from off-road vehicle use, equestrian use and sand mining remain local threats in some areas. The privately owned occurrences of E. menziesii, particularly in Monterey County, are near expanding urban centers subject to growing demand for recreational opportunities (Imper pers. obs. 2006) (USFWS, 2008).

**Stressor:** Disease and predation (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Deer have significantly impacted a population of E. m. ssp. eurekense on the South Spit of Humboldt Bay (Clifford 2006), and nearly all E. m. ssp. menziesii occurrences on the Monterey Peninsula Disease caused by the crucifer rust (Albugo candida), a pathogenic fungus, affects a significant portion of E. m. ssp. menziesii in Humboldt County (Pickart 2004). An unidentified fungus was also observed affecting Erysimum menziesii ssp. yadonii (Zoger and Pavlik 1987). In E. m. ssp. eurekense, disease symptoms are more prevalent on reproductive individuals, where they can decrease fecundity by reducing seed number or viability (Pickart and Sawyer 1998) (USFWS, 2008).

**Stressor:** Climate change (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). However, predictions of climatic conditions for smaller sub-regions such as California remain uncertain. It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects. The effects to particular species is unknown at this time (USFWS, 2008).

**Stressor:** Invasive species (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** The primary threat to Erysimum menziesii when it was listed, and which continues to be the major threat for most populations is displacement by invasive non-native plant species. In Humboldt County the primary threats are European beachgrass, yellow bush lupine, iceplant, and jubata grass (Cortaderia jubata). European beachgrass and iceplant are the primary threats in Mendocino County, and iceplant in Monterey County. No efforts have yet been made to control or map burclover (Medicago polymorpha), ripgut brome (Bromus rigidus), or other invasive species that may be competing with E. m. ssp. menziesii within MacKerricher State Park.

***Recovery***

**Reclassification Criteria:**
1. Habitat occupied by the three endangered subspecies of Erysimum menziesii needed to allow delisting has been secured, with long-term commitments and, if possible, endowments to fund conservation of the native vegetation (USFWS, 2008).

2. Management measures are being implemented to address the threats of invasive species and other problems, including grazing, pedestrians, and off-road vehicles at some sites (USFWS, 2008).

3. Monitoring reveals that management actions are successful in reducing threats of invasive non-native species (USFWS, 2008).

Additional restored habitat has been secured, with evidence of either natural or artificial long-term establishment of additional populations, and long-term commitments (and endowments where possible) to fund conservation of the native vegetation (USFWS, 2008).

**Delisting Criteria:**
1. Studies have elucidated its life history requirements so that it is possible to predict the responses of populations to management and their viability (USFWS, 2008).

2. The dune systems supporting the 3 subspecies are actively protected from recreational violations, particularly by off-road vehicles (guaranteed funding to enforce ordinances), development, invasive weeds (including European beach grass, iceplant, and yellow bush lupine for subspecies eurekense in Humboldt County and iceplant for the entire species), and predators (deer in Monterey County) (USFWS, 2008).

3. Each occupied dune system has reasonable numbers of plants distributed widely enough to minimize the risk from accidental or catastrophic events. Erysimum menziesii ssp. eurekense (Humboldt Bay dune system) Goals: 3 populations with minimum 300 plants each; 2 populations with minimum 5,000 plants; Erysimum menziesii ssp. menziesii (Ten Mile Dunes system/Monterey Peninsula) Goals: 4 distinct sites and 5 total populations across the range; 3 populations averaging at least 300 plants; 2 populations averaging at least 5,000 plants; Erysimum menziesii ssp. yadonii (Marina dune system) Goals: Taxon to be present throughout its present range from south of Salinas River to Marina Dunes and potentially the Fort Ord area, with 2 populations averaging at least 5,000 individuals, and 3 populations averaging 300 plants or more (USFWS, 2008).

**Recovery Actions:**

- Protect existing populations and habitats (USFWS, 1998).
- Minimize the threats to the plant (USFWS, 1998).
- Develop management strategies incorporating ecological and land use strategies (USFWS, 1998).
- Manage populations and habitats to achieve delisting (USFWS, 1998).
- Monitor population trends to evaluate recovery success (USFWS, 1998).
- Coordinate recovery actions to protect other listed and sensitive species (USFWS, 1998).
- Develop and implement an outreach program (USFWS, 1998).
- Completion of population estimates for the Monterey and Mendocino County populations of Erysimum menziesii (USFWS, 2008).
- Establishment of a uniform reporting protocol for agencies conducting population inventories and habitat restoration across the range (USFWS, 2008).
- Increased Service support, in the form of funding and staff involvement, of habitat restoration and population enhancement efforts along the Marina Dunes on private and public lands (USFWS, 2008).
- completion of a Genetics evaluation and taxonomic review of E. menziesii across its range to help resolve outstanding questions on the identity of several large populations (USFWS, 2008).
- Investigation of methods and reliable funding mechanisms for ensuring future invasive species monitoring and control programs at critical sites (USFWS, 2008).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: The recommendations in the 2008, 5-Year Review remain our top priorities for the recovery of Menzies' wallflower. These include: 1. completion of population estimates for the Monterey and Mendocino County populations of Menzies' wallflower 2. establishment of a uniform reporting protocol for agencies conducting population inventories and habitat restoration across the range 3. increased USFWS support, in the form of funding and staff involvement, of habitat restoration and population enhancement efforts along the Marina Dunes on private and public lands 4. completion of a genetics evaluation and taxonomic review of Menzies' wallflower across its range to help resolve outstanding questions on the identity of several large populations 5. investigation of methods and reliable funding mechanisms for ensuring future invasive species monitoring and control programs at highly valuable sites (USFWS, 2020)

# SPECIES ACCOUNT: *Erysimum teretifolium* (Ben Lomond wallflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 03/07/1994; Pacific Southwest (R8)

**Physical Description**

Ben Lomond wallflower is a short-lived perennial plant, or occasionally an annual. Seedlings form a basal rosette of leaves which then wither as the main stem develops a raceme (flowers clustered in a terminal spike). The flowers are a deep yellow with petals 1 .3—2.5 centimeters (0.5—1.0 inch) long. The fruit, a slender capsule, reaches 10 centimeters (4.0 inches) in length and is covered with three-parted hairs. Characteristics that separate this plant from other wallflowers include simple, narrowly linear leaves that have small marginal teeth and a purplish cast. (USFWS, 1998)

**Taxonomy**

In the mustard family (Brassicaceae). Erysimum teretifolium was first collected at Glenwood, Santa Cruz County by Horace Davis in 1914. This plant was described by Alice Eastwood in 1938 as Erysimum filifolium, not realizing that this combination had already been applied to another plant (Eastwood 1938). Therefore, it was renamed Erysimum teretifolium the following year (Eastwood 1939). (USFWS, 1998)

**Historical Range**

Endemic to Santa Cruz Mtns., Santa Cruz County, California. (USFWS, 2008)

**Current Range**

Endemic to Santa Cruz Mtns., Santa Cruz County, California. (USFWS, 2008). Ben Lomond wallflower (Erysimum teretifolium) occurs within the sandhills of the Santa Cruz Mountains. The central range of the species is generally bounded by the communities of Ben Lomond, Glenwood, Scotts Valley, and Felton in Santa Cruz County (Figure 1). An outlying population is found at Bonney Doon Ecological Reserve approximately 5 miles west of the central concentration of occurrences (USFWS, 2022).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: cross-pollination (USFWS, 2008)

**Lifespan**

Adult: 1 - 2+ years (inferred from USFWS, 2008)

**Breeding Season**

Adult: March - July (NatureServe, 2015)

**Key Resources Needed for Breeding**

Adult: Insect pollinators, heavy fall rains (USFWS, 2008)

**Other Reproductive Information**

Adult: Ben Lomond wallflower is a monocarpic biennial plant that produces leaves but not flowers in the first year after germination. Flowers are typically produced in the second year (less frequently 3 years and rarely 4 years after germination) and die after seed set. Rarely will plants flower in the first year following germination or survive to flower and set seed more than once. In a recent experimental introduction study, approximately 11 percent of seedlings survived to produce an inflorescence in the second year (McGraw et al. 2020, p. 41). Herbivory pressure is high on both vegetative and flowering individuals, reducing the number of plants that set seed (McGraw and Chrislock 2019a, p. 15). Germination and survivorship have been observed to follow annual rainfall patterns, with wetter years having greater germination and survivorship than drought years (McGraw and Jordan 2021, pp. 19-20). Ben Lomond wallflower is largely self-incompatible, needing pollen from flowers not on the same plant in order to produce seed (Melen et al. 2016, p. 1983). Self-pollination sometimes results in fruit development, but the number of seed produced averages 6.5 times less than the amount of seed produced from cross pollination (Melen et al. 2016, p. 1983). Cross pollination between populations produces slightly more seed per fruit than cross pollination within population, suggesting that the small populations may be experiencing inbreeding depression (Melen et al. 2016, p. 1983). Bees, butterflies, and beetles are the most commonly observed floral visitors (Melen et al. 2016, p. 1982-1983). Pollen limitation was evaluated as a potential source of population declines, but manually adding pollen to flowers did not increase seed set, suggesting that populations of Ben Lomond wallflower are not pollen limited (USFWS, 2022).

**Reproduction Narrative**

Adult: Flowers from March to July (NatureServe, 2015). Erysimum teretifolium is a short-lived perennial or sometimes annual plant. This species is self-incompatible, and crosspollination is necessary for fertilization to occur. Chalcedon checkerspot butterflies (Euphydryas chalcedona), ants, European honeybees, and bumble bees have all been seen on the flowers of this species, but the potential for these insects to achieve pollination is unknown (McGraw 2004b). Observations by McGraw (2004b) indicate that the numbers of siliques produced per plant is quite variable (10- 107) and that seed production is positively correlated to silique length (9-15 centimeters produced 5-65 seeds). Seeds germinate after the first heavy rains in the fall, and were found to germinate at least up to 5 years after reaching maturity (McGraw 2004a and McGraw 2004b) (USFWS, 2008).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Ponderosa pine woodland, northern maritime chaparral (NatureServe, 2015); Zayante sandhills (USFWS, 2008)

**Dependencies on Specific Environmental Elements**

Adult: Periodic fire (USFWS, 2008)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs at 200 - 400 m elevation (NatureServe, 2015); succession (USFWS, 2008)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2008)

**Habitat Narrative**

Adult: Inhabits inland pockets of sandstone-derived coarse sandy soils; these are uplifted ancient marine terraces persisting in a mountain range of volcanic origin. These coarse sands create drier soil conditions than those in the surrounding substrates and support unusual, open, park-like ponderosa pine woodland and northern maritime chaparral communities. The species occurs preferentially in loose, uncompacted sand in openings between scattered chaparral shrubs, at 200 - 400 m elevation (NatureServe, 2015). The Zayante sandhills is a unique habitat type that is comprised of outcrops of sandy soils derived from marine deposits. Suppression of natural fire regimes has led to habitat conversion via the encroachment of woody invasive and native species and invasive annual grasses (Brunette 1997, USFWS 1998). This encroachment has led to conversion of much of the existing open, sandy soil habitat required by E. teretifolium and other shade intolerant sandhills plants, resulting in the establishment of shade-providing species and a build-up of leaf litter. The poor recovery record for sandhills habitat suggests a fragile system where biotic and abiotic factors coevolved in delicate balance over long time periods (USFWS, 2008).

***Dispersal/Migration***

**Dispersal**

Adult: Low (USFWS, 2008)

**Dispersal/Migration Narrative**

Adult: Seeds usually fall directly below the parent plant (USFWS, 2008).

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2008)

**Species Trends:**

Declining (USFWS, 2008)

**Number of Populations:**

17 (USFWS, 2008)

**Population Size:**

1,000 - 3,000 (USFWS, 2008)

**Additional Population-level Information:**

Population abundance data are only available for Quail Hollow Quarry Conservation Areas, Zayante Sandhills Conservation Bank, Bonny Doon Ecological Reserve, and Quail Hollow Ranch Park. The remaining locations have no information on abundance and population trends, or have infrequent single year data (Table 1). Data from Quail Hollow Ecological Reserve (also known as Quail Hollow Ranch County Park) between 2012 and 2022 suggest that the population is stable, with reproductive adults ranging between 200 and 400 plants (T. Kasteen 2022, pers. com.). The abundance of adult plants is measured as density and frequency at the Quail Hollow Quarry Conservation Areas and has remained relatively stable, but low, ranging between 1 and 6 plants within 20-meter squared plots between 2006 and 2020 (McGraw and Jordan 2021, p. 42). The number of plants within the Zayante Sandhills Conservation Bank has been historically low because that location captures only a small portion of a larger population that occurs within the Quail Hollow Quarry Conservation Areas. There was only a single adult plant observed in 2015 when annual monitoring began. However, through management and experimental outplanting the number of adult plants increased to 10 in 2021 (McGraw and Chrislock 2021, p. 27). The plants at the Zayante Sandhills Conservation Bank are best viewed as a small portion of a larger population that is increasing due to management efforts. The naturally occurring population at Bonny Doon Ecological Reserve has declined to six naturally occurring adult plants in 2022 (Kasteen 2022, pers. com.). The population has ranged between 1 and 50 adult plants since annual data began being collected in 2005. Experimental reintroductions have also taken place at this location with 837 adult plants observed in reintroduction areas in 2021 but declining to 189 plants in 2022 (Kasteen 2022, pers. com.). Herbivory, invasive species, litter, and drought have been attributed to the decline of the natural population and threaten the persistence of the reintroduction effort (Kasteen 2022, pers. com) (USFWS, 2022).

**Population Narrative:**

There are 17 extant populations. Trends are impossible to determine at many sites since either there are only data from a single survey or no survey data was available. The annual total of individuals over all populations has ranged between 1,000 and 3,000 individuals per year in the most productive recent years. Of the remaining known populations, half are either declining or possibly extirpated (USFWS, 2008).

***Threats and Stressors***

**Stressor:** Sand mining (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current sand mining is still destroying occupied E. teretifolium habitat. Unless new mining operations are proposed, future sand mining will be a reduced threat to the remaining habitat of the species because many of the mining operations are either being closed or are nearing closure (McGraw 2004b; B. Davilla, pers. comm. 2006). A substantial amount of the sandhills habitat had already been destroyed by mining operations prior to the listing of Erysimum teretifolium.

**Stressor:** Development and agriculture (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Urban development is not occurring at as rapid a rate as it was in the past, but the lasting effects of past development remain (e.g., habitat fragmentation, habitat alteration from landscaping). There are several sites that are immediately adjacent to existing homes on private

property that could provide good preservation opportunities. However, even if these areas were preserved, and little to no further development occurred, fragmentation at these sites would remain an issue. There is some grape production in the Bonny Doon area for winemaking purposes. Recent aerial photos do indicate the existence of exposed sandy soils in the area that may provide suitable habitat; however, private ownership of most of the surrounding properties has precluded any recent surveys of the area for Erysimum teretifolium. Additionally, signs posted in fallow vineyard areas indicate the application of insecticides and/or herbicides to the soil (C. West, pers. obs. 2007). Effects of these applications directly on E. teretifolium or on its pollinators are unknown (USFWS, 2008).

**Stressor:** Recreation (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At this time, recreational use continues to threaten some populations of Erysimum teretifolium. Fences are often cut and neighboring equestrians use the area, resulting in large quantities of erosion (J. McGraw, pers. comm. 2006; C. West, pers. obs. 2007). Another population (EO #14) on private land also shows much erosion due to recreation. This site is visible from nearby public land and supports some large specimens of E. teretifolium (C. West, pers. obs. 2007). Although there are “no trespassing” signs in place and wire fencing, there is extensive erosion, apparently from sandboarding (C. West, pers. obs. 2007). The effects of recreational activities are also apparent at the South Ridge site in Quail Hollow Quarry (former EO #1). Recreational activity at this site seems to be limited to hikers and dog-walkers accessing areas on foot, despite fencing and signage (C. West, pers. obs. 2007) (USFWS, 2008).

**Stressor:** Herbivory (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Observations of herbivory and potential effects at the population level have been noted by researchers (Brunette 1997, McGraw 2004b). Pocket gophers (Thomomys bottae) have been shown to consume up to 8 percent of rosettes prior to seed set in monitored populations (McGraw 2004b). Observations indicate that up to 37 percent of adult plants may be browsed by mule deer (Odecoileus hemionus), which greatly increases the likelihood of those plants dying without successfully reproducing (J. McGraw, pers. comm. 2007a) (USFWS, 2008).

**Stressor:** Fire suppression and succession (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Sandhills communities are fire-adapted, and fire plays a major role in resetting soil succession (McGraw 2004b). Fire has also been shown to play a role in the reduction of invasive non-native species in the sandhills parkland and chaparral habitat types (McGraw 2004b). Not only does suppression of fire directly leave leaf litter in place to accumulate, but McGraw (2004a) found that nonnative species prevented sloughing of this litter that otherwise occurs easily during rain and wind events from the bare sandy soil. Even with litter removal via manual methods such as raking, McGraw (2004a) found that the remaining non-native plants reduced soil moisture content, causing an increased risk of desiccation in E. teretifolium seedlings. At the

time of listing, vegetation succession leading to increased canopy density due to fire suppression was considered a threat to Erysimum teretifolium, which is relatively intolerant of shade. Perhaps more importantly, the habitat conversion leading to this increased canopy density will eventually result in a habitat type which cannot support many of the open sand specialists unique to sandhills parkland (McGraw 2004b, P. Levine, pers. comm. 2006). Many areas where E. teretifolium formerly occurred have undergone extensive habitat conversion; in several of these areas, it is doubtful whether the open sandy soil required by this species still exists (USFWS, 2008).

**Stressor:** Stochastic events (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** With increased successional pressures due to fire suppression, encroachment by nonnative plants, and human development, sandhills “islands” have shrunk in size and become even more fragmented (McGraw 2004b). Because seed dispersal distance is limited in Erysimum teretifolium (seeds usually fall directly below the parent plant), fragmented populations are likely to remain isolated. Of the populations surveyed in recent years, most have had very low numbers of individuals, and many had no individuals present. As habitat conversion increases due to various factors and remaining habitat is further fragmented and reduced in size, populations will continue to shrink and the risk of stochastic extinctions will increase (USFWS, 2008).

**Stressor:** Invasive Species (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasive species outcompete Ben Lomond wallflower by decreasing the amount and size of vegetation gaps within sand chaparral and sand parkland habitat, as well as through shading and competition for nutrients and water (McGraw 2004, pp. 240-244, 253-254). Invasive species that have established within former sand quarries are difficult to control, making reintroduction and recovery of Ben Lomond wallflower at those sites difficult. Portuguese broom (Cytisus striatus), French broom (Genista monspessulana), and silver wattle (Acacia dealbata) are three common woody invasive species that have been observed to establish rapidly in areas with low levels of disturbance (BEC 2021a, p. 6; BEC 2021b, p. 4; McGraw and Chrislock 2022, p. 4)). Once established, these and related species require annual removal efforts. Sand chaparral and sand parkland soil is typically low nutrient, which may inhibit invasive herbaceous species colonization. Pollution may increase nitrogen deposition and increase the fertility of the nutrient-poor soils, facilitating the potential establishment of invasive species (McGraw 2019a, p. 39). Herbaceous exotic species such as rat-tail fescue, rip-gut brome, rattlesnake grass, smooth cat’s ears, and sheep sorrel already constitute a major component of sand parkland habitat. These species are in lower densities in sand chaparral habitat (McGraw 2019a, pp. 7, 10-19). Complete removal of herbaceous exotic species is difficult due to established seed banks and presence in surrounding areas facilitating passive dispersal. Where herbaceous invasive species are limiting Ben Lomond wallflower presence continued active management will be required for recovery (USFWS, 2022)

***Recovery***

**Reclassification Criteria:**
1. The 17 currently known populations have been secured through fee-title acquisition, conservation easements, or Habitat Conservation Plans. (USFWS, 1998)

2. Management plans for populations on Quail Hollow Ranch County Park and Bonny Doon Ecological Reserve are developed and being implemented. (USFWS, 1998)

3. Management plans for populations on Quail Hollow Ranch County Park and the adjacent State-owned parcel, Bonny Doon Ecological Reserve, Henry Cowell Redwoods State Park, Big Basin State Park, and Gray Whale Ranch State Park are developed and being implemented.

4. Population numbers are stable or increasing. (USFWS, 1998)

Recovery Priority Number: 5

**Delisting Criteria:**
When the downlisting criteria have been met for a species the species can be considered for delisting if: 1. Threats are reduced or eliminated so that populations are capable of persisting without significant human intervention or perpetual endowments are secured for management necessary to maintain the continued existence of the species. (USFWS, 1998)

**Recovery Actions:**
- 1. Protect habitat for Santa Cruz Mountains species on private land through Habitat Conservation Plans and landowner agreements. Because of the extremely limited amount of habitat that exists, recovery cannot be achieved by the management of State and County lands alone (see task 2). Habitat Conservation Planning with local governments, quarry owners, and developers will provide additional protection. The long-term survival of these species will depend to a large extent on the protection that can be achieved on private lands (USFWS, 1998)
- 2. Manage habitat for Santa Cruz Mountains species. Management of the seven species included in this recovery plan and the habitats that support them will depend on data gathered from monitoring, threat analyses, and available conservation measures. Development and implementation of management programs should be specific to the species complex, ecological process, landowner, and particular threats to be managed. (USFWS, 1998)
- 3. Conduct research on the life history. ecology, and population dynamics of these species that will contribute to appropriate management strategies Research is needed to ensure that management actions that are undertaken are appropriate and will contribute to the long-term survival of these species and the habitats on which they depend. (USFWS, 1998)
- 4. Locate additional habitat/populations within the historic range of the species. The status of any new populations of these species that are discovered in the future should be evaluated and an assessment made of appropriate management actions. The value to the recovery strategy for these species of any additional habitat that is located should be assessed. (USFWS, 1998)
- 5. Develop and implement a public outreach program. An educational program should be established for the public, including private landowners whose property supports these taxa or suitable habitat, to encourage conservation and proper management of the taxa. Nongovernmental organizations such as the California Native Plant Society and the Santa

Cruz Mountains Biodiversity Task Force should be approached about participating in this effort. (USFWS, 1998)

- 6. Evaluate progress of recovery effectiveness of management and recoverv actions and revise management plans. (USFWS, 1998)
- Recommended Action from 2008 5-Year Review: Surveys and monitoring should be undertaken for all known populations and potential habitat to ensure that potential populations are identified and reliable demographic information is collected. Outreach to owners of private holdings with potentially conservable habitat and populations should be attempted and permission should be secured to survey these private holdings where necessary. Specifically, all populations listed in the CNDDB and McGraw (2004b) should be surveyed to focus future recovery efforts, especially the areas between and surrounding Vista Robles Drive and Marion Avenue in Ben Lomond and the area around the intersection of Pine Flat Road and Bonny Doon Road in Bonny Doon. In addition, coordination of recovery partners and consolidation of population data into the CNDDB records should be undertaken. Additionally, survey methods should be standardized to insure data accuracy. Methods employed by Brunette (1997) may be suitable for this purpose (USFWS, 2008).
- Recommended Action from 2008 5-Year Review: Expand research efforts focusing on potential causes of reproductive failures and methods to increase reproductive success as mentioned in the “Needed Recovery Actions” section of the recovery plan. As part of these efforts, the effects of predation on the species should be examined and pollination mechanisms should be identified. With clarification of such processes, management of landscape level influences on the species may be undertaken, such as predatory deterrence and management of potential pollinator barriers. Such research may contribute greatly in the form of increased survival, boosting reproductive success, and maintaining interfragment pollination to maximize gene flow, thereby avoiding inbreeding depression (USFWS, 2008).
- Recommended Action from 2008 5-Year Review: More detailed knowledge of populations and completion of management plans should allow active management to prevent encroachment of both native and non-native species in fire-suppressed areas, which threaten type conversion of the habitat and potential extirpation of individual populations. Prescribed burns mimicking natural fire cycles would be the most effective way to thin vegetation and restore open habitat; however, in many areas the proximity of human habitation precludes this as an option. Mechanical means of vegetation and leaf litter removal (i.e., raking) have proven effective in reducing the chances of habitat type conversion (McGraw 2004a and McGraw 2004b). Effectiveness of this method to improve Erysimum teretifolium habitat and increase reproductive success is being examined at Bonny Doon Ecological Reserve. If these studies prove effective, this method should be initiated in occupied habitat where fire would create unacceptable risk to local communities. Outreach to local landowners in such areas may facilitate the implementation of such management strategies over larger, contiguous pieces of occupied habitat and thereby maximize the conservation potential of all remaining populations. Such vegetation clearing efforts should be approached from a fuels reduction angle, which further benefits all parties involved (USFWS, 2008).
- Recommended Action from 2008 5-Year Review: Increased USFWS oversight as time allows may accelerate completion of the draft HCP with the County of Santa Cruz and other management plans under development. These plans need to be completed to help guide implementation of effective recovery efforts (USFWS, 2008).

- Recommended Action from 2008 5-Year Review: We suggest the USFWS consider revising the third criterion for downlisting in the recovery plan. This criterion lists specific HCPs by name. Many HCP projects are abandoned for various reasons. Additionally, entities listed on HCPs may change name and ownership over time. Such changes may in turn lead to alterations of the HCP title or content. For these reasons, including specific HCPs in draft form as downlisting or delisting criteria should be avoided. A blanket statement reflecting the need to include the species in any HCP that covers its occupied range would be more appropriate (USFWS, 2008).

# SPECIES ACCOUNT: *Euphorbia telephioides* (Telephus spurge)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 6/8/1992; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

Euphorbia telephicides is a perennial herb with a stout storage root. Stems are numerous, giving the plant a bushy appearance, and are up to 30 cm (1 ft)2 tall. Stems and leaves are smooth and have latex (milky sap). The largest leaves are 3-6 cm (1-2 in) long, elliptic or oblanceolate, with the midrib and margins usually maroon. The inflorescence is a cyathium (a structure resembling a flower, containing a single stalked female flower and several male flowers, each reduced to a single stamen). flowering is from April through July (Kral 1983). Clewell (1985) and Kral (1983) provide guidance for distinguishing this species from the most similar species, Euphorbia inundata, a taller plant of moister habitats. (USFWS, 1994)

**Taxonomy**

Euphorbia telephioides is a member of the spurge family (Euphorbiaceae). It was named by Alvin Wentworth Chapman (1860), who provided no explanation for his choice of name, but rather clearly intended to indicate a resemblance to another plant, most likely the garden plant Sedum telephium (orpine, live-forever, or stonecrop) or the similar North American Sedum telephioides. Small (1933) preferred to split the huge genus Euphorbia into smaller genera, renaming this species Galarhoeus telephioides. Taxonomists since then have left the genus Euphorbia intact. Webster (1967) established a new subsection of the genus Euphorbia, Inundatae, that includes Euphorbia telephioides and two other species native to the Florida panhandle: Euphorbia floridana and E. inundata (USFWS, 1994).

**Historical Range**

Endemic to the Florida panhandle and restricted to Bay, Gulf, and Franklin counties. It is unknown whether E. telephioides was once continuously distributed throughout the three counties or populations were restricted to local habitat patches (USFWS, 2015).

**Current Range**

Currently known from Bay, Gulf, and Franklin counties from Panama City Beach to east of Apalachicola (USFWS, 2015).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (NatureServe, 2015)

**Breeding Season**

Adult: April - July (USFWS, 1994)

**Reproduction Narrative**

Adult: Several staminate flowers surrounding a pistillate flower in a cyathium (Gleason, 1952). The species is monoecious and reproduction is sexual (NatureServe, 2015). Flowering is from April through July (Kral 1983) (USFWS, 1994).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015); wetland (USFWS, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Longleaf pine-slash pine savanna/flatwoods (NatureServe, 2015); coastal pinelands (USFWS, 1994)

**Dependencies on Specific Environmental Elements**

Adult: Periodic fire (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Excessive shade, development (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Wiregrass dominated, longleaf pine-slash pine savanna/flatwoods or on contiguous low, sandy rises dominated by pine-scrub oak near the coast. Cannot tolerate shade, needs fire to maintain community structure; can survive initial conversion of flatwoods to pine plantation. Separation barriers are created by clearing and development of habitat; fire-suppressed scrub and flatwoods (NatureServe, 2015). Although uncommon, telephus spurge was observed growing in wetlands with seepage slope species and in small thick clumps of wire grass surrounded by pine or cypress (Rountree et al. 2005). In general, the plants do well on sandy, acidic soil, with no litter, and low organic and moisture content (Peterson & Campbell 2007) (USFWS, 2015). Inhabits poorly-drained coastal pinelands (USFWS, 1994).

***Dispersal/Migration***

**Dispersal**

Adult: Low (USFWS, 2015)

**Dispersal/Migration Narrative**

Adult: Seeds are not dispersed over large distances (Negrón-Ortiz, 2014, pers. observ.) (USFWS, 2015).

***Population Information and Trends***

**Population Trends:**

Not available

**Species Trends:**

Stable (USFWS, 2015)

**Number of Populations:**
42 (USFWS, 2021)

**Population Size:**
>20,000 individuals

**Population Narrative:**
The species status is stable; seven populations are properly protected; three new occurrences were documented; recent surveys conducted on several sites found the species in excellent condition. The number of populations has increased to 41 sites based on recent survey work (FNAI 2007; 2013 -2014 FWS surveys; consultation surveys). Trapnell et al. (2012) found species-wide genetic diversity was high, ranking E. telephioides among the highest 10% of plant species surveyed. However, genetic differentiation among populations is lower than that observed for other herbaceous outcrossing perennial plant species (USFWS, 2015).

***Threats and Stressors***

**Stressor:** Habitat destruction and degradation (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Urban development continues to threaten telephus spurge since most E. telephioides documented locations are found in private land. 380,000 acres of land will maintain timber and agriculture uses, included timberlands in Bay, Calhoun, Franklin, Gadsden, Gulf, Jefferson, Leon, Liberty and Wakulla counties. Many E. telephioides' locations are found along US 98, and powerline ROW maintenance (removal of existing and installation of new transmission poles), road widening and new roads continue to negatively affect plant abundance and habitat loss. Urbanized land in Florida, statewide, is projected to double by 2060 along with doubling of the population to 36 million. Suppression of fire during the dormant season continues to threaten the pineland and savanna's flora as fire is an important factor in the maintenance of flatwoods (Abrahamson and Hartnett 1990). Fire influences community structure and composition (Abrahamson and Hartnett 1990), and with insufficient frequency in longleaf pine communities, a woody midstory quickly develops (Glitzenstein et al. 1995), negatively affecting the understory diversity (USFWS, 2015).

**Stressor:** Sea level rise (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Sea level rise (SLR) as a result of climate change is a growing concern for much of Florida's coastline and the endemic species that occur there because about 10% of Florida is less than 1 meter (m) above current sea level. Wolf and Lopez (2014) estimated the potential for inundation of habitat areas for the Telephus spurge at sea level rise projections from 0.305 to 1.83 m (one to six feet) within this century. The projections indicated that coastal habitat areas in Escambia, Bay, Franklin, and Gulf Counties would be largely inundated beginning at 0.305 m (one foot) of SLR. Therefore, SLR projections of changes, under above all scenarios, will most likely

affect several coastal populations specifically those located in Gulf and Franklin counties. Euphorbia telephioides is at risk of further decline from SLR because its seeds are not dispersed over large distances (Negrón-Ortiz, 2014, pers. observ.), so sea level may rise more quickly than the species can establish populations further inland. In addition, E. telephioides does not respond well to transplantation (Ecological Resource Consultants 2006; Negrón-Ortiz, 2010, pers. observ.). Another major concern is that as more coastline is inundated with water, urban development will expand, decreasing the amount of suitable habitat for E. telephioides and impeding the ability of these species to move landward (USFWS, 2015).

***Recovery***

**Reclassification Criteria:**
Not defined (USFWS, 1994; USFWS, 2015)

Recovery Priority Number: 2C

**Delisting Criteria:**
1. When 15 populations are adequately protected and managed throughout its historic range. Existing public land (mainly the Apalachicola National Forest) does not suffice for recovery (USFWS, 1994; USFWS, 2015).

**Recovery Actions:**

- Protect populations in Apalachicola National Forest and on other public lands. This includes Management/general monitoring in Apalachicola National Forest, Conduct of population biology studies, and Conduct of botanical inventories on public land, possible purchase areas, and selected private land. (USFWS, 2015)
- Manage rights-of-way. Highway and utility rights-of-way (mostly electric powerlines along highways) harbor populations of all four plant species. Experience with managing Harperocallis flava (Harper's beauty), an endangered plant, on a highway right-of-way in Apalachicola National Forest may suggest approaches for conserving these species. (USFWS, 2015)
- Protect and manage populations outside Apalachicola National Forest through purchase, conservation easements, or other means; develop conservation plans for these sites (USFWS, 2015).
- Conduct systematic and other studies; arrange reintroduction where appropriate and feasible (USFWS, 1994).
- Garden propagation and reintroduction. Reintroduction of Euphorbia telephioides depends on suitable, protected habitat being available and methods being developed. It is not yet clear whether it would be useful to maintain garden populations of this species. (USFWS, 2015)
- Establish monitoring program: i. Identify additional populations of conservation importance based on information from the genetic studies (ongoing). ii. Conduct a demographic population viability analysis to assess whether the species is declining, increasing, or stable, and where in the life cycle the management should be targeted. This is an ongoing action conducted by Ms. Natali Miller, a graduate student from FL State University (USFWS, 2015).
- Collect voucher specimens (e.g., herbarium specimens, samples for DNA analyses, preserve material, seeds and whole plants) from areas proposed to be developed and 1) transplant to

suitable sites, and 2) distribute to herbaria, botanical gardens, and interested scientists (USFWS, 2015).

- Expand germination studies. i. Determine seasonal fluctuations that influence germination timing and recruitment and identify traits that correlate with seed viability and dormancy ii. Conduct ex situ germination studies and clarify limits of seed desiccation and cold tolerance (USFWS, 2015).
- Develop a Species Distribution Model (SDM) to assist with locating new populations and identifying prospective sites for reintroductions such as areas that will not be affected by SLR and future development. Sites should be validated or inspected for plants, and then protected by land acquisitions, conservation easements. This is an ongoing action conducted by Ms. Alexa Mainella, a graduate student from Miami University, OH (USFWS, 2015).
- Phenological data (timing, duration and abundance of recurrent biological processes, including reproductive events such as flowering, fruiting, seed dispersal and germination) have emerged as useful tools for studying the impact of climate change on plants. Lacking phenological adaptability may require a stronger signal or may be unable to adapt to climate warming, and therefore may experience greater stress or even extinction during extended climate change. Therefore, phenological studies should include both long-term observations coupled with herbarium specimens' records (USFWS, 2015).
- Since E. telephioides occurs in fire prone habitats, the effect of this disturbance on survival and fecundity should be monitored to determine the best frequent fire regimes, on selected areas to maintain optimal conditions of E. telephioides populations (USFWS, 2015).
- Continue fostering a working partnership with the St. Joe Company, AgReserves, Inc. and other developing companies and consulting agencies, such as Flatwoods Consulting Group to address and minimize potential impacts associated with development and fire suppression (USFWS, 2015).
- Outreach: Promote the implementation of the recovery actions via academia, private landowners, and public agencies. Develop and distribute information to the general public (USFWS, 2015).
- The recovery plan should be updated to define objective measurable criteria and better address the five factors (USFWS, 2015).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Establish monitoring program i. Conduct a demographic population viability analysis to assess whether the targeted populations are projected to decline, increase, or remain stable, and where in the life cycle the management should be targeted. This is an ongoing action conducted by Ms. Natali Ramirez-Bullon, a graduate student from FL State University. Projected completion late 2021. She constructed and analyzed stage-structured stochastic demographic models for three E. telephioides populations to answer the projected growth rate of each population, and whether incorporation of a larger sample alters the projected growth rate. Overall, the models suggested a decline over the next 100 years. ii. Identify additional populations of conservation importance based on information from the genetic studies (ongoing). a. Collect seeds targeting all E. telephioides sexual morphs for ex-situ seed conservation -ongoing and conducted by the ABG b. Establish permanent plots on at least three additional protected locations throughout the species' historical range. For each plot: a. Estimate the sex ratio, density, and abundance of individuals. b. If possible, investigate basic ecological questions (e.g., pollinators; flowering period; annual variability in flowering; seed production and seedling survival). c. Monitor the effect of fire (if the areas are burned) on density, fecundity, and size structure. 2. Collect voucher specimens (e.g., herbarium specimens, samples for DNA analyses, preserve material, seeds and whole plants) from areas proposed to be developed and 1) distribute to herbaria, botanical gardens, and interested scientists, and 2) relocate to suitable sites with appropriate tools and best management (e.g., avoid transplant shock and high temperatures, and whether dormant plants are the optimal stage for relocation). For details see Negrón-Ortiz & Kaeser (2020). i. Knowledge of this species' sexual expression is necessary during plant rescue and the establishment of new populations. For establishment, all E. telephioides sexual morphs should be represented. ii. If seeds are collected for establishment or ex-situ approaches, a large number may be required to overcome low germination and seedling establishment, and the unpredictability of the sex ratio. 3. Develop a Species Distribution Model (SDM) to assist with locating new populations and identifying prospective sites for reintroductions such as areas that will not be affected by SLR and future development. Sites should be validated or inspected for plants, and then protected by land acquisitions, conservation easements. This is an ongoing action, see Appendix 1, recovery criterion 4. 4. Expand germination and seedling survivorship studies. i. Determine seasonal fluctuations that influence germination timing and recruitment and identify traits that correlate with seed viability and dormancy ii. Conduct ex situ germination studies and clarify limits of seed desiccation and cold tolerance. This is an ongoing action conducted by the ABG for 2021-2023 iii. Look at historical data, such as herbarium specimens recorded observations, to understand what abiotic and biotic factors influenced germination timing and recruitment in the past. Note: Atlanta Botanical Garden planned to collect seeds from known and any discovered populations (based on SDM, action 3) to conduct germination and viability studies, establish collections in their Conservation Seed Bank, and for propagation for use in reintroduction experiments within protected lands where suitable habitat is found (ongoing action 2021-2023); funds were obtained from the Coastal Program. iv. Further investigate in-situ seedling survivorship and growth across years to help to understand E. telephioides population persistence (see NegronOrtiz & Kaeser 2020) 5. Phenological data (timing, duration and abundance of recurrent biological processes, including reproductive events such as flowering, fruiting, seed dispersal and germination) have emerged as useful tools for studying the impact of climate change on plants. Lacking phenological adaptability may require a stronger signal or may be unable to adapt to climate warming, and therefore may experience greater stress or even extinction during extended climate change. Therefore, phenological studies should include both long-term observations coupled with herbarium specimens' records. Complete for long-term in-situ observations (Negron-Ortiz & Kaeser 2020); Not initiated: document phenology using herbarium specimens' records. 6. Since E. telephioides occurs in fire prone habitats, the effect of this disturbance on survival and fecundity should be monitored to determine the most appropriate fire return intervals, on selected areas to maintain suitable habitat conditions of E. telephioides populations. Complete for the effect of this disturbance on survival and fecundity (Negron-Ortiz & Kaeser 2020); partially complete/understood: determining the appropriate fire return intervals. 7. Euphorbia telephioides changes in sex expression occurred in response to factors such as temperature, specifically after fire (Negron-Ortiz & Kaeser 2020). The impact of elevated temperatures (and photoperiod) on changes in sex expression should be further investigated as it can provide insights into the performance of this species under the impacts of frequent disturbance and climate change. i. The long-term effect of temperature on tagged individuals can be measured by establishing permanent monitoring plots across the entire range of E. telephioides at sites maintained with prescribed fire. 8. Continue fostering a working partnership with the St. Joe Company, AgReserves, Inc. and other developing companies and consulting agencies, such as Flatwoods Consulting Group to address and minimize potential impacts associated with development and fire suppression. 9. Outreach: Promote the implementation of the recovery actions via academia, private landowners, and public agencies. Develop and distribute information to the general public. This is an ongoing action, see Appendix 1, recovery criterion 4. (USFWS, 2021)

# SPECIES ACCOUNT: *Galactia smallii* (Small's milkpea)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 8/19/1985; Southeast Region (R4)

**Physical Description**

Galactia smallii is a small, trifoliolate, perennial legume with small, purple flowers and a prostrate habit. The stems are grayish, due to a covering of short hairs, and grow up to 2 m long. The stem internodes are well-developed and have long, straight, soft hairs. The 1 to 2.2 cm long leaflets are broadly ovate to elliptic. The undersides of the leaves have long, soft, wavy hairs lying almost flat against the surface. The upper surface of the leaves are either hairless (glabrate) or have sparse, stiff hairs, lying flat on the surface (strigose). The inflorescences are 2 to 6 cm long with one to five flowers at the apex or along the axis. The flower buds are 5 to 7 mm long, and the calyx is about 7 mm long and loosely strigulose. The corolla is 11 to 12 mm long and pinkish purple or lavender. The legume is 3 to 4 cm by about 4 m in size and is strigulose or villosulous (Isley 1990). (USFWS, 1999)

**Taxonomy**

Small's milkpea was originally described as G. prostrata by Small in 1933. However, H.J. Rogers (unpublished dissertation, Duke University, 1949) discovered that this name is a homonym, unavailable for use, and suggested G. smallii. Since Rogers' proposal was never published, the incorrect name persisted. Herndon (1981) published Rogers' finding and proposed the name change to G. smallii. (USFWS, 1999)

**Historical Range**

The historic range of Small's milkpea is not well known. When this species was listed, it was known from two sites near Homestead in Miami-Dade County. (USFWS, 2010)

**Current Range**

Miami-Dade County, Florida, in a narrow region across a 6.5-mile area, and the Homestead Air Reserve Base (USFWS, 2019).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

Adult: Small's milkpea is a perennial legume that usually flowers during the summer months. However, numerous flowers may occur following a burn at anytime throughout the year (Small 1933, and Long and Lakela 1971). Fire may synchronize and intensify flowering of plants in the burned area (A. Herndon, personal communication 1998). Its pollinators include three species of bees, one species of wasp, and the Cassius blue butterfly (Leptotes cassius theonus). (USFWS, 1999)

**Habitat Type**

Adult: Pine rocklands/rockland hammocks (USFWS, 1999)

**Environmental Specificity**

Adult: Very Narrow (inferred from USFWS, 1999)

**Habitat Narrative**

Adult: Preliminary results of a study of the abundance, distribution, and habitat preferences of Galactia species in Miami-Dade County pine rocklands indicate that G. smallii prefers higher elevations and lower shrub cover than the more common Galactia species (O'Brien 1994). The distribution of G. smallii is correlated with soil depth and color in Redland pine rocklands. It does not occur in sites with a high amount of exotic plant cover, specifically, Schinus terebinthifolius and Neyraudia reynaudiana (O'Brien and Koptur 1995). (USFWS, 1999)

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

24 sites (USFWS, 2019)

**Population Size:**

~120,000 (USFWS, 2019)

**Population Narrative:**

Galactia smallii is only known from the pine rocklands of Miami-Dade County. The remaining G. smallii populations occur entirely within a narrow region of pine rockland fragments that includes 24 sites – 8 public and 16 private (Bradley, 2010b; Lange, pers. comm. 2017; Possley, pers. comm. 2017) across a 6.5-mile (10.5 km) area within Miami-Dade County. However, a single population at Homestead Air Reserve Base (HARB), contains up to 100,000 individuals (Bradley 2009). Miami-Dade County owns seven of the public sites, purchased for conservation purposes, and is working to restore and manage these lands through their Environmentally Endangered Lands (EEL) program. The final public site, HARB, is seeking to develop their lands, however, they are also coordinating with the Service and IRC to retain and manage the population at this site. G. smallii populations on the 16 private sites range in size from 3 to 1,000 individuals per site (Bradley, 2010b; Lange, pers. comm. 2017; Possley, pers. comm. 2017a). (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Habitat loss and fragmentation
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The pine rockland community of south Florida is critically imperiled globally (FNAI 2010b). In Miami-Dade County, development and agriculture have reduced pine rockland habitat by 90 percent. Continued habitat loss (Factor A) and fragmentation threaten the existence of this species, and less than 1 percent of the original acreage of pine rockland habitat remains outside

of Everglades National Park (Herndon 1998). Populations on private sites remain threatened with destruction or habitat modification due to improper or lack of management (Factors A and E). (USFWS, 2019)

**Stressor:** Indequacy of existing regulatory mechanisms
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Currently, regulatory mechanisms (Factor D) provide limited protections for this species. The Florida Department of Agriculture and Consumer Services designated these species as endangered under Chapter 5B-40, Florida Administrative Code. This law regulates the taking, transport, and sale of listed plants. This law does not prohibit private property owners from destroying listed plants, nor does it require them to manage habitats to maintain populations. The Natural Forest Communities (NFC) program was established by Miami-Dade County to encourage but not require private landowners to protect forested lands by making it necessary to apply for a permit with the County prior to working in designated NFCs (i.e., pinelands, hammocks). (USFWS, 2019)

**Stressor:** Inadequate fire management
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire suppression continues to affect Amorpha crenulata(Factor E). Historically, frequent (approximately twice per decade), lightning-induced fires were a vital component in maintaining native vegetation and ecosystem functioning within south Florida pine rocklands. A period of just 10 years without fire may result in a marked decrease in the number of herbaceous species due to the effects of shading and litter accumulation (FNAI 2010b). The majority of extant populations of this species is affected by some degree of inadequate fire management, with the primary threat being shading by hardwoods (Bradley and Gann 1999; Bradley and Gann 2005). (USFWS, 2019)

**Stressor:** Nonnative invasive plants
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasion by exotic plant species continue to affect Amorpha crenulata (Factor E). Nonnative invasive plants compete with native plants for space, light, water, and nutrients, and make habitat conditions unsuitable for this species, which prefers open conditions (Factor E). Bradley and Gann (1999) indicated that the control of nonnative plants is one of the most important conservation actions for the pine rockland species and a critical part of habitat maintenance. Nonnative plants have significantly affected pine rocklands and negatively impacted all occurrences of this species to some degree (Bradley and Gann 1999; Bradley 2006; Bradley and Saha 2009; Bradley and van der Heiden 2013). (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**
Not developed (USFWS, 1999; USFWS, 2010)

Recovery Priority Number: 5C

**Delisting Criteria:**
1. Existing natural populations achieve and maintain a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (addresses Factors A and E) (USFWS, 2019)

2. A network of 5 new populations are either discovered or reintroduced that exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (addresses Factors A and E) (USFWS, 2019)

3. All populations (criteria 1 and 2) are protected by a conservation mechanism. (addresses Factors A, D, and E) (USFWS, 2019)

4. Threats have been reduced or eliminated to the degree that this species will remain viable for the foreseeable future. (addresses Factors A, D, and E) (USFWS, 2019)

**Recovery Actions:**
- Conduct surveys to determine distribution of pine rockland plants. Pine rockland plants have been thoroughly surveyed in Miami-Dade County. However, other populations may be noted during acquisition and restoration program implementation. Fire may eliminate litter concealing listed species, or enable seeds in the seed bank to germinate. For that reason, pine rocklands that did not contain listed species when unmanaged should be resurveyed after fire events. (USFWS, 1999)
- Protect and enhance existing populations. It is imperative for the recovery of pine rockland plants that populations not be lost. (USFWS, 1999)
- Conduct research on the biology of G. smallii. Additional information on the ecology and life history of pine rockland plants needs to be collected. Determine size and viability of all populations. Known populations of the listed pine rockland plants should be evaluated. Population viability needs to be investigated and determined for each listed plant species. (USFWS, 1999)
- Develop standardized monitoring. Standardized monitoring needs to be developed for listed pine rockland species in order to determine the effect of management actions on these species. Use existing standardized monitoring protocols developed by the Florida Natural Areas Inventory to record baseline data regarding the biology and ecology of G. smallii. Initiate quarterly monitoring program. (USFWS, 1999)
- Continue to provide public information about pine rocklands and their unique flora. Public support will increase the chances of recovery for these species. Informational and educational materials have been produced. DERM and Miami-Dade County Natural Areas Management have developed flyers, displays, newsletters, and press releases, and have held workshops with the general public. Organizations best able to carry out information and education programs include: Miami-Dade County Parks and Recreation Department, the Florida Native Plant Society, Everglades NP, and Miami-Dade County DERM. Support of local press coverage should continue. DERM has developed a web page that will also aid in disseminating information about this endangered plant community to the public. (USFWS, 1999)

- Habitat-level Recovery Actions: Continue to protect and prevent degradation of pine rockland plant habitat. Restore areas to suitable habitat. Continue to investigate and refine the habitat needs of each species. Monitor habitat and ecological processes. Continue implementation of the fire education program and modify as necessary any fire management education program that has been developed. (USFWS, 1999)

# SPECIES ACCOUNT: *Geocarpon minimum* (No common name)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 6/16/1987; Southeast Region (R4) (USFWS, 2017)

**Physical Description**

A small (1-4 cm tall), ephemeral, succulent winter annual that usually completes its life cycle within a 4-week period in the spring. Young plants are grayish; mature plants reddish-purple. Flowers are inconspicuous. This unusual species comprises the monotypic genus Geocarpon (NatureServe, 2015).

**Taxonomy**

Kartesz & Kartesz (1980) had placed this genus in Aizoaceae but Kartesz (1994 checklist) subsequently placed it in Caryophyllaceae (NatureServe, 2015).

**Historical Range**

Historically found in St. Clair & Jasper Counties, Missouri (NatureServe, 2015).

**Current Range**

Found in southwestern Missouri (Dade, Polk, Greene, and Lawrence Counties). Found in three southeastern counties in Arkansas (Cleveland, Drew, and Bradley) and one Northwestern County (Franklin). Also found at two locations in Louisiana (Wynn Parish). This species was discovered in Texas in 2004 in Anderson County (Keith et al. 2004) (NatureServe, 2015). The range of Geocarpon has been extended farther west within the Arkansas River Valley and the habitat at this site appears similar to that described for the other known site within this region (Baker and Witsell 2015) (USFWS, 2016).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (inferred from NatureServe, 2015)

**Lifespan**

Adult: 4 - 6 weeks (NatureServe, 2015)

**Breeding Season**

Adult: February - June (USFWS, 2016)

**Key Resources Needed for Breeding**

Adult: Spring temperature and moisture patterns, possibly centipede pollinators (NatureServe, 2015)

**Reproduction Narrative**

Adult: Geocarpon minimum has been variously described as an annual (Tucker 1983, Palmer and Steyermark 1950) and as a winter annual (Mackenzie 1914, Bridges 1986, Morgan 1986), and this question has not been fully resolved to date. The timing of emergence in the spring can vary widely from year to year with temperature having the greatest influence on initiation of growth. Winter rosettes at Bona Glade begin producing flowering stems anywhere from March to mid April (Morgan 1986). Tucker (1983) lists March 23 to April 23 as flowering dates for Geocarpon in Arkansas; however, following a warm winter, Bridges (1986) found plants on the Warren Prairie site producing stems in late January, flowering by mid-February, and dead or dying by April 1. Although the initiation of growth in the spring is controlled by temperature, Morgan (1986) suggests that the vigor of plants and the number of flowers and seeds produced is probably dependent on soil moisture and temperature conditions experienced after the initiation of growth in the spring. Tucker (1983) states that the life cycle of individual plants is completed in a four week period, and Morgan (1986) indicates that a period of 4-6 weeks passes from the initiation of growth in spring to senescence. To date, no insect pollinators have been observed; however, Shephard (pers. comm.) has observed numerous small centipedes within Geocarpon populations and suggests that they be considered as possible pollinators. Flower production varies from plant to plant with some plants producing 5-7 stems with 2-4 flowers per stem and other plants being single stemmed with only 1-2 flowers produced (Morgan 1986). Shephard (pers. comm.) observed that even in apparently good years, a high percentage (ca. 90%) of the plants produced on the Warren Prairie site were one stemmed, one flowered individuals. Morgan (1986) collected 16 capsules and found from 9 to 72 seeds produced per capsule with a mean of 27 seeds per capsule. Groups of seedlings have been observed growing from capsules produced the previous season (Morgan 1986). Although it is apparent that seeds do survive in seed banks since plants are produced in years following poor seed production, little is known about seed viability and longevity. Tucker (1983) suggests that slight disturbance of the soil surface is necessary for Geocarpon seed germination and seedling establishment. This annual species is also known to have good seed set, with lots of capsules (pers. comm. E. Keith) (NatureServe, 2015). The flowering and fruiting period when the plant is usually most visible ranges from late February to early June (Bates 1994; McInnis and Larke 1997; Smith in litt. 1998; MDC 2000; TNC 2004, 2005) (USFWS, 2016).

**Habitat Type**

Adult: Terrestrial, palustrine (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Sandstone glades, saline prairie, riparian (NatureServe, 2015)

**Environmental Specificity**

Adult: Very narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Inhabits sandstone glades and saline prairies. In Missouri, Geocarpon grows on moist, sandy soils on exposed sandstone outcrops or glades, where ledges of fine sandstone, interbedded with shale, are exposed along small streams. The surrounding area, where deeper soils prevail, is savannah. Sites in Arkansas and Louisiana are characterized by very thin soils that are high in sodium and magnesium. Woody plants are nearly absent. In these saline prairies, the species occurs mostly in very thinly vegetated, barren-like areas. The presence of high concentrations of magnesium in the soil may be a critical factor in Geocarpon distribution, since the soils of Geocarpon sites in Arkansas are characteristically high in magnesium and/or sodium. All of the Geocarpon sites currently known from Arkansas occur on saline soil prairies on natric or saline soils. Geocarpon is very sensitive to competition from other species of vascular plants and occurs only in very open areas. The environmental specificity of this species is very narrow as it is a specialist only growing in salt prairies of one kind (NatureServe, 2015).

***Dispersal/Migration***

**Dispersal**

Adult: Low (NatureServe, 2015)

**Dispersal/Migration Narrative**

Adult: Seeds remain in dead capsules and are most likely dispersed near the parent plant by wind or rain or by plants simply falling over). Results of monitoring in Missouri (Morgan 1986) and Arkansas (Shephard 1987) indicate that Geocarpon appears in the same areas from year to year and has low vagility. Tucker (1983) suggests that ants be considered as a possible secondary dispersal mechanism since ant mounds are often found in the vicinity of Geocarpon populations in Arkansas (NatureServe, 2015).

***Population Information and Trends***

**Population Trends:**

Decline of <30% to increase of 25% (NatureServe, 2015)

**Species Trends:**

Stable (USFWS, 2009)

**Number of Populations:**

40 (USFWS, 2016)

**Population Size:**

2500 - 100,000 individuals (NatureServe, 2015)

**Adaptability:**

High (inferred from NatureServe, 2015)

**Population Narrative:**

Survives fairly harsh environmental conditions. Although the long term trend of this species isn't documented, it is suspected that is has been stable (pers. comm. E. Keith). This species has experienced a long-term decline of <30% to increase of 25%. As with many annual species, the size of Geocarpon populations varies greatly from year to year. Shephard (1987) indicates that 2033 plants were found within plots in 1986 (Warren Prairie, Arkansas) and 6761 plants were found within the same plots in 1987. Similarly, Morgan (1986) found 1900 plants in plots (Bona Glade, Missouri) in 1984 and 4055 plant present in the same plots 1986. There are at least 13 occurrences with good viability (NatureServe, 2015). Population surveys indicate that the species status is stable. Populations are currently documented to occur at a total of 37 sites (including three plantings in Missouri) within 17 counties in four states (Osborne in litt. 2005;

Smith in litt. 2006a, 2006c; Reid in litt. 2009; Singhurst in litt. 2009) (USFWS, 2009). Populations are currently documented to occur at a total of 40 sites (including three plantings in Missouri) within 19 counties in four states (Baker in litt. 2015; Baker and Witsell 2015; Briggler in litt. 2015; Reid in litt. 2015; Singhurst in litt. 2015) (USFWS, 2016).

***Threats and Stressors***

**Stressor:** Habitat destruction and degradation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The primary threat continues to be soil development on suitable sites within saline prairies (slick spots) and sandstone glades (shallow sandy soils) (Logan 1998; Witsell 2004a; Smith and Ely 2006). Geocarpon thrives in these harsh conditions that exclude competing plant species. Accumulation of more suitable soils quickly leads to an invasion of other plants that shade Geocarpon. Such soil development may be facilitated by lack of disturbances such as fire and use by large mammals (Witsell 2004a; Smith and Ely 2006). Excessive soil development and subsequent colonization by competitive plants may also occur when excessive soil movement occurs due to dense cattle use, ATV use, or other factors. Movement of dirt can also alter the microhydrology of sites which may lead to localized extirpation of subpopulations (TNC 2004; Witsell pers. comm. 2006) (USFWS, 2009).

**Stressor:** Small, isolated populations (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Geocarpon is vulnerable to local extirpations because it occurs in isolated populations and depends on the presence of specific microhabitats in order to compete with other plants. Although extirpations of subpopulations due to encroachment of other vegetation have been observed (Witsell 2004), no known populations have disappeared due to this factor (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change may affect Geocarpon, although the exact mechanisms and whether these effects will be negative or positive is unknown. Some authors have suggested that plant diversity, species phenology and distribution, and increases in extinction risk are all potential outcomes of climate change (Iverson and Prasad 2002; Bertin 2008; and Maclean and Wilson 2011). Changes in localized weather patterns associated with climate change may lead to more frequent and long-lasting droughts (Rind et al. 1990; Seager et al. 2007; and Rahel and Olden 2008). Climate warming may also increase the spread of non-native species (Rahel and Olden 2008). Changes in drought cycles and increases in air and soil temperatures could have effects on seed set, germination, and general fitness of Geocarpon (USFWS, 2016).

***Recovery***

**Reclassification Criteria:**
Not available

Recovery Priority Number: 7

**Delisting Criteria:**
1. A total of 15 viable populations, representing the diversity of habitats and the geographic range of the species, are protected as necessary to ensure their continued existence (USFWS, 2009).

2. Populations include the wide spectrum of current genetic variation (USFWS, 2009).

3. Population viability is confirmed through periodic monitoring for at least a 15-year period (USFWS, 2009).

**Recovery Actions:**
- Protect viable populations across the species' geographic range (USFWS, 1993).
- Evaluate potential habitat and search for additional populations (USFWS, 1993).
- Continue to monitor known sites to determine population trends (USFWS, 1993).
- Support basic research investigating the chemical characterization of the plant's substrate and species biology, dispersal ecology, and population genetics (USFWS, 1993).
- Determine the effects of disturbance factors (natural and manmade) and incorporate findings into management prescriptions (USFWS, 1993).
- Preserve genetic stock (USFWS, 1993).
- Establish additional populations in the Arkansas Valley Natural Division, if deemed necessary (USFWS, 1993).
- Seek funding to complete an investigation into the genetic variability of Geocarpon throughout the range, including the newly discovered populations in Texas and Louisiana (USFWS, 2009).
- Continue to investigate the role of disturbance in the distribution and success of Geocarpon in sandstone glades and saline prairies (USFWS, 2009).
- Initiate studies to determine the mode of seed dispersal. Promising theories include movement by water, insects, and large mammals (USFWS, 2009).
- Continue to search for new populations in suitable sandstone glade habitats in Missouri and Arkansas and saline prairie habitats in the Arkansas River Valley of Arkansas and Oklahoma and other saline prairie sites in Arkansas, Louisiana, and Texas (USFWS, 2009).
- Continue to monitor known sites (USFWS, 2009).
- Work cooperatively with landowners to conserve privately owned sites through fee title or easement purchases or development of management agreements (USFWS, 2009).
- Complete the investigation into the genetic variability of Geocarpon throughout the plant's range (funded in 2015 with completion expected in 2017) to get a better understanding on possible completion of recovery criteria #2 (USFWS, 2016).
- Continue to investigate the role of disturbance in the distribution and success of Geocarpon in sandstone glades and saline prairies. The impacts of extreme disturbance due to feral hogs should be incorporated into these studies. As an understanding develops regarding the role of disturbance, a threats assessment should be conducted to determine which threats should be addressed first (USFWS, 2016).

- Develop standardized monitoring protocols and reach consensus among states regarding the delimitation of populations and sub-populations (USFWS, 2016).
- Continue to search for new populations in suitable sandstone glade habitats in Missouri and Arkansas and saline prairie habitats in the Arkansas River Valley of Arkansas and Oklahoma and other saline prairie sites in Arkansas, Louisiana, and Texas (USFWS, 2016).
- Select sites throughout the range to be demographically monitored. Where it is already occurring this should continue and it should be instituted at other representative sites throughout the range that are currently only monitored opportunistically for presence/absence or rough estimations of population (USFWS, 2016).
- Develop a long-term management plan based on the results of studies on genetics, the role of disturbance, and other life history studies. Specific recovery criteria that address the long-term protection and viability of Geocarpon should be developed as new information becomes available (USFWS, 2016).
- Work cooperatively with landowners to conserve privately owned sites through fee title or easement purchases or development of management agreements (USFWS, 2016).

# SPECIES ACCOUNT: *Gilia tenuiflora ssp. arenaria* (Monterey gilia)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 06/22/1992; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

An erect, densely pubescent herb with basal rosette leaves and funnel-shaped purple flowers (NatureServe, 2015).

**Taxonomy**

A member of the phlox family (Polemoniaceae). It has been observed that in the more inland areas of its distribution, Gilia tenuiflora ssp. arenaria has morphological characteristics that intergrade with G. t. ssp. tenuiflora (Dorrell-Canepa, 1994) (USFWS, 2008).

**Historical Range**

This subspecies is endemic to the Monterey Bay and Peninsula dune complexes (USFWS, 2008).

**Current Range**

Restricted to isolated sites within two coastal dune scrub communities along Monterey Bay and the Monterey Peninsula (NatureServe, 2015). Occurrences are distributed in discontinuous populations from Spanish Bay on the Monterey Peninsula north to Moss Landing in Monterey County, CA (USFWS 2008).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (NatureServe, 2015); self-pollination (USFWS, 1998)

**Lifespan**

Adult: 1 year (USFWS, 2008)

**Key Resources Needed for Breeding**

Adult: Insect pollinators (NatureServe, 2015); soils seed bank, semi-open areas (USFWS, 2008)

**Reproduction Narrative**

Adult: Entirely animal pollinated; mixture of bees, butterflies, moths, long-tongued flies, hummingbirds (NatureServe, 2015). It is an annual plant. A recent study has shown that Gilia tenuiflora ssp. arenaria may have long-lived seeds which create a relatively persistent soil seed bank (Fox et al. 2005). Gilia t. ssp. arenaria requires semi-open areas of sandy soil to germinate and to thrive (L. Madison, pers. comm. 2006; B. Collins, pers. comm. 2006; B. Delgado, pers. comm. 2006) (USFWS, 2008). The species is thought to be primarily self-pollinating based on its stamens not protruding from the flower, no observations of pollinators, and very viable seed

(Dorrell-Canepa, in litt., 1995) (USFWS, 1998).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Coastal strand (NatureServe, 2015); dune scrub, coastal sage scrub, maritime chaparral (USFWS, 2008)

**Geographic or Habitat Restraints or Barriers**

Adult: Dense vegetation (USFWS, 2008); occurs at or below 100 ft. elevation (USFWS, 1998)

**Environmental Specificity**

Adult: Narrow (USFWS, 2008)

**Tolerance Ranges/Thresholds**

Adult: Moderate (inferred from USFWS, 1998)

**Habitat Narrative**

Adult: Inhabits coastal strand (sandy beaches and dunes) (NatureServe, 2015). Gilia t. ssp. arenaria is typically associated with sandy soils of dune scrub, coastal sage scrub, and maritime chaparral vegetation types. The taxon is generally found in sparse scrub communities, and does not compete well in the denser vegetation structure often exhibited by many non-native species. (USFWS, 2008). The species occurs at elevations no higher than 30 meters (100 feet). The species is usually tolerant of small amounts of drifting sand, but tends to occur in stable sites with minimal sand accretion or deflation (USFWS, 1998).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Dust-like seeds in many desert species, assumed to be wind dispersed (NatureServe, 2015).

***Population Information and Trends***

**Population Trends:**

Not available

**Species Trends:**

3 populations extirpated since listing (USFWS, 2008)

**Number of Populations:**

24 (USFWS, 2008)

**Population Size:**

Variable from year to year; 1,665 - 25,000 depending on location (USFWS, 2008)

**Population Narrative:**

There are likely 24 currently extant occurrences of Gilia tenuiflora ssp. arenaria. Three coastal populations have likely been extirpated since the time of listing. As an annual plant, Gilia tenuiflora ssp. arenaria can go through large changes in number of individuals from year to year, and late-season rainfall can markedly affect germination and growth (Dorrell-Canepa 1994; Fox et al. 2005). Population censuses that span at least 10 years have been conducted at only a few locations. The number of individuals at Marina State Beach has fluctuated from a low of 5,000 individuals in 1987 to a high of 25,000 individuals in 1993; the number of individuals at Salinas River State Beach has fluctuated from a low of 1,665 individuals in 1987 to a high of 13,500 individuals in 1993 (CNDDB 2006) (USFWS, 2008).

***Threats and Stressors***

**Stressor:** Development (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** One of the greatest current threats to this subspecies is continuing destruction of habitat due to development. While future development will be precluded at some sites by virtue of being transferred to entities that will manage for their conservation (e.g., Big Sur Land Trust, University of California, and BLM at former Fort Ord), other sites are slated for future development. The western areas of former Fort Ord that are to be developed are relatively small in acreage, but contain a high density of individuals. Six of 11 inland occurrences (55%) on public lands are under threat of at least partial development (USFWS, 2008).

**Stressor:** Herbivory (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbivory has been observed by individuals conducting surveys and research on this subspecies (L. Fox in litt. 2006; T. Hyland pers. com. 2006). This poses a potentially serious threat to this subspecies (Service 1998), but actual effects are currently unknown. Herbivory has been found to increase with an increase in cover for small herbivorous species such as rabbits (McGraw 2004) (USFWS, 2008).

**Stressor:** Nonnative plants (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** One of the main threats to this taxon is competition from invasive, non-native species (57 FR 27848). These species are typically able to colonize disturbed habitats and quickly reach high densities. In coastal areas, iceplant (Carpobrotus ssp.) and exotic annual grasses are the most problematic invasive species for Gilia tenuiflora ssp. arenaria. In inland areas, jubata grass (Cortaderia jubata), iceplant, and annual grasses (Festuca spp., Avena spp., and others) are the most problematic invasive species for G. t. ssp. arenaria (Mactec Engineering and Consulting Incorporated 2002, 2003, and 2004). Annual grasses are particularly difficult to remove once they have colonized an area. Non-native grasses decrease the suitability of habitat for G. t. ssp. arenaria due to excessive soil stabilization and litter accumulation (Pickart 1997, Russo et al. 1988) (USFWS, 2008).

**Stressor:** Inadequate vegetation management (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Other human-caused factors that could affect the inland occurrences at former Fort Ord, aside from those previously mentioned, are vegetation management activities that fail to create or maintain the open, sandy conditions necessary for continued survival and colonization by Gilia tenuiflora ssp. arenaria. These include the elimination of fire from chaparral communities, poorly timed (e.g., wet season) prescribed fires, the use of pre-fire treatments that result in increases in non-native species, and the use of mechanical vegetation clearing that leaves the chipped vegetation on the soil surface (Zander and Associates 2007) (USFWS, 2008).

***Recovery***

**Reclassification Criteria:**
1. Habitat occupied by the taxon that is needed to allow delisting has been secured with long-term commitments and, if possible, endowments to fund conservation of the native vegetation (USFWS, 2008).

2. Management measures are being implemented to address the threats of invasive species and other problems, including grazing, pedestrians, and off-road vehicles at some sites (USFWS, 2008).

3. Monitoring indicates that management actions are successful in reducing threats of invasive non-native species (USFWS, 2008).

4. Additional restored habitat has been secured, with evidence of either natural or artificial long-term establishment of additional populations, and long-term commitments (and endowments, where possible) to fund conservation of the native vegetation (USFWS, 2008).

**Delisting Criteria:**
1. Habitat throughout this taxon's range is protected from encroachment of non-native species, recreational activity (including off-road vehicles [ORVs] and horses), and development (USFWS, 2008).

2. Habitat throughout this taxon's range is restored to native vegetation at proper densities to allow natural colonization by this plant (USFWS, 2008).

3. Habitat throughout this taxon's range is monitored sufficiently to assure that local threats are spotted promptly (USFWS, 2008).

4. Enough plants are at enough locations throughout this taxon's range and within the protected vegetation to reasonably assure the viability of the taxon (USFWS, 2008).

5. (Re)introduced populations should be naturally reproducing in vegetation that also appears to be persisting without excessive maintenance or "gardening" (USFWS, 2008).

6. The determination that delisting is possible must be based on at least 15 years of monitoring for the endangered taxa, to include wet and drought years (USFWS, 2008).

**Recovery Actions:**

- Protect existing populations and habitats (USFWS, 1998).
- Minimize the threats to the plant (USFWS, 1998).
- Develop management strategies incorporating ecological and land use strategies (USFWS, 1998).
- Manage populations and habitats to achieve delisting (USFWS, 1998).
- Monitor population trends to evaluate recovery success (USFWS, 1998).
- Coordinate recovery actions to protect other listed and sensitive species (USFWS, 1998).
- Develop and implement an outreach program (USFWS, 1998).
- A reworking of the recovery criteria listed in the recovery plan should be undertaken. The specific population sizes recommended in delisting criteria #4 are difficult to correlate with the observed distribution of occurrences in the field. Using specific numbers for annual species with persistent seed banks, as previously discussed, is not necessarily valuable as an indicator of species status. A more useful indicator should be identified to indicate the quality and status of the habitat that is supporting the various populations (USFWS, 2008).
- Improved coordination between State and Federal agencies and local landowners would increase information sharing and maximize conservation and recovery efforts. Aside from the work being done for the re-use of former Fort Ord properties, very little communication is currently occurring between different parties involved with the management of this subspecies. Little or no information was available for many of the privately owned parcels of land believed to support occurrences of this subspecies. Attempts to establish conservation easements or acquire properties containing coastal dune habitat that supports this and other rare and endangered species should be made. Conducting surveys of these lands to determine whether or not extant populations still exist would be valuable. Directed oversight through coordination of information, overall strategies, and implementation of uniform methodologies would allow for implementation of much more powerful adaptive management techniques (USFWS, 2008).
- Long-term monitoring programs at more known occurrences of Gilia tenuiflora ssp. arenaria should be undertaken. Due to the strong influence of annual precipitation on observable population size, this monitoring should be habitat-based or in another way address the issue of dormant soil seed banks. This monitoring should include monitoring of pre-fire vegetation and herbivory rates on portions of former Fort Ord that will be burned under the prescribed burn plan in the Fort Ord draft HCP. Information regarding control of non-native plants, community structure, herbivory, and germination of G. t. ssp. arenaria from persisting seed banks or new colonization in cleared areas may provide invaluable information for future management efforts (USFWS, 2008).
- Initiate surveys to locate suitable habitat for out-planting sites in areas that are managed for conservation and that could support Gilia tenuiflora ssp. arenaria. For instance, outplantings to areas such as Salinas River National Wildlife Refuge could complement recovery efforts elsewhere. If populations were to become established in such areas, they could also function as seed bank sources or reserves for other populations that are at risk of extirpation (USFWS, 2008).
- Seed collection should be initiated where populations are at risk of extirpation, including at former Fort Ord. Seeds should be stored at appropriate facilities, such as the Rancho Santa

Ana Botanic Garden, for future greenhouse seed production, genetic analyses, or direct recovery plantings. In conjunction with this, genetic analyses should be initiated to determine the geographic boundaries of Gilia tenuiflora ssp. arenaria and G. t. ssp. tenuiflora and the level of interbreeding, if any, occurring in the wild populations. This should be done prior to out-plantings from questionable populations in order to maintain genetic distinctiveness and accurately assess habitat requirements for each taxon (USFWS, 2008).

- Initiate controlled burn studies on former Fort Ord to determine the recovery potential of inland populations lost to unnaturally dense shrub communities. This should be undertaken to determine the conservation value of potential reserve areas prior to the finalization of proposed HCPs (USFWS, 2008).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: The following actions are recommended based on the current 5-year review: 1. Use the recently completed range-wide surveys to establish and implement a series of monitoring areas to evaluate population trends throughout the range. 2. Convene a working group of land managers to discuss funding for invasive species control, monitoring, restoration, and best management practices for Monterey gilia. 3. Expand invasive species control programs throughout the coastal occurrences of Monterey gilia. 4. Establish ex situ seed banks for long term preservation of Monterey gilia. 5. Conduct genetic analyses and collect morphological data where overlap between closely related subspecies occur. (USFWS, 2020)

# SPECIES ACCOUNT: *Gilia tenuiflora ssp. hoffmannii* (Hoffmann's slender-flowered gilia)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 07/31/1997; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

An annual herb, 6-12 cm tall. Flowers (April) are purplish and funnel-shaped, the top of the "funnel" widening to flat, pink lobes (NatureServe, 2015).

**Taxonomy**

A member of the phlox family (Polemoniaceae) (USFWS, 2009). In 1959, Munz included the varieties of tenuflora as subspecies, including ssp. hoffmannii, as per a 1956 treatment by the Grants (Munz and Keck 1973). This nomenclature was used in the latest treatment of the genus (Day 1993). Of the four subspecies of G. tenuiflora, the subspecies hoffmannii is the only one that occurs in southern California (USFWS, 2000).

**Historical Range**

Known from three locations on Santa Rosa Island of the northern Channel Islands. A collection was made by Reid Moran from the “arroyo between Ranch and Carrington Point” in 1941 (Rutherford and Thomas 1994). In 1994, Kathy Rindlaub located a population of 88 individuals covering 2 square meters (m) (21 square feet (ft.)) that reasonably corresponded to Moran’s site, and was grazed by cattle (Rindlaub 1994). The other historical location is at the type locality near East Point, where the species is still found today. It was not until 1994 surveys that Rindlaub discovered a third population that was 5 comprised of three colonies at Skunk Point on Santa Rosa Island. This population was comprised of approximately 3,000 to 3,500 individuals in 1994 and had been cropped by cattle (Rindlaub 1994) (USFWS, 2009).

**Current Range**

It is restricted to Santa Rosa Island off the coast of southern California. A third population was discovered in 1994 at Skunk Point (Rindlaub 1994) (USFWS, 2009).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (inferred from USFWS, 2009)

**Lifespan**

Adult: 1 year (USFWS, 2009)

**Breeding Season**

Adult: April - May (USFWS, 2009)

**Key Resources Needed for Breeding**

Adult: Winter and spring rains (USFWS, 2009); insect pollinators (USFWS, 2000)

**Reproduction Narrative**

Adult: This is an annual plant. Plants germinate with winter or spring rains, primarily in January or February, and flowers and produces seed by late April or early May. An individual can produce from 200 to several hundred seeds (Faulkner and Chaney 2007) (USFWS, 2009). A small beefly (Otigodranes spp., Bombyliidae) was observed to be the most numerous and effective pollinator, and a soft-winged flower beetle (Melyridae) was observed as a casual visitor in a pollination study on south coast range Gilia tenuflora populations (Grant and Grant 1965). It is unknown if these species or their counterparts occur on Santa Rosa Island (USFWS, 2000).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Dune scrub (NatureServe, 2015); lupine scrub (USFWS, 2000)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2000)

**Habitat Narrative**

Adult: Inhabits sandy soils with dune scrub vegetation. (NatureServe, 2015). Gilia tenuiflora ssp. hoffmannii thrives in open patches of habitat where bare ground ranges from about 50 to 95 percent (Faulkner and Chaney 2007). Gilia tenuiflora ssp. hoffmannii can be found growing on ancient stabilized sand dunes on the northeastern side of Santa Rosa Island where soil textures are characterized by loamy sand. The species prefers open habitat among other low herbaceous vegetation where competition for resources is low (Faulkner and Chaney 2007) (USFWS, 2009). Hoffmann’s slender-flowered gilia is also a component of lupine scrub vegetation (USFWS, 2000).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Not available

**Species Trends:**

Stable (USFWS, 2009)

**Number of Populations:**

3 (USFWS, 2022)

**Population Size:**

Variable depending on year; East Point: 20,000 - 256,000; Skunk Point: 3,000 - 3,500 (USFWS, 2009).

**Population Narrative:**

At the time of listing, three populations of Gilia tenuiflora ssp. hoffmannii were known on Santa Rosa Island; currently there are two known populations. Gilia tenuiflora ssp. hoffmannii populations exhibit large inter-annual fluctuations. The East Point and Skunk Point populations appear to be relatively stable since the time of listing (USFWS, 2009).

***Threats and Stressors***

**Stressor:** Grazing (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In response to browsing, Gilia forms multiple side branches, and although a branched plant may produce a greater number of flowers, this does not necessarily increase the fecundity of the plant (Painter and Belsky 1993). Flowers produced later in the season out of synchrony with pollinator activity results in lower seed productivity (Painter in litt. 1997 as referenced in Service 1997). In the step-down narrative portion of the recovery plan, effective elimination of habitat damage from nonnative animals, particularly the deer and elk on Santa Rosa Island, was considered one of the most important management tasks needed for recovery of this species and other listed plant taxa (Service 2000). Some progress has been made toward eliminating nonnative animals from Santa Rosa Island since the time of listing. Although habitat conditions on Santa Rosa Island show the effects of long-term grazing, the USGS believes that at the landscape level, conditions are improving (McEachern in litt. 2007) (USFWS, 2009).

**Stressor:** Stochastic events (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Gilia tenuiflora ssp. hoffmannii is threatened by the risk of stochastic extinction due to small population size and limited distribution (Service 2000). In particular, the small size of each population makes it difficult for this species to persist while sustaining the impacts of soil damage and habitat alteration from nonnative species. The species remains vulnerable to extirpation due to its small population size, high inter-annual variability in plant numbers, and limited distribution (USFWS, 2009).

**Stressor:** Nonnative species (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Competition from nonnative grasses currently threatens the existence of Gilia tenuiflora ssp. hoffmannii and its habitat. An invasive annual grass, false brome (Brachypodium distachyon), was recently discovered within Gilia tenuiflora ssp. hoffmannii habitat on East Point on Santa Rosa Island. Both false brome and Gilia tenuiflora ssp. hoffmannii prefer open patches

of habitat. The invasive grass has the potential to displace Gilia as it fills in the open areas of habitat (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Gilia tenuiflora ssp. hoffmannii may be particularly threatened by climate change because its geographic distribution is so narrow and its current range is unlikely to overlap regions that would be climatically favorable in the future (Levine et al. 2008). This potential threat is particularly acute for species on islands because they are unable to disperse to more favorable habitat as the environment changes. Sea level rise as a result of climate change has the potential to adversely affect Gilia tenuiflora ssp. hoffmannii and its habitat. In particular, ocean bluffs along the coast will be subject to greater and more frequent wave attack, resulting in erosion and shoreline retreat (CCC 2001). In addition, Gilia tenuiflora ssp. hoffmannii may also be threatened by climate change because of its germination cues. According to the study conducted by Levine et al. (2008), Gilia tenuiflora ssp. hoffmannii exhibited the highest germination rates in the years of the coldest germination-inducing storms (USFWS, 2009).

***Recovery***

**Reclassification Criteria:**
Establish 10 populations on Santa Rosa Island that are stable or increasing for a period of 15 years that includes the normal precipitation cycle. A precipitation cycle includes periods of drought and wet years, with annual rainfall starting at 100 to 135 percent of average, dropping below 65 percent of average, and returning to at least average (Service 2000) (USFWS, 2009).

Recovery Priority Number: 6

**Delisting Criteria:**
1. Discover or establish five additional populations (USFWS, 2009).

2. No decline after downlisting for 10 years (USFWS, 2009).

**Recovery Actions:**
- Support and intensify active control programs where herbivory or habitat alteration by alien animals exists (USFWS, 2000).
- Develop and implement a plan to achieve the goals and standards of the Conservation Strategy. The Conservation Strategy is a draft strategy for conservation of island resources prepared by biologists from the National Park Service, U.S. Fish and Wildlife Service, and the U.S. Geological Survey, Biological Resources Division. This Strategy is essentially a primer or guide that provides the basis for the recovery of the species in this recovery plan and should be referred to as a supporting document (USFWS, 2000).
- Restore habitats and control competitive weeds for long-term management of the species and its habitats (USFWS, 2000).
- Conduct thorough surveys for the species (USFWS, 2000).
- Conduct research that aids in the conservation and recovery of the species (USFWS, 2000).

- Store seeds at facilities certified by the Center for Plant Conservation and develop successful seed germination and propagation techniques (USFWS, 2000).
- Develop successful outplanting techniques (USFWS, 2000).
- The USGS and NPS should seek additional funding to continue field surveys and monitoring, demographic monitoring, population viability analyses, and further investigations into recovery projects (USFWS, 2009).
- The Service should work cooperatively with NPS and USGS to refine the generalized downlisting criteria to take into consideration new information. Attaining the recovery criteria outlined in the recovery plan is unrealistic for this species (USFWS, 2009).
- The Service should work cooperatively with NPS and USGS to refine delisting criteria to emphasize long-term population growth trends rather than short-term gains or declines in the species (USFWS, 2009).
- The USGS and NPS should investigate the community-level factors that influence population abundance, distribution, and demographic trends of the species (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Continue monitoring the East Point population of Gilia tenuiflora ssp. hoffmannii. 2. Better define suitable germination and growth microhabitat for Gilia tenuiflora ssp. hoffmannii, especially in relationship to non-native grass Brachpodium distachyon competition. 3. Control and strive for eradication of Brachypodium distachyon at the East Point occurrence. 4. Establish a regular survey monitoring schedule for Gilia tenuiflora ssp. hoffmannii at the Skunk Point and Carrington Point populations. 5. Collect seed, especially from the Skunk Point and Carrington Point populations, for restoration seed bulking, and augment these populations with population-specific seed to boost population sizes. 6. Improve the completeness of coverage of Gilia tenuiflora ssp. hoffmannii in conservation seed banks, with all populations over a wider range of years (USFWS, 2022).

# SPECIES ACCOUNT: *Grindelia fraxinipratensis* (Ash Meadows gumplant)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 05/20/1985; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

It is an erect biennial or more commonly a perennial herb, reaching 25 to 40 inches in height and has yellow flowers with heads measuring 0.3 to 0.4 inches in diameter (Mozingo and Williams 1980). The gumplant genus is so named because of their very sticky (gummy) flower heads (USFWS, 2007).

**Taxonomy**

Kartesz (1999) used the spelling 'fraxinopratensis'. According to comments in the Index to California Plant Names (part of the Jepson Interchange for California Floristics, April 2012) "fraxinipratensis" is the correct spelling. It is a member of the Asteraceae (sunflower family) (NatureServe, 2015).

**Historical Range**

It is endemic to the greater Ash Meadows region in Nye Co., Nevada and Inyo Co., California. (NatureServe, 2015). Cochrane (1981) believes that its distribution was continuous prior to perturbation for agriculture (USFWS, 1990).

**Current Range**

Most of its distribution is within the Ash Meadows National Wildlife Refuge (Refuge). One population occurs outside the Refuge boundary in the Carson Slough, primarily within the Ash Meadows Area of Critical Environmental Concern (ACEC) managed by Bureau of Land Management (BLM) in Nevada. Based on anecdotal observations and assessments of biologists, it appears Ash Meadows gumplant distribution has likely increased since the species was listed (Service 2001) (USFWS, 2008).

**Critical Habitat Designated**

Yes; 5/20/1985.

**Legal Description**

On May 20, 1985, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Grindelia fraxinipratensis (Ash Meadows gumplant) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes two critical habitat units (CHUs), in California and Nevada (50 FR 20777-20794).

**Critical Habitat Designation**

The critical habitat designation for Grindelia fraxinipratensis includes two CHUs in Inyo County, California and Nye County, Nevada (50 FR 20777-20794).

Nevada, Nye County, Ash Meadows.

California, Inyo County, Ash Meadows.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Grindelia fraxinipratensis critical habitat consists of one component (50 FR 20777-20794):

Known primary constituent elements include saltgrass meadows along streams and pools or drier areas with alkali clay soils.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (inferred from USFWS, 2008)

**Lifespan**

Adult: 2+ years (NatureServe, 2015)

**Breeding Season**

Adult: Summer - fall (USFWS, 1990)

**Reproduction Narrative**

Adult: It is a biennial or more commonly a perennial plant (NatureServe, 2015). In a good year, each plant may produce several hundred seeds (Lane 1993) (USFWS, 2008). It flowers during the summer and autumn (USFWS, 1990).

**Habitat Type**

Adult: Terrestrial, riparian, wetland (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Saltgrass meadows (NatureServe, 2015); ash-screwbean mesquite woodlands, desert shadscale scrub, clay barrens (USFWS, 2008)

**Environmental Specificity**

Adult: Very narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Inhabits saltgrass meadows along streams and pools; occasionally occurs in alkali clay soils in drier areas. Dependent on moisture available from streams (NatureServe, 2015). Ash Meadows gumplant is found primarily in the vicinity of ash-screwbean mesquite woodlands and desert shadscale scrub vegetation. It occasionally occurs sparsely in drier shadscale habitats or in the unique clay barrens. Over 30 percent of the Refuge has been mapped as wet meadow and is dependent on flows from several dozen springs and seeps (Otis Bay 2006). These springs and seeps are fed by an extensive groundwater system (USFWS, 2008). Extant populations are scattered throughout the area at sites that have not been disturbed or have been allowed to restabilized from disturbance for extended periods (USFWS, 1990).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Dispersal of the small seed is most likely accomplished by strong winds because they could be blown for some distance. Those seeds which fall within close proximity of the parent plant could be further transported by water during the winter rainy season or during summer flash floods. Mammals and birds may also be responsible for dispersal of seeds (Cochrane 1981) (USFWS, 2008).

***Population Information and Trends***

**Number of Populations:**

2 Population Services (USFWS, 2020)

**Population Size:**

~ 898,404 (USFWS, 2020)

**Population Narrative:**

The Ash Meadows gumplant is concentrated in three main populations and several smaller ones over an area of approximately 2,260 acres (BLM and Service 2000). There is little quantitative population or demographic data to describe trends for the Ash Meadows gumplant. The 2000 Environmental Assessment to withdraw lands from mineral entry estimated the entire Ash Meadows gumplant population to contain 81,000 plants within 2,260 acres (BLM and Service 2000). This number, based on visual estimates, is a serious underestimate of the total number of plants because a 2002 survey of the California population, which used transects to develop a population estimate, estimated 241,514 ± 69,660 plants within 88 acres (Soil Ecology and Restoration Group 2004) (USFWS, 2008).

***Threats and Stressors***

**Stressor:** Groundwater pumping (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Groundwater availability is a regional phenomenon; thus groundwater pumping in the vicinity would impact the entire Ash Meadows ecosystem, including habitat that supports the Ash Meadows gumplant. Groundwater rights in Nevada are regulated by the State Engineer. In theory, the water rights owned by the Refuge are protected. However, in recent hearings, the National Park Service testified the number of water rights issued by the State of Nevada for the Amargosa Valley has grossly exceeded sustainable withdrawal levels and the resource is over-allocated (Baldino 2006a). It is important that current groundwater monitoring continues to ensure regional extractions do not affect the species (USFWS, 2008).

**Stressor:** Nonnative species (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** As in the case of noxious agricultural weeds present on the Refuge, many invasive species have adaptations that allow them to outcompete native vegetation and colonize previously undisturbed habitat. The wet meadows that support Ash Meadows gumplant provide an especially favorable environment for invasive species that would not otherwise be able to survive in the desert. On the Refuge, there are an estimated 4,460 acres of former agricultural fields previously used for crop production and livestock grazing (Service, 2006). These fields, situated adjacent to two of the largest Ash Meadows gumplant populations, are now largely monocultures of Russian knapweed, bassia and Malta star thistle. In many parts of the Refuge, these non-native species are expanding beyond the fields into surrounding Ash Meadows gumplant habitat (Service 2006). Fire facilitated by non-native species is a new threat to Ash Meadows gumplant not identified in the original listing. Non-native species are known to alter fire regimes and are a threat to biodiversity (Brooks et al. 2004). In some areas of the Refuge, non-native salt cedar trees (Tamarix sp.) and red brome grass (Bromus madritensis) increase the ease with which fire spreads through riparian corridors and along the spring channels that comprise Ash Meadows gumplant habitat. In the past two years, three major fires (the Meadows Fire, Longstreet Fire, and Ash Fire) have burned 144 acres (roughly 6%) of Ash Meadows gumplant habitat. Following the Meadows Fire, Russian knapweed populations exploded to create monocultures that now likely prevent regrowth and colonization of native vegetation, including the Ash Meadows gumplant (Baldino 2006a). Ash Meadows gumplant habitat is extremely vulnerable to being altered by non-native species. If left untreated the consequences would likely be decreases in the population of Ash Meadows gumplant, both due to competitive exclusion, and additional population reductions resulting from increased fire frequencies (USFWS, 2008).

**Stressor:** Surface mining (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Active mineral claims within Ash Meadows could cause direct loss of habitat, as well as indirect impacts to the species by diverting or draining water away from habitat during mining activities. There are 29 active mining claims on BLM lands in and near the Refuge and critical habitat for the species (BLM 2007). Approximately 45 percent of the occupied Ash Meadows gumplant habitat within the Refuge boundary is on BLM and Service lands with a high mineral potential and are open to public minerals (BLM and Service 2000) (USFWS, 2008).

**Stressor:** Off-highway vehicles (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Illegal OHV activity has recently become a problem again on the Refuge, possibly due to a fence in need of repair (Baldino 2006b). Repairs to the fence and monitoring of OHV activity will be an ongoing necessity at the Refuge (USFWS, 2008).

**Stressor:** Stochastic events (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Small populations have an inherent risk of extinction due to stochastic and natural catastrophic events. Fire and flooding are natural catastrophic events that occur within Ash Meadows gumplant range. Given the species' distribution on the Refuge, fire is the catastrophic event most likely to affect the Ash Meadows gumplant. Although possible, it is unlikely that any one fire could affect a major portion of the Ash Meadow gumplant distribution throughout its entire range. However, increased fuel loads from non-native species can lead to more frequent fires in the Mojave Desert (Brooks and Pyke 2001) (USFWS, 2008).

**Stressor:** Feral Horses (USFWS, 2020)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** We received a correspondence from Rancho Santa Ana Botanic Garden (2019). They state results are preliminary and not yet available for surveys of the Ash Meadows gumplant in California. They also reported that feral horses have been documented in occupied Ash Meadows gumplant habitat in lower Carson Slough in 2018 and 2019, and thus remain a threat. We received a recent monitoring report from Ash Meadows NWR (Pyramid Botanical Consultants, 2019). The results indicate the species is still present at all previously known populations within the refuge, and species distribution remains the same as described in our most recent 5-year review (Service, 2008). (USFWS, 2020)

***Recovery***

**Reclassification Criteria:**
Not available

Recovery Priority Number: 14

**Delisting Criteria:**
1. Secure, protect, and maintain the species in natural vegetation corridors and adjacent buffer areas for gene flow and dispersal of the species within essential habitat (USFWS, 2008).

2. Native plant communities and aquatic communities have been reestablished to historic structure and composition within all essential habitat (USFWS, 2008).

3. The species is present in all the sites that it has historically occupied (USFWS, 2008).

4. The listed plant has a frequency value equal to or greater than the frequency value determined by comparison with unaltered reference sites as an indicator of a self-sustaining plant populations (USFWS, 2008).

**Recovery Actions:**
- Secure habitat and water sources for the Ash Meadows ecosystem (USFWS, 1990).
- Conduct research on the biology of the species (USFWS, 1990).
- Conduct management activities within essential habitat (USFWS, 1990).
- Reestablish populations/monitor new & existing populations (USFWS, 1990).
- Determine/verify recovery objectives (USFWS, 1990).

- The population monitoring described in the Recovery Plan should be carried out (USFWS, 2008).
- The Refuge is implementing many restoration projects that could benefit the Ash Meadows gumplant. To document recovery of the Ash Meadows gumplant, these projects should include pre- and post-site sampling to verify and quantify that restoration actions are benefiting the species (USFWS, 2008).
- Non-native weeds are a major threat to the Ash Meadows gumplant, and the IPM Plan is an important step towards addressing this problem. Long-term funding should be secured for non-native species control on the Refuge (USFWS, 2008).
- Interactions between fire and non-native weeds within Ash Meadows gumplant habitat and effects on the Ash Meadows gumplant need to be studied (USFWS, 2008).
- Surface mining remains a threat to the Ash Meadows gumplant. Service and BLM lands with a high mineral potential must be withdrawn from future mineral entry. In addition, existing mining claims should be acquired when possible. Unless these mineral rights are purchased or transferred to the Service, a program needs to be put in place to renew existing mineral withdrawals every 20 years (USFWS, 2008).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS I. Monitor compliance with Nevada Revised Statute Order 1197A (January 12, 2018), Curtailment of New Appropriations of Groundwater within the Amargosa Valley Hydrographic Basin 230, that prohibits new applications for water or water diversions within 25 miles of Devils Hole (and by proximity Ash Meadows NWR). Order 1197A supersedes 1197, which imposed similar regulations at 10 miles from Devils Hole. Water levels in Devils Hole are affected by pumping centers in the Amargosa Desert and the Ash Meadows groundwater basins (Halford and Jackson 2020). II. Collaborate with the Ash Meadows NWR to implement the Desert National Wildlife Refuge Complex – Ash Meadows, Desert, Moapa Valley, and Pahranagat National Wildlife Refuges Final Comprehensive Conservation Plan and Environmental Impact Statement, Volume I – August 2009 (Service 2009) and also the Draft Ash Meadows Natural Resource Management Plan in review (Service 2020); and III. Support Ash Meadows gumplant research at the Ash Meadows NWR to monitor the population as identified in the Recovery Plan for the Endangered and Threatened Species of Ash Meadows (Service 1990); and IV. Monitor the future activity of mineral rights in the Ash Meadows area. The BLM ACEC surrounding the refuge is withdrawn from mining and entry until 2029 (PLO# 7737, signed November 2nd, 2009), but requires renewal every 20 years. Mining can still occur on private inholdings within the refuge, but no active mining permits exist at this time. (USFWS, 2020)

# SPECIES ACCOUNT: *Hackelia venusta* (Showy stickseed)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 03/08/2002; Pacific Region (Region 1)

**Physical Description**

Hackelia venusta is a moderately stout perennial plant, 20-40 cm (8-16 inches) tall, with numerous flowering stems arising from a slender taproot. Large showy flowers are white or white washed with blue, with five lobes topping the end of a short corolla tube. Flowering occurs in April or May. Leaves are basal and numerous on the flowering stem. The fruit consists of four prickly nutlets which drop near the plant but the spurred fruit can be dispersed by clinging to the hair of passing animals (USFWS 2007). (NatureServe, 2015)

**Taxonomy**

This species was first described within the genus Lappula (annual plants) but later transferred to the genus Hackelia (perennial plants). Carr (1974) undertook a taxonomic study of the genus in western North America and recognized Hackelia venusta as a morphologically uniform, distinct species that exhibited little variability. A further taxonomic review (Harrod et al 1999) indicated that certain high elevation populations previously assigned to H. venusta were a distinct undescribed species, Hackelia taylori (Harrod et al. in review). Harrod and his colleagues (1999) further outline that no affinities exist between the low and high elevation taxon, nor with nearby populations of H. diffusa var. arida. (NatureServe, 2015)

**Historical Range**

See current range/distribution.

**Current Range**

This species is known from one location only in Chelan County, Washington. (USFWS, 2011)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (outcrossing) (USFWS, 2007)

**Lifespan**

Adult: >10 years (USFWS, 2007)

**Dependency on Other Individuals or Species**

Adult: Insect pollinators (USFWS, 2007)

**Breeding Season**

Adult: April to June (USFWS, 2007)

**Reproduction Narrative**

Adult: Hackelia venusta is perennial, and individual plants can live for at least 10 years. Flowers begin to open in late April, and new flowers are continuously added to each inflorescence until late June. By mid-June, the lowest flowers have nearly mature fruits. Dispersal begins with the lowest flowers and continues for several weeks into early July (Gamon 1997). It is possible that H. venusta could be pollinated by moths; however, this is unlikely because the relatively long tongues of moths are an apparent mismatch with the short corolla tube length of H. venusta. If the species is insect pollinated, bee and fly species appear to be the most likely candidates, as they have shorter tongues that better match the corolla tube length of H. venusta. In the past, H. venusta has been assumed to be an obligate outcrosser (Harrod 1999). Three pollinators were verified on the H. venusta plants: two bees, Andrena nigrocaerulea and Protosmia rubifloris, and one fly, Eulonchus sp. This work has indicated H. venusta is primarily outcrossing, with the possibility of geitonogamous selfing (pollination by other flowers on the same plant); autogamous selfing (pollination within a single flower) is possible since the stigma and anthers do appear to be in close proximity with one another at anthesis, but is unlikely to be a major contributor because most of a flower's pollen is produced before its stigma is receptive (J. Taylor, pers. comm. 2005, 2007). (USFWS, 2007)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Bare rock/talus/scree, cliff, forest- conifer, forest/woodland (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Found at elevations between 472 meters (1,550 feet) to 823 meters (2,700 feet); prefers open, sparsely vegetated areas (shade intolerant) (USFWS, 2007)

**Spatial Arrangements of the Population**

Adult: Scattered (USFWS, 2007)

**Environmental Specificity**

Adult: Very narrow. Specialist or community with key requirements scarce. (NatureServe, 2015)

**Habitat Narrative**

Adult: Hackelia venusta is shade-intolerant (R. Carr, pers. comm. 1998) and grows in openings within Pinus ponderosa (ponderosa pine) and Pseudotsuga menziesii (Douglas-fir) forest types. This vegetation type is described as the Douglas-fir zone by Franklin and Dyrness (1973). Common associates include Penstemon subserratus (finetooth beardtongue), Phacelia hastata (silverleaf phacelia), Lomatium triternatum (nineleaf biscuitroot), Lupinus wyethii (Wyeth's lupine), Eriogonum compositum (arrowleaf buckwheat), Eriogonum umbellatum var. hypoleium (sulphur-flower buckwheat), Hieracium cynoglossoides (houndstongue hawkweed), and Pseudoroegneria spicata (bluebunch wheatgrass). Hackelia venusta is found on open, steep slopes (minimum 80 percent inclination) of loose, well-drained, granitic weathered and broken rock fragmented soils, and on ledges and cracks on granitic cliff faces, at elevations between 472 meters (1,550 feet) to 823 meters (2,700 feet). Aspect ranges from 192 degrees (south-southwest [SSW]) to 310 degrees (west-northwest [WNW]), with most plants at an aspect of 265 degrees (west [W]). Plants are found on concave, convex, or flat slopes. The primary subpopulation is on an area of slope between drainages, but a number of the smaller subpopulations occur along the steep south-facing sides of dry drainages or on vertical cliff faces. Hackelia venusta appears to be somewhat adapted to natural and possibly human-caused substrate disturbance (R. Carr, pers. comm. 1998), and occurs within the right of way along both sides of Highway 2. Although potential habitat for this species exists elsewhere in Tumwater Canyon, and occasionally single plants are seen elsewhere along Highway 2, no other populations have yet been found. Wildfires play a role in maintaining open, sparsely vegetated sites as suitable habitat for Hackelia venusta, a requirement of this shade-intolerant plant (R. Carr, pers. comm. 1998, in litt. 2000). The range of Hackelia venusta has been reduced to a small single population occurring in a scattered distribution across roughly 16 hectares (40 acres) in Tumwater Canyon. (USFWS, 2007)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Most nutlets seem to fall directly to the ground around the parent plant, but the topography is so steep and unstable that many nutlets are carried downslope. Small concave areas near parent plants often have seedlings (L. Malmquist, pers. comm. 2003). The prickly nutlets are also well adapted for dispersal by adhesion to the coats of passing animals (Gamon 1997). (USFWS, 2007)

***Population Information and Trends***

**Number of Populations:**

1 core pop, 5 outplanted with limited success (USFWS, 2020)

**Population Size:**

~477 at core pop and an unknown number of reintroduced (USFWS, 2011)

**Population Narrative:**

The core population was last surveyed in 2012 when 477 plants were documented (Fertig 2019, p. 36-37). Since 2012 only outplanting plots have been surveyed. The core population has not been surveyed since 2012 due to concerns about the potential for on foot surveys to damage seedlings and decrease the stability of the granitic sandy soils where the plants occur in unstable, steep slopes. Visual surveys indicate the species is still present at the core population without noticeable change, but no quantitative assessment of the core population has occurred since 2012. Implementation of recovery actions since 2011 include seed collection, growing plants from seed at the UW Rare Care Program and conducting outplantings in Tumwater Canyon and Icicle Creek Canyon in 2015 and 2019. A total of 228 individuals were planted at four sites in Tumwater Canyon adjacent to the core population in 2015 and another 39 were reintroduced to a former outplanting site near Icicle Creek (Arnett and Goldner 2017). According to the most recent surveys in May of 2020 by the UW Rare Plant Care Program the overall survival rate of the 2015 outplantings is 22 percent (with only three plants remaining at the Icicle Creek site) (Gibble 2020). In 2019 seedlings were observed at the outplanting sites and in 2020 two, second year plants were observed in the Tumwater Canyon outplanting site. In October of 2019, approximately 200 plants were planted at three plots adjacent to the core population and between the 2015 outplanting plots in Tumwater Canyon. The first year survival rate of these outplantings was 61 percent, which was much lower than the first year survival rate of the 2015 outplantings (80 percent survival rate). Evidence indicated 85 percent of the plants survived the winter, and most of the loss occurred in April, which was much drier than normal. Highest mortality occurred at the sites with the most sun exposure and least shade. (Gibble 2020). One new outplanted population was also planted in October of 2019 approximately 1.5 miles north from the core population in Tumwater Canyon on an area of Forest Service land with similar soils and aspect to the core population. The new outplanted population consisted of approximately 100 individuals. When surveyed in May of 2020, the plants at the new population north of the core population had an overall survival rate of 37 percent, with approximately half of the mortality occurring over the winter and half in the spring. (Gibble 2020). (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Plant succession (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The primary loss of habitat for Hackelia venusta has resulted from changes in habitat due to plant succession in the absence of fire. Fire suppression has been a factor in reducing the extent of the Tumwater Canyon population (Gamon 1988a, b; D. Werntz, in litt. 2000), and most likely the few hundred acres of occupied habitat recorded in 1968 (Gentry and Carr 1976) represented a population that had already been reduced in both numbers and range due to fire suppression activities that had been ongoing for many years. Historically, fuels in the forest type where H. venusta is found were rarely at high levels because of the frequent fires that consumed forest floor fuels and pruned residual trees (Agee 1993). In the past, fires suppressed the encroachment of woody vegetation and maintained open areas presumably more conducive to H. venusta reproduction and growth. As described above, wildfires play a role in maintaining open, sparsely vegetated sites as suitable habitat for this shade-intolerant species (R. Carr, pers. comm. 1998; D. Werntz, in litt. 2000). (USFWS, 2007)

**Stressor:** Non-native plants (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Two nonnative, Washington State-listed noxious weeds (Washington Administrative Code Chapter 16-750 and Revised Code of Washington Chapter 17-10) occur within the habitat of Hackelia venusta in Tumwater Canyon. Linaria dalmatica (dalmatian toadflax) and Centaurea diffusa (diffuse knapweed) are present along the roadside, and the former also occurs above the main portion of the population (F. Caplow, pers. obs. 2004). During visits to the H. venusta population in 1995 through 1998, U.S. Fish and Wildlife Service staff noted that the cover and distribution of the noxious weeds had increased over this time period (T. Thomas, pers. obs. 1998). Both of these noxious weeds outcompete many native plant species through uptake of water and nutrients, interference with photosynthesis and respiration of associated species, and production of compounds that may directly affect seed germination and seedling growth and development. Without intervention, these species have the ability to outcompete H. venusta and replace native vegetation, and eventually dominate the site (J. Wentworth, King County Noxious Weed Control Board, in litt. 2001). (USFWS, 2007)

**Stressor:** Highway maintenance (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Highway maintenance activities are an ongoing threat to the population of Hackelia venusta. The highway is sanded during winter months, and de-icers are also occasionally applied, affecting the immediate roadside habitat where H. venusta is found. Since 1998, the Washington Department of Transportation has been using de-icers on the roadway during winter months. The de-icer used by the Department is called CalBan, a formulation of calcium chloride, which is a salt. Solutions of the salts accumulate in the soil and are retained on soil particles. The decline of H. venusta along the roadcut and right of way corresponds to an increase in noxious weeds and the Washington Department of Transportation's use of de-icers starting in 1998. De-icers may be associated with the decline of individual plants in the right-of-way and it is now considered a threat to the species. A study of the effect of de-icers used by the Washington Department of Transportation on surrogate species found deleterious effects on survival and biomass at concentrations above 1:100 (Chalker-Scott and Brickey 2004), although the authors do not believe concentrations this high occur at the H. venusta site. The Washington Department of Transportation is aware of the potential threat to H. venusta, and has been actively cooperating with the U.S. Fish and Wildlife Service, U.S. Forest Service, and the Washington Department of Natural Resources to plan and manage their maintenance activities so as to minimize impacts on the rare plant species of Tumwater Canyon (Washington Department of Transportation [WDOT] 2000; see Section G, Conservation Measures, for further details). (USFWS, 2007)

**Stressor:** Herbicides (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Although the roadsides have not been sprayed with herbicides in recent years by the Washington Department of Transportation, spraying did occur for a considerable period of time prior to 1980. The residual effect of herbicide spraying on Hackelia venusta is unknown. Some herbicides are known to reside in the soil for long periods of time, affecting the plants that persist there. In 1999 and 2000, the application of herbicides by U.S. Forest Service personnel was used as a method for reducing the amount and distribution of nonnative, noxious weeds (L. Malmquist, pers. comm. 2003). Although they were used with great caution by U.S. Forest Service staff with knowledge of H. venusta's presence, the threat from herbicide drift and residue remains. (USFWS, 2007)

**Stressor:** Erosion and landslides (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Small surface erosion events and large landslides on the unstable slope where the Hackelia venusta population is located are a continuing threat to the species. The steepness of the slope exceeds 100 percent (45 degree) inclination in many places, and the slope's instability constitutes a significant threat as a major landslide could bury most of the population (Gamon 1997). The last time a large landslide occurred, in 1992, the road was closed for emergency

repairs by the Washington Department of Transportation. The repairs undercut the slope and at least 50 H. venusta plants were destroyed (R. Harrod, pers. comm. 2001). The population census numbers continued to decrease for several years after the landslide. (USFWS, 2007)

**Stressor:** Burying, trampling, or dislodging of plants by soil releases (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The threat of soil being dislodged and the burying, trampling, or dislodging of plants below these soil releases has been witnessed as more people visit the habitat to photograph or collect Hackelia venusta (S. Ballinger, Biologist in litt. 2000; P. Camp, Bureau of Land Management, in litt. 2000; F. Caplow, in litt. 2000; J. Frazee, U.S. Forest Service, in litt. 2000; K. Robson, Cowlitz and Wahkiakum Conservation Districts, in litt. 2001). The potential for slumping (deep-seated mass movement) at the site has increased since 1994, when wildfires burned through the forest in Tumwater Canyon where the species is located. The increased potential for landslides occurs when water uptake by trees and other vegetation that were killed by the 1994 fire is reduced, along with transpiration, so there is more soil water, which increases instability. This is a case where the response to fire may have negative consequences. Another contributing factor is that when tree roots decompose, their ability to bind soil particles and water is decreased. When this happens, the potential for landslides increases. A large landslide in the location of the Tumwater Canyon population of H. venusta would severely degrade the habitat and reduce the plant population. (USFWS, 2007)

**Stressor:** Automobile emissions (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Although there are no data regarding the effects of automobile emissions on Hackelia venusta specifically, such emissions should be considered a potential threat, given the proximity of the road to the population. The highway is heavily used, with between 3,900 to 5,200 automobiles traveling daily through Tumwater Canyon, which is very narrow (WDOT 1996). Automobile emissions are likely to increase along this heavily traveled corridor. These emissions, containing ozone and sulphur and nitrate oxides, are known to negatively affect photosynthesis of coniferous and herbaceous plants (Bega 1979), and may increase nitrogen in the soil, thereby increasing the cover and vigor of competing vegetation. (USFWS, 2007)

**Stressor:** Collection pressure
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** There is a long history of collection pressure on Hackelia venusta. (R. Carr, in litt. 2000; L. Malmquist, in litt. 2000; J. Brickey, University of Washington, in litt. 2001; R. Crawford, Washington Department of Natural Resources, in litt. 2001; E. Guerrant, in litt. 2001; K. Robson, in litt. 2001). H. venusta is very showy and has been collected by scientists, amateur wildflower enthusiasts, and other visitors to the population for more than 30 years. The availability of highway turnouts, and a general increase in knowledge and interest in the species are likely to have increased collecting pressure. Collecting activities may have reduced the number of plants in the population and have also degraded the habitat (Gamon 1997; R. Carr, in litt. 2000; R.

Crawford, in litt. 2000, 2001; R. Harrod, in litt. 2000; G. Hoffman, U.S. Forest Service, in litt. 2000; F. Caplow, in litt. 2001). (USFWS, 2007)

**Stressor:** Human activities (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** An associated and serious threat is physical disturbance to the habitat and the individual plants from people trampling the slope to collect or see plants, photograph the plants, and monitor the population. Physical disturbance to the substrate increases instability, may damage the root systems of adult plants, and may also cause higher mortality of germinants (F. Caplow, pers. obs. 2003). (USFWS, 2007)

**Stressor:** Biocontrol agent (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** However, there is a potential threat from a new biocontrol agent. Mogulones cruciger is a weevil that attacks the nonnative hound's-tongue, Cynoglossum officinale (gypsyflower), which is also in the borage family. Cynoglossum officinale is known from Chelan County. The biocontrol agent has not been formally released in the United States, but has been released in Canada. (USFWS, 2007)

**Stressor:** Predation by weevils (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A laboratory-based study, using tissue-culture clones of H. venusta, found that M. cruciger was able to develop and feed to a limited extent on H. venusta. However, in both laboratory and field experiments M. cruciger demonstrated a strong preference for Cynoglossum (J. Andreas, University of Idaho, in litt. 2004). The investigator concluded that M. cruciger could pose some risks to native species of Boraginaceae and recommended that the weevil not be released in the United States. However, the weevil may spread from Canada and has been identified in the Okanagan Region of British Columbia (S. Reichard, pers. comm. 2003). (USFWS, 2007)

**Stressor:** Low seed production (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Low seed production is a factor in the decline of Hackelia venusta. At the Tumwater Canyon site, an estimated high proportion (60 to 70 percent) of H. venusta seeds did not develop in 1984 (Barrett et al. 1985). Fruit development was poor on many plants; only a few individuals exhibited mature fruit development. Low fruit production has been observed in other years as well (L. Malmquist, pers. comm. 2002). This low or variable reproductive potential may be a major factor in the small number of plants at the type locality. The age structure of the extant population at Tumwater Canyon, poor seed production and germination of new seedlings, and historical estimates of population size indicate that the population has been in decline (Barrett et

al. 1985; Gamon 1997), although recent monitoring of the population shows that the population has increased during the period from 1995 to 2004. The increase in population size can likely be attributed to the improved habitat conditions brought on by restoration activities and the effects of a wildfire that burned through Tumwater Canyon in 1994. (USFWS, 2007)

**Stressor:** Small population size (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The small size of the only known population of Hackelia venusta is a major problem for recovery. Seedling establishment is most critical, and trampling may significantly affect the germination of seedlings (R. Carr, pers. comm. 1998, in litt. 2000; K. Robson, in litt. 2001). The small number of individuals (roughly 600 plants) remaining in the sole population located in Tumwater Canyon makes H. venusta vulnerable to extinction due to random events such as slope failure (mass wasting or surface erosion) or drought. A single random environmental event could extirpate a substantial portion or all of the remaining individuals of this species, leading to extinction. Also, changes in gene frequencies within small, isolated populations can lead to a loss of genetic variability and a reduced likelihood of long-term viability (Franklin 1980; Soulé 1980; Lande and Barrowclough 1987; R. Carr, in litt. 2000). (USFWS, 2007)

***Recovery***

**Reclassification Criteria:**
Hackelia venusta may be considered for downlisting to threatened status when all of the following conditions have been met to address the threats to the species: (USFWS, 2019)

1. Listing/Recovery Factor A: The present or threatened destruction, modification, or curtailment of its habitat or range. In order to ensure the long-term recovery needs of Hackelia venusta, threats to the species habitat must be reduced or removed. This will have been accomplished if the following have occurred: (a) Tree and shrub cover in all populations is maintained at a level equal to or more open than that present in 2007 in the original population, through manual removal or controlled burns. (b) Noxious weed populations are not present within any populations or close enough to them to pose a significant threat of invasion, or are annually removed. (c) Herbicide and de-icer use continues to be minimized within all populations or close enough to them that individuals may be affected. (d) All population sites have been evaluated for mass wasting potential and plans have been developed and implemented to minimize the effects of landslides on H. venusta. (USFWS, 2019)

2. Listing/Recovery Factor B: Overutilization for commercial, scientific, or educational purposes. Hackelia venusta is vulnerable to overcollecting of seeds or plants, and to habitat damage through substrate disturbance. In order to ensure the long-term recovery of H. venusta, threats to the species through collecting and visitation must be reduced or removed. This will have been accomplished if the following have occurred: (a) Seed collection guidelines are established. (b) A guideline of not sharing specific site information with the public or the press has been accepted by the U.S. Forest Service. * The quantitative measure of tree and shrub cover must be determined (Recovery Action 1.7.1). (c) The pullout across the highway from the population has been modified or removed to discourage the public from stopping their vehicles and crossing the highway. (d) The U.S. Forest Service has an entry log in place and all permitted entries into

the population are logged. (e) All research within the population is approved by the U.S. Fish and Wildlife Service and the U.S. Forest Service after review by the recovery team. (USFWS, 2019)

3. Listing/Recovery Factor C: Disease or predation. The viability of Hackelia venusta could be compromised by the presence of the borage-specific biocontrol weevil, Mogulones cruciger. In order to ensure the long-term recovery needs of H. venusta, threats to the species through predation by the biocontrol agent must be reduced or removed. This will have been accomplished if the following have occurred: (a) A monitoring program is in place to inspect H. venusta and identified populations of Cynoglossum officinale (gypsyflower) in Chelan County on an annual basis for the presence of the biocontrol weevil, Mogulones cruciger. (b) A written plan is in place for actions to undertake if the weevil is found and determined to have negative effects on H. venusta. (USFWS, 2019)

4. Listing/Recovery Factor D: Inadequacy of existing regulatory mechanisms. In order to ensure the long-term recovery needs of Hackelia venusta, regulatory mechanisms need to be strengthened. This will have been accomplished if the following have occurred: (a) Habitat management plans have been developed and implemented by the U.S. Forest Service. Management plans will include provisions, as appropriate, for habitat maintenance and restoration, noxious weed control, fire management, recreational activities, monitoring, and research. (b) A revised management plan has been developed and implemented by the Washington Department of Transportation. The management plan will include provisions, as appropriate, for habitat maintenance and restoration, noxious weed control, and highway maintenance activities. (c) All H. venusta populations on public lands are within management areas where maintenance of the species is a primary management goal. (USFWS, 2019)

5. Listing/Recovery Factor E: Other natural or manmade factors affecting its continued existence. The long-term recovery needs of Hackelia venusta require more populations that are stable and self-sustaining. The genetic resources of the species must also be adequately protected through seed storage, in case of catastrophic events in Tumwater Canyon. This will have been accomplished if the following have occurred: (a). At least three stable, self-sustaining populations are present within Tumwater Canyon on protected sites (owned or managed by a government agency or private conservation organization that identifies maintenance of H. venusta as the primary management objective for the site), separated by at least 2 kilometers (1.2 miles) or by the Wenatchee River. These populations could be the result of identification through further inventory, or through reintroduction or augmentation. If a new population is discovered outside of Tumwater Canyon, it may contribute to meeting this criterion. To be deemed stable and self-sustaining, a population must maintain a 5-year average of at least 1,000 adult plants, must show evidence of positive or neutral population growth over the same 5-year period, and must show evidence of natural reproduction and establishment. b. Genetic material, in the form of seeds adequately representing the geographic distribution and genetic diversity within the species, is stored in at least one facility approved by the Center for Plant Conservation. (USFWS, 2019)

6. Monitoring. In order to ensure the efficacy of recovery actions and allow for adaptive management, as necessary, population and habitat monitoring will have been established for all populations of the taxon at appropriate intervals. Habitat monitoring should include census, monitoring of Hackelia venusta, and of shrub and tree cover and nonnative species. Monitoring

must be planned and conducted to minimize the potential negative impacts on the species and its habitat. Written agreements to continue monitoring after downlisting must be in place. (USFWS, 2019)

Recovery Priority Number: 5

**Delisting Criteria:**
Delisting of Hackelia venusta may be considered when all of the following conditions, in addition to the downlisting criteria set in the Recovery Plan (USFWS 2007), have been met to address threats to the species: (USFWS, 2019)

Criterion A/1: The primary threats are removed or adequately managed in all five populations counted toward recovery in delisting criteria (see also Criterion E/1). (USFWS, 2019)

Criterion B/1: Threats to the species through visitation should be removed. (USFWS, 2019)

Criterion E/1: There are at least five stable, self-sustaining populations typically separated by 1.5 miles or by a geographical barrier such as the Wenatchee River on protected sites where protection of the species is a priority.  (USFWS, 2019)

Criterion E/2: To be deemed stable and self-sustaining, a population should maintain a 20- year running average of at least 2,000 adult plants, show evidence of positive or neutral population growth over the same 20-year period, and be sustained through natural regeneration. (USFWS, 2019)

**Recovery Actions:**
- Maintain the current geographic distribution of the species through maintaining habitat integrity. There is only 1 known native population of Hackelia venusta, of about 572 to 772 plants, covering approximately 16 hectares (40 acres). Because there are threats from the presence of the nearby State highway, continuing and increasing coordination between the U.S. Forest Service and the Washington Department of Transportation will be necessary. Planning for the future maintenance of this habitat is essential to facilitate the timely implementation of recovery actions. (USFWS, 2007)
- Continue surveys in Tumwater Canyon and other appropriate areas; identify potential habitat for reintroductions.  Although considerable inventory work has been undertaken for this species, the discovery in the last few years of previously unknown sites, and the highly convoluted terrain of the Wenatchee Mountains, suggests that other populations may yet be discovered. (USFWS, 2007)
- Establish if necessary, new populations of H. venusta within the estimated historical range of the species. Further field inventory may reveal previously unknown  populations which meet the criteria for recovery. If so, reintroduction efforts will not be necessary. However, if no other large populations are found through further inventory work, reintroduction may be necessary to ensure the viability of the taxon into the foreseeable future. A carefully prepared reintroduction plan and propagation and reintroduction research will be necessary before reintroduction is undertaken. Reintroduction may only take place in the Tumwater Canyon watershed, which is the only watershed known to have supported populations of the species, based on historical collections. Based on habitat surveys to date, there appear to be few locations suitable for reintroduction having all habitat attributes necessary to

support H. venusta. (USFWS, 2007)

- Collect seed adequately representing the genetic diversity within the species and store in a Center for Plant Conservation approved facility. The single known population, small number of individuals, and extremely restricted distribution of Hackelia venusta make this species highly vulnerable to random environmental and human-caused events. As a hedge against the loss of significant genetic material, seed representing the diversity within the taxon should be collected and stored in at least one Center for Plant Conservation approved facility. The stored seed could also be used in efforts to establish new populations. Periodic testing will be necessary to estimate the rate of viability loss of stored seed. This will help estimate the correct interval and adequate quantity of seed to recollect for storage. (USFWS, 2007)
- Establish a technical working group to periodically review the status of the species and assess the effectiveness of management plans and other recovery actions. Annual review of all progress toward recovery and all ongoing research and monitoring is critical for successful implementation of this plan and for modifications to the plan that may be needed in future. (USFWS, 2007)
- Determine the suitability for establishing appropriate delisting criteria (Priority 3). As more information becomes available over time, the conditions necessary for delisting Hackelia venusta should become apparent. (USFWS, 2007)
- Recommendation for Future Actions from 2011 5-Year Review: Continue efforts for establishing additional populations of H. venusta. This work will require refining propagation and reintroduction methods, and continuing to search for potential sites for outplanting the species. This includes continuing to collect and store genetically representative samples of seeds and determining optimal germination requirements. (USFWS, 2011)
- Recommendation for Future Actions from 2011 5-Year Review: Dr. Darlene Zabowski, Soil Science Professor at the University of Washington, has proposed a study of soil requirements for H. venusta. This study may help to clarify the substrate requirements of this species. As researchers have shown with other species, the success or failure of small outplantings in different sites may also provide a useful indicator of habitat requirements for the species (Dunwiddie 2010, Lawrence and Kaye 2009), Taylor 2008, WNHP 2007). (USFWS, 2011)
- Recommendation for Future Actions from 2011 5-Year Review: As the next step in monitoring, it would be useful to establish a yearly record of temperature, rainfall, and soil moisture. Together with annual pollinator censuses and assessments of the general condition of plants, it might then be possible to find patterns of pollinator abundance or scarcity, and relate them to seed set on H. venusta in the context of environmental conditions. (USFWS, 2011)
- Recommendation for Future Actions from 2011 5-Year Review: Continue the examination of life history: reproductive/pollination biology, seed production, germination requirements, seedling establishment, life span. (USFWS, 2011)
- Recommendation for Future Actions from 2011 5-Year Review: Investigate the natural history of H. venusta - What was its potential historic range? Could the white-flowered population have been at higher elevations at one time? (USFWS, 2011)
- Recommendation for Future Actions from 2011 5-Year Review: Continue to study the effects road de-icer formulas have on H. venusta. (USFWS, 2011)
- Recommendation for Future Actions from 2011 5-Year Review: Resolve the taxonomy of H. venusta and H. “taylori” and provide an appropriate name for these high elevation plant

populations of conservation concern. (USFWS, 2011)
- Recommendation for Future Actions from 2011 5-Year Review: Continue work to improve the existing population and reduce the threats to the species sufficient to accomplish increases in population size and geographic distribution across its presumed historical range so that the species is no longer in danger of extinction. (USFWS, 2011)
- Recommendation for Future Actions from 2011 5-Year Review: Continue investigations for potential suitable habitat for H. venusta to find potential reintroduction sites, with emphasis on studying sites that have been found to be promising such as Icicle Canyon, and other sites within a two miles radius of the extant site. (USFWS, 2011)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Future research and management recommendations include: (1) Develop an improved monitoring plan for the core population and outplantings that is replicable and minimizes impacts. (2) Research potential outplanting sites, and potential sites where undiscovered populations may occur. (3) Establish additional populations to meet downlisting and delisting criteria. (4) Monitor for the threat of invasive Mogulones cruciger in Washington and near Hackelia venusta sites. (5) Continue to supplement core and outplanting sites with plants until populations are self-sustaining (USFWS, 2020)

# SPECIES ACCOUNT: *Harrisia (=Cereus) aboriginum (=gracilis)* (Aboriginal Prickly-apple)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 11/25/2013; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

Harrisia aboriginum is a sprawling cactus, usually with multiple stems arising from a single base. The stems are erect, slender, and cylindrical. They possess 9 to 11 longitudinal ribs, and may reach 6 m (20 ft) in height. Spines are 1.0 cm (0.4 in) long and originate in clusters of 7 to 9 spines, with up to 20 spines in a cluster at the base of the stem. Flowers are funnel-shaped, white, up to 18 cm (7.1 in) long; have a slight scent; and are nocturnal, lasting only one night. The bracts on the outside of the flower has sparse white hairs. Fruits are yellow, round in shape, and 6.1 to 7.6 cm (2.4 to 3.0 in) in diameter. (USFWS, 2013)

**Taxonomy**

Harrisia aboriginum (Family: Cactaceae) was described by John Kunkel Small, after he discovered it in Manatee County in 1919. The most recent revision of the genus Harrisia supports H. aboriginum as a morphologically and genetically distinct species endemic to the west coast of Florida (USFWS, 2013).

**Historical Range**

Harrisia aboriginum was known historically from coastal areas of southwest Florida along the Gulf coast in Manatee, Charlotte, Sarasota, and Lee Counties. The species was documented on six keys along approximately 125 km (78 mi) of Gulf of Mexico coastline (USFWS, 2013).

**Current Range**

Currently occurs along the Gulf Coast of Florida, in Sarasota, Lee, and Charlotte Counties (NatureServe, 2015).

**Critical Habitat Designated**

Yes; 2/22/2016.

**Legal Description**

On January 22, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective February 22, 2016) for Harrisia aboriginum (Aboriginal Prickly-apple) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes 11 critical habitat units (CHUs), in Florida (81 FR 3866-3925).

**Critical Habitat Designation**

The critical habitat designation for Harrisia aboriginum includes eleven CHUs in Manatee, Charlotte, Sarasota, and Lee Counties, Florida. This species' critical habitat encompasses approximately 3,444 acres (ac) (1,394 hectares (ha)). Nine of these units (approximately 44 percent of the area) were occupied by the species at the time of listing; the remaining two units (approximately 56 percent of the area) were unoccupied. The critical habitat includes lands under Federal (11 percent), State (48 percent), county (15 percent), and private or other (26 percent) ownership. General descriptions are presented below. Maps depicting the CH units are available in the Final Rule (81 FR 3866-3925).

Unit APA1: Terra Ceia, Manatee County, Florida: Unit APA1 consists of approximately 222 ac (90 ha) in Manatee County, Florida. This unit is composed of State lands within Madira Bickel Mound State Historical Park, Terra Ceia Preserve State Park, Cockroach Bay State Buffer Preserve, and the Tampa Bay Estuarine System (66 ac (27 ha)); Manatee County lands at Emerson Point Preserve and parcels owned by the Manatee County Port Authority (70 ac (28 ha)); and parcels in private or other ownership (87 ac (35 ha)). This unit includes lands west of Highway 41 extending from just south of South Dock Street south to Snead Island. The unit also includes areas of Harbor Key, Mariposa Key, Horseshoe Key, Joe Island, Skeet Key, Paradise Island, Ed's Key, and Rattlesnake Key.

Unit APA2: Longboat Key, Sarasota County, Florida: Unit APA2 consists of approximately 54 ac (22 ha) in Sarasota County, Florida. This unit is composed entirely of parcels in private or other ownership. This unit includes lands west of Gulf of Mexico Drive, extending from 0.40 mi (0.6 km) south of the intersection of Bay Isles Parkway and Gulf of Mexico Drive, to the southern tip of Longboat Key. It also includes lands on the north side of Gulf of Mexico Drive, east of Longboat Club Key Drive, on the northwest tip of Longboat Key.

Unit APA3: Osprey, Sarasota County, Florida: Unit APA3 consists of approximately 116 ac (47 ha) in Sarasota County, Florida. This unit is composed of Sarasota County lands within Palmer Point County Park (50 ac (20 ha)) and parcels in private or other ownership (66 ac (27 ha)). This unit extends along the barrier island (Casey Key) from the south terminus of Blind Pass Road, south for approximately 1.2 mi (1.9 km) along North Casey Key Road. On the mainland, the unit includes lands bordered on the north by Vamo Way, to the east by Highway 41, and to the south by Palmetto Avenue.

Unit APA4: Manasota Key, Sarasota and Charlotte Counties, Florida: Unit APA4 consists of approximately 415 ac (168 ha) in Sarasota and Charlotte Counties, Florida. This unit is composed of State lands within Stump Pass Beach State Park (58 ac (23 ha)); County lands within Blind Pass Park, Brohard Beach and Paw Park, Manasota Beach Park, Casperson Beach Park, and Service Club Park (111 ac (45 ha)); and parcels in private or other ownership (245 ac (99 ha)). This unit extends from Beach Road in the City of Venice, south along Manasota Key to the barrier islands southern tip, including a portion of Peterson Island.

Unit APA5: Charlotte Harbor, Charlotte County, Florida: Unit APA5 consists of 51 ac (21 ha) in Charlotte County, Florida. This unit is composed entirely of State lands within the Charlotte Harbor Preserve State Park. This unit includes the Big Mound, Boggess Ridge, and a shell mound located on the east side of Charlotte Harbor, south of the City of Charlotte Park.

Unit APA6: Gasparilla North, Charlotte and Lee Counties, Florida: Unit APA6 consists of approximately 98 ac (40 ha) in Charlotte and Lee Counties, Florida. This unit is composed of State land (0.006 ac (0.02 ha)), county land (22 ac (9 ha)), and parcels in private or other ownership (77 ac (31 ha)). This unit includes most of Kitchen Key (Live Oak Key) and the area east of Gasparilla Road, from the intersection of Grouper Hole Road and Grouper Hole Court, south to 0.15 mi (0.24 km) north of Snail Island Court, from approximately 0.10 mi (0.21 km) south of 35th Street to 23rd Street, including the small island separated from Gasparilla Island by a canal; and from

22nd Street to 20th Street.

Unit APA7: Gasparilla South, Lee County, Florida:  Unit APA7 consists of approximately 92 ac (37 ha) in Lee County, Florida. This unit is composed of Federal land owned by the Service and Bureau of Land Management (3 ac (1 ha)), State lands within Gasparilla Island State Park (69 ac (28 ha)), Lee County lands (12 ac (5 ha), and parcels in private or other ownership (8 ac (3 ha)). This unit includes lands located from south of 1st Street to the southern tip of Gasparilla Island.

Unit APA8: Cayo Pelau, Charlotte and Lee Counties, Florida:  Unit APA8 consists of approximately 25 ac (10 ha) in Charlotte and Lee Counties, Florida. This unit is composed of Lee County lands within Cayo Pelau Preserve, and parcels in private or other ownership (0.6 ac (0.2 ha)). This unit includes lands located from 0.13 mi (0.21 km) south of the northern tip of Cayo Pelau, extending south to the southeastern tip of Cayo Pelau.

Unit APA9: Cayo Costa, Lee County, Florida:  Unit APA9 consists of approximately 1,702 ac (689 ha) in Lee County, Florida. This unit is composed of State lands within Cayo Costa State Park (1,379 ac (558 ha)), lands owned by Lee County (94 ac (38 ha)), and parcels in private or other ownership (230 ac (93 ha)). This unit includes lands located from the northern tip to the southern tip of Cayo Costa.

Unit APA10: Bocilla, Lee County, Florida:  Unit APA10 consists of approximately 33 ac (13 ha) in Lee County, Florida. This unit is composed of Lee County lands within the Bocilla Preserve (32 ac (13 ha)) and parcels in private or other ownership (0.7 ac (0.3 ha)). This unit includes lands located on the undeveloped portion of Bokeelia Island from 0.02 mi (0.03 km) west of the terminus of Ebbtide Way, extending south and west to the northwestern and southeastern corners of Bokeelia Island.

Unit APA11: Sanibel Island and Buck Key, Lee County, Florida:  Unit APA11 consists of approximately 635 ac (257 ha) in Lee County, Florida. This unit is composed of Federal lands owned by the Bureau of Land Management, and Service lands within the J.N. `Ding' Darling National Wildlife Refuge (NWR) (373 ac (151 ha)), State lands (47 ac (19 ha)), lands owned by Lee County (90 ac (36 ha)), and parcels in private or other ownership (126 ac (51 ha)). This unit includes lands on Buck Key, Runyan Key, and Sanibel Island. On Sanibel Island, the unit includes a portion of Bowman's Beach, from just south of Silver Key to the western terminus of Water's Edge Lane; uplands within J.N. `Ding' Darling NWR; and a shell mound located near the northern terminus of Tarpon Bay Road.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation.  The PCEs of Harrisia aboriginum critical habitat consists of the following components (81 FR 3866-3925):

(i) Areas of upland habitats consisting of coastal berm, rockland hammocks, and buttonwood forest. (A) Coastal berm habitat that contains: (1) Open to semi-open canopy, subcanopy, and understory; and (2) Substrate of coarse, calcareous, and storm-deposited sediment. (B) Rockland hammock habitat that contains: (1) Canopy gaps and edges with an open to semi-open canopy, subcanopy, and understory; and (2) Substrate with a thin layer of highly organic soil covering limestone or organic matter that accumulates on top of the limestone. (C) Buttonwood forest habitat that contains: (1) Open to semi-open canopy and understory; and (2) Substrate with calcareous marl muds, calcareous sands, or limestone rock.

(ii) A plant community of predominately native vegetation with no invasive, nonnative animal or plant species or such species in quantities low enough to have minimal effect on survival of Consolea corallicola.

(iii) A disturbance regime, due to the effects of strong winds or saltwater inundation from storm surge or infrequent tidal inundation, that creates canopy openings in coastal berm, rockland hammocks, and buttonwood forest.

(iv) Habitats that are connected and of sufficient size to sustain viable populations in coastal berm, rockland hammocks, and buttonwood forest.

(v) Habitats that provide populations of the generalist pollinators that visit the flowers of Consolea corallicola.

**Special Management Considerations or Protections**

Management considerations or protection are necessary throughout the critical habitat units to avoid further degradation or destruction of the habitat that provides those features essential to the species' conservation. The primary threats to the physical or biological features that Harrisia aboriginum depends on include: (1) Habitat destruction and modification by development and sea level rise; (2) Competition with nonnative, invasive plant species; (3) Herbivorous nonnative animal species; (4) Wildfire; and (5) Hurricanes and storm surge. Some of these threats can be addressed by special management considerations or protection while others (e.g., sea level rise, hurricanes, storm surge) are beyond the control of landowners and managers. However, even when landowners or land managers may not be able to control all the threats, they may be able to address the results of the threats. Management activities that could ameliorate these threats include the monitoring and minimization of impacts from recreational activities, nonnative species control, and protection from development. Precautions are needed to avoid the inadvertent trampling of Harrisia aboriginum in the course of management activities and public use. Development of recreational facilities or programs should avoid impacting these habitats directly or indirectly. Ditching should be avoided because it alters the hydrology and species composition of these habitats. Sites that have shown increasing encroachment of woody species over time may require efforts to maintain the open nature of the habitat, which favors these species. Nonnative species control programs are needed to reduce competition, predation, and prevent habitat degradation. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All critical habitat units require active management to address the ongoing threats above and those presented in the Summary of Factors Affecting the Species sections in the proposed and final listing rules. The Service, State of Florida, and Manatee, Sarasota, Charlotte, and Lee Counties own and manage conservation lands within the historical range of Harrisia aboriginum. The CCP for J.N. 'Ding' Darling National Wildlife Refuge (JDDNWR) promotes the enhancement of wildlife populations by maintaining and enhancing a diversity and abundance of habitats for native plants and animals, especially imperiled species. This CCP provides specifically for maintaining populations of H. aboriginum. The State Management Plans for Charlotte Harbor Preserve, Cayo Costa, Stump Pass Beach, DelnorWiggins Pass, and Gasparilla Island State Parks and Bocilla Preserve promote the protection of habitats and native species. The Service, State of

Florida, and Manatee, Sarasota, Charlotte, and Lee Counties conduct nonnative species control efforts on sites that support, or have suitable habitat for, H. aboriginum. The Service monitors the population of H. aboriginum at JDDNWR. FDEP monitors the H. aboriginum population at Charlotte Harbor Preserve State Park. Nonnative species control is currently lacking at Manasota Beach Park and Kitchen Key in areas that support H. aboriginum. Poaching, vandalism, and wildfire have been observed at Manasota Beach Park. Most populations are at elevations close to sea level and may require assisted migration as sea level rise continues to drive the transition toward salt-tolerant plant species in these areas. Reintroduction is needed to restore the species' historical distribution on Cayo Costa and Madira Bickell Mound State Historical Park. Augmentation of small populations at Longboat Key, Terra Ceia, Lemon Bay Preserve, Kitchen Key, Gasparilla Island, and Cayo Pelau would reduce the risk of population loss to hurricanes, storm surge, or wildfire. Harrisia aboriginum is listed on the Regulated Plant Index as endangered under chapter 5B–40, Florida Administrative Code. Florida Statutes 581.185 sections (3)(a) and (b) prohibit any person from willfully destroying or harvesting any species listed as endangered or threatened on the Regulated Plant Index, or growing such a plant on the private land of another, or on any public land, without first obtaining the written permission of the landowner and a permit from the Florida Department of Plant Industry.

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: May - September (USFWS, 2013)

**Key Resources Needed for Breeding**

Adult: Insect pollinators (USFWS, 2016)

**Reproduction Narrative**

Adult: Insect visitors recorded on other species of Harrisia include hawk moths (Nitidulidae), stingless bees (Meliponidae), and several types of beetles. Flowers are produced May through September. Ripe fruits have been observed from June through October (USFWS, 2013). Generalist pollinators (e.g., bees, butterflies, and beetles) pollinate H. aboriginum (USFWS, 2016).

**Habitat Type**

Adult: Terretrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Coastal hammocks, shell middens (NatureServe, 2015); tropical savanna: berm, grassland (USFWS, 2013)

**Dependencies on Specific Environmental Elements**

Adult: High sunlight exposure, disturbance regime (USFWS, 2016)

**Geographic or Habitat Restraints or Barriers**

Adult: Dense canopy cover, elevations significantly above sea level (USFWS, 2016)

**Spatial Arrangements of the Population**

Adult: Linear (inferred from NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Open coastal hammocks and shell middens at low elevations. This species has a narrow environmental specificity (NatureServe, 2015). The climate of south Florida where Harrisia aboriginum occurs is classified as tropical savanna. Harrisia aboriginum occurs in coastal berm, coastal strand, coastal grassland, and maritime hammock. It also occurs on shell mounds with a calcareous shell substrate (Bradley et al. 2004, pp. 4, 14) (USFWS, 2013). Harrisia aboriginum requires adequate rainfall and does not tolerate freezing temperatures. Substrates supporting Harrisia aboriginum include sand and calcareous shell material (Bradley et al. 2004, pp. 4, 14). Harrisia aboriginum requires upland habitats that occur above the daily tidal range, but are potentially subject to flooding by seawater during extreme tides and storm surge. H. aboriginum will not tolerate hydric or saline soils. The species occurs in habitats that have a vegetation composition and structure that allows for adequate sunlight. Disturbance regimes, including hurricanes, and infrequent inundation events that maintain the habitat suitability for H. aboriginum (USFWS, 2016).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Studies on the pollination biology of Harrisia aboriginum are unknown. Insect visitors recorded on other species of Harrisia include hawk moths (Nitidulidae), stingless bees (Meliponidae), and several types of beetles. Harrisia fruits are sweet and fleshy, suggesting that seed dispersal by birds may be important. (USFWS, 2013)

***Population Information and Trends***

**Population Trends:**

Decline of <30% to increase of 25% (NatureServe, 2015)

**Species Trends:**

Relatively stable (NatureServe, 2015)

**Number of Populations:**

12 (USFWS, 2013)

**Population Size:**

300 - 500 (USFWS, 2015)

**Adaptability:**

Low (inferred from USFWS, 2013)

**Population Narrative:**

The long-term population trend is a decline of <30% to an increase of 25%. Recently the species appears to be relatively stable (NatureServe, 2015). In total, the species was represented by an estimated 300 to 500 individuals in 2007, when population sizes were last estimated. The current range of Harrisia aboriginum spans a small geographic area (100-km (62-mi) stretch of coastline north to south). Of 12 extant populations, all but 2 have fewer than 100 plants (USFWS, 2013).

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Destruction and modification of habitat from development throughout the species' range continue to be a threat to Harrisia aboriginum. The coastal habitats of this species have been heavily impacted by development over the past 50 years. Despite the recent downturn in residential construction, coastal development is ongoing in the habitat of H. aboriginum. Populations on private land or non-conservation public land are most vulnerable to habitat loss. Threats include residential development, road widening, and landscape maintenance . Suitable habitat within the species' range was recently destroyed by encroachment from a private development onto State land (FNAI 2011, pp. 207–208). The threats of habitat loss, modification, and degradation are expected to increase with increased human population, development pressure, and infrastructure needs. Sarasota, Charlotte, and Lee Counties, where this plant currently occurs, are expected to build out before 2060, placing further pressure on remaining natural areas. Populations located on public lands are better protected than those on private land, but still may face the threat of habitat loss through development of park facilities such as new buildings, parking lots, and trails (USFWS, 2013).

**Stressor:** Poaching (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Overutilization (collection by hobbyists, also known as poaching) is a major threat to Harrisia aboriginum. The rarity of H. aboriginum, coupled with its showy flowers, makes this cacti particularly desirable to collectors. Evidence of poaching was recently observed at a site in Sarasota County that has high public visitation (USFWS, 2013).

**Stressor:** Disease and predation (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** An as yet unidentified pathogen can attack Harrisia aboriginum and cause stems to rot and die within about a week. However, no signs of this disease were observed at several sites visited in 2011. Herbivory of flowers by iguanas (Iguana sp.) and stems by gopher tortoises (Gopherus polyphemus) has been noted. Scale insects have been observed in some H. aboriginum populations, occasionally causing severe damage to plants. Overall, evidence indicates disease and predation are relatively minor stressors to H. aboriginum at present, but could become threats in the future if they become more prevalent in the cacti populations

(USFWS, 2013).

**Stressor:** Fire (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At a site in Sarasota County, a large illegal bonfire pit is located within the habitat that supports one of the larger populations of H. aboriginum. The bonfires occur just a few yards from the plants (Bender 2011, pp. 5–6). At least one plant was killed by an escaped fire that affected part of this site in 2006 (Woodmansee et al. 2007, p. 108), and should another fire escape into occupied habitat in the future, it is reasonable to conclude this could result in the loss of individuals or extirpation of populations (USFWS, 2013).

**Stressor:** Nonnative plant species (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Schinus terebinthifolius can dramatically change the structure of rockland hammocks, coastal berms, and shell mounds, making habitat conditions unsuitable for Harrisia aboriginum, which prefer moderate to full sun exposure. For example, at more than one site, numerous H. aboriginum plants occurring in the shade of S. terebinthifolius were observed to have died. Casuarina equisetifolia forms dense stands that exclude all other species through dense shade and a thick layer of needles that contain substances that leach out and suppress the growth of other plants. Coastal strand habitat that once supported Harrisia aboriginum has experienced dramatic increases in C. equisetifolia over the past 30 years. Other invasive plant species that are a threat to Harrisia aboriginum include Scaevola taccada (beach naupaka), Neyraudia reynaudiana (Burma reed), Cupaniopsis anacardioides (carrotwood), Thespesia populnea (Portia tree), Manilkara zapota (sapodilla), Hibiscus tiliaceus (hau), and Hylocereus undatus (night blooming cactus).  (USFWS, 2013)

**Stressor:** Vandalism and recreation (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Vandalism is a threat to Harrisia aboriginum, and has caused population declines in both species. At a Sarasota County site, the Service has documented numerous H. aboriginum plants that have been uprooted, trampled, and hacked with sharp implements. This population is impacted by people who use the coastal berm and hammock interface to engage in a variety of recreational (including unauthorized) activities as evidenced by a very large bonfire site and vast quantities of garbage, bottles, and discarded clothing.Due to their historic significance and possible presence of artifacts, shell mounds are susceptible to vandalism by artifact hunters. Despite regulations that protect these sites on State lands (Florida Statute 267.13), there is a long history of artifact hunters conducting unauthorized excavation of shell mounds in Florida, including some mounds where Harrisia aboriginum has been found, causing erosion and opening areas for invasion by nonnative plants (USFWS, 2013).

**Stressor:** Small population size and limited distribution (USFWS, 2013)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** The current range of Harrisia aboriginum spans such a small geographic area that all populations could be affected by a single event (e.g., hurricane). Six of the 12 remaining populations have 10 or fewer individual plants. Threats exacerbated by small population size include hurricanes, storm surges, freezing temperatures, recreation impacts, wildfires, and poaching. Due to ongoing and pervasive threats, the number and size of existing populations of this species are probably not sufficient to sustain it into the future (USFWS, 2013).

**Stressor:** Sea level rise (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Downscaled projections suggest that sea level rise is the largest climate-driven challenge to low-lying coastal areas and refuges in the subtropical ecoregion of southern Florida. The current occurrences of Harrisia aboriginum at Live Oak Key (1), Gasparilla Island (2), Bokeelia Island (1), Cayo Pelau (1), Lemon Bay Preserve (1), and Buck Key (1) would be inundated by a 1.8-m (5.9-ft) sea level rise, leading to the loss of these populations. Occurrences at Longboat Key (1), North Manasota Key (2–3), and on a coastal berm in Charlotte Harbor Preserve (1) would not be completely inundated, but would experience significant loss and modification of habitat, and what remains would be highly susceptible to further losses to storm surge and salinization (USFWS, 2013).

***Recovery***

**Reclassification Criteria:**
Not available - this species does not have a recovery plan.

**Delisting Criteria:**
Not available - this species does not have a recovery plan.

**Recovery Actions:**
- Not available - this species does not have a recovery plan.
- The Service; National Park Service (NPS); State of Florida; Manatee, Sarasota, Charlotte, Lee, Miami-Dade, and Monroe Counties; and several local governments own and manage conservation lands within the range of Harrisia aboriginum (USFWS, 2013).
- The Service; NPS; State of Florida; Sarasota, Charlotte, Lee, Miami-Dade, and Monroe Counties; and several local governments conduct nonnative species control efforts on sites that support Harrisia aboriginum (USFWS, 2013).

# SPECIES ACCOUNT: *Helenium virginicum* (Virginia sneezeweed)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 11/03/1998; Northeast Region (R5) (USFWS, 2015)

**Physical Description**

A perennial herb, 7-11 dm tall. Some Missouri plants reach 17 dm in height (Tim Smith, Missouri Dept. of Conservation, pers. comm. 2006). Basal leaves form a rosette and may be broad in the middle tapering toward the ends, but otherwise may appear oblong. Stem leaves are lanceolate and become progressively smaller from the base to the tip of the stem. Stems are winged, wings being continuous with the base of the stem leaves. Flower ray petals are yellow and wedge shaped with three lobes at the ends. Central disk is nearly ball-shaped. Clusters of golden-yellow flower heads bloom from July to September (NatureServe, 2015).

**Taxonomy**

A member of the Ateraceae (Aster family) (USFWS, 2000). Knox et al. (1995) determined that H. virginicum is distinct from H. autumnale morphologically and ecologically. Genetic work by Simurda and Knox (2000) supported treating H. virginicum and a Pomona, Missouri, Helenium sp. as a monophyletic group. Additional genetic work with a larger number of Helenium populations over a broader geographic range strengthened this conclusion and determined a narrow-leaved Helenium autumnale population from the Bruce Peninsula in Ontario, Canada, to be a sister group to the Virginicum group (Simurda et al. 2005) (NatureServe, 2015).

**Historical Range**

It was first found in Augusta County, Virginia, in 1935 (Blake 1936) and the known range was expanded to Rockingham County by C. E. Stevens in 1967 (Roe 1977) (USFWS, 2000).

**Current Range**

As of 2000, 23 populations have been documented in Augusta county and 7 in Rockingham County. Recent studies from a sinkhole pond in southern Missouri suggest that it may represent a disjunct population, but further studies are needed to resolve this (USFWS, 2000).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Asexual: vegetative; sexual: cross-pollination (USFWS, 2000)

**Lifespan**

Adult: 5 years (USFWS, 2000)

**Breeding Season**

Adult: July - October (NatureServe, 2015)

**Key Resources Needed for Breeding**

Adult: Insect pollinators, abundant soil moisture, seed bank (NatureServe, 2015)

**Reproduction Narrative**

Adult: Flowers from early July to October, with peak flowering occurring in late July to early August at most sites. The pollination biology has not been studied in detail; however, cursory observations conducted at Kennedy Mountain Meadow suggest that the primary insect pollinators are bees, wasps (Hymenoptera: Apidae, Halictidae, Sphecidae), butterflies (Lepidoptera: Hesperiidae and Lycaenidae, among others), and hoverflies (Diptera: Syrphidae) (C. Williams, pers. obs.). During favorable years at Kennedy Mountain Meadow, approximately one quarter of the population may flower (Knox and Williams 1988). Flowering appears to correlate with water availability during late spring and early summer, a critical period for bolting and flower formation (Knox et al. 1987). Seasonal water fluctuation, particularly inundation, is probably a key factor affecting recruitment and maintenance of populations (J. Knox, unpubl.). For example, extensive periods of inundation during the growing season may greatly limit recruitment and result in high levels of mortality in established plants. Reestablishment of inundation-depleted populations may be facilitated by a soil seed bank; viable seeds can persist in the soil for at least two years (J. Knox, pers. obs.). Thus H. virginicum appears to be a "boom-bust" species in which recruitment is keyed by water fluctuations: population peaks occur in years of abundant soil moisture and troughs in years of excessive and persistent inundation. In addition, seasonal water fluctuations may also modulate populations of co-occurring plants that compete with H. virginicum for space and resources. (NatureServe, 2015). In a nine year demographic field study at one population, plants were found to live up to five years and flower two to three times (Knox 1997). Individual plants identified in the field are nearly always genets (Knox 1997). Research by Messmore and Knox (1997) determined that plants from at least one site have a self-incompatible breeding system (USFWS, 2000).

**Habitat Type**

Adult: Wetland (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Ephemeral pond, wet meadow (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Seasonal inundation (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Shade (USFWS, 2000)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: In Virginia, Helenium virginicum is a wetland plant restricted to shallow, seasonally inundated ponds (which are in or near sinkholes) in Augusta and Rockingham Counties, Virginia (Blake 1936; Roe 1977; Harvill et al. 1986). The pond basins in which this species occurs are usually flooded from January to July. The substrate at most H. virginicum sites consists of poorly drained, acidic, low fertility Purdy silt loams (USDA 1979) underlain by gray clays and dolomitic bedrock (Werner 1966; Rader 1967). The level of disturbance present at the sinkhole ponds includes relatively undisturbed ponds surrounded by forest, more meadow-like habitats around farm ponds actively used by cattle, a backyard seasonal wetland maintained in an open state by the landowner, a seasonally wet mowed lawn, and a seasonal wetland degraded by severe cattle trampling and an ongoing attempt to fill the site. In Missouri it is found on sinkhole pond margins and wet meadows in the Ozark Highlands (Rimer and McCue 2005). The plant has been found to prefer open growing conditions and is found in a variety of sites in addition to the less disturbed sinkholes and wet meadows including rural airports, roadside ditches, and cattle ranches (R. Rimer and J. Summers, pers. comm. 2005). It appears to be less confined to discrete wetlands in Missouri and can occur in a temporarily wet portion of a hayfield or in roadside ditches (Tim Smith pers. comm.) (NatureServe, 2015). Data from one site indicate that H. virginicum is shade intolerant (USFWS, 2000).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Unknown (NatureServe, 2015)

**Resiliency:**

Resiliency - In VA, 42 percent of the EOs are classified as having excellent to good viability, 32 percent as fair viability, and 26 percent as poor viability. In MO, 43 percent of the EOs are classified as having excellent to good viability, 43 percent as fair viability, and 14 percent as poor viability. Across the species range, 43 percent are classified as excellent to good, 39 percent as fair, and 17 percent as poor. Viability is currently estimated based on the persistence of above-ground plants over time, among other factors like habitat condition and evident threats. However, we now know that populations of adult plants can fluctuate significantly between observations due to the highly variable hydrology of their preferred habitat. In addition, seeds retain high germinability in the seed bank for at least 11 years providing the ability for the species to re-establish populations of flowering plants at sites following periods of unfavorable conditions. The combination of a self-incompatibility reproductive strategy and low gene flow between neighboring populations is cause for some concern regarding reproductive failure if individual populations get so small that there are only a limited number of compatible mates; however, there is no evidence of this occurring thus far in populations that have been observed over the course of 10 to 15 years, including those that have declined due to habitat disturbances. (USFWS, 2020)

**Representation:**

Representation - The species shows a high level of genetic diversity and structuring, while there is evidence of low diversity within populations and low gene flow among populations. In VA, populations in close proximity have been demographically asynchronous in the same year, despite experiencing similar climates and hydrology (Knox 1997, Adams et al. 2005) possibly indicating metapopulation structure. Populations in MO and VA show significant genetic differences indicating high representation for the species. The species has specific habitat requirements like variable hydrology and acidic soils; however, there are multiple circumstances under which those conditions occur including natural sinkhole ponds as well as human made features like roadside ditches, farm ponds, and other depressions or areas that act as seasonal wetlands. The species occurs in three states and four physiographic provinces, adding to its representation. (USFWS, 2020)

**Redundancy:**

Redundancy - At the time of listing (1998), there were 25 known populations in VA and one suspected occurrence in MO. Through additional survey work (and a revision of how EOs are defined), there are currently 76 EOs in 3 states spanning 4 physiographic provinces: 19 EOs in VA, 56 EOs in MO, and 1 EO in IN. Several recovery criteria are no longer relevant due to the increased distribution and number of occurrences. There has been no range contraction among the originally identified populations in VA, and significant range expansion in MO with the discovery of 55 additional EOs. Currently, a large number of populations occur across a broad geographic range, increasing the species' ability to withstand catastrophic events. Redundancy has therefore increased significantly since listing. (USFWS, 2020)

**Number of Populations:**

26 - 30 (USFWS, 2000)

**Population Size:**

10,000 - 100,000 individuals (NatureServe, 2015); 1 - 500,000 per occurrence (USFWS, 2000)

**Population Narrative:**

Species exhibits high tolerance to mechanical disturbance. Surprisingly, it appears to benefit from grazing. The stems and leaves of this species are extremely bitter in taste and apparently unpalatable, thus selective grazing by cattle may eliminate competing plants (John Knox, pers. obs.). Moreover, the largest (100,000 - 1,000,000 plants) and densest H. virginicum population (> 400 plants/m2) grows at a site that is mowed yearly. The estimated population size in Virginia is 2500-10,000; in Missouri over 10,000. Widely fluctuating population numbers have been taken into consideration: a population of 10,000 one year may be reduced to a handful in years of drought or prolonged inundation. The long term population trend is unknown (NatureServe, 2015). As of 2000, 30 populations have been documented, four of which have not been seen since the late 1970's and may be locally extirpated. Population sizes documented among the different occurrences range from one individual to 500,000 (USFWS, 2000). In summary, the best available information currently indicates the existence of 76 EOs of H. virginicum across 3 states; this represents a significant increase in spatial distribution (redundancy, representation) and abundance (resilience) from the 25 known populations in 2 counties in VA at the time of listing. As discussed in more detail below in section 2.3.1.3, it also represents a significant increase in genetic diversity (representation) since Knox (2016) reported all sampled populations as being genetically distinct. The following sections provide more detailed information on abundance estimates in each state. (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (NatureServe, 2015)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** In Virginia the long-term viability of existing populations is primarily threatened by human-induced disruptions of hydrologic regimes, particularly by encroaching agriculture, residential land development, and logging (Van Alstine 1991; J. Knox, C. Williams pers. obs.). In addition, a private site and adjacent sites on the George Washington National Forest are sporadically impacted by off road vehicles (e.g., during summer 1991 on the private land; J. Knox, C. Williams, pers. obs.). The following paragraphs are taken, with modifications, from U.S. Fish and Wildlife Service (2000): The most serious threat to H. virginicum appears to be habitat loss, most often arising from changes in the natural hydrological regime of the sinkhole pond habitat. Four of the sites, three of which are grazed by cattle, have had a portion of the wetland deepened to create a permanent pond; prior to being excavated, much of this section once undoubtedly supported H. virginicum and so loss of some habitat has occurred. Input from groundwater sources may be decreased by withdrawals for wells for adjacent developments such as subdivisions. Overland surface water flow may be altered by activities such as timber harvesting or road building in upslope areas. A variety of site-specific threats to H. virginicum from habitat loss have appeared over the last ten years. The Virginia Department of Transportation (VDOT) has proposed to widen to four lanes Route 340, a currently two lane north-south corridor on the east side of the Shenandoah Valley. A portion of one site in Augusta County is immediately east of Route 340. Another H. virginicum population is near the site of silos built in the early 1990's that are used to store septic waste. Mowing occurs in at least 3 of the Virginia sites. Repeated mowing before seed is set and the seed bank is replenished, may lead to local extinction as vegetative plants die out and the seed bank ultimately becomes depleted. As the soils of the H. virginicum sites have been found to be nutrient-limiting (Knox 1997), long-term nutrient enrichment from cattle could ultimately create more favorable habitat for other plant species (NatureServe, 2015).

**Stressor:** Nonnative species (NatureServe, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Exotic organisms may pose threats to H. virginicum populations in the near future. Purple loosestrife, L. salicaria, is slowly spreading through Virginia and may eventually invade some H. virginicum sites, especially following disturbances to hydrologic regime and/or substrate. The gypsy moth, L. dispar, is currently defoliating large areas of the George Washington National Forest and adjacent lands but it is unclear whether the gypsy moth will negatively impact H. virginicum populations. For example, as H. virginicum is shade-intolerant, defoliation of trees and shrubs that grow on the periphery of sinkholes may increase light availability and allow H. virginicum to expand into areas from which it was formerly excluded (NatureServe, 2015).

**Stressor:** Stochastic events (USFWS, 2000)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Extremes in the fluctuating hydroperiod of the ponds could, when preceded by a low investment in the seed bank, result in local extirpations of populations. The self-incompatible breeding system may eventually lead to local extinction at sites with low population numbers

(Messmore and Knox 1997) (USFWS, 2000).

***Recovery***

**Reclassification Criteria:**
Not available

Recovery Priority Number: 2

**Delisting Criteria:**
1. Twenty self-sustaining populations and their habitats have received permanent protection across the species' Virginia range (USFWS, 2000).

2. Monitoring over a 15-year period indicates that populations in the 20 sites are viable (USFWS, 2000).

3. Life history and ecological requirements are understood sufficiently to allow for effective protection, monitoring, and, as needed, management (USFWS, 2000).

4. Seeds representing the range of genetic diversity in H. virginicum are placed in long-term storage to provide a source of genetic material in the event of extinction (USFWS, 2000).

5. If determined to be H. virginicum, the Missouri population and its habitat are permanently protected and seeds placed in long-term storage (USFWS, 2000).

**Recovery Actions:**
- Protect the extant populations and their habitat (USFWS, 2000).
- Monitor extant populations (USFWS, 2000).
- Definitively identify the range and distribution of the species (USFWS, 2000).
- Continue investigations into the life history and ecology of Helenium virginicum (USFWS, 2000).
- Maintain seed sources for the species (USFWS, 2000).
- Develop informational materials to create more awareness of H. virginicum and its status (USFWS, 2000).
- H. virginicum has been listed as endangered by the Commonwealth of virginia since 1989 under the Endangered Plant and Insect Species Act. This law protects listed plant and insect species from take in the form of collection or translocation, except by the landowner (USFWS, 2000).
- Site-specific conservation planning, funded by the U.S. fish and Wildlife Service and the Virginia Department of Agriculture and Consumer Services, was conducted by the Virginia Department of conservation and Recreation's Division of Natural Heritage at five privately-owned sites (Erdle 1996, Erdle 1997) (USFWS, 2000).
- If the Missouri Helenium sp. is confirmed to be H. virginicum, sinkhole pond habitat in Missouri, intervening states, and other areas of virginia will need to be targeted for surveys to determine the distribution of this species (USFWS, 2000).
- A fact sheet on H. virginicum was developed by the Virginia Department of Conservation and Recreation's Division of Natural Heritage in 1995 (USFWS, 2000).

- Six of the sites that have been documented to support populations of H. virginicum are on land managed by the U.S. Forest Service (USFWS, 2000).
- A number of studies are underway or planned for the near future by J.S. Knox and associates at Washington and Lee University (USFWS, 2000).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Because we have determined that H. virginicum no longer meets the definition of T or E, the following recommendations are not required to achieve or maintain recovery. They reflect the need for post-delisting monitoring and highlight actions that have already been proposed but not yet carried out and would contribute to our understanding of population genetics for this geographically disjunct species. 1. Develop a post-delisting monitoring plan and continue monitoring EOs for viability over time. a. Develop and implement methodology to survey and monitor the seed bank instead of relying on observations of above ground plants for improved viability estimates. 2. Conduct surveys in IN in suitable habitat near the EO in Hamilton County. In addition, complete genetic analysis of the IN EO to help determine whether it is a natural or introduced occurrence. 3. Opportunistically collect seeds from VA populations,additional MO populations, and IN populations if more are discovered, representing adequate genetic diversity and place them in long-term storage. 4. Conduct additional genetic analysis with larger sample sizes from VA and MO populations using both contemporary plants and seed bank samples. (USFWS, 2020)

# SPECIES ACCOUNT: *Helianthus paradoxus* (Pecos (=puzzle, =paradox) sunflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 10/20/1999; Southwest Region (R2) (USFWS, 2016)

**Physical Description**

An annual herb with stems 1-2 m tall. Flower heads have yellow rays and are 3-5 cm across (NatureServe, 2015).

**Taxonomy**

Puzzle sunflower is a species of hybrid origin (Rieseberg et al. 1990; Rieseberg 1991). The parental species are the common sunflower and the prairie sunflower, H. petiolaris. These two species occupy different habitats from puzzle sunflower (NatureServe, 2015).

**Historical Range**

Historically there were six other locations within Pecos and Reeves Counties; however all except one of these sites have not been relocated due to imprecise locality data and the lack of access to private land. The relocated site was heavily invaded by salt cedar and had little water left. No puzzle sunflowers were found, although the entire site was not searched (NatureServe, 2015).

**Current Range**

At present puzzle sunflower occurs in two general areas in Pecos and Reeves Counties in west Texas and four general areas in New Mexico (NatureServe, 2015). Pecos sunflower populations occur at alkaline wetlands in the arid regions of west Texas, lower Pecos River of eastern New Mexico, and the Rio Grande and Rio San Jose of west-central New Mexico (USFWS, 2015).

**Critical Habitat Designated**

Yes; 4/1/2008.

**Legal Description**

On April 1, 2008, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Helianthus paradoxus (Pecos (=puzzle, =paradox) sunflower) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes five critical habitat units (CHUs), in New Mexico and Texas (73 FR 17762-17807).

**Critical Habitat Designation**

The critical habitat designation for Helianthus paradoxus includes five CHUs (ten sub-units) in Chaves, Cibola, and Guadalupe counties, New Mexico, and in Pecos County, Texas. This species critical habitat encompasses approximately 1,305 acres (ac) (528 hectares (ha)) (73 FR 17762-17807).

Unit 1: West-Central New Mexico: Subunit 1a is located at Rancho del Padre Spring Cienega. This subunit is 26 ac (10 ha) in Cibola County, New Mexico. The subunit consists of an area of Rancho del Padre Spring Cienega from the spring on the south side of I– 40 then northeast approximately 0.5 mi (0.8 km) to the Rio San Jose. This population consists of large patches of several thousand plants on areas owned by two private landowners (23 ac (9 ha)) and the Pueblo of Acoma (3 ac (1 ha)). This site was known to be occupied at the time of listing and has been visited or observed from a public right-of-way by species experts during four or more seasons. These experts have found the site occupied by H. paradoxus on every visit (Sivinski 2007a, p. 3). This unit is currently occupied, contains all of the PCEs in the appropriate spatial arrangement and quantity, and is threatened by water withdrawal, wetland filling and development, and livestock grazing during H. paradoxus's growing and flowering season. Therefore, special management or protections may be required to minimize these threats. At this time, we are not aware of any management plans that address H. paradoxus in this area. Subunit 1b is located at Grants Salt Flat Wetland. This subunit is 63 ac (25 ha) of private land in Cibola County, New Mexico. The subunit consists of an area of wet alkaline playa (i.e., a seasonal, shallow desert lake) between railroad tracks and I–40 and west of Hwy 122 (Road from Interstate to downtown Grants). Playas are nearly level areas at the bottom of undrained desert basins that are sometimes covered in water. This population consists of large patches of several thousand plants mostly on private property. This site was occupied at the time of listing and has been visited or observed from a public right-of-way by species experts during four or more seasons. These experts have found the site occupied by Helianthus paradoxus on every visit (Sivinski 2007). This unit is currently occupied, contains all of the PCEs in the appropriate spatial arrangement and quantity, and is threatened by wetland filling and development, encroachment by nonnative vegetation, and livestock management not compatible with H. paradoxus physiology. Therefore, special management or protections may be required to minimize these threats. At this time, we are not aware of any management plans that address H. paradoxus in this area. Subunit 1c is located at the Pueblo of Laguna. This subunit's acreage is undefined in Valencia County, New Mexico. The subunit consists of an area along the Rio San Jose, South Garcia, New Mexico. At this site, Helianthus paradoxus plants are located in patches at springs along the Rio San Jose. Each patch consists of several hundred to several thousand plants, and a few scattered plants grow along the river (Sivinski 1995, p. 4). The entire site belongs to the Pueblo of Laguna. This site was occupied at the time of listing, is currently occupied, contains all of the PCEs in the appropriate spatial arrangement and quantity, and is threatened by water withdrawal, encroachment by nonnative vegetation, and livestock grazing during H. paradoxus' growing and flowering season. The Pueblo has developed a management plan for H. paradoxus. On the basis of this plan and our partnership with the Pueblo of Laguna, we are excluding this area from the final critical habitat designation pursuant to section 4(b)(2) of the Act (see ''Application of Section 4(b)(2) of the Act'' section below for additional information).

Unit 2: La Joya Wildlife Management Area: Unit 2 is located in the La Joya Wildlife Management Area. This unit is 854 ac (346 ha) in Socorro County, New Mexico. This population is located about 7 mi (11 km) south of Bernardo within Socorro County near the confluence of the Rio Grande and the Rio Puerco. The La Joya population is bounded to the west by I–25 and to the east by the Unit 7 Drain. The north boundary is adjacent to River Mile 126 of the Rio Grande and the south boundary is adjacent to River Mile 123. One of the largest populations of Helianthus paradoxus occurs adjacent to the Rio Grande at La Joya. This Rio Grande population consists of 100,000 to 1,000,000 plants and occurs on the La Joya Wildlife Management Area (Service 2005, p. 4). It is within the La Joya Unit of the Ladd S. Gordon Waterfowl Complex. This property is owned by the New Mexico State Game Commission. It is managed by the NMDGF for migratory waterfowl habitat, which is compatible with preservation of wetlands for H. paradoxus. We believe this area was not occupied at the time of listing. It was discovered in 2004. This site has been found to be occupied every year since then and represents one of the largest populations of Helianthus paradoxus in the range of the species (Hirsch 2006, p. 1). This unit is currently occupied by a stable population (Blue Earth Ecological Consultants, Inc. 2007c, p. 3), contains all of the PCEs in the appropriate spatial arrangement and quantity, and is threatened by encroachment of nonnative vegetation. We have determined this site to be essential to the conservation of the species because it is currently occupied by a stable, very large population of Helianthus paradoxus, and is sufficiently distant (over 40 mi (64 km)) from other populations to serve as an additional locality that contributes to the conservation of genetic variation. This population may prevent extirpation of the species resulting from encroachment of nonnative species, degradation of habitat, or a catastrophic event because it is the sole representative located in an area distinct from any other population in the range of the species. As such, it may contain genetic variation not found anywhere else in the range of the species. Because the water source for this population is stable, this population can be expected to persist in very large numbers every year. As described below, we are excluding Unit 2, the La Joya Wildlife Management Area, from the critical habitat designation for Helianthus paradoxus (see ‘‘Exclusions Under Section 4(b)(2)’’ section).

Unit 3: Santa Rosa: Subunit 3a is located at Blue Hole Cienega/Blue Hole Fish Hatchery Ponds. This subunit is 134 ac (54 ha) in Guadalupe County, New Mexico. The Blue Hole Fish Hatchery Ponds population of Helianthus paradoxus is part of the same population as and nearly contiguous with the Blue Hole Cienega in Santa Rosa, New Mexico. The Blue Hole Fish Hatchery Ponds population is immediately north of Blue Hole Road and the Blue Hole Cienega is immediately south. This subunit was occupied at the time of listing and has been visited by species experts during four or more seasons. These experts found the subunit to be occupied by Helianthus paradoxus on every visit (Sivinski 2007a, p. 2). This subunit is currently occupied (Blue Earth Ecological Consultants, Inc. 2006, p.1), contains all of the PCEs in the appropriate spatial arrangement and quantity, and is threatened by encroachment of nonnative vegetation, wetland filling, and park maintenance activities. Therefore, special management or protections may be required to minimize these threats. At this time, we are not aware of any management plans that address H. paradoxus in this area. The part of this population at Blue Hole Cienega consists of 100,000 to 1,000,000 plants and is the largest population of Helianthus paradoxus in the upper Pecos River basin. A nontraditional section 6 grant was awarded to the State of New Mexico in 2004 for acquisition of the Blue Hole Cienega, which was finalized in July 2005. At this site, shallow ground water seeps to the surface to create cienega communities. This subunit is currently occupied, contains all of the PCEs in the appropriate spatial arrangement and quantity, and is threatened by encroachment by nonnative vegetation. Therefore, special management or protections may be required to minimize these threats. At this time, we are not aware of any management plans that address H. paradoxus in this area. The part of this population at the Blue Hole Fish Hatchery Ponds is owned and administered by the City of Santa Rosa and consists of approximately 1,000 plants. This site is maintained as a recreational area. City of Santa Rosa park maintenance staff have voluntarily stopped mowing and cutting Helianthus paradoxus during the months of August and September. An information kiosk on endangered wetland plants is being planned for the bike/foot path along the creek at Blue Hole Park. This subunit was confirmed to be occupied in 2006 (Blue Earth Ecological Consultants, Inc. 2006, p. 4), contains all of the PCEs, and is threatened by encroachment from nonnative vegetation, wetland filling, and park maintenance activities. Therefore, special management or protections may be required to minimize these threats. At this time, we are not aware of any management plans that address Helianthus paradoxus in this area. Subunit 3b is located at Westside Spring. This subunit is 6 ac (3 ha) of private land in Santa Rosa, Guadalupe County, New Mexico. The subunit consists of an area along an unnamed spring on the west side of the Pecos River, located to the west of River

Road and 1 mi (1.6 km) east of Highway 54. We believe this area was not occupied at the time of listing. It was discovered in 2005, and contained thousands of plants. This site was found to be occupied again in 2006 by a species expert observing from a public right-ofway (Sivinski 2007). This subunit is currently occupied by a stable population, contains all of the PCEs in the appropriate spatial arrangement and quantity, and is threatened by water withdrawal, wetland filling and development, and encroachment of nonnative vegetation. Therefore, special management or protections may be required to minimize these threats. At this time, we are not aware of any management plans that address Helianthus paradoxus in this area. We have determined this site to be essential to the conservation of the species because it is currently occupied by a stable, large population of Helianthus paradoxus, and is one of only two stable, large populations in Unit 3. This subunit is sufficiently distant (over 40 mi (64 km)) from other populations to serve as an additional locality that contributes to the conservation of genetic variation. This population may prevent extirpation of the species resulting from encroachment of nonnative species, degradation of habitat, or a catastrophic event that could occur to the other subunit in Unit 3. It may also contain genetic variation specific to this Unit. Because the water source for this population is stable and not anticipated to be subject to any known future water withdrawals, this population can be expected to persist in large numbers every year.

Unit 4: Roswell/Dexter:  Subunit 4a includes 576 ac (233 ha) of Bitter Lake National Wildlife Refuge and City of Roswell land located in Chaves County, New Mexico. This subunit is located approximately 5 mi (8 km) northeast of the city of Roswell. One of the largest Helianthus paradoxus populations occurs on the Bitter Lake National Wildlife Refuge in New Mexico on Federal lands managed by the Service. Several hundred thousand to a few million plants occur nearly continuously along the shores and small islands of all the artificial lakes in the southern unit of the refuge. Also, a few small patches of plants occur on the west side of Bitter Lake Playa and adjacent springs on the Lost River. This area was occupied at the time of listing and has been visited by species experts during four or more seasons. These experts found the site occupied by Helianthus paradoxus on every visit (Ulibarri 2006a, p. 1; Sivinski 2007a, p. 2; Blue Earth Ecological Consultants, Inc. 2007a, p. 3). This area is currently occupied, contains all of the PCEs essential to the conservation of the species, and is threatened by water withdrawal and encroachment of nonnative vegetation. Additional threats occurring on the City of Roswell lands include wetland filling and development, and incompatible livestock management. Therefore, special management or protections may be required to minimize these threats. Subunit 4b includes 96 ac (39 ha) of land within the Bitter Lake National Wildlife Refuge Farm (Refuge Farm). This subunit is located in Chaves County, New Mexico, approximately 5 mi (8 km) east of Roswell on the west side of the Pecos River. Subunit 4b consists of a few large patches with several thousand plants on alkaline seeps behind the dikes on the western edge of the Refuge Farm south of Highway 380. This land is owned and managed by the Service as a grain farm and feeding area for migratory birds. The eastern portion of the Refuge Farm is a marshy spring-seep area that contains a large population of Helianthus paradoxus. The wet soils in this population are not cultivated. This area was known to be occupied at the time of listing and has been visited by species experts during four or more seasons. The experts found the site occupied by Helianthus paradoxus on every visit (Ulibarri 2006b, p. 1; Sivinski 2007a, p. 2; Blue Earth Ecological Consultants, Inc. 2007a, p. 3). This subunit is currently occupied and contains all of the PCEs in the appropriate spatial arrangement and quantity essential to the conservation of the species. Subunit 4c is located at the Oasis Dairy. This subunit is 104 ac (42 ha) of private land in Chaves County, New Mexico. The subunit is located on the east side of Roswell, west side of Pecos River Valley, approximately 4 mi (7 km) southeast of the Hwy 380 bridge, and beside an unnamed spring approximately 0.6 mi (1 km) west of the Pecos River and 6 mi (9 km) south of Highway 380. This site contains a very large, dense patch of several thousand Helianthus paradoxus in a low alkaline sink area approximately 0.5 mi (0.8 km) west of the Pecos River on private land. It also contains a large patch with many thousands of H. paradoxus in a low area below a spring, also on private land. This site was occupied at the time of listing and has been visited by species experts during at least three seasons. These experts found the site occupied by H. paradoxus on every visit (Sivinski 2007a, p. 3). This subunit is currently occupied, contains all of the PCEs in the appropriate spatial arrangement and quantity, and is threatened by livestock grazing during H. paradoxus' growing and flowering season, water withdrawal, and wetland filling and development. Therefore, special management or protections may be required to minimize these threats. At this time, we are not aware of any management plans that address H. paradoxus in this area. Subunit 4d is located at Lea Lake at Bottomless Lakes State Park. This subunit is 20 ac (8 ha) in Chaves County, New Mexico. It includes the wet margins of Lea Lake. This site contains a few thousand plants on the riparian margins of Lea Lake. This land belongs to the State of New Mexico and is managed by the New Mexico Parks and Recreation Division. The lands adjacent to Lea Lake are used as a picnic area and campground for the State Park. This site was occupied at the time of listing and has been visited by species experts during four or more seasons. These experts found the site occupied by Helianthus paradoxus on every visit (Sivinski 2007a, p. 3). This subunit is currently occupied (Sivinski 2007a, p. 3; Blue Earth Ecological Consultants, Inc. 2007a, p. 3), contains all of the PCEs in the appropriate spatial arrangement and quantity, and is threatened by encroachment of nonnative vegetation, and recreational and park maintenance activities. Therefore, special management or protections may be required to minimize these threats. At this time, we are not aware of any management plans that address H. paradoxus in this area. Cienega. This subunit is 41 ac (17 ha) of private land in Chaves County, New Mexico. The subunit is located in a small valley west of the Pecos River, east of the Hagerman Irrigation Canal, and 3 mi (5 km) north of Dexter. This site consists of several thousand plants on private land along a wide, boggy drainage bottom. This site was known to be occupied at the time of listing based upon observations from a public right-of-way by species experts during at least three seasons (Sivinski 2007a, p. 2). This subunit is currently occupied, contains all of the PCEs in the appropriate spatial arrangement and quantity, and is threatened by water withdrawal, wetland filling and development, and livestock grazing during Helianthus paradoxus' growing and flowering season. Therefore, special management or protections may be required to minimize these threats. At this time, we are not aware of any management plans that address H. paradoxus in this area.

Unit 5: West Texas Unit 5 includes 240 ac (97 ha) of private land located on Diamond Y Spring in Pecos County, Texas. The unit is located approximately 12 mi (20 km) north-northwest of Fort Stockton, Texas. Unit 5 consists of several hundred thousand to one million plants found on The Nature Conservancy's Diamond Y Spring Preserve and a contiguous parcel of private land. This site was occupied at the time of listing and has been visited by species experts during four or more seasons. These experts found the site occupied by Helianthus paradoxus on every visit (Poole 2006, p. 2). This unit is currently occupied (Blue Earth Ecological Consultants, Inc. 2007b, p. 3) and contains all of the PCEs essential to the conservation of the species. The land within The Nature Conservancy's Diamond Y Spring Preserve was purchased to protect Diamond Y Spring Preserve and other rare or endangered aquatic species in the Diamond Y Spring system. This habitat is managed for the conservation of such species (Service 2005, p. 12). Diamond Y Spring Preserve has recently expanded from 1,500 ac (607 ha) to 4,000 ac (1,618 ha). However, Helianthus paradoxus on the Preserve is threatened by water withdrawal occurring outside the

Preserve. On the adjacent private land, H. paradoxus is also threatened by water withdrawal, wetland filling and development, and livestock grazing during the growing and flowering season. As a result, special management or protections may be required to minimize these threats. At this time, we are not aware of any completed management plans that address H. paradoxus in this area.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Helianthus paradoxus critical habitat consists of two components (73 FR 17762-17807):

(i) Silty clay or fine sand soils that contain high organic content, are saline or alkaline, are permanently saturated within the root zone (top 50 cm (19.7 in) of the soil profile), and have salinity levels ranging from 10 to 40 parts per thousand; and

(ii) A low proportion (less than 10 percent) of woody shrub or canopy cover directly around the plant.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the areas occupied by the species at the time of listing contain the physical and biological features essential to the conservation of the species, and whether these features may require special management consideration or protections. As stated in the final listing rule (64 FR 56582), threats to Helianthus paradoxus and its physical and biological features include drying of wetlands from groundwater depletion, alteration of wetlands (e.g., wetland fills, draining, impoundment, and development), competition from nonnative plant species, overgrazing by livestock during H. paradoxus' flowering season, impacts from recreational activities, mowing, and highway maintenance. The loss or alteration of wetland habitat continues to be the main threat to Helianthus paradoxus. The scattered distribution of cienegas makes them aquatic islands of unique habitat in an arid-land matrix (Hendrickson and Minckley 1984, p. 169). There is evidence these habitats have been historically, and are presently being, reduced or eliminated by aquifer depletion, and severely impacted by agricultural activities and encroachment by exotic plants (Poole 1992, pp. 1–2; Sivinski 1995, p. 11). The lowering of water tables through aquifer withdrawals for irrigation and municipal use, diversion of water from wetlands for agriculture and recreational uses, and wetland filling for conversion to dry land uses destroy or degrade desert wetlands. In Grants, New Mexico, Helianthus paradoxus has been observed in close proximity to building sites that may have contained suitable wetland habitat prior to filling (Service 2005, p. 8). A cienega containing H. paradoxus near Dexter, New Mexico, was dried when a wellhead was placed on the spring and the water diverted for other uses (Service 2005, p. 8). Springs that have fed H. paradoxus habitats have been converted to swimming pools and fishing ponds in the towns of Roswell and Santa Rosa, New Mexico (Service 2005, p. 8). Groundwater withdrawals for agriculture in Pecos and Reeves counties in Texas have had an especially severe impact on desert springs (Service 2005, p. 8). Of the 61 historical desert springs in these two counties, only 13 were still flowing in 1980 (Brune 1981 in Poole 1992, p. 5). Beginning around 1946, groundwater levels fell as much as 400 feet (ft) (120 meters (m)) in Pecos County and 500 ft (150 m) in Reeves County. Groundwater pumping has lessened in more recent years due to the higher cost of removing water from deeper aquifers, but rising water tables and resumption of spring flows are not expected (Poole 1992, p. 5). We are not aware of any protections afforded by Texas water law for the remaining springs that support H. paradoxus populations on The Nature Conservancy properties, which limits options for addressing this threat. Livestock will eat Helianthus paradoxus when other green forage is scarce, and when the buds are developing and abundant (Service 1999, p. 56587). Cattle and horses tend to pull off the flower heads, which can reduce seed production (Bush and Van Auken 1997, p. 416). However, well-managed grazing during non-flowering months may have a beneficial effect on H. paradoxus populations by decreasing the density and biomass of potentially competing plant species in these habitats. This sunflower germinates earlier than most associated plants and grows vigorously on wet, bare, highly insolated soils (Service 2005, p. 9). Actions that remove shading grass cover, such as grazing, appear to enhance growth and reproduction of sunflower plants that are later protected from grazing while they are reproductively maturing. Therefore, properly managed livestock grazing can be compatible with H. paradoxus conservation. Livestock grazing operations that are not managed to protect H. paradoxus occur in populations in the Grants and Roswell areas of New Mexico (Service 2005, p. 9). Although water contamination is a significant threat for the Roswell springsnail, Koster's springsnail, Noel's amphipod, and the Pecos assiminea found on Bitter Lake National Wildlife Refuge (70 FR 46304), we have no information on whether contamination of water would affect Helianthus paradoxus. We did not find that reduced water quality was a threat to the species when it was listed in 1999 (64 FR 56582). Moreover, we are not aware of any research or information that documents the species' response to elevated nutrients or contaminants. For these reasons, we do not believe that water contamination is a significant threat to H. paradoxus at this time. We have determined that each area included in this designation meets the definition of critical habitat for the reasons described in our unit descriptions below.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: cross-pollination (inferred from NatureServe, 2015)

**Lifespan**

Adult: 1 year (inferred from USFWS, 2015)

**Breeding Season**

Adult: August - October (USFWS, 2015)

**Key Resources Needed for Breeding**

Adult: Possibly ground disturbance (inferred from NatureServe, 2015); pollinators unknown - likely various insects (USFWS, 2005)

**Reproduction Narrative**

Adult: No specific research has been conducted on the reproduction of this species. The reproductive biology is likely to be very similar to that of the common sunflower, H. annuus. Cattle disturbance of the surrounding vegetation may supply puzzle sunflower with light gaps for germination and growth, and lessen competition (Bush and Van Auken 1997). Numerous experiments have been conducted both in and ex situ on competition between puzzle sunflower and its associates (Van Auken and Bush 1993, 1994, 1995). With competitors removed, puzzle sunflower exhibited greater basal stem diameter, more flower heads, and greater flower head, leaf, and stem dry mass (Bush and Van Auken 1997). Annual species of sunflowers hybridize in cultivation, but have reduced pollen viability and seed fertility (Heiser 1965, 1969). Hybrids of puzzle and common sunflower have been observed at Diamond Y Preserve in west Texas and in the Santa Rosa area of New Mexico (NatureServe, 2015). The Pecos sunflower is an annual plant that must re-establish each population by seeds produced during preceding years. It is annual plant that germinates in the spring, and flowers and makes seed from late August through October (USFWS, 2015). Pollination vectors for the Pecos sunflower have not been studied. However, most radiate-headed plants in the aster family are generalists in attracting a variety of insect pollinators (USFWS, 2005).

**Habitat Type**

Adult: Wetland (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Cienega (NatureServe, 2015), wet meadow, spring seeps (USFWS, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Disturbance regime, 10 - 40 ppt soil salinity, < 10% canopy cover (USFWS, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 3,280 - 6,561 ft. elevation (USFWS, 2015)

**Spatial Arrangements of the Population**

Adult: Patches of dozens to thousands (USFWS, 2005)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from USFWS, 2015)

**Habitat Narrative**

Adult: Helianthus paradoxus is the only sunflower in the Southwest United States that requires permanent wetlands for its survival. Puzzle sunflowers grow in saline soils that are permanently saturated. Areas that maintain these conditions are commonly called cienegas (desert wetlands) associated with springs. However, the required conditions may also be found at stream margins and at the margins of impoundments. Where plants are associated with the latter the impoundments have replaced the natural cienegas. Van Auken and Bush (1995) tested puzzle sunflower to determine if it was mycorrhizal. The greenhouse experiments, done with non-native soil, indicated that puzzle sunflower was an obligate mycorrhizal species (NatureServe, 2015). This species is associated with spring seeps and desert cienegas, or wet meadows, which are very rare in the dry regions of New Mexico and Texas. The cienega climax community has been described as mid-elevation, 3280.84 to 6561.68 feet (ft.). Disturbance regimes, such as fire or tillage, which eliminate vegetation thatch and expose bare ground surface tend to increase Pecos sunflower cover and productivity (Van Auken and Bush 2004; New Mexico Forestry Division 2008). Based on knowledge of the life history, biology, and ecology of the Pecos sunflower and the habitat requirements for sustaining the essential life history functions of the species, the PBFs for Pecos sunflower are the desert wetland or riparian habitat components that provide: (1) Silty clay or fine sand soils that contain high organic content, are saline or alkaline, are permanently saturated within the root zone in the top 19.69 inches (in) (50 centimeters (cm)) of the soil profile, and have salinity levels ranging from 10 to 40 parts per thousand; and (2) low proportion (less than 10 percent) of woody shrub or canopy cover directly around the plant (U.S. Fish and Wildlife Service 2008b). The Pecos sunflower is intolerant of habitats that are too wet at the surface and prefers soils that are relatively dry at the surface and wet in the lower root zone (Bush 2006) (USFWS, 2015). Populations tend to grow in crowded patches of dozens or even thousands of individuals (USFWS, 2005).

***Dispersal/Migration***

**Dispersal**

Adult: Low (USFWS, 2015)

**Dispersal/Migration Narrative**

Adult: Limited seed mobility restricts the ability of the Pecos sunflower to disperse to other suitable habitats or away from habitat that becomes unsuitable (USFWS, 2015).

***Population Information and Trends***

**Population Trends:**

Unknown (NatureServe, 2015)

**Number of Populations:**

7 (USFWS, 2005)

**Population Size:**

< 100 to > 200,000 per site, fluctuates yearly (USFWS, 2015)

**Adaptability:**

Low (inferred from USFWS, 2015)

**Population Narrative:**

At some occurrences it is locally abundant - maybe > 3000 individuals in total - but some New Mexico occurrences are small and nonviable. At present there are six general areas where the species occurs: four in New Mexico and two in Texas. There are between 1 and 11 sites at each of these six general locations for a total of 25 sites. Ten of the 11 Pecos River sites occur within a 22 mile (36 km) stretch of the Pecos River Valley. All eight observations in the Santa Rosa area occur within a four square-mile area. The two sites in Grants are near the San Jose River and separated from the Laguna population by approximately 44 miles (73 km). The two Diamond Y sites are within three miles of each other. The Diamond Y and East Sandia Springs Preserves are within 50 miles (80 km) of each other. The Texas sites are approximately 150 miles (241 km) south of the most southerly New Mexico site. The overall trend for the species is unclear as the historical distribution, with few exceptions, is unknown (NatureServe, 2015). The Pecos sunflower has a small, localized range, such that either a natural (e.g., drought) or anthropogenic (e.g., water withdrawal) perturbation can eliminate many or all of the existing populations. The number of sunflowers per site varies from less than 100 to several hundred thousand. Because Pecos sunflower is an annual, the number of plants per site can fluctuate greatly from year to year with changes in precipitation and depth to ground water. The Pecos sunflower has a small, localized range, such that either a natural (e.g., drought) or anthropogenic (e.g., water withdrawal) perturbation can eliminate many or all of the existing populations (USFWS, 2015). Pecos sunflower occurs in seven populations; two occur in west Texas and five are located in New Mexico (USFWS, 2005). The Pecos sunflower is a wetland plant that was known from only a single population near Fort Stockton, Pecos County, Texas, when it was proposed as a candidate for listing as endangered under the Act on December 15, 1980 (45 FR 82480). Subsequent field surveys for this species found additional populations in New Mexico and Texas. At the time of listing, Pecos sunflower was known from 25 sites that occurred in five general areas. These areas were Pecos and Reeves counties, Texas, in the vicinity of Fort Stockton and Balmorhea; Chaves County, New Mexico, from Dexter to just north of Roswell; Guadalupe County, New Mexico, in the vicinity of Santa Rosa; Valencia County, New Mexico, along the lower part of the Rio San Jose; and Cibola County, New Mexico, in the vicinity of Grants. There were three sites in the Fort Stockton to Balmorhea area, eleven in the Dexter/Roswell area, eight in the Santa Rosa area, one along the lower Rio San Jose, and two in the Grants area (Service 1999). In addition, since listing, two new sites on the middle Rio Grande have been added, additional sites at the Ladd S. Gordon Waterfowl Complex, population expansion on BLM land in the Dexter/Roswell area, several new sites in the Santa Rosa area, and expansion of a site in Texas. There are occurrences of Pecos sunflower on State, Federal, tribal land, and several private land holdings (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Reduction of water in springs (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Loss or alteration of spring habitat continues to be the main threat to Pecos sunflower. Lowering water tables from aquifer withdrawals for irrigation and municipal use has degraded many desert spring habitats. The primary threat to the Pecos sunflower in west Texas is the potential failure of spring flow due to excessive groundwater pumping or drought or both, which would result in total habitat loss for the species. There is evidence that spring habitats have been historically reduced or eliminated by aquifer depletion on the Bitter Lake NWR (Jones and Balleau 1996). In addition, recent drought years may have impacted the size of Pecos sunflower populations on La Joya WMA (Hirsch 2012). Here, the total number of acres occupied by Pecos sunflower fell from 261 ac (105.622 ha) in 2010, to 224 ac (90.65 ha) in 2011, to 200 ac (80.94 ha) in 2012, as the drought in New Mexico intensified (USFWS, 2015).

**Stressor:** Nonnative plants (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Exotic plants have potential to seriously impact the native plant community composition and ecological integrity of arid land springs and cienegas. Exotic trees, especially salt cedar and Russian olive can almost completely convert a treeless cienega to a dense woodland with little understory vegetation. Aggressive, rhizomatous non-native grasses and forbs compete with, and replace, native cienega plants, especially in areas of soil disturbance. Herbaceous

exotics that are currently degrading some arid land springs and cienegas include Persoon (Johnsongrass) (Sorghum halepense), Hudson meadow fescue and perennial pepperweed (USFWS, 2015).

**Stressor:** Water contamination (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Water contamination, particularly from oil and gas operations, could be a potential threat for Pecos sunflower, but the effects on this species have not been studied. In order to assess the potential for contamination, a study was completed in September 1999 to delineate the area that serves as sources of water for the springs on Bitter Lake NWR (Balleau Groundwater, Inc. 1999). This study reported that the sources of water that will reach Bitter Lake NWR's springs include a broad area beginning west of Roswell near Eightmile Draw, extending to the northeast to Salt Creek, and southeast to Bitter Lake NWR. This area represents possible pathways from which contaminants may enter the groundwater that feeds the springs on the Refuge. This broad area is located within a portion of the Roswell Basin and contains a mosaic of Federal, State, City, and private lands with multiple land uses, including expanding urban development. There are 378 natural gas and oil wells in the 12-township area encompassing the source-water capture zone for the Middle Tract of Bitter Lake NWR that are potential sources of contamination (Go-Tech 2010). The Diamond Y Springs Complex is within an active oil and gas extraction field. At this time, there are still many active wells and pipelines located within approximately 330 ft. (100 m) of the surface waters at the springs. In addition, a natural gas refinery is located within 0.5 mi (0.8 km) upstream of Diamond Y Spring (USFWS, 2015).

**Stressor:** Climate change (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Increased air temperatures lead to higher evaporation rates, which may reduce the amount of runoff, groundwater recharge, and consequently spring discharge. Increased temperatures across the Southwest may also increase the extent of area influenced by drought (Lenart 2003), decreasing groundwater recharge regionally, and thereby reducing spring discharge. Prolonged drought leading to diminishment or drying of springs would have a negative impact on Pecos sunflower. Springs would not have to dry out completely to have an adverse effect. In addition, as water becomes increasingly scarce, conflict over its use becomes more intense. The proportion of human and livestock consumption of water would be expected to increase during drought. Any of these factors, alone or in combination, could lead to either the reduction or extirpation of Pecos sunflower populations. Therefore, climate change is a significant threat to the Pecos sunflower into the foreseeable future (USFWS, 2015).

**Stressor:** excessive livestock grazing (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** excessive livestock grazing (USFWS, 2023)

**Stressor:** Highway maintenance (USFWS, 2023)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** mowing, and highway maintenance (USFWS, 2023)

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 8

**Delisting Criteria:**
1. Identify and establish at least one core conservation area for Pecos sunflower in each of the four distinct recovery regions that would collectively, if protected, ensure the long-term survival of the species. Each core habitat must occur on wetlands that are not threatened by depletion of the contributing aquifer and have demonstrated a self-perpetuating stand of Pecos sunflowers of greater than 5,000 individuals for a minimum of 7 out of 10 years. In addition to the core conservation area, each region should have at minimum one isolated stand of protected Pecos sunflowers with greater than 1,600 individuals for at least 7 out of 10 years to protect against catastrophic loss of the regional population (USFWS, 2015).

2. Assure long-term protection of designated core conservation areas and designated isolated stands in perpetuity through the implementation of appropriate management plans, conservation easements, or land acquisitions (USFWS, 2015).

**Recovery Actions:**
- Identify and establish core conservation areas and isolated stands (USFWS, 2005).
- Identify and address information gaps, compatible uses, and management actions regarding Pecos sunflower distribution, biology and aquifer stability (USFWS, 2005).
- Protect core conservation areas and isolated stands through landowner education, implementation of management plans, conservation easements, and land acquisition (USFWS, 2005).
- Monitor Pecos sunflower conservation areas and management actions as needed to satisfy delisting criteria (USFWS, 2005).
- Habitat protection through land acquisition or conservation agreements with landowners is the most important remaining recovery task. The development of management plans for the different agencies, as outlined in the recovery plan, should continue to be pursued. Government programs that acquire cienegas or assist landowners with their management are greatly needed (USFWS, 2015).
- Non-native tree species and thatch should continue to be removed in occupied and potential Pecos sunflower habitats. Pecos sunflowers should be re-seeded in suitable areas with willing land owners or managers within the range of the species to expand occupied habitats. The Pecos sunflower would also make an excellent focal species for public education and awareness of the importance of wetlands and the recovery of listed species. These opportunities should be explored and implemented where appropriate (USFWS, 2015).
- The recovery criteria in the Pecos Sunflower Recovery Plan (U.S. Fish and Wildlife Service 2005) should be collectively re-evaluated to determine if they constitute the most effective

strategy for conservation and recovery of the species. Of most significance, the actual size of existing core populations is between 50 and 100 times, or even higher multiples in some years of, the minimum number required in the recovery plan. The current recovery criteria may not have considered this much higher number of plants extant throughout the range of the species (USFWS, 2015).

- Survey efforts in occupied and potential habitats should be increased and improved, and surveys should employ an agreed-upon standardized protocol. Surveys should cover the entire range of the species and be repeated at least every 3 years. Existing populations should be monitored to document population trends in response to habitat restoration and maintenance (USFWS, 2015).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Continue management actions and encourage partnerships and agreements in the conservation areas of the Recovery Regions with an emphasis on minimization or elimination of threats to core populations, isolated stands, and aquifer security. Research water contamination potential and point and nonpoint source pollutants relative to core and isolated populations. Continue monitoring of the populations in their respective Recovery Regions. This may include analysis of core area mapping for changes in density, continued monitoring on the Overflow wetlands and surrounding BLM lands, the population on the Bernardo Unit of the Ladd S. Gordon Complex, the effects of fire, the water table at Blue Hole Ciénega with a prioritization of the mechanisms regulating groundwater availability, and consider similar monitoring efforts for water availability for populations in Texas. Study the impacts of different types of grazing in the isolated populations of the Recovery Units, and monitor the impacts of feral hogs in the West Texas recovery unit. There is opportunity for cooperation with NMDOT's plans to restore, create or enhance wetlands to benefit Pecos sunflower with excavation, plantings, fencing, natural channel design modifications, and follow-up monitoring (NMDOT 2023) (USFWS, 2023).

# SPECIES ACCOUNT: *Helianthus schweinitzii* (Schweinitz's sunflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 5/7/1991; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

A perennial herb that produces solitary stems, up to 2 m tall and bears yellow flower heads in late summer and early autumn (NatureServe, 2015).

**Taxonomy**

Heiser et al. (1969), in the most recent monograph of the genus Helianthus, placed H. schweinitzii in Section Divaricati, Series Gigantel. Its closest relatives include other members of the Gigantei series, such as H. giganteus Linnaeus. H. maximiliani Schrader, H. resinosus Small, and H. grosseserratus Martens. The small heads, however, make H. schweinitzii anomalous in the Gigantei (USFWS, 1994).

**Historical Range**

Endemic to Piedmont (and central Plateau) of North Carolina and South Carolina (NatureServe, 2015). Past reports known from other parts of North and South Carolina, including Columbus County. North Carolina, and Horry County, South Carolina (both in the outer Coastal Plain), and Stokes County, North Carolina (in the upper Piedmont of North Carolina near the Virginia border) (USFWS, 1994).

**Current Range**

The species' distribution includes 13 NC counties (the original five plus Anson, Davidson, Gaston, Montgomery, Randolph, Richmond, Stokes, Surry) and two SC counties (Lancaster and York) (USFWS, 2010).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual, vegetative (USFWS, 1994)

**Lifespan**

Adult: > 10 years (USFWS, 1994)

**Breeding Season**

Adult: August - first frost (USFWS, 1994)

**Reproduction Narrative**

Adult: It is a long-lived perennial with individuals probably living for decades. The species blooms from late August to frost. The relative importance of sexual (by seed) and asexual (by rhizome) reproduction is not known in this species. Schweinitz's sunflower can also be propagated from pieces of the tubers. New plants readily sprout from entire or partial tubers (Creel, personal communication, 1992) (USFWS, 1994).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Oak-pine-hickory woods, piedmont longleaf pine forests (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Full to partial sun (NatureServe, 2015); periodic fire (USFWS, 1994)

**Geographic or Habitat Restraints or Barriers**

Adult: Dense vegetation (USFWS, 1994)

**Spatial Arrangements of the Population**

Adult: Clumped (see population narrative)

**Environmental Specificity**

Adult: Broad (inferred from USFWS, 1994)

**Habitat Narrative**

Adult: Clearings in, and edges of, upland oak-pine-hickory woods and piedmont longleaf pine forests in moist to dryish sandy loams. Requires the full to partial sun of an open habitat, which was formerly maintained over the species' range by wildfires and grazing by herds of bison and elk. Now most occurrences are confined to roadsides and powerline clearings. (NatureServe, 2015). Although H. schweinitzii substrates in the Carolina Slate Belt are primarily mafic rocks (of either volcanic, plutonic, or sedimentary origin), the species also appears to occur on intermediate and even felsic rocks. With fire operating in the landscape to maintain open and semi-open habitats (Piedmont prairies and oak barrens or oak savannas), it is possible that Schweinitz's sunflower had a wider ecological amplitude than is apparent to us in the modern landscape. They also appear to be detrimentally affected by growing in dense competing vegetation, even if the other vegetation does not shade them (Bradford-Clebsch. personal communication. 1992) (USFWS, 1994).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Increasing (USFWS, 2024)

**Number of Populations:**

94 total, 54 protected (USFWS, 2024)

**Population Size:**

>56,000 (USFWS, 2024)

**Population Narrative:**

Although monitoring for all 90 populations (278 extant EOs) is mostly infrequent and inconsistent, available data does suggest an increase in abundance in populations with potential to provide recovery (24 populations in NC and SC); however, only five populations in NC (representing four counties) and possibly one population in SC (representing one county) are currently of good to excellent viability. Threats identified in the 1990 listing rule and the 2010 5-year review are still current threats. Development pressure remains a significant threat to Schweinitz's sunflower and a TaILS database search yielded 380 consultations associated with the species range-wide since the 2010 5-year review. The Metrolina MSA, which includes York and Lancaster Counties in SC, continues to urbanize. While deer browse is known to be a threat to the species, small mammal and weevil herbivory has also been identified as impacting the species. Populations that are stable or increasing have maintained that status only through active land management to maintain suitable habitat conditions. Accidental herbicide spraying and lack of ROW maintenance impacts the species range-wide. Data and information outlined in this review highlight the need for continued management and consistent monitoring of abundance and threats throughout the range. Schweinitz's sunflower continues to meet the definition of an endangered species under the Endangered Species Act. (USFWS, 2019) Currently, there are 242 occurrence records (EOs and subEOs) in North Carolina that aggregate into 85 extant populations. The North Carolina records also include 17 occurrences with 41 suboccurrences that are classified as extirpated, historical, or failed-to-find. In South Carolina, there are 76 occurrences that aggregate into the 9 populations in the state's database (SCHTP 2023), with 5 occurrences listed as extirpated. Therefore, there are 94 total extant populations for the known range of Schweinitz's sunflower (Figure 1) that collectively contain 56,000 stems (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Habitat destruction and degradation (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Threats to the species continue to escalate with rapid urbanization and suburban sprawl in the greater Charlotte area. Throughout the species' range, over 90% of known sites occur in managed ROW, where vegetation management practices occasionally mimic patterns of natural disturbance (from fire or native grazers) now largely absent from the present day landscape. However, these same vegetation management practices pose a threat to these occurrences, in that inappropriately timed mowing (e.g., during the growing season, prior to seed set) or excessive herbicide application have adversely impacted the species at several of these locations. Many of these ROW occurrences are along existing roads which are subject to widening and improvement projects which disturb or eliminate the existing adjacent ROW. The NCDOT has a program in which roadside occurrences of federally listed plant species are posted with signs prohibiting growing season mowing or herbicide application. Despite these efforts, 28 of 63 NCDOT sites containing H. schweinitzii were reportedly adversely impacted at least once as of 2003 (USFWS, 2010).

**Stressor:** Herbicides (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The two most recent accidental herbicide spraying events involving Schweinitz's sunflower occurred in York County, SC in 2015 and Mecklenburg County, NC in 2018. As a result of these, and similar incidents, Duke Energy is implementing several precautionary measures (Fletcher 2019, Duke, pers. comm.). They are developing an "on-board" Geographic Information System to aid employees and contractors in identifying locations of sensitive habitats and species. In-field employees and contractors, as well as machinery, will be equipped with mobile tablets and mapping software that identifies "red zones" that should not be sprayed or that have specific management requirements. This technology should be in use by spring of 2020. Additionally, in 2018, recovery biologists with the Asheville and Raleigh field offices provided comments and recommendations for updated signage on Duke Energy powerline ROWs and species fact sheets. Installation of updated and new signs, at the sensitive habitat areas, began in the spring of 2019 (a total of 650 signs) and fact sheets are distributed to employees and contractors prior to ROW maintenance activities. The updated signs are in both English and Spanish, and are posted at eye-level. (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**
1. 10 geographically distinct, self-sustaining populations are protected in at least 4 counties in North Carolina and one in South Carolina (USFWS, 2010).

2. Managers have been designated for each population (USFWS, 2010).

3. Management plans have been developed and implemented (USFWS, 2010).

4. Populations have been maintained for 5 years (USFWS, 2010).

Recovery Priority Number: 2C

**Delisting Criteria:**
1. 15 geographically distinct, self-sustaining populations are protected in at least 4 counties in North Carolina and one in South Carolina (USFWS, 2010).

2. Management plans have been implemented (USFWS, 2010).

3. Populations (as measured by number of adult plants) have been stable or increasing for 10 years (USFWS, 2010).

4. Permanent conservation ownership and management of at least 10 populations are assured by legally binding agreements (USFWS, 2010).

**Recovery Actions:**
- Implement emergency protective management of known remnant populations (USFWS, 1994).
- Survey suitable habitat for additional populations and potential reintroduction sites (USFWS, 1994).
- Protect viable populations through a range of protection tools (management agreements, acquisition, registry, cooperative agreements, etc.) (USFWS, 1994).
- Monitor existing populations (USFWS, 1994).
- Conduct research on the biology of the species and on suitable management tools for maintaining the natural ecosystem in which it occurred (USFWS, 1994).
- Implement management on protected populations (USFWS, 1994).
- For sites with the potential to contribute toward the species' recovery (Appendix B, Tables B.1 and B.2), work with appropriate owners/managers to implement monitoring capable of

producing reliable trend data at each site. Range-wide standardized monitoring protocol are generally not regarded as feasible for this species, due to the widely varying sizes of populations and the resources available to monitor them. However, site-specific protocol could be implemented such that counts or estimates provided at a given site are directly comparable from one monitoring period to the next (USFWS, 2010).

- For sites with the potential to contribute toward the species' recovery (Appendix B, Tables B.1 and B.2), characterize existing vegetation using standardized community classification methods (e.g., NatureServe's community classification systems and Schafale and Weakley (1990)). Use this information to inform restoration objectives and direct future site protection efforts toward the highest quality habitats (USFWS, 2010).
- Devise recovery criteria which balance the availability of suitable habitat with opportunities for restoration, management, and protection as dictated by landowner willingness and resource availability. These criteria should emphasize the role of prescribed fire in site restoration and management, but allow for those instances in which sites cannot be managed with fire (USFWS, 2010).
- Work with Dr. Richard Houk (Winthrop University, retired) to find successors to continue his monitoring efforts in South Carolina (USFWS, 2010).
- Clarify the role of controlled propagation, rescue and relocation, and public demonstration gardens in the species' recovery, so that sites supporting native populations in conjunction with remnants of native plant communities are prioritized for protection (above sites characterized by rescued and introduced plant material) (USFWS, 2010).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTION The 2010 5-year review included a list of recommendations to improve recovery of the species. These actions, listed below, remain applicable to species recovery. For sites with the potential to contribute toward the species' recovery, work with appropriate owners/managers to implement monitoring capable of producing reliable trend data at each site. Range-wide standardized monitoring protocol are generally not regarded as feasible for this species, due to the widely varying sizes of populations and the resources available to monitor them. However, site-specific protocol could be implemented such that counts or estimates provided at a given site are directly comparable from one monitoring period to the next. For sites with the potential to contribute toward the species' recovery, characterize existing vegetation using standardized community classification methods (e.g., NatureServe's community classification systems and Schafale and Weakley (1990)). Use this information to inform restoration objectives and direct future site protection efforts toward the highest quality habitats. Devise recovery criteria which balance the availability of suitable habitat with opportunities for restoration, management, and protection as dictated by landowner willingness and resource availability. These criteria should emphasize the role of prescribed fire in site restoration and management, but allow for those instances in which sites cannot be managed with fire. Work with Dr. Richard Houk (Winthrop University, retired) to find successors to continue his monitoring efforts in South Carolina. Clarify the role of controlled propagation, rescue and relocation, and public demonstration gardens in the species' recovery, so that sites supporting native populations in conjunction with remnants of native plant communities are prioritized for protection (above sites characterized by rescued and introduced plant material). In light of new information, additional future actions are recommended below: Convene a working group of species experts to focus on species recovery. The working group would concentrate on, but not be limited to: o Defining populations, identifying populations on which to focus recovery, and assigning a responsible party for each identified population. o Determining what constitutes a "self-sustaining" population and determining the appropriateness of the criterion for a species dependent on active management. o Developing a standardized, tiered monitoring protocol that could be used on many different types of Schweinitz's sunflower sites. o Determining what constitutes a "natural" habitat considering the species' current relationship to the landscape (i.e. primarily in ROWs). o Clarifying the role of controlled propagation and relocation in recovery o Providing support and, if feasible, pooling resources for management and monitoring. o Prioritizing unprotected sites that are critical for recovery and working towards permanent protection. o Having a regularly scheduled meeting to share resources and information. Support research to determine the geographical extent of Smicronyx pinguis (weevil) and level of threat to Schweinitz's sunflower. Support research to determine if Schweinitz's sunflower is hybridizing with other Helianthus species and to what extent. Encourage Departments of Transportation and utility companies to maintain ROWs in a manner that is beneficial to Schweinitz's sunflower. (USFWS, 2019)

- RECOMMENDED FUTURE ACTIVITIES Recovery Activities The 2010 and 2019 5-year reviews include a list of recommendations to improve recovery of the species. These highlight some recovery activities listed below. • Continue to work with appropriate owners/managers to implement monitoring capable of producing reliable trend data at each site. However, site-specific protocols could be implemented such that counts or estimates provided at a given site are directly comparable from one monitoring period to the next. • For potential reintroduction or restoration sites, characterize existing vegetation using standardized community classification methods (e.g., NatureServe's community classification systems, Schafale (2024) Classification of the Natural Communities of North Carolina). Use this information to inform restoration objectives and direct future site protection efforts toward the highest quality habitats. • Continue coordination of controlled propagation, rescue and relocation, and public demonstration gardens for species' recovery. Consider prioritization of sites supporting native populations in conjunction with remnants of native plant communities prioritized for protection. • Work with species experts to consider: o Defining populations. o Prioritizing populations for recovery. o Determining traits of a "self-sustaining" population. o Developing a standardized, monitoring protocol. o Assisting in management and monitoring. • Support research to enhance conservation efforts and address current knowledge gaps: o Investigate the geographical extent of Smicronyx pinguis (weevil) and its threat level to Schweinitz's sunflower. o Examine whether Schweinitz's sunflower is hybridizing with other Helianthus species. o Assess the performance of the species outside of its current climatic niches across projected novel environments and its threat level. o Expand knowledge on the species' life history, biology, and ecology. • Encourage the Departments of Transportation and utility companies to maintain rights-ofways in a manner that is beneficial to Schweinitz's sunflower (USFWS, 2024).

# SPECIES ACCOUNT: *Helianthus verticillatus* (Whorled Sunflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 8/1/2014; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

A tall, perennial, herbaceous sunflower 1-2 meters in height with flower heads about 1 cm wide (Matthews et al. 2002). Flowers from August into October (NatureServe, 2015).

**Taxonomy**

The U.S. Fish and Wildlife Service (Call 2009) accepts this taxon as a species in considering it a candidate for federal listing; Matthews et al. (2002) and Flora of North America Editorial Committee (2006) also treat it as a species. Two supporting studies are cited by the USFWS: (1) morphological studies and root-tip chromosome counts which showed it to be a distinct, fertile diploid (Matthews et al. 2002); and (2) comparative genetic studies with its putative parents (H. grosserratus and H. angustifolius), which showed that it does not exhibit a mixture of parental alleles at nuclear loci and does not share chloroplast DNA haplotype with either of its putative parents (Ellis et al. 2006). In contrast, the Kartesz checklists (1994 and 1999) treat this taxon as a hybrid between Helianthus angustifolius and H. grosseserratus, following earlier treatments written when it was known from only the type specimen (NatureServe, 2015).

**Historical Range**

The species is known from Cherokee County, Alabama; Floyd County, Georgia; and McNairy and Madison Counties, Tennessee (USFWS, 2013).

**Current Range**

This species occurs in remnant prairie habitats found in uplands and swales of headwater streams in the Coosa River watershed in Georgia and Alabama and in the East Fork Forked Deer and Tuscumbia Rivers' watersheds in Tennessee (USFWS, 2014).

**Critical Habitat Designated**

Yes; 8/26/2014.

**Legal Description**

On August 26, 2014, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Helianthus verticillatus (Whorled Sunflower) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes four critical habitat units (CHUs), in Indiana, Alabama, Georgia and Tennessee (79 FR 50990-51039).

**Critical Habitat Designation**

The critical habitat designation for Helianthus verticillatus includes four CHUs in Cherokee County, Alabama; Floyd County, Georgia; and Madison and McNairy Counties, Tennessee. This species critical habitat encompasses approximately 1,542.3 acres (ac) (624.2 hectares (ha)) (79 FR 50990-51039).

Unit 1: Mud Creek: Unit 1 consists of 210.6 ha (520.4 ac) of privately owned lands in Cherokee County, Alabama, located approximately 11.6 km (7.2 mi) southeast of the city limits of Cedar

Bluff. The unit begins approximately 0.06 km (0.04 mi) north of the junction of CR–164 and CR–29 and extends in a northerly direction to encompass much of the drainage area of an unnamed tributary to Mud Creek and to the northeast to encompass much of the drainage area of a second unnamed tributary to Mud Creek. The easternmost boundary of this unit is adjacent to CR– 101, from approximately 1.0 km (0.6 mi) to 1.4 km (0.9 mi) north of its junction with CR–164. Silt loam and silty clay loam soils are present throughout the unit, spanning broad uplands, and terraces and flood plains of headwater streams in the Coosa River watershed (PCE 1). The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats of soil disturbance due to silvicultural site preparation or timber harvest; indiscriminate herbicide use or mowing for silvicultural purposes or road right-of-way maintenance; conversion of remnant prairie habitat to agricultural or industrial forestry uses; and excessive shading or competition from native woody species or invasive, nonnative plants.

Unit 2: Coosa Valley Prairie: Unit 2 consists of 366.9 ha (906.5 ac) of privately owned lands in Floyd County, Georgia, located approximately 4.5 km (2.8 mi) northwest of the city limits of Cave Spring. This unit corresponds to the boundary of The Nature Conservancy's conservation easement on lands formerly owned by The Campbell Group and now owned by Plum Creek, a site commonly referred to as the Coosa Valley Prairie. The northern boundary of this unit follows Jefferson Road for approximately 1.4 km (0.9 mi) in a southeasterly direction, beginning approximately 1.7 km (1.0 mi) east of the Alabama-Georgia State line. From the eastern extent on Jefferson Road, the unit boundary follows an unnamed dirt road south for a distance of approximately 1.5 km (0.9 mi), where the boundary turns to the west and south before turning back to the north and again to the west, reaching the Alabama–Georgia State line. Here, the unit follows the State line in a northwest direction for approximately 0.8 km (0.5 mi) before turning east and following an unnamed dirt road in a northeasterly direction for approximately 2.7 km (1.7 mi) and reuniting with the northern boundary on Jefferson Road. Silt loam and silty clay loam soils are present throughout the unit, spanning broad uplands, depressions, and terraces and flood plains of headwater streams in the Coosa River watershed (PCE 1). Prairie openings and woodlands with low levels of canopy cover (PCE 2) are present throughout much of the unit. While Ellis and McCauley (2009, pp. 1837–1838) found very few viable achenes and low germination rates at this site, whorled sunflower has responded favorably to habitat management efforts by increasing in numbers, and there likely are now a sufficient number of compatible mates for production of viable achenes (PCE 3) at this site. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats of soil disturbance due to silvicultural site preparation or timber harvest; indiscriminate herbicide use or mowing for silvicultural purposes or road right-of-way maintenance; conversion of remnant prairie habitat to agricultural or industrial forestry uses, and excessive shading or competition from native woody species or invasive, nonnative plants.

Unit 3: Prairie Branch: Unit 3 consists of 6.0 ha (14.9 ac) of privately owned land in McNairy County, Tennessee, and is located approximately 0.6 km (0.5 mi) south of the easternmost city limit of Ramer. This unit is located along Prairie Branch, a tributary to Muddy Creek, beginning approximately 0.42 km (0.26 mi) upstream of the point where it passes under Mt. Vernon Road and extending downstream for approximately 2.0 km (1.2 mi). Within this reach, the critical habitat unit forms a buffer extending 15 m (50 ft) upslope from the tops of the banks on both sides of Prairie Branch. Sandy loam soils (PCE 1) are present throughout the unit, as are small patches of vegetation containing whorled sunflower and other wet prairie species (PCE 2). The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats of soil disturbance due to agricultural practices; indiscriminate herbicide use or mowing for road or railroad right-of-way maintenance; conversion of remnant prairie habitat to agricultural uses; and competition from invasive, nonnative plants.

Unit 4: Pinson: Unit 4 consists of 40.7 ha (100.5 ac) of privately owned land in Madison County, Tennessee, and is located approximately 4.1 km (2.5 mi) northwest of the city limits of Henderson, Tennessee. Beginning approximately 0.7 km southeast of the junction of U.S.–45 and Bear Creek Road, this unit extends approximately 0.08 km (0.05 mi) northeast of U.S.–45, crossing a railroad track, and then turns in a southeasterly direction, paralleling the track for a distance of approximately 0.5 km (0.3 mi). From this corner, the unit boundary turns southwest for a distance of approximately 0.79 km (0.49 mi), and then turns to the northwest for a distance of approximately 0.65 km (0.4 mi). From this corner, the unit boundary turns to the northeast for a distance of approximately 0.63 km (0.39 mi). Silt loam soils (PCE 1) are present throughout the unit, small patches of vegetation containing whorled sunflower and wet prairie species (PCE 2) are present, and a sufficient number of compatible mates are present for the production of a limited number of viable achenes (PCE 3) (Ellis and McCauley 2009, p. 1838). The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats of soil disturbance due to agricultural practices; indiscriminate herbicide use or mowing road or railroad right-of-way maintenance; conversion of remnant prairie habitat to agricultural uses; and excessive shading or competition from native woody species or invasive, nonnative plants. Much of the land within this unit has been converted to agricultural uses, but is included because of the potential for decreasing fragmentation among the subpopulations that are present in this unit by restoring suitable vegetation within previously converted lands.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Helianthus verticillatus critical habitat consists of three components (79 FR 50990-51039):

(i) Silt loam, silty clay loam, or fine sandy loam soils on land forms including broad uplands, depressions, stream terraces, and floodplains within the headwaters of the Coosa River in Alabama and Georgia and the East Fork Forked Deer and Tuscumbia rivers in Tennessee.

(ii) Sites in which forest canopy is absent, or where woody vegetation is present at sufficiently low densities to provide full or partial sunlight to whorled sunflower plants for most of the day, and which support vegetation characteristic of moist prairie communities. Invasive, nonnative plants must be absent or present in sufficiently low numbers to not inhibit growth or reproduction of whorled sunflower.

(iii) Occupied sites in which a sufficient number of compatible mates are present for outcrossing and production of viable achenes to occur.

**Special Management Considerations or Protections**

The features essential to the conservation of whorled sunflower may require special management considerations or protection to reduce the following threats: (1) Soil disturbance due to silvicultural site preparation, timber harvest, or cultivation of row crops; (2) indiscriminate herbicide use or mowing; (3) conversion of remnant prairie habitat to agricultural or industrial forestry uses; and (4) excessive shading or competition from native woody species or invasive, nonnative plants. Management activities that could ameliorate these threats include, but are not limited to: (1) Avoiding areas located in close proximity to whorled sunflower sites when planning for establishing new sites for agriculture or pulpwood and timber production; (2) ensuring that herbicide use or mowing does not occur in whorled sunflower sites during the species' growing season; (3) locating suitable habitat, determining presence or absence of whorled sunflower, and protecting or restoring as many sites or complexes of sites as possible; (4) managing, including prescribed burning, mowing, and bushhogging, to reduce canopy cover, minimize competition from native and invasive, nonnative plants, and maintain characteristic moist prairie vegetation; (5) reaching out to all landowners, including private, State, and Federal landowners, to raise awareness of the plant and its habitat; and (6) providing technical or financial assistance to landowners to help in the design and implementation of management actions that protect the plant and its habitat.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Vegetative (NatureServe, 2015); sexual (inferred from USFWS, 2014)

**Breeding Season**

Adult: August - October (USFWS, 2013)

**Reproduction Narrative**

Adult: The low number of populations in the wild may be due to poor in situ seed germination (Matthews et al. 2002). However, seed germination is high in the laboratory and the species can reproduce rapidly from rhizomes, forming a dense colony (Call 2009) (NatureServe, 2015). This species is self-incompatible (USFWS, 2014). It produces flowers from August into October (Matthews et al. 2002, pp. 17–20; Ellis and McCauley 2008, p. 1837) (USFWS, 2013).

**Habitat Type**

Adult: Terrestrial, wetland (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Wet prairie, calcareous barrens, riparian (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Full to partial sunlight (USFWS, 2014)

**Geographic or Habitat Restraints or Barriers**

Adult: Succession (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (USFWS, 2013)

**Environmental Specificity**

Adult: Very narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: A narrow habitat specialist occurring in remnant wet prairie areas and calcareous barrens, in moist, prairie-like openings in woodlands and along adjacent creeks. Soils are sandy clays which are alkaline, high in organic matter, and seasonally wet. Some associated plant species, including Schizachyrium scoparium, Sorghastrum nutans, Andropogon gerardii, and Panicum virgatum, suggest a strong prairie affinity. Other associates include Carex cherokeensis, Sporobolus heterolepis, Physostegia virginiana, Silphium terebinthinaceum, Pycnanthemum virginianum, Symphyotrichum novae-angliae, Hypericum sphaerocarpum, H. angustifolius, Helenium autumnale, and Marshallia mohrii. Most remaining wet prairies are remnants along rights-of-way where succession is artificially impeded (Call 2009) (NatureServe, 2015). The soil types are silt loams, silty clay loams, and fine sandy loams at the sites where whorled sunflower occurs. These soils share the characteristics of being strongly to extremely acidic and having low to moderate natural fertility and low to medium organic matter content (USDA 1997, pp. 73–76; USDA 1978a, pp. 24–54; USDA 1978b, p. 20; USDA 1978c, p. 44). Full or partial sunlight for most of the day is an essential feature for this species (USFWS, 2014). Initial efforts to estimate population sizes of whorled sunflower relied on counting individual stems (Allison 2002, pp. 3–8; Schotz 2001, pp. 8–10); however, due to the species' clonal growth habit, stem counts overestimate the true number of genetically distinct individuals (genets) (USFWS, 2013).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Unknown (NatureServe, 2015)

**Species Trends:**

Unknown (NatureServe, 2015)

**Number of Populations:**

26 extant (USFWS, 2025)

**Additional Population-level Information:**

Whorled sunflower, a perennial member of the aster (or sunflower) family, is known from nine natural populations in Alabama, Georgia, Mississippi, Tennessee, and Virginia, of which eight are extant. In addition, there is one established population in Tennessee. Natural populations are threatened by mechanical and chemical vegetation management for industrial forestry, rightofway maintenance, and agriculture; shading and competition resulting from vegetation succession; and limited distribution and small population sizes (USFWS, 2023).

**Population Narrative:**

Whorled sunflower was known from five populations in 2020 and increased to eight extant populations in 2023 (Service 2020, 2023b, respectively). Surveys and chance discoveries have revealed additional populations in Mississippi and Virginia, most of which were found in Mississippi (Kees 2022; Breeden 2024b) so that 26 natural, extant populations are now known across the species' range. Mississippi. These recent discoveries have increased whorled sunflower's known range by six counties in Mississippi (including new discoveries in both counties with previously known populations; Table 1; Figure 1). While recent surveys have revealed substantially more populations in Mississippi (3 populations in 2023 versus 21 now), these populations are generally small, consisting of one to several stems, but can be locally abundant with 100s of stems (Breeden 2024b). These surveys may have also found 20 additional populations in Mississippi, but lack of access to plants prevented confirmation of species identity (Breeden 2024b). Virginia. In Virginia, one new population was recently discovered in Roanoke County; however, this is considered to be a planted population (Townsend 2023, pers. comm.; Virginia Botanical Associates 2025). The provenance of Virginia's previously discovered population has also been questioned and may have also been planted (see Service 2023c for more detail). Both Virginia's previously known population and recently discovered planted population occur on conservation lands—the National Park Service's Blue Ridge Parkway in Franklin County and county owned land Roanoke County, respectively. Additional monitoring and evaluation of Roanoke County's whorled sunflower will be required. Tennessee. Recent discovery surveys in Tennessee did not identify any new populations (Breeden 2024b). Two small populations in Tennessee have been transplanted (Table 1), one on Freed-Hardeman University in Chester County (described in more detail in Service 2020) and another established on Madison County's Pinson Mounds Archaeological Park in 2022 and 2023 (Breeden 2024b). Additional potential reintroduction sites in Tennessee have also been identified. Of Tennessee's two remaining natural populations, one is small (less than 10 stems in 2022) and the other consists of several patches collectively supporting over 200 stems as of 2022 (Tennessee Department of Environment and Conservation 2024). Georgia. Georgia's population, located on private timber lands protected by a conservation easement, is in apparent decline possibly due to the lack of prescribed fire in recent years (Breeden 2024a, pers. comm.; Brown 2024, pers. comm.). The Georgia population was previously robust and one of the largest known populations (Service 2020, 2023c). Alabama. Alabama's population is split among two small sites in Cherokee County (Service 2023c; Thompson and Kirby 2023). A small test planting of 10 rhizomes in DeKalb County, Alabama, was completed during 2021 (Thompson and Kirby 2023), but this site is not yet counted toward recovery given its preliminary nature. (USFWS, 2025)

### *Threats and Stressors*

**Stressor:** Habitat destruction and modification (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The threats to whorled sunflower from habitat destruction and modification are occurring throughout the entire range of the species. These threats include mechanical or chemical vegetation management associated with industrial forestry practices, maintenance of transportation and utility rights-of-way, agricultural practices, and shading and competition. While a conservation easement and suitable habitat management alleviate threats from industrial forestry that otherwise would adversely affect the Georgia population, one of the Alabama whorled sunflower subpopulations currently is threatened by industrial forestry

practices. The population-level impacts from these activities are expected to continue into the future (USFWS, 2013).

**Stressor:** Small, isolated populations (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The whorled sunflower is vulnerable to localized extinction because of its extremely restricted distribution and small population sizes at most known locations, which reduces the resilience of these populations to recover from acute demographic effects of threats to its habitat. the highly fragmented distribution of populations within Tennessee, combined with their disjunct location with respect to those in Georgia and Alabama, presumably precludes gene flow among them and leaves little chance of natural recolonization of these populations in the event of localized extinctions. Small population size could be affecting reproductive fitness of the whorled sunflower. The findings of Ellis and McCauley (2008, entire) suggest that the Madison County, Tennessee, population is reproductively less fit than the Alabama population. Ellis and McCauley (2008, p. 1840) offered two possible explanations for reduced reproductive fitness of the Tennessee population, including limited mate availability due to limited diversity of self-incompatibility alleles, or more extensive inbreeding. Both could be contributing to reduced seed production and viability rates (USFWS, 2013).

**Stressor:** Industrial Forestry Practices (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Industrial forestry practices have altered much suitable whorled sunflower habitat in Georgia and Alabama and currently threaten one known subpopulation in Alabama. While surveying potential habitat for additional populations, Jim Allison (Botanist, GDNR, pers. comm., March 9, 1999) observed that much of this species' prairie habitat in Georgia had been converted to pine plantations. Nearly all the Georgia subpopulations and one of the Alabama subpopulations of whorled sunflower are located on lands that are currently owned by Weyerhaeuser. The Georgia subpopulations on Weyerhaeuser Company lands are protected from habitat destruction or degradation by their inclusion in the conservation easement area at the Coosa Valley Prairie, which was donated to TNC by a previous landowner. On lands outside of the conservation easement area at the Coosa Valley Prairie, site preparation for planting pine seedlings has included subsoil plowing sites to improve drainage and conditions for tree root development. Mechanical and chemical methods to control competing vegetation have also been employed for site preparation. These site preparation activities may continue under Weyerhaeuser's ownership, depending on site conditions and needs, but buffers and alterations to specific site preparation practices are employed to limit impacts to rare species (Muckenfuss, pers. comm., September 14, 2017), such as whorled sunflower. Without adequate precautions, these practices could cause direct mortality of whorled sunflower plants at one of the Alabama subpopulations and contribute to habitat degradation due to shading and competition (see "Shading and Competition", below) from planted pines. During timber harvests, either to thin (i.e., reduce density of pine trees to improve growth conditions for remaining trees) or to clear-cut the stand, whorled sunflower plants at this subpopulation could be subjected to indirect adverse effects from soil disturbance or to direct mortality due to movement of harvesting equipment (USFWS, 2023)

**Stressor:** Right-of-Way Maintenance (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Incompatible maintenance activities in utility and transportation ROWs have adversely affected whorled sunflower in Alabama, Mississippi, and Tennessee, and could affect one subpopulation in Georgia. At one of the Alabama subpopulations, whorled sunflower occurs in a narrow strip of vegetation between a roadside and adjacent pine forest, where it is vulnerable to mortality or reduced vigor and reproductive output due to indiscriminate use of herbicides or mowing for ROW maintenance. Poorly timed mowing of this ROW prevented flowering and seed production in some plants at this site in 2008; however, the Alabama Department of Conservation and Natural Resources (ADCNR), Alabama Department of Transportation, and Cherokee County Highway Department cooperated in placing signs at the site to mark the presence of whorled sunflower and attempt to prevent this in the future (Dr. Wayne Barger, Botanist, ADCNR, pers. comm., February 10, 2009); although, periodic replacement might be needed due to vandalism or removal of the signs (Barger, pers. comm., March 6, 2012). In Mississippi, whorled sunflower plants discovered growing in a road ROW in August 2017 were apparently been sprayed with herbicide during the intervening weeks between the initial discovery and a follow-up visit later in the month, which visibly stressed the plants, but did not apparently kill them (Brandon, pers. comms., August 12, 2017, and August 17, 2017). These plants remained extant into 2018 (Brandon, pers. comm., August 6, 2018); however, follow-up visits in 2020 could not relocate plants within the ROW (Breeden, pers. comm., September 14, 2020). Both of Mississippi's remaining two populations also occur in road ROWs and are vulnerable to similar indiscriminate herbicide application. Similarly, plants extending onto a roadside within a power line ROW at the Madison County, Tennessee population were sprayed with herbicide during roadside and power line maintenance in 2004, causing significant mortality (David Lincicome, Rare Species Protection Program Administrator, TDNA, pers. comm., September 22, 2006; Andrea Bishop, Botanist, TDNA, pers. comm., February 21, 2008). Likewise, plants extending into the railroad ROW at the McNairy County, Tennessee, population are vulnerable to adverse effects from potential indiscriminate herbicide application used for railroad ROW maintenance, but installation of appropriate signage may alleviate this threat. A small cluster of plants in one of Georgia's subpopulations is located on the bank of a road adjacent to the Coosa Valley Prairie easement area and is not protected. These examples indicate that incompatible vegetation management (such as indiscriminate herbicide application or poorly timed mowing) along transportation and utility ROWs could adversely affect whorled sunflower populations in Alabama, Mississippi, and Tennessee, and a small subpopulation in Georgia. Regular coordination with parties responsible for maintenance of these ROWs locations will be necessary to avoid future adverse effects to local whorled sunflower populations from indiscriminate mowing or herbicide application (USFWS, 2023).

**Stressor:** Agricultural Practices and Land Conversion (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Whorled sunflower has not been rediscovered at the type locality in Tennessee despite intensive surveys of that area (Nordman 1998, pp. 1–2, Nordman 1999, p. 2). This record is from an 1892 collection and locality information is vague (Matthews et al. 2002, p. 13), so it is

not possible to determine why this population was lost. In Tennessee, much of this species' suitable habitat has presumably been converted to agricultural use, as substantial proportions of the counties in the state where the species has been found have been in row crop production since 1850 (Table 3) (Waisanen and Bliss 2002, p. 13; geographic information system [GIS] data available at http://landcover.usgs.gov/cropland, accessed January 9, 2013). Because this species was not seen following the initial 1892 collection until it was rediscovered in 1994, and was not seen again in Tennessee until 1998, it is impossible to be certain about the historical distribution and abundance of its habitat. However, the data presented in Table 3 indicate that land conversion to agricultural uses has a long and sustained history in the Tennessee counties where whorled sunflower has been found and has likely contributed to loss of the species' habitat and populations (USFWS, 2023).

**Stressor:** Shading and Competition (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Absent natural or human-caused disturbance, habitats where whorled sunflower occurs are threatened by succession of vegetation to a shrub-dominated or forested condition. The largest concentration of plants at the Madison County, Tennessee, population is in a successional old field approximately 1 ha (2.5 ac) in size, which has become almost entirely wooded (Lincicome, pers. comm., November 30, 2017), degrading the largest patch of contiguous habitat where most of this population occurs. Woody species present at this site include Acer negundo (box elder), Liquidambar styraciflua (sweetgum), and Salix nigra (black willow) (TDNA 2006, p. 5), all of which can rapidly invade moist old-field habitats if left unmanaged. No conservation agreements or management plans are in place to ensure that this site receives periodic disturbance to maintain open conditions needed for the growth and sexual reproduction of whorled sunflower. Invasive plants, including, Lonicera japonica (Japanese honeysuckle), Microstegium vimineum (Nepalese browntop, Japanese stiltgrass), and Rosa multiflora (multiflora rose), have been noted at both natural populations in Tennessee (Caitlin Elam, Botanist, Division of Natural Areas, Tennessee Department of Environment and Conservation, pers. comm., October 14, 2019). Likewise, the invasive Ligustrum sinense (Chinese privet) is a persistent problem for Georgia's population (USFWS, 2023)

**Stressor:** Climate Change (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since 1970, the average annual temperature across the Southeast has increased by about 2°F, with the greatest increases occurring during winter months. The geographic extent of areas in the Southeast region affected by moderate to severe spring and summer drought has increased over the past three decades by 12 and 14 percent, respectively (Karl et al. 2009, p. 111). These trends are expected to increase. Rates of warming are predicted to more than double in comparison to what the Southeast has experienced since 1975, with the greatest increases projected for summer months. Depending on the emissions scenario used for modeling change, average temperatures are predicted to increase by 4.5°F to 9°F by the 2080s (Karl et al. 2009, p. 111). While there is considerable variability in rainfall predictions throughout the region, increases in evaporation of moisture from soils and loss of water by plants in response to warmer temperatures are expected to contribute to increased frequency, intensity, and duration of

drought events (USFWS, 2023)

***Recovery***

**Reclassification Criteria:**
CRITERION 1. At least 20 geographically distinct populations—separated by at least 1 mile (1.6 kilometer)—of at least moderate size (at least 100 individuals) are distributed across the species' range, with each of the 4 known ecoregions (Loess Plains, Northern Hilly Gulf Coastal Plain, Southern Crystalline Ridges and Mountains, and Southern Shale Valleys)1 supporting at least 3 such populations, including 1 population within each of the 4 designated critical habitat units. (Addresses Factors A and E.) (USFWS 2023).

CRITERION 2. At least 3 large populations (at least 500 individuals), protected by long-term conservation mechanisms, occur in each of the 4 known ecoregions, for a total of 12 protected populations, and are managed to promote open-canopied habitat, native plant community integrity, and support resilient populations2 of whorled sunflower. (Addresses Factors A, D, and E.) (USFWS, 2023).

CRITERION 3. Monitoring demonstrates that these populations (described in Criteria 1 and 2) are viable, as evidenced by natural recruitment and having stable to increasing populations for at least 10 years (approximately 10 generations). (Addresses Factor E.) (USFWS, 2023).

Recovery Priority Number: 5

**Delisting Criteria:**
Whorled sunflower may be considered for delisting when the above criteria are met and when:
CRITERION 4. At least 20 additional geographically distinct populations of at least moderate size occur within the species' known range for a total of at least 40 extant populations. (Addresses Factors A and E.) (USFWS, 2023).

**Recovery Actions:**
- Not available - this species does not have a recovery plan.
- Avoiding areas located in close proximity to whorled sunflower sites when planning for establishing new sites for agriculture or pulpwood and timber production (USFWS, 2014).
- Ensuring that herbicide use or mowing does not occur in whorled sunflower sites during the species' growing season (USFWS, 2014).
- Locating suitable habitat, determining presence or absence of whorled sunflower, and protecting or restoring as many sites or complexes of sites as possible (USFWS, 2014).
- Managing, including prescribed burning, mowing, and bush hogging, to reduce canopy cover, minimize competition from native and invasive, nonnative plants, and maintain characteristic moist prairie vegetation (USFWS, 2014).
- Reaching out to all landowners, including private, State, and Federal landowners, to raise awareness of the plant and its habitat (USFWS, 2014).
- Providing technical or financial assistance to landowners to help in the design and implementation of management actions that protect the plant and its habitat (USFWS, 2014).

- 1. Work with rights-of-way stakeholders to develop and implement management agreements (USFWS, 2023).
- 2. Work with federal and state agencies, non-governmental conservation organizations, and private landowners to obtain protection for populations on privately owned lands (USFWS, 2023).
- 3. Work with partners and stakeholders to develop and implement management plans for all populations (USFWS, 2023).
- 4. Work with partners and stakeholders to develop and implement a monitoring strategy for all populations (USFWS, 2023).
- 5. Increase the representation and genetic diversity of ex situ (offsite) safeguarding collections of whorled sunflower (USFWS, 2023).
- 6. Facilitate and support surveys to identify new whorled sunflower populations (USFWS, 2023).
- 7. Population augmentation and establishment (USFWS, 2023).
- 8. Conduct research that enhances knowledge of whorled sunflower biology and ecology to facilitate the development of scientifically sound management plans, population viability models, and species/habitat distribution models (USFWS, 2023).
- 9. Coordinate with federal, state, county, and local agencies, and other stakeholders to promote whorled sunflower recovery and identify innovative ways to increase public awareness of the need to protect this species and its habitats (USFWS, 2023).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Finalize the recovery plan. 2. Continue and expand work with federal and state conservation agencies, nongovernmental organizations, right-of-way owners and managers, and private individuals and organizations to protect and manage existing habitats and populations, including the development and implementation of management plans, as needed. 3. Safeguard representative genetic material from all known populations. 4. Search for new populations. 5. Investigate efficacy of habitat management techniques (e.g., fire). Update and improve monitoring and habitat management methods. 6. Conduct studies into the species' life history, biology, and ecology to improve management of the species and its habitat. 7. Conduct studies to determine the number and distribution of populations required to maintain the species' genetic diversity and long-term viability. 8. Investigate metapopulation structure and dynamics of the species. (USFWS, 2020)
- RECOMMENDED FUTURE ACTIVITIES A detailed discussion of recovery criteria and actions are presented in the species' Recovery Plan (Service 2023b) and Recovery Implementation Strategy (Service 2023a). During this status review, new and/or targeted potential recovery activities were identified. These actions are recommended to support and promote recovery of whorled sunflower. Recommendation numbers are for convenient reference only and do not imply prioritization of any activity over others. Recovery Activities 1. Expand searches for additional locations throughout the species' range to identify additional populations. 2. Continue pursuing population establishment and augmentation on protected lands. 3. Continue to expand ex situ (off-site) conservation activities, such as seed banking and growing plants in cultivation, to encompass more populations and increase genetic representation in safeguarding collections. 4. Work with landowners and other interested parties to improve habitat management and pursue protection of populations. Monitoring and Research Activities 1. Complete genetic and morphological study to determine if Mississippi's populations are taxonomically distinct from other whorled sunflower populations. 2. Create species distribution model to guide future population searches and identify potentially

suitable areas for potential population establishment. 3. Study pollinator community associated with the whorled sunflower to inform population delineation, understanding of population connectivity, and habitat management needs. 4. Expand genetics studies to better understand population delineation, connectivity, and dynamics. (USFWS, 2025)

# SPECIES ACCOUNT: *Hesperolinon congestum* (Marin dwarf-flax)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 02/03/1995; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

An annual herb with linear leaves and slender stems, generally 5-15 cm tall but occasionally reaching 40 cm. Flowers (May-July) are white to rose-colored with purple anthers; they are borne in congested clusters. Anthers are purple at time of pollen release. 3 carpels and styles (NatureServe, 2015).

**Taxonomy**

A member of the flax family (Linaceae) (USFWS, 2011). J. K. Small (1907) established Hesperolinon as a distinct genus in 1907 (USFWS, 1998).

**Historical Range**

Its historical range has not been established, but likely included all occurrences at the time of listing, as well as extirpated occurrences on former serpentine areas in San Francisco and San Mateo Counties that are now urban development (USFWS, 2011).

**Current Range**

It is known to occur in serpentine soils in San Mateo, San Francisco, and Marin Counties, typically in association with bunchgrasses, chaparral, or other dry grasslands (USFWS, 2023).

**Critical Habitat Designated**

Yes;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (inferred from USFWS, 1998)

**Lifespan**

Adult: 1 year (NatureServe, 2015)

**Breeding Season**

Adult: May - July (USFWS, 2011)

**Key Resources Needed for Breeding**

Adult: Insect pollinators (USFWS, 1998)

**Reproduction Narrative**

Adult: This species is an annual (NatureServe, 2015). The species generally flowers from early May through June or July, and is sensitive to the amount and timing of rainfall (USFWS, 2011). The species is pollinated by native insects including bee flies and pollen beetles (Robison and

Morey 1992a) (USFWS, 1998).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Grasslands and chaparral (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 100 - 1,200 ft. elevation (USFWS, 1998)

**Environmental Specificity**

Adult: Very narrow (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: High (inferred from USFWS, 2011)

**Habitat Narrative**

Adult: Inhabits grasslands and chaparral on serpentine soils. The environmental specificity is very narrow; it is a narrow serpentine endemic only known from serpentine sites in parts of the S. F. Bay area (NatureServe, 2015). Serpentine soils are formed from weathered volcanic rock, with a low calcium-magnesium ratio, lack of soil nitrogen, potassium, or phosphorus, and elevated heavy metals (mineral toxicity). It is believed that Hesperolinon congestum's tolerance for this soil chemistry allows it to grow where most other plant species cannot (USFWS, 2011). Known populations occur between approximately 30 and 370 meters (100 to 1,200 feet) (California Natural Diversity Data Base 1996) (USFWS, 1998).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Decline of 50-70% (NatureServe, 2015)

**Species Trends:**

10 - 30% decline (NatureServe, 2015)

**Number of Populations:**

23 extant (USFWS, 2023)

**Population Size:**

10,000 - 1,000,000 individuals (NatureServe, 2015)

**Adaptability:**

Low (inferred from NatureServe, 2015)

**Additional Population-level Information:**

The final listing rule did not provide abundance estimates for any of the known Marin dwarf-flax occurrences but did note they can fluctuate in size from hundreds to thousands of plants (Robison and Morey 1992, p. 7; Service 1995, p. 6675). In the previous 5-year review we stated abundance estimates for most locations had been occasional and often qualitative, and when recorded would vary greatly among occurrences and between years. Similar to the previous review, we do not have abundance estimates for most locations; however, for the locations we do have data for, abundance varied greatly (Chassé et al. 2019; Williams and O'Herron 2019, p. 68; Diversity Database 2020) (see Appendix, Table B). The widespread variability in Marin dwarfflax abundance is not surprising as numbers are known to be greatly affected by rainfall, with more individuals in years with abundant spring rains (Service 2011, p. 6). Because of this variability, it is difficult to determine population dynamics and trends of each occurrence without multiple years of tracking, and currently only a few occurrences of Marin dwarf-flax are being regularly monitored (see Appendix, Table B). Moreover, for many occurrences the only available information is what was submitted to the Diversity Database, which often includes little quantitative information on the species, making it difficult to analyze abundance trends (USFWS, 2023).

**Population Narrative:**

Vulnerable due to its fluctuating population numbers based on rainfall and due to its frail, annual habit. The population numbers of this annual fluctuate with rainfall. There may be a few hundred at a site one year and 10's of thousands the next. One recently reported site at Lucasfilms property had 200,000 plants one year. The total estimated population size is 10,000 - 1,000,000. The long term trend for this plant is one of severe decline due to urbanization of its habitat; decline of 50-70%. This species has experienced a short term decline of 10 - 30% due to urbanization. The population numbers of this annual fluctuate with rainfall. There may be a few hundred at a site one year and 10's of thousands the next. One recently reported site at Lucasfilms property had 200,000 plants one year (NatureServe, 2015). At the present time, there are 23 extant occurrences of the species (USFWS, 2011). The 1995 final listing rule stated there were fourteen known occurrences: six from Marin County, one from San Francisco County, and seven from San Mateo County (Service 1995, p. 6679). The previous 5-year review reported 23 extant, 2 unreliable, and 5 extirpated occurrences of the Marin dwarf-flax. Of these extant occurrences, 11 were from Marin County, 2 from San Francisco County, and 10 from San Mateo County (Service 2011, pp. 3–6). Currently, there are 23 extant occurrences, 1 unreliable occurrence, 2 possibly extirpated occurrences, and 1 extirpated occurrence reported in the Diversity Database (2020) (see Appendix, Table A). Although CNDDB labels 23 occurrences as “Presumed Extant,” most of these occurrences have not been seen and/or surveyed in several years and therefore are labeled as “Unknown” in the Appendix, Table A. Since the previous 5-year review, two new occurrences have been reported to the Diversity Database (occurrence #34 and #35) and some of the previous occurrences have been combined (#30 included in #3, #2 included in #1, #15 included in #14, and #10 included in #9) (see Appendix, Table A). New occurrence #34 expands the previously known range further north. New occurrence #35 is within the range known at the time of listing. Of the 23 extant occurrences, 13 are from Marin County, 2 are from San Francisco County, and 8 are from San Mateo County (USFWS, 2023)

***Threats and Stressors***

**Stressor:** Development (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The threat of habitat destruction continues in several forms, and varies both regionally and with specific location. Recent information concerning the Alta Robles development indicates there would be some direct impacts to Hesperolinon congestum, as well as likely indirect impacts due to construction at distances of 25-to-125 feet from the species and/or potential habitat (MCL 2011; MIJ 2010; Town of Tiburon 2010). These distances are far less than the 500-foot buffer recommended in our Recovery Plan for protection of this species (FWS 1998). Not only do such developments result in direct losses of the species and its habitat where the development takes place, but could result in numerous indirect effects on adjacent areas due to runoff, landslides, foot traffic, dogs, and non-native plant competition. These indirect effects may occur on both private and public lands, particularly in areas which lack permanent protections. Such indirect effects are likely to be ongoing to some extent at all of the Tiburon populations due to nearby developments. Based on information provided by the SFPUC and review of Service files, several planned actions may affect the species (E. Natesan, SFPUC, pers. comm. 2011). One such activity is the Crystal Springs/San Andreas Transmission Upgrade project, whose modest effect on Hesperolinon congestum will be mitigated through conservation and enhancement measures addressed in formal consultation (FWS 2010; Table 2). There is also a planned dam improvement project for Crystal Springs Reservoir which could affect Hesperolinon congestum or presently unoccupied serpentine area which is potential habitat over a more widespread area by allowing a higher maximum water level than at the present time. More development, even without actual direct impacts, may indirectly impact Hesperolinon congestum through occasional foot traffic, or local atmospheric pollutants. These effects have not yet been evaluated (USFWS, 2011).

**Stressor:** Ground disturbance (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Ground disturbance in serpentine areas from unmonitored casual recreational activities continues to be a threat to the species. Hiking and biking activity has been mentioned as a potential or actual threat for at least fourteen occurrences. At Middle Ridge (#8), unleashed dogs are mentioned to be the main cause of ground disturbance (often by professional dog-walkers), and hiking and bike traffic were also noted (Bittman, in litt. 2009a, 2009b; Buxton, in litt. 2010, pers. comm. 2011; LSA 2010) (USFWS, 2011).

**Stressor:** Succession (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Atmospheric nitrogen deposition derived from combustion sources like motor vehicles and industry in urban areas may be enriching otherwise low-nutrient serpentine soils. This may be allowing other native and nonnative plant species, such as rye grass (Lolium spp.) or wild oats (Avena spp.), to invade some serpentine areas and compete with serpentine specialist species such as Hesperolinon congestum. Over time, thatch and soil buildup from the invading plants can further enrich serpentine soils. Based on the estimated critical load of 4.5-5.0 kg-N/ha/year for

serpentine natives such as Hesperolinon congestum, nitrogen is a potential threat to this species throughout its range with the exception of more rural parts of Marin County (Weiss, in litt. 2011; Fenn et al. 2010). Studies in the south bay suggest that non-natives have had an effect on other native serpentine plants at Edgewood Park (Weiss 1999), although it has not yet been demonstrated for Hesperolinon congestum in particular (USFWS, 2011).

**Stressor:** Maintenance activities (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Maintenance as a potential threat was noted at a number of locations and in various forms. Maintenance activities identified since listing included access roads, pipeline maintenance, highway maintenance, disking, herbicide spraying, and "other" maintenance. Maintenance can have a direct effect by disturbing the plants and its habitat, or indirect effects by altering the hydrology/runoff or land stability of a site (USFWS, 2011).

**Stressor:** Climate change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Preliminary results indicate an increase in average maximum summer air temperature at Golden Gate National Recreation area, located near the Presidio (near occurrences #16 and 20), and a statewide reduction in fog frequency (Madej et al. 2010; Johnstone and Dawson 2010). Hesperolinon congestum abundance and flowering period is believed to be affected generally by year-to-year variations in rainfall, so it may be sensitive to climate change. However, there is inadequate information to make accurate predictions regarding its effect on this species at this time (USFWS, 2011).

**Stressor:** Stochastic events (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Low plant number remains a threat to the smaller population size occurrences of Hesperolinon congestum. The small areas of these occurrences render them susceptible to extirpation as a result of localized stochastic events or disturbances from threats already discussed (USFWS, 2011).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 8C

**Delisting Criteria:**
1. Secure and protect specified recovery areas from incompatible uses: Occupied habitat or 21 populations representing the range of the species along with adjacent unoccupied habitat and a 150-meter (500-foot) buffer (USFWS, 2011).

2. Management plan approved and implemented for recovery areas, including survival of the species as an objective; for all populations and any occupied or unoccupied habitat identified as essential to survival (USFWS, 2011).

3. Population monitoring in specified recovery areas shows stable or increasing plant numbers for a period of 20 years that include the normal precipitation cycle (or longer if suggested by the results of demographic monitoring) (USFWS, 2011).

**Recovery Actions:**
- Habitat protection (USFWS, 1998).
- Habitat management and restoration, including removal of invasive non-native species (USFWS, 1998).
- Surveying and monitoring (USFWS, 1998).
- Ex-situ conservation measures such as artificial rearing and seed banking (USFWS, 1998).
- Research (USFWS, 1998).
- Public participation, outreach, and education (USFWS, 1998).
- Secure and protect all occurrences and potential (unoccupied) serpentine grassland habitat necessary for recovery of Hesperolinon congestum on SFPUC lands in the Crystal Springs group (as previously mentioned, our Formal Consultation applies only to a portion of the occurrences, see FWS 2011). The conservation easements, together with a comprehensive and complete management plan, should be sought to permanently protect all occurrences and potential habitat from future habitat loss due to changes in land use. The management plan should include provisions for monitoring, actions as necessary to quantify and address threats of non-native species encroachment, and means to resolve foreseeable potential conflicts created by human use or operations and maintenance activities (USFWS, 2011).
- Secure and protect to the maximum extent practicable, all occurrences and potential (unoccupied) serpentine grassland habitat necessary for recovery of Hesperolinon congestum at the St. Hilary's Church (#6) and Middle Ridge (#8) locations. In addition to recreational and non-native plant threats, portions of these sites are believed to be imminently threatened by potential conversion to housing developments. Avoidance of any loss is the preferred strategy. Permanent conservation easements should be sought to preclude future loss. One venue for Service participation would be during consultations pursuant to issuance of a permit from the Corps under CWA Section 404. Additionally, there need to be assurances that management, including regular monitoring and corrective action, will be timely implemented as needed to address other primary threats of non-native vegetation and human passive use. Reported adverse human impacts from recreational uses (primarily dog-walking; other uses mentioned include hiking, biking, photography, horse-back riding, photography) to this species or its habitat should be investigated, monitored, and prevented by necessary means, including restricted use/entry where other means have proven ineffective (USFWS, 2011).
- Surveys should be conducted at least once (preferably more often) in this next five years at all known locations of Hesperolinon congestum. In order of priority, surveys should be done for the 10 sites for which this review found no observational information at all in the last five years (#17, 5, 1, 30, 3, 21, 22, 31, 23, and 28), the non-CNDDB site (a), and all other sites. A survey protocol should be developed, which will ideally allow detection of the peak flowering period, a reasonable estimate of population area and size, photodocumentation (of entire area, and closeups of plant forma), establishment of reproducible photo points,

and a rapid assessment of the extent of visible threat factors of human-caused ground disturbance, and non-native/native species invasion (USFWS, 2011).
- Assess the effectiveness of one or more weed control measures on Hesperolinon congestum. This may involve comparing weed densities in areas (occurrence area and adjacent buffer) which are controlled for weeds versus those which are not, or evaluating a chronosequence before, during, and after weed control measures; or comparing different measures. For example, where grazing is used, a study might seek to establish empirical relationships between the control measure (e.g., grazing or grazer density) and weed densities, and the response by Hesperolinon congestum (or lack thereof) (USFWS, 2011).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of the Marin dwarf-flax. Recommendations #2–5 were discussed in the previous 5-year review (Service 2011, pp. 19–20) and remain valid. 1. Work with partners to develop a standardized methodology to delineate Marin dwarf-flax populations to allow the Service and partners to accurately assess population trends. 2. Secure and protect all occurrences and potential habitat (i.e., unoccupied serpentine grasslands) necessary for recovery of Marin dwarf-flax on SFPUC lands in the Crystal Springs group. Conservation easements, together with a comprehensive and complete management plan, should be sought to permanently protect all occurrences and potential habitat from future habitat loss due to changes in land use. The management plan should include provisions for monitoring, actions as necessary to quantify and address threats of non-native species encroachment and means to resolve foreseeable potential conflicts created by human use or operations and maintenance activities. 3. Secure and protect to the maximum extent practicable, all occurrences and potential habitat (i.e., unoccupied serpentine grasslands) necessary for recovery of Marin dwarfflax at the St. Hilary's Church (Diversity Database #6) and Middle Ridge (Diversity Database #8) occurrences. In addition to recreation and non-native plant encroachment, portions of these sites are threatened by potential conversion to housing developments. Avoidance of any loss is the preferred strategy and permanent conservation easements should be sought to preclude future loss. Additionally, there need to be assurances that management, including regular monitoring, will be implemented as needed to address other primary threats of non-native vegetation and recreational use. Reported adverse human impacts from recreational uses (primarily dog-walking; other uses mentioned include hiking, biking, photography, horse-back riding, photography) to this species or its habitat should be investigated, monitored, and prevented by necessary means, including restricted use/entry where other means have proven ineffective. 4. Conduct surveys at least once (preferably more often) over the next five years at all known locations of Marin dwarf-flax. Develop a survey protocol, which will ideally allow detection of the peak flowering period, a reasonable estimate of occupied area and size, photo documentation (of entire area, and closeups of plant forma), establishment of reproduceable photo points, and a rapid assessment of the extent of visible threat factors of human-caused ground disturbance, and non-native/native species encroachment. 5. Assess the effectiveness of one or more weed control measures on promoting Marin dwarf-flax growth. This may involve comparing weed densities in areas (occurrence area and adjacent buffer) which are controlled for weeds versus those which are not, evaluating areas before, during, and after weed control measures, or comparing different measures. For example, where grazing is used, a study might seek to establish empirical relationships between the control measure (e.g., grazing or grazer density) and weed densities, and the response by Marin dwarf-flax (or lack thereof). 6. There are a variety of other key research needs for the recovery of this species mentioned in our recovery plan that should also be conducted, including: (1) studies on the effects of vegetation management practices (grazing, burning, herbicide), fertilizer, and runoff; (2) demographic studies such as soil seed bank, and other reproductive features (mating system, pollination); and (3) surveys of potential habitat to identify new occurrences. Surveys of potential habitat could also be useful to identify candidate unoccupied serpentine areas for enhancement (i.e., usually tree/scrub removal) and outplanting. Population genetic studies could be done to determine the extent of differentiation throughout the species' range and how this compares to phenotypic variation noted between occurrences (Smith, in litt. 2011a in Service 2011, p. 7, cover photo). These studies may be useful to select outplanting material should unoccupied restoration sites be identified. If such studies are warranted, collection and preservation of material for genetic study could be done at the same time of surveys (recommendation #2, above). As mentioned in the Recovery criteria section above, there is also a need to refine the recovery criteria in order to objectively assess progress towards recovery. These actions and others listed in our recovery plan may be essential for recovery of the species but may require additional information and analysis to prioritize and implement (USFWS, 2023).

# SPECIES ACCOUNT: *Hibiscus dasycalyx* (Neches River rose-mallow)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 10/11/2013; Southwest Region (R2)

**Physical Description**

The rose-mallow is a nonwoody perennial in the Malvaceae (mallow) family that grows 1.9-7.5 feet (ft.) (0.6-2.3 meters (m)) tall. Leaves are alternate, simple, generally t-shaped, and deeply three-lobed with petioles 1.1-1.8 inches (in) (3-5 centimeters (cm)) long. The species generally produces a single creamy white (rarely pink) flower at the base of the leaf stalk along the uppermost branches or stems. Plants are single to multi-stemmed. Each branch or stem can have numerous leaves, with the total number of flowers per plant numbering in the hundreds. Flowering is rain dependent, spanning a few weeks in June and July. Seeds are set in August (T. Philipps, pers. comm. 2016a). Large, numerous stamens are monadelphous, forming a tube that is united with the base of the petals. Potential pollinators may include, but are not limited to: the American bumble bee (Bombus pensylvanicus), Hibiscus bee (Ptilothrix bombiformis), moths, and the scentless plant bug (Niesthrea louisianica) (Klips 1995, Warnock 1995, Warriner 2011). (USFWS, 2018)

**Taxonomy**

In the Malvaceae (mallow) family (USFWS, 2013)

**Historical Range**

The natural range is within Trinity, Houston, Harrison, and Cherokee Counties, Texas (USFWS, 2013a)

**Current Range**

Known from Trinity, Houston, Harrison, Cherokee, and Nacogdoches Counties in east Texas, in the Neches, Sabine, and Angelina River basins and the Mud and Tantabogue Creek basins (USFWS, 2013a).

**Critical Habitat Designated**

Yes; 10/11/2013.

**Legal Description**

On September 11, 2013, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective October 11, 2013) for Hibiscus dasycalyx (Neches River rose-mallow) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes eleven critical habitat units (CHUs), in Cherokee, Harrison, Houston, Nacogdoches, and Trinity Counties, Texas (78 FR 56072-56120).

**Critical Habitat Designation**

The critical habitat designation for Hibiscus dasycalyx includes eleven CHUs in Cherokee, Harrison, Houston, Nacogdoches, and Trinity Counties, Texas. This species critical habitat encompasses approximately 166.5 acres (ac) (67 hectares (ha)). Brief descriptions are provided below; maps depicting these areas are included in the Final Rule (USFWS, 2013).

Unit 1: SH 94 ROW: Unit 1 consists of 3.4 ac (1.4 ha) on both the 94 ROW and on private land in Trinity County.

Unit 2: Harrison County: Unit 2 is found at a location between 0.2–0.4 mi (0.3–0.6 km) north of Farm to Market Road 2625 in Harrison County.

Unit 3: Lovelady: Unit 3 in Houston County, found northwest of Farm to Market 230, extends 0.3 mi (0.5 km) north and contains 6.3 ac (2.5 ha) of private land.

Unit 4: SH 204 ROW: Unit 4 in Cherokee County contains 8.7 ac (3.5 ha) of occupied habitat along SH 204 ROW and within the Mud Creek basin.

Unit 5: Davy Crockett NF, Compartment 55: Unit 5 is the only unit that contains a natural population of the Neches River rose-mallow on Federal lands within the Davy Crockett NF.

Unit 6: Davy Crockett NF, Compartment 11: Unit 6 includes 7.3 ac (3.0 ha) of occupied habitat on Compartment 11 on Federal land in the Davy Crockett NF within Houston County.

Unit 7: Davy Crockett NF, Compartment 20: Unit 7 includes 3.4 ac (1.4 ha) of Federal land in Compartment 20 of the Davy Crockett NF, Houston County.

Unit 8: Davy Crockett NF, Compartment 16: Unit 8 encompasses 32.8 ac (13.3 ha) of occupied Federal habitat in the Davy Crocket NF, Houston County.

Unit 9: Champion: The Champion site, Trinity County, is located on private land approximately 0.7 mi (1.1 km) south-southeast of the Houston County line, about 0.8 mi (1.2 km) north of the confluence of White Rock Creek and Cedar Creek (TXNDD 2012a, p. 55).

Unit 10: Mill Creek Gardens: Unit 10 is an introduced site at Mill Creek Gardens, Nacogdoches County. Stephen F. Austin State University Mass Arboretum purchased the land and created the gardens in 1995 as part of a conservation agreement.

Unit 11: Camp Olympia: Unit 11 is located on private property in Trinity County. The unit contains 0.2 ac (0.1 ha) of palustrine wetland habitat north of Lake Livingston.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Hibiscus dasycalyx critical habitat consists of two components (78 FR 56072-56120):

(i) Hydric alluvial soils and the potential for flowing water when found in depressional sloughs, oxbows, terraces, side channels, or sand bars; and

(ii) Native woody or associated herbaceous vegetation, largely with an open canopy providing partial to full sun exposure with few to no nonnative species.

**Special Management Considerations or Protections**

Threats to those features that define the primary constituent elements for the Neches River rose-mallow include: (1) Alteration of naturalized flow regimes through projects that require channelization; (2) water diversions or hydrologic change to streams and rivers; (3) encroachment from native woody riparian species and nonnative species; (4) detrimental roadside management practices including inappropriate frequency and timing of mowing during the species' blooming period; (5) herbivory and, (6) trampling from hog and cattle; and (7) drought. Special management considerations or protection are required within critical habitat areas to address these threats. Special management activities that could ameliorate these threats include, but are not limited to: • Construction of cattle exclusion fencing to remedy herbivory at Lovelady to maintain plant survival and suitable habitat; • Restoration of the cattle stock pond back to a natural flatwoods pond at Lovelady to restore the sites hydrology; • Coordination with TXDOT to establish and continue effective management along ROWs for control of native woody species and nonnatives (including, but not limited to mowing, brush-hogging, or other hand-clearing techniques) and completion of these techniques only during the appropriate life stages of the Neches River rose-mallow to maintain open habitat; • Coordination with the Angelina and Neches River Authority and consultation with the U.S. Army Corps of Engineers on the proposed construction of Lake Columbia Reservoir in Cherokee County to maintain hydrology at the downstream Neches River rose-mallow site; • Consultation between the Service and the U.S. Army Corps of Engineers for any filling or draining of Federal jurisdictional wetlands to ensure maintenance of hydrology; and • Clearing or burning on the Davy Crockett NF for control of Chinese tallow and to maintain an adequate level of openness in habitat. (USFWS, 2013)

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect (USFWS, 2013a)

**Lifespan**

Adult: Unknown (USFWS, 2013a)

**Breeding Season**

Adult: Flowering occurs between June and August, sometimes into late October (USFWS, 2013a)

**Key Resources Needed for Breeding**

Adult: Insects for pollination (USFWS, 2013a)

**Reproduction Narrative**

Adult: This perennial species dies back to the ground every year and resprouts from the base; however, the plant still maintains aboveground stems. Longevity of the species is unknown, but it may be long- lived. Cross-pollination occurs within populations, and the species has high reproductive potential (fecundity). Flowering occurs between June and August, sometimes into late October; the blooming period may only last 1 day. The species produced an average of 50 fruits per plant, but seed viability and survivorship are not known. Potential pollinators of the Neches River rose-mallow may include, but are not limited to, the common bumblebee (Bombus pensylvanicus), Hibiscus bee (Ptilothrix bombiformis), moths, and the scentless plant bug

Niesthrea louisianica (USFWS, 2013a).

**Habitat Type**

Adult: Wetlands (USFWS, 2013a)

**Habitat Vegetation or Surface Water Classification**

Adult: Seasonally or regularly inundated sloughs, oxbows, terraces, sand bars, and bottomlands (USFWS, 2013a)

**Environmental Specificity**

Adult: Narrow. Specialist or community with key requirements common (NatureServe, 2015)

**Habitat Narrative**

Adult: The Neches River rose-mallow is endemic to relatively open habitat of the Pineywoods (or Timber belt) of east Texas, within Cherokee, Houston, Harrison, and Trinity Counties, and has been introduced into Nacogdoches and Houston Counties. It is known from seasonally or regularly inundated sloughs, oxbows, terraces, sand bars, and bottomlands, with hydric alluvial soils (loamy to clayey). An open canopy is typical, but plants also grow in partial sun. Sites are both perennial and intermittent wetlands with water levels between sites varying due to their proximity to water, amount of rainfall, and floodwaters. Intermittent wetlands are inundated during the winter months but become dry during the summer months (USFWS, 2013a).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Neches River rose-mallow seeds are likely to be dispersed by flowing water. Research has not been done to identify methods of seed dispersal upstream; however, avian species may facilitate this process (USFWS, 2013a).

***Population Information and Trends***

**Number of Populations:**

11 ( 8 natural; 3 introduced) (USFWS, 2018)

**Population Size:**

Approximately 2200 - 2500 individuals (NatureServe, 2015)

**Minimum Viable Population Size:**

At least 10 viable populations of the rose-mallow, each containing an average of about 1,400 individuals (USFWS, 2018)

**Population Narrative:**

When the species was listed in 2013, 11 populations were determined to be occupied by the rose-mallow. Of those 11 populations, 3 sites have not been verified in over 20 years and 3 included introductions on the Davy Crockett National Forest. In addition to these natural populations, the Service is also aware of 8 reintroductions, introductions, or display gardens, some of which were coordinated through the Service. (USFWS, 2018)

### *Threats and Stressors*

**Stressor:** Habitat destruction or modification (USFWS, 2013a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A primary threat to the Neches River rose- mallow is the ongoing encroachment of nonnative and native woody species into its generally open, intermittent or perennial wetlands. Altered hydrology (including beaver dams) can have huge impacts on habitat since this species is water-dependent. Right-of-way populations are vulnerable to bridge and road expansion, new road construction, and upgrade projects, which could impact the sites' hydrology, soil stability, wetland and riparian vegetation, and water quality. Conversion of wetlands to silvicultural uses and associated herbicide use to remove unwanted vegeation is a threat. Habitat damage from trampling by feral hogs and cattle is also a threat, as is drought periods possible related toc limate change (USFWS, 2013a).

**Stressor:** Predation (USFWS, 2013a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Mammalian herbivory has affected the majority of sites; however, grazing pressures are largely attributed to the lack of other available food resources during periods of drought. Neches River rose-mallow recovers quickly from herbivory incidents and can produce secondary growth, minimizing the overall negative effects of mammalian herbivory. This type of herbivory is not considered to be a threat to the species. Insect herbivory was also observed on several of the sites and was not rangewide, but, with anticipated climate change shifts in temperature and the likelihood that insect populations will increase, the Services conclude that insect predation is a minor stressor that will likely continue into the future, but it is not a threat to the species (USFWS, 2013a).

### *Recovery*

**Reclassification Criteria:**
Not applicable.

Recovery Priority Number: 8

**Delisting Criteria:**
A Recovery Plan has not been developed.

**Recovery Actions:**
- A Recovery Plan has not been developed.  The following present the summary statement of recovery needs presented in the 2018 Recovery Outline. (USFWS, 2018)
- - Survey sites that have not been visited in over 20-30 years and determine if they contain the physical and biological features of habitat. - Engage landowners to conduct conservation and stewardship on their property. - Using current niche mdels to identify other areas of potential habitat for rose-mallow and plan to  conducty surveys at those sites. Niche models can also be used in future scenarios where climate change might alter the species current

range (i.e. range expansion). - Consider introductions and reintroductions that would further the representation and resiliency of the rose-mallow across its range, but that are also in-line with the species' propagation and reintroduction plan. - Communicate with partners, academics, nurseries, and plant communities about proper introduction procedures and encourage collaboration with the Service. - Continue to monitor existing populations for threats. - Conduct key biological studies to better understand the species reproductive needs (i.e. longevity, seed dispersal, age structure). This information can inform the recovery targets and needs in a recovery plan. - Develop a species Recovery Plan in FY2020. (USFWS, 2018)

- Not available.

# SPECIES ACCOUNT: *Hoffmannseggia tenella* (Slender rush-pea)

***Species Taxonomic and Listing Information***

**Commonly-used Acronym:** SRP

**Listing Status:** Endangered; 12/02/1985; Southwest Region (Region 2)

**Physical Description**

Hoffmannseggia tenella is a perennial legume (Fabaceae: pea family) with spreading stems 8-15 cm long terminating in 3-5 flowered, eglandular inflorescences and having a long woody taproot. Leaves are bipinnately compound with petioles to 13 cm long; leaflets are oblong, 2-4 mm in length, and 1-2 mm broad in 5 or 6 pairs on each of 3-7 pinnae. Flowers are orange and approximately 5 mm long with 10 stamens. Filaments have retrorse hairs. The legumes are 12-15 mm long, 4-6 mm broad and contain 2-4 seeds. Flowering usually occurs from early March to June, sporadically thereafter depending on rainfall (USFWS, 1985b; Mahler, 1982). (USFWS, 1988)

**Taxonomy**

Slender rush-pea is in the class Magnoliopsida, order Fabales, and family Fabaceae (Poole 1988). There are currently no other scientific or common names for this species (Poole 1988). Although the final rule (FR) listed SRP as belonging to the pea family, Fabaceae, it was later listed under the family Leguminosae. These two family names are used interchangeably. Family Fabaceae is the more widely accepted classification for legumes like the SRP. In addition, the International Union for Conservation of Nature and Natural Resources (IUCN) clarified the correct spelling of the genus as Hoffmannseggia, not Hoffmanseggia (USFWS 1985). (USFWS, 2008)

**Historical Range**

Historically known from Nuceces and Kleberg Counties, Texas.

**Current Range**

In Texas, extending from Robstown, Nueces County, on the most northeastern extent of the range to east-central Kleberg County, then west to a point near Kingsville, and north to the vicinity of the Nueces/Jim Wells County line, encompassing approximately 221,000 acres. (USFWS, 2008)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 2008)

**Breeding Season**

Adult: March to June (USFWS, 2008)

**Reproduction Narrative**

Adult: The SRP has monoclinous flowers, bearing both male and female reproductive parts in the same flower (Poole 1988). The species appears to be reproductively active during the spring and summer months, however this activity can be prolonged into the fall in a sporadic fashion in response to rainfall events, even if the prevailing climatic conditions are dry (Mahler 1982a, Bush 1990). Fruiting dates are documented from February through July (USFWS 1988) and seed/fruit dispersal dates from March through June (Mahler 1982a). (USFWS, 2008)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Grassland/herbaceous (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Prefers sparsely vegetated areas (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Patches (USFWS, 2008)

**Environmental Specificity**

Adult: Low (inferred from USFWS, 2008)

**Habitat Narrative**

Adult: Slender rush-pea occurs in the eco-region known as the Gulf Prairies and Marshes biotic zone (Correll and Johnston 1970). All documented SRP sites occur in patches of short-grass native prairies adjacent to intermittent or permanently flowing creeks, with the exception of the two most southeastern Kleberg County populations described by Jones in 1964 as being in a “pasture opening on clay loam” and on a “clayey roadside” (TNDD 2007). This species if found in sparsely vegetated openings within bluestem-sacahuista grasslands on heavy clay soils of the South Texas Coastal Plain. The SRP occurs in areas of Victoria Clays which are calcareous, crumbly, clay soils that are self-mulching and greatly cultivated for crops. This species is a perennial legume that occurs in patches of native short- and mid-grass prairie adjacent to watercourses, such as permanent and intermittent creeks. This species is a member of the lower seral stages of succession, perhaps even a pioneer species” or an invader species of highly disturbed soils where it persists until crowded out by other species. (USFWS, 2008; NatureServe, 2015)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available.

***Population Information and Trends***

**Population Trends:**

Not available.

**Number of Populations:**
8 (USFWS, 2018)

**Population Size:**
>10,000 (NatureServe, 2015)

**Population Narrative:**
As a result of work funded through a 2008-2010 Preventing Extinction cooperative agreement and other monitoring efforts, 8 populations were found to be extant (Table 5), although four of these (Hwy 77, St. James Cemetery, Bishop City Park, and a private residence in Bishop) are less than 2.5 km (1.6 miles) apart from the others and probably function as a single metapopulation. Three of the eight (Sablatura County Park, Bishop City Park, and a private residence between St. James Cemetery and Bishop City Park) are new discoveries, and the Petronila site has been temporarily recovered through suppression of the nonnative grass Kleberg bluestem with grassspecific herbicide. Although the King Ranch training area (KRTA) sites have not been visited since 1993, the populations (probably subpopulations of another metapopulation) are likely extant since we have no knowledge that habitat has been disturbed to the point that it is not suitable for rush-pea. (USFWS, 2018)

***Threats and Stressors***

**Stressor:** Habitat alteration (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Historically, conversion of native prairie to row crops and improved pasture was probably the largest factor contributing to losses of SRP populations and habitat (Poole 1988). The range of SRP has likely been considerably contracted by these types of land conversion activities in Nueces and Kleberg counties. Slender rush-pea populations were probably reduced in size or eliminated altogether as habitat was converted to cropland or deliberately planted to monoculture pastures of non-native grasses. Increased cover by woody species may also have impacted some SRP habitat (USFWS 1988). (USFWS, 2008)

**Stressor:** Non-native plants (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** More recently, threats to the integrity of the remaining habitat have increased as non-native pasture grasses, including Kleberg bluestem, King Ranch bluestem, Coastal Bermudagrass, and other introduced grasses have continued to spread throughout this region (Mahler 1982a, Poole 1988, Kuvlesky et al. 2002). These grasses are opportunistic species, either producing copious amounts of seed that can be spread both deliberately and/or inadvertently, or spreading rapidly by vegetative means. Seeding of highway and pipeline ROWs and highways to reduce erosion has helped to increase the distribution of some of these non-native grasses into the native prairie remnants that constitute natural habitat for SRP, as seen at the Petronilla Creek and Highway 77 ROW sites (Poole 1988). The condition of short-grass prairie habitat within the

unplowed rangeland in Kleberg County is not known. Prescribed winter burns and cattle grazing are the primary land management known to occur in this area.Non-native, pasture grasses, predominantly Kleberg bluestem, King Ranch bluestem (Bothriochloa ischaemum), and Coastal Bermudagrass (Cynodon dactylon), have encroached and altered the composition of the native vegetation community at the three accessible SRP population sites at Petronilla Creek/Highway 70, Highway 77 ROW, and St. James Cemetery (Mahler 1982a, Poole 1988, D. Price pers. comm. 2006). These non-native grasses tend to produce dense monocultures with few short-grass native species able to persist (Mahler 1982a). Woody species, including honey mesquite (Prosopis glandulosa), huisache, retama, and others have also become more prevalent in the remnant prairie fragments where SRP persists (Mahler 1982a, USFWS 1988, Ruth 2000). Kleberg bluestem, native to India, China, North Africa, and Egypt, is considered highly competitive, with long creeping rhizomes and continual seed production throughout the year under favorable conditions. Drought tolerance has enabled people to use this grass as a stabilizer on roadsides and pipeline ROWs, and seeds are highly mobile by several means of transport (Drawe 2004). The shallow, fibrous roots of many grass species such as Kleberg bluestem allow quicker absorption of moisture and nutrients than is capable by tap-rooted species, such as SRP, which must wait for deeper moisture penetration (D'Antonio and Mahall 1991).In addition to subsurface competition, fast growing non-native grasses can spread quickly and potentially out-compete SRP for both space and sunlight (Pressly 1998). Greenhouse shadecloth studies using SRP plants grown at the Kika de la Garza PMC demonstrated significant differences in petiole heights and lengths between non-shaded (controls) verses shaded treatments and also differences in the growth pattern (Pressly 2002). Non-shaded plants grew in a prostrate manner while the petioles of the shaded plants grew upwards (Pressly 2002). However, this greenhouse study did not show significant mortality of SRP at 30%, 40%, or 50% shading (Pressly 2002). (USFWS, 2008)

**Stressor:** Disturbances from construction and maintenance (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Localized disturbances causing losses of individual SRP plants have been attributed to highway construction projects as well as ROW maintenance procedures, maintenance of gas pipelines, and excavation of burial plots (Poole 1988). Survey reports indicated some damage to SRP individuals at St. James Cemetery caused by mowing with blades set low to the ground. Other observations at the cemetery reported on damage associated with equipment tracking through the population, and from piling of cleared brush on top of SRP. Consequently, TPWD recommended mowing at a height of no less than 6 inches (approximately 15 cm), which has been incorporated into cemetery groundskeeping procedures (Perez 1992). Also, a management agreement between TxDOT and TPWD included recommendations to continue established mowing practices on the Highway 77 ROW with a full-width mowing 4 times a year and a strip mowed every 6 weeks between May through December. (USFWS, 2008)

**Stressor:** Grazing (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This was not known as a threat at the time of listing. Poole (1986) did observe that 4 SRP plants at the Petronilla/Hwy 70 population “looked as though rabbits had been biting them.”

However, no other evidence, anecdotal or otherwise, exists regarding the effects of grazing or browsing on this species. Data on abundance and distribution of cottontails (Sylvilagus floridanus) and jackrabbits (Lepus californicus) in Nueces and Kleberg counties is lacking; however, it is possible that rabbit populations may have become more concentrated in the remnant strips of habitat in Nueces County. Plants may be susceptible to insect vectors and/or grazing effects, but no research has been conducted to document such effects. No new information regarding the predation or disease of SRP has been found. (USFWS, 2008)

**Stressor:** Herbicide Use (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbicide Use (USFWS, 2022)

***Recovery***

**Reclassification Criteria:**
Downlisting Criteria 1: To downlist rush-pea, 15 populations should have an estimated 1,500 mature individual plants per population. Downlisting may be possible if each of these populations is stable or increasing over the next 35 years. The extant populations (eight total), as well as any that may be restored, augmented, or created, should be maintained with at least five natural populations located in the drainage systems (Petronila, Oso, Chilipitin Creek-San Fernando, Alazan Bay-Baffin Bay Creek basins) where the species is known to naturally occur to ensure genetic representation. (USFWS, 2018)

Downlisting Criteria 2: Each rush-pea site should be managed for and support high quality shortgrass prairie habitat. High quality shortgrass prairie habitat has these characteristics: 1) occurs in unplowed, relatively undisturbed soils; 2) has a high diversity and high vegetative cover of native grasses and forbs; 3) has a low vegetative cover of introduced grasses; and, 4) has a low vegetative cover of woody species (i.e. native brush). High quality shortgrass prairie habitat should contain species commonly associated with rush-pea (see Table 7 of 2018 Recovery Plan). Prolific and aggressive nonnative grasses should not constitute more than small patches within each high quality shortgrass prairie site and invasive grasses and woody species should not be spreading throughout the site or inhibiting growth and reproduction of rush-pea. Each rush-pea site should be managed and monitored appropriately to ensure the maintenance and restoration of high quality shortgrass prairie habitat conditions and to minimize and control threats over a period of 35 years. (USFWS, 2018)

Recovery Priority Number: 2

**Delisting Criteria:**
Delisting Criteria 1: A minimum of 20 populations are necessary for delisting and should have at least 1,500 mature individual plants per population. Delisting may be possible if each of these populations remains stable or increasing over a period of 60 years. All existing populations, including those that have been restored, created, or reintroduced, are protected and a minimum of five natural populations are extant within each drainage system (Petronila, Oso, Chilipitin Creek-San Fernando, Alazan Bay-Baffin Bay Creek basins). (USFWS, 2018)

Delisting Criteria 2: Populations will be protected long-term (protection in perpetuity being optimum) through fee title acquisition, conservation easements, or conservation or management agreements. Species-specific, USFWS-approved annual monitoring and management plans will guide these efforts. Each population site should have high quality shortgrass prairie habitat (see Downlisting Criteria 1 for a description). (USFWS, 2018)

**Recovery Actions:**

- 1. Habitat protection and management of all known population sites of Slender rush-pea in the United States. - Establish positive working relationships with landowners and land managers of all known sites. Maintain contact with all landowners or land managers each year. Educate landowners about the extreme rarity and significance of both the ecosystem and species on their property. Encourage the long-term stewardship of the shortgrass prairie at these sites through technical assistance to landowners; also potentially through long-term leases, conservation easements, and conservation agreements. - Cooperate with landowners and land managers to develop and implement management plans that address landowner and species goals. With willing landowners, determine short- and long-term land use goals and their effects on Slender rush-pea. With all cooperating landowners, develop and implement management plans that are beneficial to the species as well as acceptable to landowners and land managers. Develop a monitoring program that is reviewed by the USFWS and other interested parties, with voluntary landowner assistance, to evaluate the effects of management practices on the species and ensure consistent and reliable monitoring of plant populations and management. - Enforce applicable laws and regulations. Work with regulatory agencies (DOD– NASK, TXDOT, TPWD, USDANRCS, and through internal USFWS coordination) to ensure that existing regulations are used to provide adequate protection of current habitat. (USFWS, 2018)
- 2. Monitor Slender rush-pea on an annual basis. - Use the approved monitoring plans to annually monitor rush-pea, its habitat, management actions, and threats at extant sites. - Monitor species and biotic communities and assess ecological integrity and conservation status of historic sites. (USFWS, 2018)
- 3. Initiate studies to gather biological information needed for effective management and recovery of rush-pea. - Determine specific habitat requirements (specifically limiting factors). Study soils and underlying geology. Determine the plant community structure for Slender rush-pea. Study community dynamics/ecology. - Study population dynamics. Analyze the demographic structure of all populations. Characterize phenology and assess the most vulnerable stages of life cycle. Determine the primary means of reproduction in the wild. Study pollination biology and determine effective pollination requirements and effective pollinators. Study seed production and dispersal. Study seedling recruitment. Study population genetics to determine the genetic diversity within and among populations. (USFWS, 2018)
- 4. Survey for additional populations of rush-pea. As more information about the habitat and biology of the species becomes available, determining areas capable of supporting the species may be more predictable. Models, maps, and other tools will be developed showing the vegetative and edaphic characteristics of occupied sites. This information will help to determine where coastal shortgrass prairie habitats currently might remain intact and/or where the species could be located. These potential areas are a high priority to survey and engage in stewardship efforts. These surveys should be performed to locate existing and new populations and for use as potential reintroduction sites in Texas. (USFWS, 2018) (USFWS, 2018)

- 5. Cooperatively work with landowners and land managers to restore additional shortgrass prairie sites located in one or more of the drainage areas from which rush-pea is known to co-occur. (USFWS, 2018) (USFWS, 2018)
- 6. Establish seed or propagule banks and ex-situ (botanical garden, refugium, research institute, etc.) populations for the species. These banks and ex-situ populations will be established using approved reintroduction plans for Slender rush-pea (see Recovery Action 7 below). (USFWS, 2018)
- 7. Conduct a reintroduction program on public and private lands where there are willing partners. Evaluate and document the success of different cultivation techniques, site preparation, and other management techniques based on research, and assess any additional information necessary to attempt reintroduction. Reintroduced populations for Slender rush-pea should not be considered successful until they are established, reproductively active, self-perpetuating, and demonstrated to be demographically and genetically viable. (USFWS, 2018)
- 8. Develop an education and outreach program. Develop any necessary educational or outreach materials. Provide educational and outreach materials to landowners and land managers. Provide educational and outreach materials to interested parties including agencies, engineering and consulting firms, developers, utilities, county road associations, and others.
- 9. Conduct Population Viability Analyses (PVA) and update the existing MVPs for the species based on current biological and ecological information. Investigate Slender rush-pea’ population genetics to ensure long-term persistence. Develop traditional MVP estimates for Slender rush-pea. Reassess the MVP size when new information is made available. (USFWS, 2018)
- 10. Review and track recovery. Maintain the STXPRT to help review the status of Slender rush-pea and assess the effectiveness of the management plans and other recovery tasks. Revise the Recovery Plan as appropriate. Develop a post-delisting monitoring plan when appropriate. (USFWS, 2018)
- Continued loss and degradation of habitat due to invasion by non-native, fast-spreading grasses is the most pressing threat to the continued existence of SRP populations at sites in Nueces County. There is an immediate need to implement and experiment with management actions involving mowing treatments, selective applications of herbicides, hand removal, and potentially even prescribed burning to control exotics at the cemetery and the Highway 77 ROW sites. Monitoring of SRP response will be needed to document effectiveness of various management techniques. Effective methodologies should be incorporated into management plans for both populations. Annual monitoring should be carried out to determine if populations are stable, increasing, or declining. The Service and/or TPWD should establish a cooperative agreement with the cemetery owner to assist the landowner in implementing the management plan. Based on the results of SRP’s response to various management treatments, TxDOT should consider changes to their management of the Highway 77 ROW, including changes to mowing schedules. (USFWS, 2008)
- A systematic approach to surveying for new populations is needed, particularly in Kleberg County where the natural habitat is potentially in better condition. If additional populations are located in rangeland settings, the effects of prescribed burns on SRP should be analyzed. (USFWS, 2008)

- A reintroduction plan should be established for the SRP to allow experimental plantings into natural habitat, particularly at the former population sites on the western side of the Highway 77 ROW and at the Petronilla Creek/Highway 70 ROW. The SRP has proven to be easily germinated from untreated seed and prospects seem good for propagating the species. A thorough genetics analysis of SRP is needed to develop a sound reintroduction plan. (USFWS, 2008)
- Knowledge regarding species' habitat requirements, population biology, and population ecology needs to be gathered and analyzed in order to develop down-listing and delisting recovery criteria. Additional research needs include determination of habitat requirements, demographic trends, population biology, reproductive biology, and pollinators. (USFWS, 2008)
- The recovery plan for SRP needs to be revised to incorporate all new information on biology, ecology, and management recommendations. Objective and measurable recovery criteria that relate directly to the 5 listing factors should be developed. (USFWS, 2008)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The 2018 Recovery Plan includes actions that are needed to recover the slender rush-pea. The status of the species is still precarious, and we continue to recommend all the actions be implemented and that conservation partners actively seek funding to implement the actions (USFWS, 2022).

# SPECIES ACCOUNT: *Holocarpha macradenia* (Santa Cruz tarplant)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 03/20/2000; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

An annual herb with stiffly spreading stems that are bristly and glandular. Inflorescence dense with heads in the upper axils; flowers yellow; phyllaries gland-tipped (NatureServe, 2015).

**Taxonomy**

A member of the aster family (Asteraceae). Holocarpha macradenia is one of only four species of the genus Holocarpha, all geographically restricted to California (USFWS, 2014).

**Historical Range**

Historically, habitat for Holocarpha macradenia occurred on grasslands and prairies found on coastal terraces in elevations below 330 feet (100 m), from Monterey County, north to Contra Costa and Marin Counties (USFWS, 2014).

**Current Range**

Holocarpha macradenia occurs in coastal grasslands and prairies in Contra Costa, Santa Cruz, and Monterey Counties, California (Service 2000) (USFWS, 2014).

**Critical Habitat Designated**

Yes; 10/16/2002.

**Legal Description**

On October 16, 2002, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Holocarpha macradenia (Santa Cruz tarplant) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes eleven critical habitat units (CHUs), in California (67 FR 63968-64007).

**Critical Habitat Designation**

The critical habitat designation for Holocarpha macradenia includes eleven CHUs in Contra Costa, Santa Cruz, and Monterey Counties, California. This species critical habitat encompasses approximately 2,902 acres (ac) (1,175 hectares (ha)) (67 FR 63968-64007).

Unit A: Mezue: Unit A consists of grassland habitat on sloping alluvial deposits from old marine terraces within Wildcat Regional Park in Contra Costa County. This entire unit of approximately 50 ha (130 ac) is on lands managed by the EBRPD. Management activities at this site include controlled grazing, removal of invasive artichoke thistle, and annual population monitoring (EBRPD 1992, 2001). Of the 22 sites that were used as sites to introduce Holocarpha macradenia seed in the East Bay region between 1982 and 1986, this population has been the only one that has consistently supported a large population of H. macradenia. In the year 2000, this population supported over 17,000 individuals (CDFG 2000). Although this population is an introduced population, this unit is essential to the survival and conservation of the species because this population represents the genetic variability in the northernmost portion of the plant’s range and is important for the expansion of the existing population. In recognition of the conservation value of this population, the Service is contributing funding toward nonnative species removal at this site (Service 2002).

Unit B: Graham Hill: Unit B consists of grasslands on a relatively flat coastal terrace prairie on the west side of Graham Hill Road, approximately 1 mile north of the City of Santa Cruz in Santa Cruz County. This entire unit of approximately 12 ha (30 ac) is on privately owned lands. The unit includes a 7-ha (17-ac) area that has been set aside through a conservation easement to the County of Santa Cruz for conservation of coastal prairie habitat and Holocarpha macradenia as mitigation for an adjacent development that comprises 52 residences and associated amenities. The population has been fenced and nonnative species have been removed; however, efforts to enhance the population, as called for in a management plan (Environmental Science Associates 1996), have not yet been initiated. In 1994, this population numbered 12,000 individuals; by 1998, 675 individuals were counted; and in 2001, approximately 550 individuals were counted (V. Haley, consultant, Felton, California, pers. comm., 2001). This unit is important because it currently supports a population of H. macradenia and because it represents the western limit of the cluster of populations that are found on the northern end of Monterey Bay. This unit, along with the Fairway Unit, occurs at the highest elevation of the native populations (122 m (400 ft)) and consequently the farthest away from the influence of the coastal climate. Preserving the genetic variability within the species that has allowed it to adapt to these different environmental conditions is essential for the long-term survival and conservation of the species.

Unit C: De Laveaga: Unit C consists of grasslands on a relatively flat coastal terrace prairie within De Laveaga Park just north of the City of Santa Cruz in Santa Cruz County. This entire unit of approximately 2 ha (5 ac) is on State lands managed by the CANG and supported by Federal funds from the National Guard Bureau. The CANG does not anticipate undertaking any new military activities on this parcel beyond its current use as an assembly point for monthly drills and as storage for equipment. In 2001, a maintenance crew from the adjacent city-owned golf course spread wood chips from a felled tree over half the population. The CANG has initiated management actions to restore and enhance habitat for H. macradenia, including removal of the wood chips and chunks of eucalyptus logs. In addition, the CANG has initiated development of an INRMP (CANG 2002); if the final plan meets the criteria outlined earlier in our response to comment number eight, the critical habitat designation may be removed from this unit in the future. This unit is essential because it currently supports a population of H. macradenia and because it is one of only seven populations in the cluster of populations that are found on the northern end of Monterey Bay. Despite its small size, this unit is essential because it is located between the Graham Hill, Arana Gulch, and Rodeo Gulch Units, and is important for maintaining connectivity between these other units.

Unit D: Arana Gulch: Unit D consists of grasslands on a relatively flat coastal terrace prairie within an open space preserve just north of Woods Lagoon in the City of Santa Cruz. This entire unit of approximately 26 ha (65 ac) is on lands owned and managed by the City of Santa Cruz. It is bounded on the west, east, and north sides by existing development and on the south side by the Santa Cruz Harbor. Huge population fluctuations have occurred on this site, ranging from 100,000 individuals in the late 1980s when the site was being grazed by cattle, to no plants in 1995 (K. Lyons, in litt., 2001). The City entered into a Memorandum of Understanding with the CDFG in 1997 to manage Holocarpha macradenia, which includes utilizing a variety of management techniques to enhance the population. As of 1998, individuals numbered approximately 12,820; in 2000, they numbered 234; and in 2002 they numbered approximately 10,000 (K. Lyons, in litt., 2001; Seals 2002). This unit is essential because it currently supports a population of H. macradenia and because it is one of only seven populations in the cluster of populations that are found on the northern end of Monterey Bay. This unit and the Twin Lakes Unit occur at the lowest elevation of the native populations in the northern Monterey Bay area (12 to 18 m (40 to 60 ft)) and are consequently the closest to the influence of the coastal climate. Moreover, these two units are within one-half mile of each other and therefore could retain connectivity between them. It is also essential for the recovery of the species because current management by the City of Santa Cruz has allowed this site to support the third largest standing native population of tarplant. It therefore contributes significantly to the seed bank reserve for the species and is large enough to support management activities that may be necessary to maintain the population at this site.

Unit E: Twin Lakes: Unit E consists of grasslands on relatively flat coastal terrace prairie just north of Schwan Lagoon within the City of Santa Cruz. This entire unit of approximately 11 ha (26 ac) is on lands owned by the CDPR within Twin Lakes State Park. It is bounded on the west, north, and east sides by existing development, and on the south side by Schwan Lagoon. Since 1997, CDPR has been actively managing Holocarpha macradenia habitat by removing invasive, nonnative species and attempting various methods of enhancing the population (Service 2000). CDPR has also funded research on H. macradenia seed bank dynamics (Bainbridge 1999). This population has ranged in size from 120 individuals in 1986 to 21 individuals in 2002 (Hyland 2002). This unit is essential because it currently supports a population of H. macradenia and because it is one of only seven populations in the cluster of populations that are found on the northern end of Monterey Bay. As with the Arana Gulch Unit, it occurs at the lowest elevation of the native populations in the northern Monterey Bay area (12 to 18 m (40 to 60 ft)) and consequently the closest to the influence of the coastal climate. Moreover, the two units are within onehalf mile of each other and therefore could retain connectivity between them.

Unit F: Rodeo Gulch: Unit F consists of sloping alluvial deposits and adjacent relatively flat coastal terrace prairie that straddles the Arana Gulch and Rodeo Gulch drainages north of the community of Soquel in Santa Cruz County. It is bounded on the north, east, and south sides by existing development; the western side is bounded by lands that have not been developed. This entire unit of approximately 11 ha (26 ac) is on privately owned lands. This unit includes a parcel that has recently been proposed for a housing development known as Santa Cruz Gardens Subdivision Unit 12 (Denise Duffy and Associates 2001). This parcel was previously set aside in a ‘‘temporary open space easement’’ as mitigation for destroying a portion of the H. macradenia population by an earlier phase of the development in 1986 (Service 2000). The current development proposal calls for setting aside approximately 23 ha (56 ac) for conservation and recreation purposes, and includes much of the habitat that supports H. macradenia. Salvage of soil and an H. macradenia seed bank is being proposed for another portion of the project site that will be impacted by development (Lyons 1999). This population numbered approximately 60 individuals in 1993; none have been observed since then (CNDDB 2001). However, a seed bank likely persists at this site. This unit is essential because of the likely presence of an H. macradenia seed bank and because it is one of only seven populations in the cluster of populations that are found on the northern end of Monterey Bay. In addition to the seed bank for this population, this unit supports grassland habitat that provides for future expansion of the population. Also, it is within one-half mile of the Soquel Unit, and therefore could retain connectivity between the units.

Unit G: Soquel: Unit G consists of grasslands on sloping alluvial deposits and adjacent relatively flat coastal terrace prairie that straddles the Rodeo Gulch and Soquel Creek drainages north of the community of Soquel in Santa Cruz County. It is bounded on the north, east, and south sides by existing development; the western side is bounded by lands that have not been developed. Approximately 22 ha (55 ac) of this 40- ha (100-ac) unit is within Anna Jean Cummings Regional Park (also known as O’Neill Ranch), which is managed by the County of Santa Cruz. The remaining portion is privately owned. On the park lands, the population has been fenced, and portions of the habitat for the plant are being mowed and raked in accordance with a management plan (Ecosystems West 1999; Joe Rigney, consultant, pers. comm., 2001). The County of Santa Cruz approved a housing development for the privatelyowned parcel (previously known as Tan, but now called Seacrest) in 1997. The development included an approximately 4-ha (10-ac) parcel to be set aside for conservation and a plan to manage the habitat for Holocarpha macradenia. Although part of the same population, the CNDDB has maintained two separate entries (O’Neill and Tan) to reflect the two land ownerships. The total number of individuals in the combined population has never been larger than 200 individuals, with the private parcel supporting only a portion of those (CNDDB 2001). To date, management activities have not resulted in enhancing the population of the species on either parcel. This unit is essential because it has recently supported a population of H. macradenia and the seed bank is still present, and because it is one of only seven populations in the cluster of populations that are found on the northern end of Monterey Bay. In addition to the seed bank for this population, this unit supports grassland habitat that provides for future expansion of the population. Also, it is within one-half mile of the Rodeo Gulch Unit, and therefore could retain connectivity between the units. Moreover, the acreage in Anna Jean Cummings Park represents one of the best remaining fragments of habitat on which to attempt recovery activities for H. macradenia, as it has been subject to fewer impacts than other sites.

Unit H: Porter Gulch: Unit H consists of grasslands on gently sloping alluvial deposits derived from a coastal terrace that straddles the Bates Creek and Porter Gulch drainages north of the community of Soquel in Santa Cruz County. It is bounded on all sides by undeveloped lands. This entire unit of approximately 14 ha (35 ac) is on privately owned lands. The population of Holocarpha macradenia at this site includes an approximately 12-ha (30-ac) parcel that was proposed for a lot split. A management plan for the species was developed as part of the proposed split (Greening Associates 1995); however, the management plan for H. macradenia has not been fully implemented. This unit also includes adjacent coastal prairie habitat, of which approximately 4 ha (9 ac) was deeded in 2001 to the Land Trust of Santa Cruz County for preservation. In 1993, the population of H. macradenia numbered approximately 1,500 individuals (CNDDB 2001). The population numbered only several hundred individuals in 2001 when the site was observed to support a large cover of rattlesnake grass that likely competed with H. macradenia (C. Rutherford, Service, pers. obs., 2001). This unit is essential because it currently supports a population of H. macradenia, and because it is one of only seven populations in the cluster of populations that are found on the northern end of Monterey Bay. Also, along with the Graham Hill Unit, this one occurs at the highest elevation of the native populations (122 m (400 ft)) and consequently the farthest away from the influence of the coastal climate. Preserving the genetic variability within the species that has allowed it to adapt to these slightly different environmental conditions is essential for the long-term survival and conservation of the species.

Unit I: Watsonville: Unit I consists of grasslands on alluvial fans and marine terraces west of the City of Watsonville in Santa Cruz County; during the remapping for the final rule we removed most of the lowlying drainages that interdigitate with the grasslands. The northern and eastern boundaries reach toward the Corralitos Creek drainage except where it runs up against existing development. The southeastern and southern boundary is formed by the Pajaro River drainage. The western boundary is formed by the Harkins Slough drainage and then generally follows Buena Vista Drive north until it intersects with the northern perimeter of the Watsonville Airport (Airport). This unit excludes paved areas of the Airport, but includes the unpaved portions surrounding the runways. This approximately 488-ha (1,205-ac) unit is partly owned by the City of Watsonville (the Airport and High School) (approximately 125 ha (309 ac)); a small portion is under easement to CalTrans (approximately 8 ha (19 ac)); a portion is designated as a Reserve by the CDFG (approximately 15 ha (37 ac)); and the remaining portion is privately owned (approximately 340 ha (840 ac)). This unit overlaps in part with an area that is targeted for regional conservation planning by the CDFG. Through its Conceptual Area Protection Plan process, CDFG, along with other Federal, State, and local agencies and organizations, are identifying opportunities to preserve sensitive species and habitats, including the Harkins Slough and Watsonville Slough wetlands and adjacent habitats (J. DeWald, in litt., 2001). This unit is essential because it currently supports multiple populations of H. macradenia including the populations known from the Airport, Harkins Slough, Apple Hill, and Bay Breeze (see Background for additional population information). This unit also supports grassland habitat that is important for the expansion of existing populations and for maintaining connectivity between the populations. It is also one of only three areas that support populations of H. macradenia that are found in the central Monterey Bay area and in the southern end of the range of the species. Preserving any genetic variability within the species that has allowed it to adapt to these slightly different environmental conditions is essential for the long-term survival and conservation of the species. Just prior to publication of this final rule, we were informed that construction of the Millennium High School had been initiated. Therefore, with this unit description, we are removing the 32 acres that are being converted to building, paved surfaces, and playing fields because these areas will no longer support the primary constituent elements. Note, however, that the 32 acres have not been removed from the map depicting this unit; nor have they been subtracted from the unit total and overall total number of acres being designated as critical habitat for the species.

Unit J: Casserly: Unit J consists of open patches of grassland interspersed with golf course greens, cattle pastures, croplands, and orchards. This entire unit of approximately 450 ha (1,110 ac) consists of privately owned lands. It is the unit for which the least amount of information is available, particularly with respect to existing land uses. The Spring Hills population of Holocarpha macradenia occurs within this unit. The population numbered approximately 4,000 individuals in 1990 (CNDDB 2001); the population was observed in 1995 and 2001, though not counted. The population was fragmented by development of the Spring Hills Golf Course, and now consists of five separate occurrences. This unit is essential because it currently supports multiple occurrences of H. macradenia that are found in the Monterey Bay area, including the five populations known from the Spring Hills Golf Course. This unit also supports grassland habitat that is important for the expansion of existing populations, and for maintaining connectivity between these populations. It is one of only three areas that support populations of H. macradenia that are found in the central Monterey Bay area and in the southern end of the range of the species as well as the most inland distribution of the species. Preserving genetic variability within the species that has allowed it to adapt to these slightly different environmental conditions is essential for the long-term survival and conservation of the species.

Unit K: Elkhorn: Unit K consists of sloping terrain on the edges of a coastal terrace, just south of the Pajaro River in northern Monterey County. The population of Holocarpha macradenia that is found here is unusual in that it occurs on a canyon bottom; it is also the only population that occurs primarily on the Santa Ynez soil series. This unit of approximately 70 ha (170 ac) is privately owned by the Elkhorn Slough Foundation (Foundation). The CDFG holds a conservation easement on an approximately 16-ha (40-ac) parcel that overlaps in part with this unit; the Foundation is managing the parcel for its biological values. Multiple Federal, State, and local government and private agencies have recently developed a conservation plan for the Elkhorn Slough watershed; this critical habitat unit is within the 18,210-ha (45,000-ac) area on which the conservation plan focuses (Scharffenberger 1999). In 1993, the population at this site comprised approximately 3,200 individuals (CNDDB 2001). Salix spp. (willow) planting that has been undertaken as part of a riparian enhancement project may increase shading on an adjacent population of H. macradenia, leading to a reduction in the size of that population (Holl, in litt., 2002). This unit is essential because it currently supports a population of H. macradenia and because it is one of only three areas that support populations of H. macradenia that are found on the central Monterey Bay area and in the southern end of the range of the species. Also, this is the only population that occurs primarily on the Santa Ynez soil series. Preserving any genetic variability within the species that has allowed it to adapt to these slightly different environmental conditions is essential for the long-term survival and conservation of the species. In addition to the current population, this unit comprises grassland habitat that is important for the expansion of the population.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Holocarpha macradenia critical habitat consists of three components (67 FR 63968-64007):

(i) Soils associated with coastal terrace prairies, including the Watsonville, Tierra, Elkhorn, Santa Inez, and Pinto series.

(ii) Plant communities that support associated species, including native grasses such as Nassella sp.(needlegrass) and Danthonia californica (California oatgrass); native herbaceous species such as members of the genus Hemizonia (other tarplants), Perideridia gairdneri (Gairdner’s yampah), Plagiobothrys diffusus (San Francisco popcorn flower), and Trifolium buckwestiorum (Santa Cruz clover); and

(iii) Physical processes, particularly soils and hydrologic processes, that maintain the soil structure and hydrology that produce the seasonally saturated soils characteristic of Holocarpha macradenia habitat.

**Special Management Considerations or Protections**

Much of what is known about the specific physical and biological requirements of Holocarpha macradenia is described in the Background section of this final rule. Additional information about appropriate management techniques is being generated by ongoing management efforts and research on life history. As discussed in the Background section, several agencies such as the CDFG, California Department of Parks and Recreation (CDPR), CalTrans, County of Santa Cruz, City of Santa Cruz, and EBRPD are undertaking efforts to learn how to better enhance habitat for H. macradenia. Some of these efforts are being carried out with the cooperation of researchers from UC Santa Cruz and Berkeley's Jepson Herbarium. Preliminary management and seed bank studies show that habitat manipulation such as burning, mowing, grazing, and scraping can increase standing numbers of plants and may be necessary to enhance and maintain populations of H. macradenia. Active management is often necessary to preserve habitat that is essential for the long-term conservation of H. macradenia. Special management considerations or protections may be needed to maintain the primary constituent elements for Holocarpha macradenia within the units being designated as critical habitat. In some cases, protection of existing habitat and current ecological processes may be sufficient to ensure that populations of H. macradenia are maintained, and have the ability to reproduce and disperse into surrounding habitat at those sites. In other cases, however, active management may be needed to maintain the primary constituent elements for H. macradenia. We have outlined below the most likely special management or protection that H. macradenia may require. (1) The native soils on which Holocarpha macradenia is found should be maintained to optimize conditions for the species. Physical properties of the soil, such as its chemical composition, salinity, texture, and drainage capabilities would best be maintained by limiting or restricting deep tilling and the use of herbicides, fertilizers, or other soil amendments. (2) The hydrologic regime of the area surrounding Holocarpha macradenia habitat should be maintained to provide for the seasonally moist soils that the species favors. Increasing or decreasing surface and subsurface water flow to these areas through habitat alteration that either artificially adds water (e.g., through irrigation) or reduces water (e.g., through diversions associated with construction projects) could decrease the suitability of these areas to support H. macradenia. (3) The grassland communities should be maintained to ensure that the habitat needs of pollinators and dispersal agents are maintained. The use of pesticides should be limited or restricted so that viable populations of pollinators are present to facilitate reproduction of Holocarpha macradenia. Fragmentation of habitat through construction of roads and certain types of fencing should be sufficiently limited to allow seed dispersal agents to move H. macradenia seed throughout the unit. (4) The grassland communities need to be maintained to facilitate germination and the establishment of seedlings, because this is a critical bottleneck in the life cycle of the species (Bainbridge, in litt., 2002b). In particular, this portion of the species' life cycle requires a reduced litter layer and canopy height of surrounding vegetation. This can be achieved through either mowing or livestock grazing. A discussion of more detailed prescriptions is beyond the scope of this rule, as the optimal regime will vary from site to site, depending on a number of variables. However, research efforts that are currently underway will assist in developing more site-specific recommendations. (5) In the grassland communities where Holocarpha macradenia occurs, invasive, nonnative species such as French broom, eucalyptus, acacia, Harding grass, bromes, artichoke thistle, and bristly ox-tongue and other species need to be actively managed to reduce competition and maintain the open habitat that H. macradenia needs. (6) Certain areas where Holocarpha macradenia occurs may need to be fenced to protect them from accidental or intentional trampling by humans and livestock, and to facilitate management of the habitat through intentional grazing or other means.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: cross-pollination (USFWS, 2014)

**Lifespan**

Adult: 1 year (USFWS, 2014)

**Breeding Season**

Adult: July - October (USFWS, 2014)

**Key Resources Needed for Breeding**

Adult: Insect pollinators, soil seed bank (USFWS, 2014)

**Reproduction Narrative**

Adult: This is an annual plant. Flowering from July to October, the inflorescences comprise yellow ray and disc flowers. Native bees, flies, wasps, and winged beetles have been observed pollinating H. macradenia (Barber 2002). Plants produce 1 to 60 inflorescences with two types of flowers that produce two types of achenes (seeds) with different morphologies and requirements for germination. Results of studies indicate that disk seeds produced by Holocarpha macradenia germinate within a year of production while ray seeds form persistent seed banks. Holocarpha macradenia is self-incompatible, meaning that individuals will not produce viable seeds without cross pollinating with other individuals (Baldwin, in litt. 2001) (USFWS, 2014).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Coastal prairies and grasslands (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Periodic fire (USFWS, 2014)

**Geographic or Habitat Restraints or Barriers**

Adult: 10 - 220 m elevation (NatureServe, 2015)

**Environmental Specificity**

Adult: Moderate (NatureServe, 2015)

**Habitat Narrative**

Adult: Inhabits coastal prairies and grasslands, often with clay or sandy-clay soils, at 10 - 220 m elevation. Most frequent associates are non-native grasses and non-native French broom (Genista monpessulana). The environmental specificity is moderate (generalist or community with some key requirements scarce) (NatureServe, 2015). Soils associated with coastal terrace prairies include the Watsonville, Tierra, Elkhorn, Santa Inez, and Pinto series. Physical processes, particularly soils and hydrologic processes that maintain the soil structure and hydrology that produce the seasonally saturated soils characteristic of H. macradenia habitat, are necessary features for the conservation of the species. Historically, coastal prairie species such as Holocarpha macradenia may have evolved under light grazing pressure and an intense fire regime used by California Native American groups (Heady et al. 1988). Grazing likely improves habitat quality for H. macradenia by removing plant biomass cover, reducing aboveground competition during the growing season, and reducing thatch accumulations that inhibit tarplant germination. Additionally, trampling by grazers can open, roughen, and compact surface layers of soil (USFWS, 2014).

***Dispersal/Migration***

**Dispersal**

Adult: Low; possibly high if dispersed by animals (USFWS, 2014)

**Dispersal/Migration Narrative**

Adult: Most seeds remain on the plant until the first significant rain (0.6-1.2 inches (15–30 millimeters (mm)) in late autumn (Service 2002, Holl and Hayes 2006). Neither type of seed appears to have a structural means for dispersal, and most fall within 17.7 inches (45 cm) of the plant (Holl and Hayes 2006) though it is possible that some ray seeds may be dispersed over long distances by animals (Satterthwaite et al. 2007) (USFWS, 2014).

***Population Information and Trends***

**Population Trends:**

Decline of 50-70% (NatureServe, 2015)

**Species Trends:**

10 - 30% decline (NatureServe, 2015)

**Number of Populations:**

15 native, 4 - 8 experimental (USFWS, 2023)

**Population Size:**

Uncertain, possibly ~25,000 (NatureServe, 2015)

**Adaptability:**

High (inferred from NatureServe, 2015)

**Population Narrative:**

The plant is not terribly vulnerable intrinsically; it is a robust composite that can colonize open areas. Long term trend has been one of substantial decline; 50-70%. The short term trend has been one of steady decline (10 - 30%) due to development. It is difficult to trust some of the population data CNDDB has received. For example, one form stated there were "millions" of plants, which seems doubtful. More solid estimates sent to the CNDDB tend to be from the early 1990's and therefore constitute old information. These add up to about 25,000 plants (NatureServe, 2015). Holocarpha macradenia occurs in 14 native and 4 to 8 experimentally seeded populations (USFWS, 2014). There are currently 19 known occurrences that support Santa Cruz tarplant or are presumed to have a viable seedbank and suitable habitat (Table 1). This is an increase of one occurrence, located on private land, since the 2014 5-year review. Eleven occurrences have regular or periodic monitoring that estimate annual abundance of Santa Cruz tarplant and also have active management and/or reintroduction efforts. The remaining eight occurrences have no monitoring and management efforts, or have ceased monitoring and management since 2014 (USFWS, 2022). At listing, Santa Cruz tarplant was known from 14 natural and 4 to 8 experimentally introduced populations in coastal grasslands and prairies in Contra Costa, Santa Cruz, and Monterey Counties, California (65 FR 14898). Santa Cruz tarplant continues to occur within Contra Costa, Monterey, and Santa Cruz Counties. Currently, 15 natural populations are located within Santa Cruz and Monterey Counties and four experimental populations are located within Contra Costa County (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Development (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In Santa Cruz County, coastal prairie habitat was converted to ranching and agricultural lands in the late 1800s and early 1900s; subsequently, this habitat was favored for the expansion of urban centers, especially around the cities of Santa Cruz and Watsonville. California coastal prairies have been affected by humans to the extent that their recovery is extremely slow or even unlikely, and will require human intervention (Stromberg and Griffin 1996; Hamilton et al. 2002, as cited in Buisson et al. 2006). The Apple Hill population is located on a small Caltrans right-of-way. The population was once comprised of three colonies, two of which were extirpated by the construction of a housing development on adjacent private property. The remaining colony occurs on a strip of land between the housing development and Highway 152. The Arana Gulch population and its designated critical habitat will be subject to additional habitat alteration and destruction with the construction of a bike path proposed by the City of Santa Cruz. A portion of the habitat associated with the Watsonville Airport may be subject to additional alteration; a proposed development project would permanently impact approximately 2 acres (0.8 ha) of Holocarpha macradenia critical habitat within the Watsonville critical habitat area (Unit I) (Olberding Environmental 2009). The Winkle population of Holocarpha macradenia, also referred to as the Santa Cruz Gardens population, was partially destroyed by development in 1986 (Arnold and Lyons 2009). Further development has been proposed within a 58.6-acre (23.7-ha) project site that includes the Winkle population (USFWS, 2014).

**Stressor:** Nonnative plants (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Overgrowth of nonnative invasive species is a principal ongoing threat for Holocarpha macradenia populations. Even with management, most populations are in decline due to H. macradenia's inability to compete with the overgrowth of nonnative vegetation. Invasive species that have been identified as threats to H. macradenia populations include but are not limited to: Genista monspessulana (French broom), Foeniculum vulgare (fennel), Eucalyptus spp. (eucalyptus); Acacia decurrens, A. melanoxylon (acacia); artichoke thistle; Rubus discolor (Himalayan blackberry); Phalaris aquatica (harding grass); Festuca arundinacea (tall fescue); Cardaria draba (hoary cress); Carduus pycnocephala (Italian thistle); Picris echioides (bristly ox-tongue); Trifolium angustifolum (narrow-leafed clover); Convolvulus arvense (field bindweed); and Conium maculatum (poison hemlock) (Service 2000, Watsonville Wetlands Watch 2009) (USFWS, 2014).

**Stressor:** Herbivory (USFWS, 2014)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A study by Maze (2009) indicated that invertebrate herbivory on Holocarpha macradenia significantly affected the survivability of H. macradenia seedlings. Most of the herbivory observed in the study was caused by the nonnative grey garden slug (Deroceras reticulatum). Although results of this study indicate that herbivory could potentially be a problem for H. macradenia, or possibly exacerbate other threats to H. macradenia populations, herbivory does not appear to be a significant threat at this time (USFWS, 2014).

**Stressor:** Low reproductive success (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The eight populations of Holocarpha macradenia in Contra Costa County are the result of 22 experimental seedings performed from 1982 to 1986, within Wildcat Canyon Regional Park on East Bay Municipal Utility District land. The 22 experimental seedings have been managed with invasive plant removal and a grazing regime, yet have resulted in only 8 lasting populations, with only one of these populations (Mezue) showing substantial numbers and an increasing trend over time. Additionally, of the 8 remaining populations, data show that only about half of these have had persistent numbers of aboveground plants over the past 10 years (Legard, unpubl. data 2010). Although some seeding attempts have been somewhat successful, it appears that the management, timing, location of plantings, and techniques greatly influence the results of the persistence of Holocarpha macradenia, and long term viability in these cases remains unclear (USFWS, 2014).

**Stressor:** Environmental stochasticity (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Much of the coastal prairie habitat that supports Holocarpha macradenia has been altered, fragmented, or destroyed, so that most of the remaining habitat is of small acreage and supports only very small populations. Because H. macradenia is not capable of self-fertilization, individuals cannot produce viable seeds without cross pollinating with other individuals. Small populations may have a more difficult time attracting pollinators and therefore may experience lower seed production rates, leading to reduced species viability and possible extirpation over time (Service 2000, Satterthwaite 2007). With only 14 naturally occurring populations in a limited portion of its historic range, environmental stochasticity remains a threat to H. macradenia, and is currently a greater threat than it was at the time of listing (USFWS, 2014).

**Stressor:** Climate change (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Impacts to H. macradenia under predicted future climate change are unclear. The potential impacts of climate change on the flora of California were discussed by Loarie et al. (2008). Based on modeling, they predicted that species' distributions will shift in response to climate change and that species will "move" to higher elevations and northward, depending on

the ability of each species to do so (USFWS, 2014).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 11

**Delisting Criteria:**
Not available - this species does not have a recovery plan.

**Recovery Actions:**
- Not available - this species does not have a recovery plan.
- Coordinate a meeting with CDFW and the Elkhorn Slough Foundation, including species experts and managers of Holocarpha macradenia populations, to collaborate on current status of the species, successful management and census techniques, and to continue efforts toward management of the species and conservation of habitat (USFWS, 2014).
- Work with the appropriate governing agencies or landowners to continue and/or improve management for Holocarpha macradenia populations, and initiate programs for populations that do not currently undergo a management regime. Possibilities may include but are not limited to: At Fairway Drive, working with the County of Santa Cruz and the Homeowners Association toward more active long-term management and restoration of habitat and populations; working with the Spring Hills Golf Course to investigate possibilities to restore and manage habitat and populations on their property; at O'Neill/Tan, working with the County of Santa Cruz and private landowners toward more active long-term management and restoration of habitat and populations; at Atkinson Lane, working with PG&E toward the possibility of long-term management and restoration of habitat and populations; at Apple Hill, working with Caltrans to better manage and restore habitat and populations; and at Arana Gulch, working with the City of Santa Cruz toward more vigorous long-term management and restoration of habitat and populations (USFWS, 2014).
- Investigate opportunities for conservation of lands that support suitable habitat for the species and for future outplanting (USFWS, 2014).
- Evaluate suitable habitat for future outplanting, and investigate seeding and transplanting techniques that will lead to large, self-sustained populations (USFWS, 2014).
- Based on research already conducted by Satterthwaite et al. (2007), Bainbridge (2003, 2007), and the California Department of Parks and Recreation (Hyland, unpubl. data 2002, 2004, 2007, 2009), undertake additional research to investigate seed bank dynamics, particularly how to maintain optimal balance between aboveground populations and the seed bank (USFWS, 2014).
- Conduct research to investigate mowing, raking, grazing, and other techniques that are beneficial to Holocarpha macradenia and develop best management strategies, particularly for management of thatch and nonnative species, utilizing these techniques (USFWS, 2014).
- Investigate the impacts of climate change on Holocarpha macradenia (USFWS, 2014).

***Conservation Measures and Best Management Practices:***
- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Identify techniques for successful reintroduction and management. 2. Secure funding for management at currently unmanaged locations. 3. Include habitat restoration as part of reintroduction efforts. 4. Identify mechanisms to promote and

preserve Santa Cruz tarplant on properties susceptible to development (USFWS, 2022).

# SPECIES ACCOUNT: *Hymenoxys herbacea* (Lakeside daisy)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 06/23/1988; Great Lakes-Big Rivers Region (R3) (USFWS, 2015)

**Physical Description**

The Lakeside daisy is a perennial herb with flowering stalks, 5-25 cm tall, arising from basal tufts of leaves. When the plants are not in bloom, the small tufts of leaves are easily overlooked, but in bloom (late April-June, or July in Canada) the plants are extremely showy, with populations simultaneously producing masses of large (3-4 cm in diameter) yellow flower heads. (NatureServe, 2015)

**Taxonomy**

The species was listed as Hymenoxys acaulis var. glabra (USFWS, 1988) and is treated that way in most floras. Based upon the work of Cusick (1991), who noted chromosomal, reproductive, and physical differences between the Lakeside daisy and the original nominate species, the Fish and Wildlife Service recognized the Lakeside daisy as a separate species, Hymenoxys herbacea. More recent treatment is Tetraneuris herbacea (USFWS, 2016). The taxonomic name for Lakeside daisy was Hymenoxys herbacea (Asteraceae). However, more recent treatment is to use Edward Greene's name of Tetraneuris herbacea. This is the name used by the Ohio Department of Natural Resources Division of Natural Areas and Preserves (DNAP), USDA, Center for Plant Conservation, Smithsonian National Museum of Natural History, and it is widely accepted by many other scientific organizations. However, this name has not been widely adopted by the Service. (USFWS, 2021)

**Historical Range**

At the time of listing, the Lakeside daisy was known from only one fragmented population in the U.S., in Ottawa County,  Ohio and from two regions in Ontario, Canada. It was presumed extirpated in Will and Tazewell, County Illinois (USFWS, 2016).

**Current Range**

Currently, the Lakeside daisy is known from sites in Ohio, Illinois, Michigan, and Ontario. It is extant on the Marblehead Peninsula of Ottawa Co., Ohio and in Ontario, Canada on Manitoulin Island and the Bruce Peninsula. The largest populations are in Ontario. Additionally, three introduced populations that are likely not functioning as an ecological community, have been transplanted into appropriate habitat in Erie County, Ohio and in DuPage and Cook County, Illinois. Sites presumed extirpated in Will and Tazewell County, Illinois are now identified as restored populations. The population in Michigan occurs in Brevort Township, Mackinac County (USFWS, 2016). Since the Lakeside daisy was listed as threatened in 1988 (53 FR 23742), the number of populations in the United States has increased from the single large, fragmented population at Marblehead Peninsula in Ottawa County, Ohio. In Michigan two populations were found and three populations were introduced. Additionally, three populations have been restored (two in Will County, Illinois, one in Tazewell County, Illinois). In Illinois three populations have been introduced (two in Cook County and one in DuPage County), two populations were introduced in Michigan (Brevort Lake Road reserve and quarry), and four populations have been introduced in Ohio (three on Kelleys Island and one in Margaretta Township, Erie County). Most populations in Illinois and Michigan appear to be stable, however some, such as the DuPage and Tazewell County, Illinois populations have been declining. (USFWS, 2021)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Obligate outcrosser (self-incompatible), but also reproduces clonally. (NatureServe, 2015)

**Lifespan**

Adult: Unknown, possibly decades (USFWS, 1990)

**Dependency on Other Individuals or Species**

Adult: According to the Recovery Plan, the following types of insects have been observed to pollinate Lakeside daisy: bumble bees (Apidae), small carpenter bees (Xylocopidae), and halictid bees (Halictidae). Recent observations in Ohio, have documented multiple insects visiting and potentially pollinating Lakeside daisy flowers. These include the pearl crescent (Phycoides tharos) (Parshall, Ohio Lepidopterists, personal communication, 2015), a small butterfly, and multiple syrphid flies (Syrphidae) including the transverse-banded flower fly (Eristalis transversa), tufted globetail (Sphaerophoria contingua), and margined calligrapher (Toxomerus marginatus) (USFWS 2021).

**Breeding Season**

Adult: Flowers late April to early June (USFWS, 1990)

**Reproduction Narrative**

Adult: The Lakeside daisy is a perennial that flowers from late April to early June. Although locally variable, an average of 75% of the adult plant population in any given area is in flower during this time. Under optimal greenhouse conditions, plants grown from seed can achieve reproductive size within seven months; in natural populations it may take two to three years (DeMauro 1990). Buds are visible by early spring at the rosette center. Flowers are visited by bumble bees (Dr. R. Betz, pers. obs.), small carpenter and halictid bees (R. Panzer, Northeastern Illinois University, pers. obs.), and the pearl crescent butterfly (USFWS, 2016). It is possible that pollination is also achieved by wind. Outcrossing is necessary for seed production because Lakeside daisy exhibits sporophytic incompatibility within a clone (DeMauro l988a). In natural populations, seed production averages 49 seeds per inflorescence (DeMauro 1988a). The number of inflorescences/plant is positively correlated with plant size and although highly variable, the two are positively correlated (DeMauro l988a). Achenes develop quickly and are wind-dispersed three to four weeks following fertilization. In natural populations, spring and fall seed germination have been observed (DeMauro pers. obs.). Under optimal artificial storage conditions, seeds can remain viable for at least three years (DeMauro unpub. data); in natural populations, it is not known how long seeds remain viable or if there is a seed bank. Although the longevity of clonal colonies is not known, plants can grow up to one meter in diameter; under field conditions it may take on the order of decades to achieve this size. (USFWS, 1990).

According to the Recovery Plan, the following types of insects have been observed to pollinate Lakeside daisy: bumble bees (Apidae), small carpenter bees (Xylocopidae), and halictid bees (Halictidae). Recent observations in Ohio, have documented multiple insects visiting and potentially pollinating Lakeside daisy flowers. These include the pearl crescent (Phycoides tharos) (Parshall, Ohio Lepidopterists, personal communication, 2015), a small butterfly, and multiple syrphid flies (Syrphidae) including the transverse-banded flower fly (Eristalis transversa), tufted globetail (Sphaerophoria contingua), and margined calligrapher (Toxomerus marginatus) (USFWS 2021). In addition, other insects appear to feed on the disk flowers. A larva of the wavy-lined emerald (Synchlora aerata) (Wagner, University of Connecticut, personal communication, 2021) was observed on a flower disk in 2021. Multiple shining flower beetles were also observed on the disk flowers (USFWS 2021) and may be responsible for the holes observed in multiple disk flower heads (USFWS, 2021).

**Habitat Type**

Adult: Alvar habitat (flat limestone or dolostone bedrock with thin to no soil, few to no tress, and subject to seasonal drought) and modified alvar habitat where original habitat has been modified or removed by quarrying activities and is in the form of gravel (USFWS, 2016).

**Habitat Vegetation or Surface Water Classification**

Adult: Limestone or dolomite outcrops (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Thin soils over limestone or dolomite outcrops or soils (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from USFWS, 1990)

**Environmental Specificity**

Adult: Very narrow. Specialist or community with key requirements scarce. (NatureServe, 2015)

**Site Fidelity**

Adult: High (USFWS, 1990)

**Habitat Narrative**

Adult: The Lakeside daisy requires full sun and occurs on limestone or dolomite outcrops, on thin soils over dolomite or limestone, and on dry limestone prairie soils. It may also occur in openings of forests. It is almost exclusively found on such soils or on bare rocks. Typically, the plains are sandy or gravelly with rocks up to one inch in size or larger. An active quarry with the open, gravelly, limestone habitat has one of the best populations of the daisy. (USFWS, 1990)

***Dispersal/Migration***

**Motility/Mobility**

Adult: Limited (inferred from USFWS, 1990)

**Dispersal**

Adult: Low (inferred from USFWS, 1990)

**Dispersal/Migration Narrative**

Adult: Achenes develop quickly and are wind-dispersed three to four weeks following fertilization, typically in early to mid-June. It is not known how far seeds disperse, however the greatest numbers of seedlings appear within one-half meter of adult plants (DeMauro pers. obs.). (USFWS, 1990)

***Population Information and Trends***

**Population Trends:**

Unknown. Inferred from information (USFWS, 2021)

**Species Trends:**

Unknown. Inferred from information (USFWS, 2021)

**Number of Populations:**

6 - 20 (NatureServe, 2015)

**Population Size:**

200 - 1,000,000 individuals (USFWS, 2016)

**Minimum Viable Population Size:**

Minimum of 5,000 individuals is necessary to maintain the balance between mutation and genetic drift; fewer than 50 individuals will result in loss of self-incompatibility alleles (USFWS, 2016)

**Adaptability:**

Low (NatureServe, 2015)

**Population Narrative:**

The species is locally abundant in good stands. There are extensive, probably millions of clumps, but the number of clonal colonies is unknown and probably far fewer. Overall, the population size is difficult to determine. Naturally occurring populations are known from two sites on Marblehead Peninsula in Ottawa County, Ohio (Lafarge Quarry and Lakeside Daisy State Nature Preserve) and Manitoulin Island and Bruce Peninsula in Ontario, Canada where 24 extant or more localities are known (Ontario CDC, 3/94). The size of the population within the Lafarge Quarry is estimated to be 10.05 million (5.78 juvenile plants and 4.27 adult plants) individuals as of 2015 but 3 million of the adult plants occur in an area planned for imminent mining in the next 3-5 years. The size of the population on the Lakeside Daisy State Nature Preserve is estimated to be 1.4-1.7 million. An introduced population occurs on Kelleys Island in Erie County, Ohio in 1989 that contained over 18,800 adult plants in 2014 and is increasing. Populations in Illinois were presumed extirpated from Will and Tazewell Counties but they have been identified as restored populations although continue to decline with the population in Will County containing less than 200 plants. Introduced populations also exist in DuPage and Cook Counties, Illinois with varying numbers from 64 to over 400 individuals surveyed in recent years. A population was discovered at a single Michigan site in Brevort Township, Mackinac County and is located on lands managed by Hiawath National Forest and the Michigan Nature Association with less than 200 plants. An additional reserve population was established by the Michigan Nature Association and planted in 2010 . These populations occur on a variety of private and federally-owned lands with different levels of protection (USFWS, 2016). Since the Lakeside daisy was listed as threatened in 1988 (53 FR 23742), the number of populations in the United States has increased from the single large, fragmented population at Marblehead Peninsula in Ottawa County, Ohio. In Michigan two populations were found and three populations were introduced. Additionally, three populations have been restored (two in Will County, Illinois, one in Tazewell County, Illinois). In Illinois three populations have been introduced (two in Cook County and one in DuPage County), two populations were introduced in Michigan (Brevort Lake Road reserve and quarry), and four populations have been introduced in Ohio (three on Kelleys Island and one in Margaretta Township, Erie County). Most populations in Illinois and Michigan appear to be stable, however some, such as the DuPage and Tazewell County, Illinois populations have been declining. It is likely that some of the populations categorized as stable may also show declining trends if long-term data were available (USFWS, 2021).

***Threats and Stressors***

**Stressor:** Habitat destruction (USFWS, 2010; 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The limestone or dolomite outcrops on which the daisy occurs are subject to commercial quarrying. Cottage and industrial development may eliminate habitat, while trampling and soil compaction can result from grazing or recreational activities and may impair habitat (NatureServe, 2015). Quarry operations have increased in recent years and have impacted a significant amount of occupied habitat and no additional habitat has been protected nor can alvar habitat be created. A survey conducted in 2015 shows that occupied habitat within the quarry has declined from 400-450 acres to approximately 92.552 acres mostly due to quarry activity. ATV use can destroy plants or habitat, or lead to the introduction of invasive species. Road and powerline right-of-way maintenance including herbicide spraying and snow plowing, may also adversely impact habitat. (USFWS, 2010; 2016) The greatest threat remains the ongoing quarry activities which occur at the largest population in the U.S. (Table 6). Quarry activities since 1989 have reduced the amount of potential habitat for this species. In addition, activities have expanded to the west and south where some of the highest densities of Lakeside daisy previously occurred. LafargeHolcim continues its quarry operations which reduces the amount of modified alvar habitat available. It is anticipated that once quarry operations are complete, the quarry will then naturally fill with water and become a large lake. The only remaining upland habitat would be limited to the periphery. Thus, without permanent protection of alvar and modified alvar habitat, the amount of suitable habitat for this species will continue to decline. (USFWS, 2021)

**Stressor:** Succession (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The species requires an open, sunny habitat. Successional growth around forest openings and at the edges male eliminate the open requirement. In some cases, past maintenance of rights-of-way has kept habitat open and needs to continue without herbicide spraying to benefit the species. (USFWS, 2010) Management requirements to maintain suitable habitat for the Lakeside daisy varies at different sites. The populations in Illinois experience

greater vegetative competition, so greater levels of management are needed to maintain open habitat. The Michigan populations are also experiencing some shading by trees, which may require some management to maintain the light levels needed by Lakeside daisy. In Ohio, some removal of cedar, and other woody species, is required to maintain sunny, open alvar habitat. This management is required infrequently. In general, Lakeside daisy is well adapted to occupying alvar habitat that other plants cannot tolerate and therefore competition is limited. (USFWS, 2021)

**Stressor:** Inadequacy of existing regulations (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Although laws and regulations exist to protect the Lakeside daisy on most public sites, enforcement is lacking and destruction is still occurring. On private land, the Lakeside daisy is not afforded protection, and some populations are being seriously impacted by quarrying activities. (USFWS, 2010) The inadequacy of state and Federal laws for plant and plant habitat protection remain the same as discussed in the 2016 5-year Review for Lakeside daisy. One recent change is that despite coordination between the Erie County Metroparks and the Service, including an MOU, impacts to this species are still occurring. During 2021 monitoring, Lakeside daisy plants were found pulled from the ground in an area where it appeared that illegal camping had also occurred. In addition, recent actions due to right-of-way work resulted in significant disturbance at the Brevort Township site in Michigan. (USFWS, 2021)

**Stressor:** Self-incompatibility (USFWS, 2010
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The self-incompatibility of the Lakeside daisy requires outcrossing between individuals with different self-incompatibility genes. Populations within larger regions, such as those on Marblehead Peninsula and Manitoulin Island, are likely in contact with many individuals that each has a different self-incompatibility gene. However, small populations tend to lose self-incompatibility genes, increasing the probability of nearby plants sharing the same gene, and therefore reducing the potential to effectively outcross. It is theorized that this may have been a leading factor in the natural disappearance of one of the last Lakeside daisy populations in Illinois (DeMauro 1982). (USFWS, 2010)

**Stressor:** Climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change may be a serious threat for a rare, endemic plant species like the Lakeside daisy. The habitat for the Lakeside daisy currently spans a narrow range of habitat types, including dry, limestone prairies and alvar communities, which are globally rare. According to regional precipitation and temperature models, increased temperatures and increased rainfall may alter the habitat for the Lakeside daisy in such a way that the plant cannot adapt or invasive plants may encroach (Union of Concerned Scientists 2009). It is not known how the Lakeside daisy will be impacted by temperature or precipitation increases, but lowered lake levels caused by increased temperature will further alter the climate (Easterling and Karl 2000). (USFWS, 2010)

Populations of Lakeside daisy cannot expand to unsuitable habitat, and some, particularly those associated with the Great Lakes, including the three sites at Kelleys Island, cannot migrate northwards due to the presence of the Great Lakes and/or development. Some subpopulations in Canada may be at risk from increased wave-wash and ice build up associated with increased storm intensity (COSEWIC, In Press, 2021). (USFWS, 2021)

**Stressor:** Herbivory (USFWS, 2021)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Disease and predation were not listed as threats to the Lakeside daisy at the time of listing (53 FR 23742), though herbivory was included as an ecological threat to both natural and restored populations in the Recovery Plan (USFWS 1990). Predation, namely deer and rabbit herbivory, of this plant continues to pose a threat to Lakeside daisy, particularly small populations.

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 5

**Delisting Criteria:**
1) 475 acres of essential habitat containing the population center at the Marblehead Quarry, Ottawa County, Ohio are acquired and managed. (USFWS, 1990)

2) 465 acres of additional essential habitat at the Marblehead Quarry is protected through easements, restrictive covenants or leases. (USFWS, 1990)

3) The variety is restored to a minimum of one large, stable population in each of two geographically distinct, protected sites of suitable size within the variety's historic range in Illinois. (USFWS, 1990)

4) Restored populations are maintained for fifteen consecutive years, with monitoring to continue for an additional ten years. (USFWS, 1990)

**Recovery Actions:**
- Provide adequate habitat protection for the only large, naturally-occurring population in the United States, i.e. Marblehead Peninsula, through the purchase or establishment of conservation easements of suitable modified alvar habitat from Lafarge. (USFWS, 2016)
- Coordinate monitoring among all three states where this species currently occurs so that information is consistent and meaningful. (USFWS, 2016)
- Provide necessary management at all protected sites, including removing non-native invasive species and woody encroachment, deterring herbivory, limiting ATV access, and reducing competition. (USFWS, 2016)
- Continue to augment introduced Lakeside daisy populations on suitable sites within the species' historical range. (USFWS, 2016)
- Revise recovery criteria to include new data prior to next 5-year review. (USFWS, 2016)

- Continue to monitor populations of Lakeside daisy, both natural and introduced, for reproductive output, recruitment, individual plant growth, and survival. (USFWS, 2016)
- Cooperatively work with Lafarge Quarry to collect seed and transplant individuals from the areas of the quarry that are at greatest threat of being quarried and have the highest genetic and habitat diversity. (USFWS, 2016)
- Cooperatively work with the ODNR Division of Mineral Resources Management to amend the Lafarge Quarry mining permit so that undisturbed areas can be recolonized by Lakeside daisy, instead of being planted with other species and creating significant competition. (USFWS, 2016)
- Increase gene pools and population numbers in restored population sites by seeding and transplanting individuals from various locations within natural populations. (USFWS, 2016)
- Improve awareness to the public about the harm of collecting federally listed plant species and the importance of protecting and maintaining unique ecosystems, such as alvars, for recovery of plant species. (USFWS, 2016)
- Botanical and geological surveys should be performed throughout Ohio, Indiana, Illinois, Michigan, and Wisconsin to assess the potential for suitable habitat of Lakeside daisy introduction. (USFWS, 2016)
- Further research into the origin of the Michigan populations to guide future recovery actions. (USFWS, 2016)
- Revise recovery criteria to include new data prior to next 5-year review. (USFWS, 2010)
- Provide adequate habitat protection for the only large, naturally-occurring population in the United States, i.e. Marblehead Peninsula, through the purchase or establishment of conservation easements of abandoned quarry property. (USFWS, 2010)
- Cooperatively work with Lafarge Quarry to protect areas of the quarry that are least likely to be quarried and have the highest genetic and habitat diversity. (USFWS, 2010)
- Determine the presence or absence of seed banks and the duration of seed viability. (USFWS, 2010)
- Establish Lakeside daisy populations on suitable sites within the species historical range. (USFWS, 2010)
- Botanical and geological surveys should be performed throughout Ohio, Indiana, Illinois, Michigan, and Wisconsin to assess the potential for suitable habitat of Lakeside daisy introduction. (USFWS, 2010)
- Continue to monitor populations of Lakeside daisy, both natural and introduced, for reproductive output, recruitment, individual plant growth, and survival. (USFWS, 2010)
- Increase gene pools and population numbers in restored population sites by seeding and transplanting individuals from various locations within natural populations. (USFWS, 2010)
- Provide necessary management at all protected sites, including removing non-native invasive species and woody encroachment, deterring herbivory, limiting ATV access and prescribed burning (in Illinois only). (USFWS, 2010)
- Conduct genetic research using highly polymorphic genetic loci to determine the genetic distance of natural populations and determine the viability of small, introduced populations. (USFWS, 2010)
- Inform the public about the harm of collecting federally listed plant species and the importance of unique ecosystems. (USFWS, 2010)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Future actions required to proceed with the recovery of this species focus on revision of current recovery criteria, population habitat management and protection, as well as research into the genetics of Lakeside daisy. These actions are listed below with highest priority actions listed first: • Provide adequate habitat protection for the only large, naturally occurring population in the United States, Marblehead Peninsula, through the purchase or establishment of conservation easements of suitable modified alvar habitat from LafargeHolcim. • Cooperatively work with LafargeHolcim to collect seed and transplant individuals from the areas of the quarry that have the greatest threat of being quarried and have the highest genetic and habitat diversity. • Conduct research into the genetics and diversity of the different populations to determine if seed from Ohio could increase the viability of the Michigan and Illinois populations. • Increase genetic diversity by continuing to augment introduced Lakeside daisy populations on suitable sites within the species' historical range with seeds and plants as feasible. • Provide necessary management at all sites, including removing non-native invasive species and woody encroachment, deterring herbivory, limiting ORV access, and reducing competition. • Coordinate monitoring among all three states and Ontario where this species currently occurs so that information is consistent and meaningful for comparisons. • Continue to monitor populations of Lakeside daisy, both natural and introduced, for reproductive output, recruitment, individual plant growth, and survival. • Improve awareness to the public about the harm of collecting federally listed plant species and the importance of protecting and maintaining unique ecosystems, such as alvars, for recovery of plant species. • Botanical and geological surveys should be performed throughout Ohio, Indiana, Illinois, Michigan, and Wisconsin to assess the potential for suitable habitat to establish Lakeside daisy populations. • Consider revising recovery criteria to include new data prior to the next 5-year review. (USFWS, 2021).

# SPECIES ACCOUNT: *Hymenoxys texana* (Texas prairie dawn-flower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 03/13/1986; Southwest Region (Region 2) (USFWS, 2016)

**Physical Description**

An annual plant 3.5—18 cm (1.4—7.1 in.) high with several divergent branches arising from a rosette of basal leaves. Basal leaves 1—16 mm (.04—59 in.) wide, up to 4 cm (1.6 in.) long, widest toward the tip, margins with short teeth or lobes from mid—blade to tip. Stem leaves few, linear. Flower heads usually few, small. Bracts of flower heads in two series 5—6 mm (.16—.20 in.) long. Ray flowers minute and concealed by the bracts. Disk flowers yellow, 3—4 mm (.12—.16 in.) long. Fruits about 2 mm (.08 in.) long with 5 apical scales 1—2 mm (.04—.08 in.) long (USFWS, 1989).

**Taxonomy**

Coulter and Rose (1891) described these plants as a new species and placed them in the genus Actinella. Greene (1898) separated the Actinella taxa with free phyllaries into the genus Tetraneuris and placed those with united outer phyllaries into the genus Picradenla. Thus, Hymenoxys texana became Picradenia texana (Coulter & Rose) Greene. Cockrell (1904) recognized Tetraneuris as a distinct genus but could not separate the North American Picradenia species from the genus Hymenoxys of South America. He, therefore, united Picradenia with Hymenoxys and transferred Hymenoxys texana into its present genus. The only specimens available to these early workers were the Thurow collections of 1889 and 1890. Hymenoxys texana was not collected again until 1981 when James Kessler discovered a few small populations north of Cypress in Harris County (Mahler 1982 and 1983). The relationship of Hymenoxys texana to four annual temperate South American species of Hymenoxys has yet to be thoroughly investigated. Three of these South American taxa lack ray flowers and perhaps one or more of them is the near relative of Hymenoxys texana, which has minute rays. A taxonomic treatment of the South American taxa is available (Parker 1962), and Sanderson (1973) reported the basic chromosome number of n = 15 for all four South American species. The North American Hymenoxys most similar to Hymenoxys texana is the annual species, Hymenoxys odorata, but the prominent long ray flowers and the deeply pinnately divided leaves of Hymenoxvs odorata easily distinguish it from Hymenoxys texana. (USFWS, 1989)

**Historical Range**

Up until about 1992, H. texana was known only from the northwest portion of Houston with only one population located in Fort Bend County (Barker Reservoir), with subsequent populations located in Addicks Reservoir in Harris County (USFWS, 2015).

**Current Range**

This species is now confirmed in five counties in Texas: Fort Bend, Gregg, Harris, Trinity, and Waller. (USFWS, 2015). A comparison of the current spatial distribution of the Texas prairie dawn flower with historical or previous reviews of this species shows the species has expanded its range westward into Waller County and beyond, and into northern regions of east Texas (USFWS, 2022).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: 1 year (USFWS, 2015)

**Breeding Season**

Adult: March to April (USFWS, 2015)

**Other Reproductive Information**

Adult: Although a potential pollinator of the Texas prairie dawn-flower was identified as composite thrips Microcephalothrips abdominalis from specimens collected north of Cypress (Young 1987), new potential pollinators were identified and photographed during the 2022 flowering season. Harvester ants in the genus Pogonomyrmex, which builds characteristic mounds more than 50 cm in diameter in large cleared flat areas with small pebbles, were observed and recorded within many of the saline barrens supporting populations at the Warren Ranch and the Jack Roads Prairies managed by the Coastal Prairie Conservancy. The harvester ants observed on the Warren Prairies during the 2022 flowering season was identified as Pogonomyrmex barbatus (Dr. Ulrich Mueller at University of Texas, Personal mail communication dated July 21, 2022). Additional pollinators were also identified as miner bees in the genus Andrena on the Warren Prairie, and the green miner bee in the genus Lasioglosusm on the Gregg County private lands (Dr. Dan Bennett at Stephen F. Austin University, personal mail communication dated July 28 and 29, 2022, respectively). Future research conducted under the section 6 grant (WSFR Grant F22AP03103-00, Biological Opinion, Reference Ecosphere 2022-0024702) will also identify potential pollinators over the next two years (USFWS, 2022)

**Reproduction Narrative**

Adult: H. texana is an annual plant that flowers from early March through mid to late April and produces yellow, cone-shaped seed heads. (USFWS, 2015)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Grassland/herbaceous, barrens, pimple mounds (USFWS, 2015; NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Found in poorly drained, sparsely vegetated areas (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Patches (USFWS, 2015)

**Environmental Specificity**

Adult: Moderate, with some key requirements (USFWS, 2015)

**Habitat Narrative**

Adult: H. texana is found in small, conspicuous, sparsely vegetated areas of fine, sandy, and compact soils. These bare spots are often located on the lower sloping portions of pimple mounds (USFWS 1990). Pimple mounds are low, roughly circular or elliptical domes or shield-like mounds, often with flat tops, composed of unstratified sandy loam soils coarser than, and distinct from, the surrounding less coarse, often clayey soil. Pimple mounds range from 1 to 30 m in diameter, and attain heights from about 10 cm to over 2 m (Johnson and Horwath Burnham 2012). H. texana thrives in disturbed, open areas with barren slicks made up of a select few soils, and where specific hydrological requirements can be met. Common soil series associated with H. texana consist of primarily Gessner Complex (Ge) and Katy Find Sandy Loam (Ka or Kf). Soils are slightly saline, sticky when wet and powdery when dry. Sometimes associated with other Texas Gulf Coastal Plain endemics such as Texas windmill-grass (Chloris texensis) and Houston machaeranthera (Machaeranthera aurea). A recent description of H. texana describes the species as found in localized patches ranging from 2 to 3 m in size or as large as 100 square meters usually associated with Gessner and Katy fine sandy loam soils which sometimes are located at the base of pimple mounds (Smeins 2014). (USFWS, 2015; NatureServe, 2015)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available.

***Population Information and Trends***

**Population Trends:**

Not available.

**Number of Populations:**

~40 - 50 populations; exact number unclear (USFWS, 2015)

**Population Size:**

~50,000 in one location surveyed in 2012; population unknown at other sites (USFWS, 2015)

**Population Narrative:**

While there are 63 known occurrences of H. texana in the TxNDD (TPWD 2014) this can not be interpreted to mean that 63 distinct populations exist. Although nearly 50 populations are known for this species, almost all are threatened by development from the expanding city of Houston. Some sites have been destroyed within a year of their discovery. In 2012, a Gregg county landowner first identified H. texana on 187 ac (75.7 ha) where surveys found the largest H. texana population with estimates greater than 50,000 individuals. (USFWS, 2015)

***Threats and Stressors***

**Stressor:** Habitat loss and alteration (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Habitat conversion, fragmentation, and degradation continue to be a threat. Expanding urbanization, paved roadways, feral hogs, alteration of watershed drainages, development of natural resources, and agricultural development contribute to the continued loss of suitable habitat. Heavy grazing and in some cases illegal grazing practices can be detrimental to H. texana and may even prevent the species from recruiting. Although efforts to restore, create, and effectively manage habitat for the H. texana are currently underway, suitable habitat continues to be degraded or lost within this species range. Considerable increases in overstory vegetation are visible in aerial photography over a majority of the current species' range. This increase in canopy cover results in significant declines in some H. texana populations (e.g. Addicks and Barker Reservoirs) where thousands of individual plants once thrived at numerous sites. Due to limited habitat management at Addicks and Barker Reservoir, there is a significant decline in the number of suitable sites with H. texana present at this location and as a result, individual plant numbers have declined as well. Management practices such as mowing (with certain restrictions) do not seem to harm H. texana, and in some instances, promote its existence. However, deep soil disturbances such as plowing and feral hog wallowing can be detrimental to its existence. Many of the current sites are not adequately fenced and are subjected to feral hog and cattle grazing. Managed grazing and installing fence panels aimed at excluding feral hogs will greatly benefit H. texana (USFWS, 2015).

**Stressor:** Drought (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The distribution of H. texana appears to be naturally restricted as a result of the specific habitat and soil requirements. However, persistent drought conditions can cause the plant to remain dormant and produce smaller, less robust plants with fewer seed heads. The drought of 2011 was especially hard on H. texana as evidenced by the reduced number of mature plants. Cool and wet winter weather seems to be conducive to early spring growth and maturation. (USFWS, 2015)

**Stressor:** Competition (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Competition from woody vegetation, such as Chinese tallow Triadica sebifera (an invasive exotic), yaupon Ilex vomitoria (native), and other native trees and grasses (at the ground and canopy layers), remains a large threat to the species. In areas where there is no on-the-ground management, the potential for loss is great as the woody vegetation continues to encroach creating a canopy cover that essentially allows other species to outcompete H. texana. The USFWS continues to work with other state and local partners to develop management guidelines to enhancing H. texana habitat. (USFWS, 2015)

**Stressor:** Climate change (USFWS, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Our analyses under the Act include consideration of ongoing and projected changes in climate. The terms "climate" and "climate change" are defined by the Intergovernmental Panel

on Climate Change (IPCC). “Climate” refers to the mean and variability of different types of weather conditions over time, with 30 years being a typical period for such measurements, although shorter or longer periods also may be used (IPCC 2012). The term “climate change” thus refers to a change in the mean or variability of one or more measures of climate (e.g., temperature or precipitation) that persists for an extended period, typically decades or longer, whether the change is due to natural variability, human activity, or both (IPCC 2012). Various types of changes in climate can have direct or indirect effects on species. These effects may be positive, neutral, or negative and they may change over time, depending on the species and other relevant considerations, such as the effects of interactions of climate with other variables (e.g., habitat fragmentation). Winter and spring field observations indicate in years where drought conditions are prevalent, H. texana plants tend to respond with fewer, less robust individuals, and fewer seed heads. Conversely, in years where rainfall exceeds normal levels and plants may be inundated for extended periods of time, H. texana respond with fewer and less robust plants with yellowish leaves. Therefore, while it appears reasonable to assume that H. texana may be affected by the intense climate swings forecasted, and climate change should be considered a threat, the Service lacks sufficient certainty to know how climate change specifically will affect this plant. (USFWS, 2015)

***Recovery***

**Reclassification Criteria:**
Hymenoxys texana can be downlisted to threatened when: (USFWS, 1989).

(1) at least 50 separate populations, each occupying at least 1 hectare (2.47 acres) of suitable habitat, are discovered or established (USFWS, 1989)

(2) when at least 50 populations are protected from land use practices or land use changes that could destroy the populations (USFWS, 1989)

Recovery Priority Number: 2C.

**Delisting Criteria:**
Hymenoxys texana can be removed from the threatened and endangered species list when management practices are developed and implemented which ensure the numbers of plants at protected populations remain stable. (USFWS, 1989)

**Recovery Actions:**
- Protect Hymenoxys texana and its habitat from existing and future threats. Contact private landowners and Federal agency personnel. Work with the landowners and agency personnel to implement management practices that will protect the species. Establish protected sites on both private and public lands. Develop and implement a long range management plan. Enforce applicable Federal and State laws and regulations. Monitor populations. Alter management plans, if necessary, to reflect improvement or deterioration of populations (USFWS, 1989).
- Gather information on the natural history of Hymenoxys texana for use in management. Determine habitat requirements, including edaphic factors, dependence on natural phenomena and cultural practices, local microclimate, and air and water quality. Determine associated species, vegetation types, and community structure. Record associated

vegetation, frequency, density, and dominance. Determine frequently associated species. Determine If the bare soil at Hymenoxys texana sites represents an edaphic climax. Study population biology, including demography, phenology, reproductive biology (types of reproduction, pollination biology, seed dispersal and biology, seeding biology). Study community ecology, beneficial and neutral effects of other species, and negative effects of other species (USFWS, 1989).

- Update management plans as new data accumulates (USFWS, 1989).
- Search for new sites and populations (USFWS, 1989).
- Establish a botanical garden population and, if needed, attempt to establish populations In suitable natural habitat. Develop and refine propagation techniques. Establish a self—sustaining botanical garden population. Search for suitable reintroduction sites (USFWS, 1989).
- Develop public awareness, an appreciation, and support for the preservation and study of Hymenoxys texana (USFWS, 1989).
- The USFWS recommends the following actions be taken for the conservation of H. texana: - Reevaluate the 1990 Recovery Plan to reflect new species information including associated species lists, species range, survey methodologies, and soil findings in partnership with local land managers, botanists, and federal and state resource agency staff. - Develop protocol to delineate and define “populations” for downlisting or delisting this species. - Develop a central database to house all pertinent site population information. - Continue to monitor and survey known populations while searching for additional populations. - Update associated species list as necessary. - Implement section 6-funded projects, USFWS Partners for Fish and Wildlife program projects, and cooperative agreements with state and federal agencies. - Continue to search for additional populations. - Acquire new landowner conservation agreements with interested parties when appropriate. - Continue to support conservation and recovery awareness efforts through public and landowner outreach. - Redefine the range of H. texana through strategic GIS mapping efforts. H. texana is now more broadly distributed than originally thought, soil characteristics may be different at various locations, and associated species may vary at the different locations across the range. - Standardize surveying and monitoring protocols to provide consistent population data. If a new site is found, include soils analysis, associated species, genetic analysis, hydrological conditions, location, identify any threats, and note any pollinators present. - Yearly survey and monitoring data should be deposited with the TxNDD to facilitate accurate and up-to-date species specific information. (USFWS, 2015)
- Research Needs for the continued existence of H. texana - Assess and quantify predator threats (terrestrial mammals and/or insects). - Soil nalysis at each identified site. - Analyze and quantify the role of pollinators at H. texana sites. - Complete a thorough habitat range assessment using GIS analysis due to the increased range spanning five counties. - Conduct further research regarding alternative propagation techniques. - Complete additional studies to optimize frozen storage techniques for H. texana. - Identify propagation and relocation strategies for successful plug and seed transplant to suitable sites within the species range. - Identify the mechanism and/or agents of dispersal, dispersal patterns, and the effects of disturbance on dispersal. - Include genetic analysis for all sites to determine any genetic variability within sites. (USFWS, 2015)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS We recommend that the following actions be taken for the conservation of the Texas prairie dawn flower (Hymenoxys texana): • Evaluate the recent SSURGO soil information on this species in conjunction with aerial imagery that identifies saline barren habitat on Gulf coastal prairies and Post Oak Savannah prairies that have not been previously surveyed, including the National Wildlife Refuges, where the Act does provide some legal protection for federally listed plants on federally owned lands. • Evaluate the genetics of at least 10 populations to determine if the species as a whole still possess levels of genetic diversity and heterozygosity that would be found among nonthreatened Hymenoxys species. • Continue to work with partners to annually monitor populations on their lands and use consistent standardized methods that were used during the 2022 field season that are comparable across all saline barren habitats. • Work with partners to acquire new habitat conservation plans for private landowners. • Investigate climate change effects on the reproductive and seed dispersal mechanisms of the species and its suitable habitat. • Evaluate and quantify predator effects (terrestrial mammals, invertebrates, and/or insects) on the species. • Evaluate and quantify the role of pollinators for this species • Work with partners to implement invasive species management plans and mowing strategies to restore suitable habitat for this species. • Work with partners to identify propagation and relocation strategies for successful plug and seed transplants to restore suitable habitat where invasive species management practices have been successfully implemented. Research conducted under the section 6 grant (WSFR Grant F22AP03103-00, BO Reference Ecosphere 2022-0024702) awarded to TPWD on July26, 2022, may provide new information on the reproductive biology, seed dispersal mechanism, genetics and pollinators for the Texas prairie dawn that will be available for the next 5-year review. We recommend once this information is reviewed, if possible given workloads, a Species Status Assessment could be conducted to guide the development of a revised recovery plan (USFWS, 2022).

# SPECIES ACCOUNT: *Hypericum cumulicola* (Highlands scrub hypericum)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 2/20/1987; Southeast Region (R4)

**Physical Description**

Hypericum cumulicola is a small, short-lived perennial herb reaching 20 to 70 cm in height. It is branched from the base and has a woody, fibrous root system. The stems are shorter and more numerous in winter and spring before reproductive stalks are differentiated. Usually there are three stems, but there can be as many as 17 stems on a healthy plant (Quintana-Ascencio and Morales-Hernández in press). During the reproductive season, all stems of mature individuals bear flowers and fruits. The leaves of H. cumulicola are opposite, simple, entire, and needle-like. Flowers are small, bisexual, and arranged in cymes. The calyx consists of five distinct sepals, while the corolla consists of five bright yellow petals shaped like the blades of a propeller. There are approximately 27 anthers. The gynoecium has three, sometimes four locules, and the ovary is superior with approximately 22 ovules aligned around the walls of the ovary (parietally). The style has three, sometimes four, white lobes. Fruits are small capsules, red when immature and dark purple at the time of dehiscence. Mature seeds are small and dark brown. This species, as other Hypericum, may contain hypericin, a promising compound with protective effect in the control of viral diseases in animals (Duke 1989) (USFWS, 1999)

**Taxonomy**

Hypericum is a predominantly temperate genus, and a member of the family Hypericaceae. This family is closely related to the Clusiaceae (Guttiferae), and some authorities include both groups together (Cronquist 1988). In central Florida, H. cumulicola is morphologically distinct from other species in its genus (Ward and Godfrey 1978). In 1924, Small first named the plant Sanidophyllum cumulicola. Later, Adams (1962) reassigned the species to the genus Hypericum, renaming it Hypericum cumulicola. Hypericum cumulicola's closest relative in Florida is H. gentianoides, which is very similar morphologically, but branches repeatedly above the base versus only at the base for H. cumulicola (Archbold Biological Station, personal communication 1998). (USFWS, 1999)

**Historical Range**

See current range.

**Current Range**

Lake Wales Ridge in Polk and Highlands counties in Florida, from just north of Sunray, Polk County (FWS 1996) to the south end of the Lake Wales Ridge near Archbold Biological Station in Highlands County. (USFWS, 1999)

**Critical Habitat Designated**

Yes;

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

Adult: Because Highlands scrub hypericum has many-flowered stems, a single large plant can have as many as 1,600 reproductive structures (fruits, flowers, or buds) by the end of the reproductive season (Quintana-Ascencio and Morales Hernández 1997). Flowers are exposed one at a time or in small numbers (up to eight per branch) each day. The new flowers open early in the morning and the petals curl up by noon depending on the weather. This species is self-compatible, but the flowers must be visited by pollinators to set seed (ABS 2003). The mature purple capsules remain attached to the stem after releasing seeds. Seeds do not show any obvious primary dispersal mechanism and probably are dispersed passively by gravity. "Native solitary bees (Dialictus spp. and Augochloropsis spp.) appear to be the primary pollinators. Other visitors include Geron sp., Copestilium nigrum, and Bombus sp. Pollinator visitation occurs at similar rates regardless of flower or plant density" (ABS 2003, citing Boyle and Menges 2001; M. Evans, personal communication in Quintana-Ascencio et al. 1998). Most flowering and fruiting occurs between June and September, coinciding with the rainy season and daily thunderstorms typical of the region. Stems dry at the end of the reproductive season and new ones sprout from the base in late winter and early spring. Germination occurs from November through June, but most seedlings germinate between December and February. Plants reach maturity in as little as a year. Highlands scrub hypericum inhabits Florida scrub vegetation on upland areas with excessively drained white sand soil (Judd 1980a). It is almost exclusively found in rosemary balds – patches of bare sand surrounding Florida rosemary within scrub vegetation. It shares these bare patches with a number of other small scrub endemic herbs, grasses, and even a few small shrubs (Christman and Judd 1990). Rosemary balds have a fire frequency from 10 to 100 years (Myers 1990) while the surrounding scrubs have higher fire return intervals. Occasionally, Highlands scrub hypericum occurs in openings in well-drained scrubby flatwoods or with turkey oak on yellow sand soil (P. Quintana-Ascencio, ABS, personal communication, 1995). Where found, it is locally common and can occur in large groups of several thousand individuals (Judd 1980a).

**Habitat Type**

Adult: Scrub

**Environmental Specificity**

Adult: Very Narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Highlands scrub hypericum is one of a suite of herbs (and a few grasses) that inhabit sunny, sandy gaps between the shrubs that dominate scrub vegetation. Many of these gap-inhabiting species are endemic to the LWR. The gap size requirements of Highlands scrub hypericum appear to be intermediate between those of two other co-occurring rosemary scrub plants: snakeroot, which is restricted to large openings (Menges and Kimmich 1996); and wireweed, which is found in large and small gaps between shrubs (Hawkes and Menges 1995). Highlands scrub populations have a high degree of genetic differentiation among populations (Menges et al. 2001).

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

34 (USFWS, 2021)

**Population Narrative:**

Most populations of Highlands scrub hypericum are relatively small. The median size for 34 populations was 539 individuals, and most populations were smaller than 1,000 plants (Menges et al. 1998). A population viability model (Quintana-Ascencio et al. 2003) concluded that “fire kills above-ground individuals, but seeds in the soil survive fire and form long-lived seed banks. Fire suppression and alteration of fire regimes constitute a threat for this species because of its dependence on fire to release local populations from competitive exclusion” (ABS 2003). “After fire in Florida rosemary scrub, Hypericum cumulicola [Highlands scrub hypericum] had higher fecundity, survival, establishment, and population growth rates than in unburned populations” (Quintana-Ascencio et al. 2003). This may be due to a number of mechanisms, including killing back of shrubs, removal of lichens, destruction of allelopathic agents that affect seed germination, and the creation of open gaps that may have higher levels of soil water (Quintana-Ascencio et al. 2003). The seed germination rate for this species is extremely low except at recently-burned sites (Quintana-Ascencio et al. 2003). The most critical life-history stage influencing Highlands scrub hypericum’s population growth rate and fitness is seed survival in the soil seed bank. The next-most-important life-history stage is seedling recruitment (Quintana-Ascencio et al. 2003). Massive recruitment of plants in favorable patches and in favorable years allows Highlands scrub hypericum populations to “increase rapidly and/or replenish the soil seed bank. Similar population explosions are documented in other short-lived perennials (Picó et al. 2002) and annual plants with a seed bank (Kalisz and McPeek 1992), which are able to cope with high or unpredictable environmental variation” (Quintana-Ascencio et al. 2003). The survival of Highlands scrub hypericum populations in fire-dependent habitats thus depends on the seed bank, while seedling recruitment is highly variable and depends on environmental cues (Picó et al. 2003). A population viability assessment model (Quintana-Ascencio et al. 2003) strongly also affirms that fire is essential for Highlands scrub hypericum to persist over the long term. Even the largest populations may be imperiled by fire intervals greater than 50 years. Smaller populations are more vulnerable to lack of fire. These authors consider fire suppression and alteration of fire regimes to constitute threats to this species “because of its dependence on fire to release local populations from competitive exclusion” (Quintana-Ascencio et al. 2003; Quintana-Ascencio and Morales Hernández 1997; Quintana-Ascencio and Menges 2000). In planning fire regimes for scrub, it is important to take into consideration the needs of multiple plant and animal species. Management that alternates short and long fire intervals may allow species to coexist, while invariant fire return intervals may harm some species (Quintana-Ascencio et al. 2003). Researchers at ABS have developed spatially explicit disturbance-demographic models of Highlands scrub hypericum. “This spatially explicit, individual-based model improves the precision of prior matrix projections that did not include Florida rosemary or spatial structure. It allows prediction of ranges of Florida rosemary densities that will allow scrub hypericum populations to persist under various fire regimes.” The model’s predictions agreed with “observed differences in scrub hypericum disappearance among gaps with contrasting rosemary densities but similar times-since-fire,” so this modeling approach is likely to prove useful in predicting the effects of fires and other disturbances, including mechanical treatments of overgrown scrub, such as roller-chopping (Quintana-Ascencio et al. 2004). Early inventories of LWR endemic plants found this species at few sites – only 69 of 254 scrub sites surveyed by Christman (1988) (ABS 2003). This severely restricted range, combined with continuing habitat loss, led to its listing. Highlands scrub hypericum is locally abundant, with populations larger than a thousand plants and presumably large seed banks in the soil at ABS, the properties of the LWRWEA (including Lake Placid, Holmes Avenue, Lake Apthorpe, and Carter Creek), Lake June-in-Winter Scrub State Park, TNC's Saddle Blanket Lakes Preserve, and the Arbuckle tract of LWR State Forest. On these lands, Highlands scrub hypericum has benefited from fire-oriented land management practices and insights provided by the intensive demographic research program at ABS. Highlands scrub hypericum is protected on 22 sites, often with large population sizes and active fire management. However, remaining unprotected populations are in imminent danger of decline and extirpation. Unprotected habitat continues to be developed for agriculture, housing, and other uses. This is likely reducing the number and size of populations of this species. The most recent estimate of the loss of xeric upland habitat on the LWR is 87 percent (Turner et al. 2006). On managed areas that include the protected occurrences, better land management is needed to ensure that protected populations remain extant. Appropriate management includes avoiding fire suppression, avoiding fires before forecasted droughts, creation of gaps, and avoiding damage by vehicles or pedestrian trampling to plants and to the cryptobiotic soil crust, which may facilitate seedling emergence. Inappropriate fire regimes remain a significant threat. Most scrub sites supporting Highlands scrub hypericum are not burned frequently enough to support viable populations and mechanical pre-treatments or surrogates may not provide the same benefits as fire. Exotic species invasion and herbivory are potential threats but have not been directly implicated as causing population declines. Few, small, isolated populations in a limited geographic range present additional risk for Highlands scrub hypericum. These factors, in conjunction with the species' limited dispersal potential, hinder population resiliency and ultimately recovery. Anticipated climate change factors such as alterations to temperature and precipitation patterns, tropical storm intensity, and sea-level risk will only exacerbate these threats. Due to these ongoing threats mentioned above, this species continues to meet the definition of endangered under the ESA. (USFWS, 2021). Highlands scrub hypericum is locally abundant at ABS, the properties of the LWRWEA (including Lake Placid, Holmes Avenue, Lake Apthorpe, Gould Road, and Carter Creek), Lake June in Winter Scrub State Park, The Nature Conservancy's (TNCs) Saddle Blanket Lakes Preserve, and the Arbuckle tract of LWRSF. Many other populations of Highlands scrub hypericum are relatively small. Population size estimates for 34 populations showed a median of 539 individuals, most populations were smaller than 1,000 plants, the largest population was estimated to be greater than 300,000 plants, and the 25th -75th percentiles for population size were 130-4,000 plants (data summarized in Table 1 of Menges et al. 2001). (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species is restricted to xeric scrub habitats in one or more of the interior Central Florida counties of Polk, Highlands, Hendry, Osceola, and Lake, where habitat destruction from development continues to occur and development pressure remains high. Areal extent of post-Columbian xeric upland habitat loss on the Lake Wales Ridge is estimated to exceed 85 percent (Weekley et al. 2008a). Increasing pressure from population growth is likely to result in further

loss of these habitats going forward. Carr and Zwick (2016) analyzed existing land use and landscape patterns to identify areas (including central Florida) most likely for development to accommodate a growing human population. They suggests that Florida's 2070 population will be early 15 millionpersons greater than in 2010, for an estimated total of 33,721,828. Using these figures, they estimated relative losses to agriculture, open space, and conservation to other land uses. If trends continue, they estimate 34 percent of land will be developed by 2070, up from 19 percent in 2010. At the same time, conservation lands will increase less than 1 percent (from 9,269,000 acres in 2010 to 9,525,000 acres by 2070). Overall, loss of habitat to development, primarily on private lands, will likely continue in Central Florida, eliminating populations and reducing the area of suitable habitat for these species. Therefore, habitat on protected lands are critical for the recovery of this scrub plants. (USFWS, 2019)

**Stressor:** Lack of adequate fire management
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire is necessary to maintain the scrub habitats upon which this species depends. Historically, lightning-induced fires were a vital component in maintaining native vegetation within the scrub community. Fire suppression started on a regional scale on the Central Florida ridges about 80 years ago. Due to the extent of residential and agricultural development throughout Central Florida, fire has all but disappeared from the region as a widespread, natural phenomenon. Prescribed fire is a crucial management component for maintenance of all scrub habitats. Because of the difficulties of applying prescribed fire on an ever-increasing urban landscape, imperiled species on unmanaged sites will almost certainly disappear over time (Turner et al. 2006). In managed areas, prescribed fire is essential to manage habitats and restore or maintain suitable conditions for scrub species. (USFWS, 2019)

**Stressor:** Limited geographic range
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species occurs occur within a relatively limited geographic range in Central Florida. The limited geographic range in combination with the loss of habitat has resulted in a highly fragmented landscape where the remaining scrub areas and their residing species have become more and more isolated from each other, thereby making resiliency, redundancy, and representation more challenging to achieve. The effects of habitat fragmentation on species richness have been exhaustively studied (MacArthur and Wilson 1967, Diamond 1975, 1978; Simberloff and Abele 1976, 1982; Zimmerman and Bierregaard 1986). For most taxonomic groups, large habitat patches in close proximity to each other provide for the greatest species diversity and minimize extinction probabilities. On the contrary, small patches that are isolated are less likely to preserve species that would otherwise be common in the mosaic of communities that existed before isolation. Since at least the Pleistocene, Florida scrub has been characterized by an insular, discontinuous distribution, but the degree of habitat fragmentation seen today is unprecedented and certainly will contribute to increases in extinction rates among scrub-dependent plants and animals. (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**
1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations and sites needed to ensure 20 to 90 percent probability of persistence for 100 years (USFWS, 1999)

2. When these populations, within the historic range of H. cumulicola are adequately protected from further habitat loss, degradation, fragmentation, and fire suppression (USFWS, 1999)

3. When these sites are managed to maintain the rosemary phase of sandpine scrub to support H. cumulicola (USFWS, 1999)

4. When monitoring programs demonstrate that populations of H. cumulicola on these sites support sufficient population sizes (USFWS, 1999)

5. When those populations are stable and distributed throughout the historic range (USFWS, 1999)

6. When H. cumulicola are sexually or vegetatively reproducing at sufficient rates to maintain the population (USFWS, 1999)

**Delisting Criteria:**
1. At least 20 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)

2. Populations (as defined in criterion 1) in rosemary scrub habitats are distributed across the known range of the species. (USFWS, 2019)

3. Populations are protected and managed via a conservation mechanism to a degree that enough suitable habitat is present for the species to remain viable for the foreseeable future. (USFWS, 2019)

**Recovery Actions:**
- Determine current distribution of H. cumulicola. This species has been relatively well-surveyed and a distribution has been ascertained. Additional surveys will confirm the species' distribution and locate new sites. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties has been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Conduct research on life history characteristics of H. cumulicola. Continue the study of basic biology and ecology of this species. To effectively recover this species more specific biological information is needed. (USFWS, 1999)
- Monitor existing populations of H. cumulicola. (USFWS, 1999)
- Provide public information about H. cumulicola. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private land owners be appropriately informed about this species. Care is needed, though, to avoid revealing specific locality information about where H. cumulicola is

found. (USFWS, 1999)
- Develop delisting criteria. Once reclassification is achieved, research and monitoring results may provide data necessary to develop delisting criteria. (USFWS, 1999)
- Habitat-Level Recovery Actions: Prevent degradation of existing habitat. Restore areas to suitable habitat. Continue habitat-level research projects. Monitor habitat/ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • Develop land management plans that address the following threats to Highlands scrub hypericum: avoiding fire suppression, avoiding fires occurring before forecast droughts, creation of gaps, avoiding disturbances from off-road vehicles, and avoid trampling of Highlands scrub hypericum and the cryptobiotic soil crust that may facilitate its seedling emergence. • Collect data on the response of Highlands scrub hypericum to management activities such as roller chopping, mowing, gyro-tracking, logging, and chain-saw felling and, to the extent that responses are dissimilar to post-fire responses, adjust fire-based population viability models. • Develop a metapopulation model using information on population dynamics within populations, the number and distribution of populations, and dispersal among populations (for plants, mainly seed dispersal) to determine the number of self-sustaining populations needed to ensure persistence. • Study seed dispersal among populations of Highlands scrub hypericum for use in a metapopulation model. • Conduct quantitative level 2 surveys (counting individuals in defined areas) at additional sites outside of ABS and the LWRSF. Surveys should track changes in population sizes over time and in response to management treatments. • Land purchase or conservation easement of key parcels (e.g., Hendrie Ranch, Lizzie Lakes) to protect important populations. • Surveys for Highlands scrub hypericum at privately-owned, unprotected sites. • Targeted collection of Highlands scrub hypericum from unprotected sites for ex situ conservation. Highlands scrub hypericum currently has limited protection in Bok Tower Garden’s ex situ collection, with 32,012 seeds collected from 1988-1990 in cryogenic storage, and two plants from one population in their living collection (P. Gonsiska, Bok Tower Gardens, pers. comm. 2020). (USFWS, 2021)

# SPECIES ACCOUNT: *Iliamna corei* (Peter's Mountain mallow)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 05/12/1986; Northeast Region (R5) (USFWS, 2015)

**Physical Description**

Iliamna corei is an erect, ascending, perennial herb growing from a woody rhizome producing densely pubescent pale-green branches up to 1 m in height. The maple-like leaves are simple, with 5-7 palmate lobes, margins serrate to dentate, bases truncate to cordate, and stellate-pubescent on both surfaces. The size of the leaves decreases gradually towards the tips of the branches. The pink flowers are solitary or clustered in the axils of the upper leaves. There are 5 radially symmetrical, separate petals 2.5-3 cm long and 5 sepals fused 1/4 to 1/2 their length into a bell-shaped, hairy calyx. Stamens are numerous, their bases fused into a tube surrounding the pistil. The flower appears generally similar to the cultivated hibiscus, or rose-of-Sharon. Fruits are lobed capsules with mature carpels 8-10 mm long, densely hairy, containing 2-3 seeds in each carpel. (USFWS, 1990)

**Taxonomy**

Considered a distinct species known only from a single site in the Virginia mountains. Bodo Slotta & Porter (2006) studied the genetic variation in North American Iliamna and analyses determined that I. corei is distinct. Additional research in the late 1980s also support that this taxon should be separated from I. remota on the basis of genetic analyses. Kartesz considers these differences minor, and includes these Virginia plants, along with Iliamna remota, in his circumscription of the nominate variety of Iliamna rivularis. Included in Iliamna rivularis var. rivularis by Kartesz, 1994 checklist and 1999 floristic synthesis; by others considered distinct from I. rivularis, but included in Iliamna remota. (NatureServe, 2015)

**Historical Range**

See current range/distribution.

**Current Range**

Only site known is Giles County in Ridge and Valley Province of Virginia. (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Asexual (vegetative) and sexual (outcrossing) (NatureServe, 2015)

**Dependency on Other Individuals or Species**

Adult: Pollinated by bees (USFWS, 1990)

**Breeding Season**

Adult: Late June to early August (USFWS, 1990)

**Key Resources Needed for Breeding**

Adult: Seed scarification is required for germination (Bodo Slotta & Porter 2006) (NatureServe, 2015)

**Reproduction Narrative**

Adult: Iliamna is rhizomatous. Seed scarification is required for germination (Bodo Slotta & Porter 2006). I. corei flowers from late June to early August. It is believed to be pollinated primarily by sweat bees of the genus Halictus, which are abundant in the area. (USFWS, 1990; NatureServe, 2015)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Forest - Mixed, Forest/Woodland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Sunny, open areas (USFWS, 1990)

**Geographic or Habitat Restraints or Barriers**

Adult: Mature Iliamna corei plants appear to prefer open sites without much competing vegetation (USFWS, 1990)

**Environmental Specificity**

Adult: Very Narrow (inferred from USFWS, 1990; NatureServe, 2015)

**Dependency on Other Individuals or Species for Habitat**

Adult: The dominant trees growing in association with I. corei include Quercus rubra, Q. prinus, Carya spp., Robinia pseudo-acacia, Pinus virginiana, Betula lenta, and Celtis occidentalis. The shrub layer is primarily composed of Berberis canadensis, Crategus spp., and Rhus typhina. The more common herbs, forbs, and vines include Verbesina occidentalis, Tradescantia ohiensis, Polymnia canadensis, Aquilegia canadensis, Chenopodium standleyanum, Rosa carolina, Dioscorea villosa, Clematis viorna, and Parthenocissus guinquefolius. The only plants that appear to be directly competing with the Iliamna are Polymnia and Berberis. (USFWS, 1990)

**Habitat Narrative**

Adult: Iliamna corei occurs in the shallow soil of the Clinch sandstone outcrops on the northwest-facing slope of Peters Mountain (elevation 1000 m), near the ridge line of a mixed deciduous-evergreen forest. Regarding the species' edaphic requirements, soil tests from the sites of two different Iliamna clones show pH ranging from 5.3 to 5.6. Quantities of macro-and micronutrients from the two sites (in parts per million) include: phosphorus (32 and 53), potassium (157 and 58), calcium (120), and magnesium (101 and 65). Soils underlying the Iliamna population are very dark and appear to be highly organic in composition. The dominant trees growing in association with I. corei include Quercus rubra, Q. prinus, Carya spp., Robinia pseudo-acacia, Pinus virginiana, Betula lenta, and Celtis occidentalis. The shrub layer is primarily composed of Berberis canadensis, Crategus spp., and Rhus typhina. The more common herbs, forbs, and vines include Verbesina occidentalis, Tradescantia ohiensis, Polymnia canadensis, Aquilegia canadensis, Chenopodium standleyanum, Rosa carolina, Dioscorea villosa, Clematis viorna, and Parthenocissus guinquefolius. The only plants that appear to be directly competing with the Iliamna are Polymnia and Berberis. (USFWS, 1990)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available.

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2008)

**Species Trends:**

Declining (USFWS, 2008)

**Number of Populations:**

1 (NatureServe, 2015)

**Population Size:**

1 - 250 individuals (NatureServe, 2015)

**Additional Population-level Information:**

Monitoring reports from The Nature Conservancy indicated that since the 2008 status review, the Peter’s Mountain Mallow numbers have fluctuated, but the overall population trend appears to be stable (USFWS 2019).

**Population Narrative:**

Peters Mountain mallow (Iliamna corei), a member of the family Malvaceae, is known from only a single site on Peters Mountain, near The Narrows of the New River, in Giles County, Virginia. The occurrence is very tolerant to on-site activities. (NatureServe, 2015)

***Threats and Stressors***

**Stressor:** Encroachment of vegetation (USFWS, 1990)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The encroachment of competing vegetation, resulting in a reduction of direct sunlight reaching the plants, appears to be contributing to the decline in the size and reproductive vigor of the population. Historical references indicate that Iliamna corei was previously exposed to a great deal more direct sunlight than is the case today (U.S. Fish and Wildlife Service, 1986). In recent years forest canopy on Peters Mountain has grown considerably, probably in association with fire suppression management. Construction of a hiking trail and a powerline near the mallow site in the early 1970s appears to have promoted the invasion of weedy competitors, primarily Polymnia canadensis. (USFWS, 1990)

**Stressor:** Lack of recruitment (USFWS, 1990)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A major concern in regard to recovery of Iliamna corei has been lack of recruitment. Although a viable seedbank exists in the soil, no seedlings are being produced because the seeds are not germinating. Recent experimental evidence indicates that germination is readily stimulated by heat (Baskin and Baskin, 1990) and light fire (C. Baskin and J. Baskin, pers. comm.). (USFWS, 1990)

**Stressor:** Low sexual fecundity (USFWS, 1990)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In addition to the lack of seed germination at the natural population site, the remaining I. corei clones have been exhibiting extremely low sexual fecundity. From 1986-1988, only 14 mature capsules were produced, despite profuse flowering. Many buds aborted before flowering, and the majority of buds that did produce flowers disarticulated from the plant after anthesis. The record drought years of 1987 and 1988 may have contributed to reproductive failure; however, the plants were watered regularly during the drought periods of those years. Seed production data from most of the years previous to 1986 are unavailable, but Strausbaugh and Core indicated that, in 1932, the plants were producing an "abundant supply of seeds." Herbarium specimens collected by Massey in 1934 and 1939 (at VPI&SU) also have mature capsules containing many seeds (J. Randall, pers. comm.). The mystery of seed production in the natural population has been largely solved and the problem ameliorated by recent work at VPI&SU, as described below. (USFWS, 1990)

**Stressor:** Small population size (USFWS, 1990)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Because so few plants comprise the natural population, removal of individual stems, whether by humans or other animals, constitutes a threat to the species' survival. In October 1987, a feral goat browsed all of the Iliamna stems to within 30 cm of the ground. In 1987 and 1988, a total of 16 stems were cut, apparently for collection. (USFWS, 1990)

**Stressor:** Herbivory (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbivory by deer and other animals is a continuing threat, mitigated by placement of small wire cages around individual and small groups of PMM. Replacement and enlargement of these enclosures to accommodate plant growth requires continuing annual effort throughout the field season (Edward and SanJule 2007). (USFWS, 2008)

**Stressor:** Fire suppression (USFWS, 2008)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Suppression of natural fires necessitates an on-going commitment to prescribed burning. (USFWS, 2008)

***Recovery***

**Reclassification Criteria:**
1. The natural population has reached carrying capacity and has been self-maintaining or expanding into new areas for at least 5 years. (USFWS, 1990)

2. Life history, ecology, and population biology are understood sufficiently to manage effectively. (USFWS, 1990)

3. There exists an established and continuing management program. (USFWS, 1990)

4. The tract of land on which it occurs is permanently protected. (USFWS, 1990)

5. Plants representing a variety of genotypes are propagated at a minimum of two plant breeding facilities. (USFWS, 1990)

Recovery Priority Number: 8

**Delisting Criteria:**
1. The natural population has reached carrying capacity and has been self-maintaining or expanding into new areas for at least 5 years. (USFWS, 1990)

2. Life history, ecology, and population biology are understood sufficiently to manage effectively. (USFWS, 1990)

3. There exists an established and continuing management program. (USFWS, 1990)

4. The tract of land on which it occurs is permanently protected. (USFWS, 1990)

5. Plants representing a variety of genotypes are propagated at a minimum of two plant breeding facilities. (USFWS, 1990)

6. Studies indicate that it is appropriate to establish new populations. (USFWS, 1990)

7. Five additional populations have been located or established. (USFWS, 1990)

8. These new populations are protected and stable or expanding for at least 5 years. (USFWS, 1990)

**Recovery Actions:**
- Monitor known population and manage as necessary. (USFWS, 1990)
- Study life history, ecological, and population parameters. (USFWS, 1990)
- Maintain representative individuals at two plant breeding facilities. (USFWS, 1990)

- Outplant individuals within historic range. (USFWS, 1990)
- Acquire full title to the population site. (USFWS, 1990)
- Research to better understand site requirements and germination and care for seedlings so new populations can be established (USFWS 2019).
- Research the seasonality and intensity of fire needed to stimulate germination of seeds in the seed bank. This would help to better manage existing population and plan burns in new areas (USFWS 2019).
- Conduct and assess effects of landscape burn in 2009. Burn implementation is already scheduled and funded. (USFWS, 2008)
- Continue ex situ seed increase efforts and assure long-term seed storage. (USFWS, 2008)
- Update reclassification criteria 1 and 5 to clarify target population size and composition (whole plants and seed production) in the wild and requirements for ex situ conservation. Updated criteria, consistent with the scope and intent of the corresponding criteria in the 1990 recovery plan, should reflect current information about PMM biology. (USFWS, 2008)
- Based on results of initial landscape scale burn, evaluate future burning requirements and associated funding needs. (USFWS, 2008)
- Develop long-term agreements for continuing management of PMM population(s) at the Narrows Preserve. (USFWS, 2008)
- Reconsider need for and desirability of establishing additional PMM populations outside the species' known historic range. Evaluate feasibility of alternative strategies to provide for long-tern security and delisting of PMM. If necessary, revise delisting criteria and recovery plan accordingly. (USFWS, 2008)

# SPECIES ACCOUNT: *Ivesia kingii var. eremica* (Ash Meadows ivesia)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 05/20/1985; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A perennial herb that forms a tuft of narrowly divided, grayish leaves. Flowering stems are about 9 cm long and bear white flowers from August to October. Some botanists question whether this taxon is distinctive enough to be maintained as a discrete variety of the species I. kingii. (The species as a whole is extremely variable and somewhat rare.) (NatureServe, 2015).

**Taxonomy**

A member of the Rosaceae family (USFWS, 1990). Kartesz (1994 checklist and 1999 floristic synthesis) does not recognize varieties in this species; however, USFWS recognizes var. eremica as distinct from the typical var. kingii. As Kartesz notes (in letter to Larry Morse, 25Nov99), he reviewed all of the available Nevada collections and concluded that "this [var. eremica] is nothing more than an extremely variable expression of Ivesia kingii"; he also notes that various individuals, including Barbara Ertter, had listed characters considered useful in separating the two taxa, she (Ertter) has more recently indicated (in a personal communication with Kartesz) that researchers in the Netherlands "also maintain it as nothing more than a taxonomic synonym of Ivesia kingii." However, Ertter (in a personal communication to Jim Morefield) as of 06 Apr 99 still considered this a valid taxon at the varietal level (NatureServe, 2015).

**Historical Range**

Endemic of Ash Meadows, south Nye County, Nevada. Type found in Coville and Funston, Nye County, Nevada in 1891 (NatureServe, 2015).

**Current Range**

Small, local populations are scattered throughout Ash Meadows in Nevada (USFWS, 1990).

**Critical Habitat Designated**

Yes; 5/20/1985.

**Legal Description**

On May 20, 1985, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Ivesia kingii var. eremica (Ash Meadows ivesia) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in Nevada (50 FR 20777-20794).

**Critical Habitat Designation**

The critical habitat designation for Ivesia kingii var. eremica includes one CHU in Nye County, Nevada (50 FR 20777-20794).

Nevada, Nye County, Ash Meadows.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Ivesia kingii var. eremica critical habitat consists of one component (50 FR 20777-20794):

Known primary constituent elements include saline seep areas of light colored clay uplands.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**
Adult: Sexual (inferred from sews, 1990)

**Lifespan**
Adult: 2+ years (inferred from USFWS, 1990)

**Breeding Season**
Adult: Summer - fall (USFWS, 1990)

**Reproduction Narrative**
Adult: Plants are perennial. It produces flowers during the late summer and autumn (Mozingo and Williams 1980) (USFWS, 1990).

**Habitat Type**
Adult: Wetland, terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**
Adult: Saltbrush scrub near springs (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**
Adult: 657 - 690 m elevation (NatureServe, 2015)

**Spatial Arrangements of the Population**
Adult: Solitary clumps (USFWS, 1990)

**Environmental Specificity**
Adult: Very narrow (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**
Adult: Low (inferred from NatureServe, 2015)

**Habitat Narrative**
Adult: Inhabits moist alkaline areas in openings of saltbrush scrub near springs. It is dependent on springs. Dust from erosion may smother plants. Found at elevations of 657 - 690 m. It is narrowly confined to a single spring-fed desert wetland area with extremely saline soils (NatureServe, 2015). It occupies highly alkaline, barren soils that remain moistened by water spreading outward from surface flow discharged by springs. Plants occur as solitary clumps (USFWS, 1990).

### *Dispersal/Migration*

**Dispersal/Migration Narrative**

Adult: Not available

### *Population Information and Trends*

**Population Trends:**

Not available

**Number of Populations:**

8-9 (USFWS, 2020)

**Population Size:**

510,744 (USFWS, 2020)

**Adaptability:**

Low (inferred from NatureServe, 2015)

**Population Narrative:**

In 1987, Ash Meadows ivesia was known from seven populations within the Ash Meadows area (Knight and Clemmer 1987, pp. 73–74). In 1998, Knight and Clemmer's populations were re-surveyed and re-confirmed, and an additional population of Ash Meadows ivesia at Jackrabbit Spring was discovered (Service, unpubl. survey, 1998). In 2001, Ash Meadows ivesia was estimated to occur across 9 minimum scale occurrences (0.1 mi (0.16 km) separation distance) or 8 maximum scale occurrences (0.6 mi (1 km) separation distance) on approximately 9.1 ac (3.7 ha) (Morefield 2001, p. 1). Refuge-wide surveys at the Ash Meadows National Wildlife Refuge (Refuge) of listed and rare plants, including Ash Meadows ivesia, were initiated in 2008 and completed in 2010 (BIO-WEST 2011, entire). As a result of these surveys, 9,000 ac (3,642 ha) were surveyed and the approximate Refuge area covered by Ash Meadows ivesia is 116.1 ac (47 ha) (BIO-WEST 2011, pp. 121– 123). On these 116.1 ac (47 ha), 19 minimum scale occurrences (0.1 mi (0.16 km) separation distance) or 2 maximum scale occurrences (0.6 mi (1 km) separation distance) were reported (BIO-WEST 2011, pp. 121–123). Distribution of Ash Meadows ivesia is depicted in Figure 1. At the time of listing, a population estimate of Ash Meadows ivesia was unknown (Service 1985, p. 20777). In 2001, the Ash Meadows ivesia population on the Refuge was estimated to be approximately 3,862 individuals (Morefield 2001, p. 1). Results from the 2008–2010 Refugewide rare plant survey produced an estimate that 510,744 individuals are present on the Refuge (Table 1; BIO-WEST 2011, pp. 121–123). This estimate remains the best available for the Refuge population. Estimates of Ash Meadows ivesia individuals on the BLM ACEC and private lands within the Refuge boundary do not exist. (USFWS, 2020)

### *Threats and Stressors*

**Stressor:** Past habitat destruction and modification (USFWS, 1985)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** The presence of water in Ash Meadows has long attracted human activity and provided a refuge for man's survival in an arid desert. The magnitude of man's impact on the local environment has increased over time and resulted in the decline of local endemic species Large-scale disturbance began in the early 1960's when approximately 2,000 acres of upper Carson Slough was mined for peat. This removed approximately six feet of substrate and eliminated on of the largest marshes in southern Nevada. Endemic plant populations were reduced or eliminated when lands were cleared for crops and pasture, roads were constructed, and when impoundments were constructed then filled (Sanchez 1981). Impoundments now inundate several hundred acres of habitats believed to support the Ash Meadows ivesia. Many roads were built through areas now designated as critical habitat for plant species. Approximately 65 miles of gravel and unimproved roads now exist within the essential habitat, directly affecting Ash Meadows ivesia. All of the endemic species were additionally affected by secondary impacts of these roads, which largely resulted from increased vehicular access to sensitive areas. Because of all past activities, small populations of species endemic to Ash Meadows presently occupy a small portion of their historic habitat (USFWS, 1990).

**Stressor:** Introduced species (USFWS, 1990)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Introduced species, including salt cedar (Tamarix), mosquitofish, sailfin mollies (Poecelia lativinna), wild horses, bullfrogs, and crayfish further reduced endemic plant and animal populations by displacement through competition for food and space, and/or predation (Miller 1948, Beatley 1977 a, b; Reveal 1978 a, b, c; Soltz and Naiman 1978, Schoenherr 1981, Knight and Clemmer 1987). Roads facilitated introduction of non-native species (particularly aquatic species), and the detrimental influence of trampling caused by water-oriented recreation. Introduced species are now widespread throughout the area, and trampling has reduced populations of endemic mollusks and plant populations adjacent to springs. Large herds of wild horses altered spring morphology and impacted endemic plant and snail populations (Hershler and Sada 1987, Landye 1973, Mozingo and Williams 1980) (USFWS, 1990).

***Recovery***

**Reclassification Criteria:**
Not available

Recovery Priority Number: 8

**Delisting Criteria:**
1. The species is present in all locales it historically occupied within Ash Meadows (USFWS, 1990).

2. The species has reached self-sustaining populations (as measured by frequency values for plants on critical habitat) (USFWS, 1990).

3. The essential habitat is free of threats from all non-native animals, exotic plants, and detrimental human disturbances (USFWS, 1990).

4. Springs have returned to historic discharge rates and water flow is reestablished into historic channels (USFWS, 1990).

5. Native plant and aquatic communities have been reestablished to historic structure and composition within all essential habitat (USFWS, 1990).

**Recovery Actions:**

- Secure habitat and water sources for the Ash Meadows ecosystem (USFWS, 1990).
- Conduct research on the biology of the species (USFWS, 1990).
- Conduct management activities within essential habitat (USFWS, 1990).
- Reestablish populations/monitor new and existing populations (USFWS, 1990).
- Determine/verify recovery objectives (USFWS, 1990).
- Approval of the Ash Meadows Habitat Management Plan by the Bureau initiated a number of more recent conservation programs on public domain lands (USBLM 1980). Barbed wire fencing was installed to prevent wild horses' entrance to approximately 425 acres surrounding Big and Jackrabbit Spring s, and emergent vegetation has been periodically removed from School Springs. Wild horses were captured during August 1985 to eliminate trampling of springs, stream banks, and rare plants (USFWS, 1990).
- The States of Nevada and California and the Service have been actively involved in recognizing the declining status of species endemic to Ash Meadows. These agencies variously list a number of local species as either threatened or endangered. Numerous botanists affiliated with various universities and native plant societies throughout the nation have surveyed the area's vegetation and documented rare plant distribution. Although much work has been conducted, much of it has been directed toward preventing further loss of populations and habitat and not toward habitat or population enhancement. The purchase of much of the area by The Nature Conservancy and subsequent purchase of these lands by the Service to establish the Ash Meadows Refuge has been the single largest step toward providing security for these species (USFWS, 1990).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: I. Monitor compliance with Nevada Revised Statute Order 1197A (January 12, 2018), Curtailment of New Appropriations of Groundwater within the Amargosa Valley Hydrographic Basin 230, that prohibits new applications for water or water diversions within 25 miles of Devils Hole (and by proximity Ash Meadows NWR). Order 1197A supersedes 1197, which imposed similar regulations at 10 miles from Devils Hole. Water levels in Devils Hole are affected by pumping centers in the Amargosa Desert and the Ash Meadows groundwater basins (Halford and Jackson 2020). II. Collaborate with the Ash Meadows NWR to implement the Desert National Wildlife Refuge Complex – Ash Meadows, Desert, Moapa Valley, and Pahranagat National Wildlife Refuges Final Comprehensive Conservation Plan and Environmental Impact Statement, Volume I – August 2009 (Service 2009) and also the Draft Ash Meadows Natural Resource Management Plan in review (Service 2020); and III. Support Ash Meadows ivesia research at the Ash Meadows NWR to monitor the population as identified in the Recovery Plan for the Endangered and Threatened Species of Ash Meadows (Service 1990); and IV. Monitor the future activity of mineral rights in the Ash Meadows area. The BLM ACEC surrounding the refuge is withdrawn from mining and entry until 2029 (PLO# 7737, signed November 2nd, 2009), but requires renewal every 20 years. Mining can still occur on private inholdings within the refuge, but no active mining permits exist at this time. (USFWS, 2020)

# SPECIES ACCOUNT: *Jacquemontia reclinata* (Beach jacquemontia)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

Beach jacquemontia is a perennial vine which has a main stem with numerous laterals spreading out from a stout rootstock (Robertson, 1971). These reclining, partly twining or ascending, slender stems are woody at the base and may twine over other plants (Robertson, 1971; Austin, 1979). The older leaves and stems of this species can be glabrous, but the pubescence makes younger leaves and stems appear whitish (Austin, 1979). The leaves are entire, alternate, estipulate, spirally arranged, and almost always petiolate, reaching one to three cm in length and 0.5 to 2.5 cm in breadth (Small, 1905; Robertson, 1971; Austin, 1979). The flowers of this species are white to light pink and the sepals are persistent. The inflorescences can be axillary cymose or solitary with branches 8-40 millimeters (mm) long, usually not exceeding the leaves (Robertson, 1971; Austin, 1979). The fruit is a light brown capsule about four to five mm long (Small, 1905; Robertson, 1971). Additional physical descriptions of beach jacquemontia can be found in Small (1905) and Robertson (1971).

**Taxonomy**

Though J. havanensis is closely related, beach jacquemontia's main distinction is its ciliolate (marginal fringe of hairs) sepals and rather succulent leaves (Robertson, 1971). This ciliolate on the outer sepals and fleshy leaves also distinguishes this species from J. curtissii, which has hairless sepals and narrow leaves that are not fleshy (Austin, 1979). There are about 100 species of the genus Jacquemontia, most of which are found in tropical and subtropical America (Robertson, 1971). Beach jacquemontia is the only species found along the beaches of southeastern Florida (Austin, 1979). Beach jacquemontia was first described from specimens collected in 1903 at northern Miami Beach (Small, 1905). The original treatment of this taxon as a distinct species was upheld by Robertson (1971) during a review of the genus Jacquemontia. Three other species are found in Florida: J. curtissii inhabits pinelands on the mainland, while J. jamaicensis and J. pentantha occur in the Florida Keys (Small, 1933). Although Small (1933) considered beach jacquemontia's range to extend into the West Indies, Austin (1979) considered it endemic to the east coast of Florida.

**Historical Range**

Found historically in Martin Co. FL (NatureServe, 2015)

**Current Range**

Palm Beach, Broward, and Dade Cos., FL; reintroduction projects initiated. (NatureServe, 2015). Beach jacquemontia is a member of the morning glory family (Convolvulaceae) that is restricted to the southeastern coast of Florida. Much of the primary habitat of this species, beach coastal strand and maritime hammock, has been destroyed or altered for residential and commercial construction. Fewer than 1,000 individual plants exist. They are found in small, widely separated populations in Miami-Dade, Broward, and Palm Beach counties, where habitat loss and modification place this species at a high risk of extinction. Habitat conservation and management and reintroduction efforts are needed to make sure of the survival of this species. The information presented here is from the Multi-species Recovery Plan for South Florida

(Service, 1999), which represents a revision of the existing recovery plan for the beach jacquemontia (Service, 1995).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: flowers from November to May

**Reproduction Narrative**

Adult: Beach jacquemontia flowers from November to May, but may vegetatively propagate at any time. The incidence or importance of vegetative propagation is not known at this time. At some sites, beach jacquemontia sets fruit and disperses seed prolifically (Robertson, 1971); however, few seedlings or young plants are ever found near adult plants. Microhabitat conditions and locations relative to adult plants probably play a major role in providing suitable germination sites (Austin, personal communication, 1997; Kernan, personal communication, 1997). For example, at Crandon Park, naturally sown seeds had extremely low germination rates (unmeasurable) compared to seeds taken from this site and germinated under greenhouse conditions (70%). Findings from these investigations indicated that germination rates were highest in more organic soils in the shade, but that the seed viability was short-lived once sowed.

**Habitat Type**

Adult: Coastal dunes/shrubby hammocks

**Environmental Specificity**

Adult: Very Narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Pine rocklands and the crest and lee side of coastal dunes. (Based on Ward 1979, Wunderlin 1982.) (NatureServe, 2015). At Crandon Park, Dade County, beach jacquemontia exists on dune faces at the edge of shrubby hammocks. At Hugh Taylor Birch State Recreation Area [SRA], Broward County, beach jacquemontia is located in coastal scrub with little canopy cover and exposed sandy substrate. There, it receives protection from direct ocean winds and sea spray (Lippincott, 1990). Seedling and young beach jacquemontia grow best when shaded. Under natural conditions, young plants are typically found growing in the shade of adjacent shrubs and trees. When mature, beach jacquemontia spread laterals from the rootstock into adjacent exposed sites (Kernan, personal communication, 1997).

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

20 populations (8 natural and 12 introduced) (USFWS, 2021)

**Population Size:**

~700

**Population Narrative:**

The barrier islands within the range of beach jacquemontia are entirely urbanized except for a few small parks and private estates. Johnson et al. (1993) inventoried all tracts of native coastal vegetation in southeast Florida that were four or more hectares in size. They found only 24 tracts of that description in the known range of beach jacquemontia, five of them entirely or mostly in private ownership. These tracts comprised about 87 hectare [ha] of beach strand vegetation in public ownership, 10.5 ha in private ownership, and 26.7 ha of maritime hammock in public ownership. In 1991, less than 1,000 individual plants of beach jacquemontia were known to occur on 12 sites (Austin 1991). Eleven of these sites were in public parks or recreation areas operated by State, county, or local governments in Palm Beach (eight sites), Broward (one site), and Dade (two sites) counties. The only known privately owned site, in Broward County, had just one plant (Johnson et al., 1993; Austin, 1991). A 1995 survey for beach jacquemontia located 450 to 600 plants at ten sites in Dade and Palm Beach counties (Kernan, personal communication, 1995). More than half of these plants were located at two sites: Red Reef Park in Palm Beach County and Crandon Park in Dade County. The remaining plants were scattered in populations of fewer than 50 individuals in Broward, Dade, and Palm Beach counties. As of 1996, beach jacquemontia was known from only nine sites in Dade and Palm Beach counties (Garview, personal communication, 1997; Davis, personal communication, 1997). Eight of these sites contained natural populations, while one site was established from restoration efforts. Several previously known sites have been lost over the past several years, including re-established populations at Coral Cove Park and Gemini Gardens (private), and Juno Beach Park, Nasa (private). There may be an additional historic site in Palm Beach County added if future surveys confirm the presence of beach jacquemontia. Since 1996, surveys have revealed that more beach jacquemontia colonies in Palm Beach County have been lost. Colonies are now known to exist at Carlin Park, Logggerhead Park, Red Reef Park, Red Reef Golf Course, South Beach Park, and South Inlet Park. Gemini Gardens, Atlantic Dunes Park and Spanish River Park were not included in those surveys (Davis, personal communication,1998). Information from specific localities of beach jacquemontia suggests that the species is relatively secure at some sites but susceptible at others. For example, it was collected at South Coral Cove Park, Jupiter Island, Palm Beach County, in 1962, but was not found there in 1990 (Johnson et al., 1993). The disappearance from this site is due to beach erosion and shading from Australian pines (Johnson et al., 1993). Several specimens identified as beach jacquemontia from the Jupiter Lighthouse on the mainland opposite the southern tip of Jupiter Island have been subsequently identified as J. curtissi (Davis, personal communication, 1998). Land clearing for residential development has eliminated beach jacquemontia from other sites in this area (Austin, 1979). Although apparently suitable habitat exists at Blowing Rocks Preserve and Hobe Sound NWR on Jupiter Island, beach jacquemontia has not been found there (Johnson et al., 1993). Surveys conducted in 2003-2004 estimate the total population to be 700 individuals on nine sites (Maschinski et al., 2004). This number is down slightly from the 2003 estimate of 760 individuals on nine of ten existing sites surveyed. The populations at Carlin Park and Loggerhead Park in Palm Beach County experienced a greater than 50% population reduction observed in the fall of 2003, probably due in part to canopy closure caused by encroachment of hardwoods. Two plants were discovered at Lake Worth Inlet in Palm Beach County in 2001, but only one remained in January 2004. Outplanted populations remained steady. At Red Reef Park in Palm Beach County, 15 of 18 outplanted individuals were surviving in January 2004, the same number observed during the 2003 visit. At Bill Baggs State Park in Miami-Dade County, seven of 93 plants remained of the outplanted population in February 2004, with one plant lost since the survey conducted in the previous year.

***Threats and Stressors***

**Stressor:** Loss and degradation of habitat
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Loss of habitat to urbanization and beach erosion led to the listing of beach jacquemontia as endangered on November 24, 1993 (Service, 1993). The vast majority of beach coastal strand and maritime hammock vegetation, the primary habitat of this species, has been destroyed by residential and commercial construction. Habitat within public lands has also been destroyed or degraded due to construction of parking lots, pedestrian routes, picnic areas, and other modifications for recreational uses. Additional habitat has been lost to beach erosion at some sites (Johnson et al. 1993, Davis, personal communication, 1997).

**Stressor:** Fragile demographics
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The limited geographic distribution, fragmentation of remaining habitat, small sizes of beach jacquemontia populations, and possibility of stochastic natural events make it doubtful that many of the existing populations will persist for 100 years.

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 2

**Recovery Actions:**

- To ensure the survival of this plant, the remaining populations of beach jacquemontia on public lands will require active management and a program of propagation, germplasm conservation, and augmentation. Basic demographic, pollination, seed dispersal, seed germination and seed establishment information is needed to recover this endangered species. Successful management will require new surveys for sites that contain beach jacquemontia, complete knowledge of where it existed historically, and surveys for sites within its historic range that would be suitable for re-establishment. In addition, threats to existing and proposed sites posed by commercial and residential development and invasion of exotic species need to be addressed. Because additional protection of beachfront property through fee title acquisition or easement is unlikely due to real estate costs, beach jacquemontia will be best protected and recovered through re-establishment efforts. Greenhouse propagated plants were successfully re-established to three sites in Crandon Park in 1989; however, two plants used in the Coral Cove Beach Dune Restoration Project in 1994 did not survive (Davis, personal communication, 1994). Although this attempt was unsuccessful, we believe the recovery of this species can be partially accomplished through re-establishment as part of dune restoration projects. Dade County is planning to re-establish about 60 beach jacquemontia plants at Bill Baggs Cape Florida SRA, Key Biscayne, Dade County (Carter, personal communication, 1997). It is important to remember that beach jacquemontia should only be re-established in areas within its historic range. Restoration efforts should also consider using other plants that occur naturally with beach jacquemontia, so that more of a representative vegetative complex is re-created. Some of the existing beach jacquemontia sites and many other potentially suitable recipient sites for beach jacquemontia translocation will require removal and control of exotic vegetation as part of the restoration process. It seems that this species does best in sparsely vegetated habitats, and that one of the factors responsible for its decline is the lack of sparsely vegetated areas that are typical of overwashed dunes (Davis, personal communication, 1998). At Crandon Park, herbicides are being used on a few plots where beach jacquemontia is suppressed by St. Augustine grass, and the plants do not seem to be adversely affected. Fire may also play an important role in habitat maintenance for beach jacquemontia as demonstrated by the short-term response to a recent burn on Bear Cut Preserve on Key Biscayne, Dade County (Kernan, personal communication, 1996). The long-term effects of burning will need to be analyzed over the next several years. Mowing or bush-hogging could also be used where fire cannot be safely used, or in areas where the plants currently exist as a result of mowing.

***Conservation Measures and Best Management Practices:***

- IV.RECOMMENDATIONS FOR FUTURE ACTIONS A detailed discussion of recovery actions and criteria are presented in the Recovery Plan (Service 1999). In the course of this status review new and/or targeted potential recovery activities were identified and are included below. Recovery Activities • Conduct hardwood reduction and invasive species removal to maintain or restore suitable habitat at all populations. • During invasive species (e.g. beach naupaka, Brazilian pepper) removal on dunes, efforts should be made to remove biomass off-site and shift toward open habitat rather than focus on dense replanting. • Increase the smaller populations (less than 30 plants; Tables 1 and 2) through augmentation using the appropriate genetic guidelines and source materials as described in Thornton et al. 2008 and Maschinski et al. 2013 (see section II.C.1.c.) to help ensure preservation of genetic diversity. • Prioritize restoring and maintaining the habitat quality of extant natural and introduced populations over establishing new introduced populations. • Prior to introducing new experimental populations or augmenting extant populations, ensure that a habitat management plan is in effect and being implemented. • Seed collections for long-term storage should be made continuously following CPC guidelines to not harvest more than 10 percent of the annual seed crop of a given population. Seeds should be separated by maternal line to maximize ability to utilize genetic diversity into future research and introduction efforts. Monitoring/Research Activities • Develop survey metrics that are more easily collected and can serve as indicators of population condition, such as patch size, total area occupied, estimated plants counts, shoot counts (quadrat system), or stem density. • Continue to assess, document, and study the impacts sea level rise (shoreline shift, king tide, storm surge, and saltwater intrusion) on this coastal dune species and its habitat. • Promote and increase partnerships to evaluate the current protection status and management needs at each park and to develop cooperative assistance and information sharing plans between parks. • Re-survey populations that do not have recent site visits or are considered extirpated (see Tables 1 and 2). Consider possible habitat management or restoration actions at these sites. • Public access should continue to be managed to prevent trespassing on the dunes and enforce "no trespassing" regulations. Public education should be implemented to educate visitors about this rare species and help control public access to the dunes. • Continue work on genetics (single sequence repeat markers) to further determine degree of genetic differentiation within the J. havanensis clade, to which J. reclinata belongs, and the species' taxonomic status in that clade (Namoff et al. 2008). • Conduct a population viability analysis when enough demographic data are available. Data need to be collected on survival of seedlings in the wild (current data are based on seedlings in a nursery setting). • The role of fire should continue to be explored and understood. On sites where prescribed fire may be used, develop appropriate methods to use fire in small areas in the coastal dune system. (USFWS, 2021)

# SPECIES ACCOUNT: *Lasthenia burkei* (Burke's goldfields)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 01/02/1992; Pacific Southwest (R8)

**Physical Description**

An annual herb that ranges in height from approximately 13 cm (5 in) (Patterson in litt. 2000) to as much as 61 cm (24 in) (Greene 1886), but is typically less than 30 cm (11.8 in) tall (Ornduff 1993). It has hairy stems, which may be simple or branched. The narrow, opposite leaves are no more than 8 cm (3.1 in) long and may be lobed or not. From April to June, the end of each branch bears one daisy-like flower head approximately 1.5 cm (0.6 in) across. The fruits are achenes (dry, one-seeded fruits) less than 1.5 mm (0.06 in) in length. The fruits of L. burkei can be distinguished from those of other goldfields by the presence of one long awn (bristle and numerous short scales) (Ornduff 1993). Individual L. burkei plants may exhibit some geographic variation in morphology (McCarten 1985 as cited in CH2M Hill 1995, Patterson et al. 1994). A diagnostic feature of Lasthenia burkei is the usual presence of a single long awn on the achene intermixed with 8 to 10 short scales (Ornduff 1993, Patterson et al. 1994). However, several occurrences have mixtures of typical achenes with a single awn and atypical achenes with a varied number of awns. Species experts consider these mixed occurrences to represent Burke’s goldfields (Ornduff 1969b, Patterson et al. 1994, CNDDB 2013). (USFWS, 2016)

**Taxonomy**

The scientific name originally given to Burke’s goldfields was Baeria burkei (Greene 1886). Both the specific epithet and the common name commemorate J. H. Burke, who collected the type specimen “near Ukiah, Mendocino County” (Greene 1886). Greene later placed the genus Baeria within Lasthenia, creating the new name Lasthenia burkei for Burke’s goldfields (Greene 1894). However, for many years other botanists (e.g., Hall 1914, Jepson 1925, Abrams and Ferris 1960) did not believe that Burke’s goldfields was distinct from Fremont’s goldfields (Lasthenia fremontii), a more widespread species to which it is very similar, nor did they agree with Greene’s (1894) decision to lump Baeria with Lasthenia. Not until 1966, when Ornduff (1966) published a comprehensive study of the genus Lasthenia, was Burke’s goldfields recognized as a distinct species and the name Lasthenia burkei accepted widely. Continuing research indicated that Burke’s goldfields, Fremont’s goldfields, and Contra Costa goldfields (Lasthenia conjugens) form a closely related species group (Ornduff 1969b, Crawford and Ornduff 1989). However, Burke’s goldfields was found to be genetically distinct from Fremont’s and Contra Costa goldfields (Crawford and Ornduff 1989). Lasthenia burkei and its relatives are members of the aster family (Asteraceae). (USFWS, 2016)

**Historical Range**

Endemic to the central California Coastal Range region and has been reported historically to be located within Mendocino, Lake, and Sonoma counties. (USFWS, 2016)

**Current Range**

In California, within Mendocino, Lake, Napa, and Sonoma Counties. (USFWS, 2019). Burke’s goldfields is known only from southern portions of Lake and Mendocino counties and from the Santa Rosa Plain, previously referred to as the Cotati Valley, in Sonoma County. (USFWS, 2024)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: insect-pollinated (USFWS, 2016)

**Lifespan**

Adult: 1 year (USFWS, 2008)

**Dependency on Other Individuals or Species**

Adult: Pollinators (USFWS, 2016)

**Breeding Season**

Adult: April - June (USFWS, 2016)

**Key Resources Needed for Breeding**

Adult: Soil seed bank, insect pollinators. heavy fall rains (USFWS, 2016)

**Other Reproductive Information**

Adult: Like many other rare vernal pool plants, Lasthenia burkei is an annual. Lasthenia burkei typically germinates in autumn following heavy rains, although late initiation of rains may delay seedling emergence (Ornduff 1969b). Laboratory germination tests (Rancho Santa Ana Botanical Garden, unpublished data) indicate that germination occurs rapidly in a single flush, with relatively high germination rates (49 to 100 percent). Both the ray and disk flowers of all goldfields species produce achenes, increasing the potential for seed production per head. However, the reproductive output of individual plants is highly variable, depending on plant density and vigor, and probably on pollinator behavior as well. Each flower head can produce as many as 35 achenes, and the number of flower heads per plant can range from 1 to more than 20 (Patterson et al. 1994). Annual survival rates and other demographic parameters have not been investigated. Lasthenia burkei has also likely adapted to “risky environments” by producing a persistent seed bank. Some occurrences have reappeared after no plants were evident for 2 years, suggesting that viable seeds remained in the soil during that period (Patterson 1990). (USFWS, 2016)

**Reproduction Narrative**

Adult: The flowers of Lasthenia burkei are predominantly pollinated by outcrossing but they are capable of self-pollination (Sloop et al. 2012c). They are thought to be insectpollinated rather than wind-pollinated. Insects known to visit the flowers of the genus Lasthenia include butterflies (Lepidoptera), beetles (Coleoptera), flies (Diptera), true bugs (Hemiptera), bees (Hymenoptera), and wasps (Hymenoptera) (Thorp and Leong 1998). Most of these insects are generalist pollinators. All of the specialist pollinators of Lasthenia spp. are solitary bees (family Andrenidae); these include two species in the subgenus Diandrena (Andrena submoesta and A. puthua) and five or six species in the subgenus Hesperandrena (Andrena baeriae, A. duboisi, A. lativentris, and two or three undescribed species) (Thorp and Leong 1998). Gilmore, Sloop and

Rank (2012) conducted a pollinator study of L. burkei, and found that although the solitary bee (Andrena submoesta) specializes on L. burkei and is apparently dependent on it as a food source, the plant may not rely on A. submoesta for pollination (Gilmore et al. 2012). The Bombyliid fly (also called a bee fly), Conophorus cristatus, was found to be the dominant visitor of L. burkei and may be its primary pollinator. Syrphid flies (members of several genera in the family Syrphidae (hover flies)) were also found to be an important part of the pollinator community for this plant (Gilmore et al. 2012). (USFWS, 2016)

**Habitat Type**

Adult: Wetland (USFWS, 2016)

**Habitat Vegetation or Surface Water Classification**

Adult: Mesic meadow, vernal pool (USFWS, 2016)

**Geographic or Habitat Restraints or Barriers**

Adult: Wide range, up to 1900 feet in elevation (USFWS, 2016)

**Environmental Specificity**

Adult: Very narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: The primary habitats of Lasthenia burkei are shallow vernal pools and wet swales within valley grassland and oak woodland habitats (CNDDB 2013). On the Plain, L. burkei grows in the bottoms of pools ranging from less than 25 cm (10 in) in depth to 50 cm (20 in) (Patterson 1990, Patterson et al. 1994, Patterson in litt. 2000). Lasthenia burkei grows in naturally-occurring pools that range in surface area from approximately 2 square m (21.5 square ft) to 0.3 ha (0.75 ac (Patterson in litt. 2000)). Most of the vernal pools where L. burkei grows are loosely classified as northern vernal pools (Keeler-Wolf et al. 1998), but the Manning Flat occurrence in Lake County is in a northern volcanic ashflow vernal pool (Sawyer and Keeler-Wolf 1995). Lasthenia burkei also has been observed occasionally in artificially-created depressions such as drainage ditches and in disturbed sites such as orchards and disked fields (Patterson 1990, Patterson et al. 1994). (USFWS, 2016)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seed dispersal mechanisms are not known. Pappus awns (needle-like appendages attached to the achene) may assist in windborne seed dispersal. Other seed dispersal mechanisms may include water or wildlife. (USFWS, 2016)

***Population Information and Trends***

**Population Trends:**

Decline of >90% (NatureServe, 2015)

**Species Trends:**

> 70% decline (NatureServe, 2015)

**Number of Populations:**

32 (USFWS, 2024)

**Population Size:**

Variable depending on year; 24,860 - 8.1 million in most recently surveyed populations (USFWS, 2016)

**Adaptability:**

Low (inferred from NatureServe, 2015)

**Population Narrative:**

This species inhabits highly vulnerable vernal pool plant endemic to small area, mostly in Sonoma County, California. It has experienced a long term decline of > 90%. It is declining rapidly (> 70% short term) due to runaway urban development in its habitat (Bittman 1998). Numbers fluctuate depending on rainfall; last counts indicated about 100,000 plants at all sites (some may now be extirpated). Known from twenty-eight occurrences. A maximum of twenty occurrences may be extant, but we believe the number to be far lower (fewer than ten viable occurrences) (California Natural Diversity Database, May/1998 report) (NatureServe, 2015). The largest known extant occurrences are at the Alton North Conservation Bank, with approximately 8.1 million plants in 2013; the Alton Lane Vernal Pool Preserve, with approximately 1.4 million plants in 2013; the Wright Preservation Bank, where the number of plants has decreased from approximately 5.3 million down to 1 million over the past 5 years; and Woodbridge Preserve, east of Fulton Road near Piner Road, where the number of plants increased from 350 plants in 1998 to 18.5 million plants in 2009, with 24,860 found at this site in 2012 (CNDDB 2014, Stromberg 2013) (see Figure 5). Sloop and Ayres (2009) found that thirteen Lasthenia burkei occurrences were genetically distinct despite showing some gene flow between them (USFWS, 2016). Currently, the 32 presumed extant occurrences have a similar distribution in these three counties (Diversity Database 2024, entire; see Appendix A). Since the 2019 review, there are two new occurrences in Sonoma County. Occurrence #44 was last seen in 2015, prior to the 2019 review, but was not included in the status review (Diversity Database 2024, p. 48). The second new occurrence, #45, is listed as a transplant outside of native habitat or range; however, it is located within Sonoma County, and the Diversity Database occurrence report notes that there is no record of seed transplants at this location, so it may be a natural occurrence (Diversity Database 2024, p. 49). Hazel Mitigation Bank attempted to establish Burke's goldfields through seeding in created and enhanced wetlands, but these occurrences only persisted a few years and have not been present since (Stromberg 2019, p. 9). Since the last review, there is no new information or monitoring reports from the other conservation banks and preserves described in the 2019 status review (see Service 2019, p. 12) (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Development and conversion to agriculture (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Today, the largest continuing threats to this species are urban development and land conversion to agriculture (such as vineyards) and associated agricultural activities and wastewater irrigation. The most recent estimates from the California Department of

Conservation (2002) are that about 71,000 acres of Sonoma County have been converted to urban uses (Sonoma County Permit and Resource Management Department 2014). The threat of urban development to these species in the Santa Rosa Plain is expected to continue. In addition to urban development, land conversion to agriculture and associated agricultural activities has reduced occurrences of these plants (CNDDB 2014). In 1991, at the time of the listing, approximately 34,500 acres of land were in wine grape production in Sonoma County (Sonoma County Agricultural Commissioner 1991). As of 2012, the acreage of wine grapes in Sonoma County had increased to approximately 58,400 acres (Sonoma County Agricultural Commissioner 2013). Additionally, irrigation with recycled water, a practice that began in the Santa Rosa Plain in the 1970s, has emerged as a major threat. Although the California Regional Water Quality Control Board regulations (Water Quality Control Plan for the North Coast Region) prohibit discharge of recycled water to surface waters during the summer, the regulations did not contemplate that recycled water would be used to irrigate vernal pools and other types of seasonal wetlands (J. Short, pers. comm., 2007). Recycled water, as opposed to wastewater, is tertiary-treated (City of Santa Rosa, in litt. 2015** [comment letter]). Wastewater, however, can come from many sources including livestock waste ponds and runoff from agricultural fields (City of Santa Rosa, in litt. 2015** [comment letter]). (USFWS, 2016)

**Stressor:** Alteration of hydrology (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Some actions, such as runoff from irrigation or irrigation with recycled water, can result in increased water on the landscape. The vernal pool habitat may receive more water than it normally would or receive it at an inappropriate time, resulting in flooding and death of listed plant seedlings. If water from urban or agricultural runoff continues to fill pools during spring and summer months, the listed plants will disappear because they cannot tolerate permanent inundation; invasion by plant species adapted to permanent inundation will occur. Additionally, irrigation with recycled water and runoff from irrigation can contain chemicals, such as herbicides, and other nutrients (Pereira et al. 1996) that can alter the vernal pool plant community, prevent germination, or kill seedlings. Nitrogen deposition from automobile traffic may also modify habitat by increasing soil nutrients, thus posing a continuing threat to remnant habitat that might otherwise be suitable for these species. Weiss and Luth (2003, p. 1) conducted research on the effects of nitrogen deposition along a highway south of the San Franciscan peninsula in San Francisco County. They found that nitrogen deposition within 100 m to 400 m from the highway was correlated with increased nonnative grass cover within these areas, resulting in competition for space with native plants. An increase in nonnative grass cover through changed habitat conditions could threaten the three plant species by competing for soil moisture and nutrients and inhibiting successful germination. (USFWS, 2016)

**Stressor:** Off-highway vehicles (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Damage by off-highway vehicles was noted as a threat to this species. Currently, on Department-owned properties that support the listed plants, some damage to preserves from vehicle trespass does occur, but without damage to the vernal pools. The most significant damage to vernal pools from vehicles has resulted from a Mosquito Vector Control vehicle

driving through the vernal pools to spray for mosquitoes during the time when the pools were wet in 2014. Disturbance to the pools included physical damage to the pools and swales from tire ruts and crushing and uprooting the plants (S. Martinelli, CDFW, in litt. 2014). The level of this threat is likely to be variable and is difficult to predict or monitor. (USFWS, 2016)

**Stressor:** Grazing managment and thatch accumulation (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Appropriate levels of grazing may provide some control of weedy plants, reduce competition between native plants and invasive plants, and can provide some bare soil for germination of native plants, all of which may provide opportunities for native plants to germinate. Cessation of cattle grazing has been found to exacerbate the negative effects of invasive nonnative plants on vernal pool inundation period. If grazing is removed, areas of bare soil can be quickly occupied by nonnative, invasive plants. Removal of grazing from vernal pool grasslands where grazing is the traditional land use practice may have devastating impacts on vernal pool habitat, particularly on upland habitat surrounding vernal pools (G. Cooley, in litt., 2014). For example, non-native grasses increased and native grasses decreased in vernal pools when grazing was discontinued at a site in the Southeastern Sacramento Valley, resulting in a 50 to 80 percent reduction in vernal pool inundation (Marty 2005). Since the time of listing, grazing has been removed at many locations and has resulted in thatch build-up. Anecdotal evidence supports the theory that thatch build-up of nonnative vegetation has caused a reduction in the size of extant populations of the listed plants. The Department is re-establishing appropriate grazing practices on some Department-owned lands to reduce thatch build-up and nonnative competitors to the three listed plants (e.g., Todd Road Unit Ecological Preserve). However, reintroduction of grazing may not return a site to its former condition because nonnative plants may continue to occupy the once-vacant niches. For example, harding grass (Phalaris aquatica), a robust, invasive perennial grass, can be present in a grazed field, and not be obvious. If grazing is removed, however, the suppressed harding grass can become vigorous and dominate the entire field within a year or two and grazing will not remove this species once it is established (G. Cooley, in litt. 2014). We recognize that there is disagreement among biologists as to the extent of the threat of inappropriate grazing on the three species. As the final rule concluded, we believe that although the effect of well-managed livestock grazing may be beneficial to vernal pool ecosystem. (USFWS, 2016)

**Stressor:** Loss of Genetic Diversity / Inappropriate Mixing of Populations(USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** An additional potential threat to these three plants is the disruption of normal gene flow due to population restoration efforts that may mix populations, which may cause unanticipated adverse effects such as disruption of locally adapted gene complexes and outbreeding depression (when offspring from individuals from different populations have lower health/fitness than progeny from individuals from the same population). Several sites are proposed as Preserves in the Santa Rosa Plain and include proposals to seed/inoculate created or restored vernal pools. Seed from a limited number of donor occurrences has already been used for several years to inoculate multiple created or restored sites, creating a risk of overrepresentation of a small gene pool (swamping). The threat level of this activity is unknown;

however, the 2007 Programmatic Biological Opinion (Service 2007) includes measures to reduce this potential threat as well as the requirement to obtain a collection permit from the Department. (USFWS, 2016)

**Stressor:** Climate change (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since the 1950s, the Northern Hemisphere has experienced warmer air temperatures and decreased snowfall (Ackerly et al. 2010, IPCC 2013). By the end of the 21st century, climate change is predicted to result in more intense precipitation events in the form of rain, increased summer continental drying, extreme weather events, and increased wildfire (Ackerly et al. 2010, IPCC 2013). However, current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2013). Climate simulations have shown that California temperatures are likely to increase by 2.7 degrees Fahrenheit (1.5 degrees Celsius) to 8.1 degrees Fahrenheit (4.5 degrees Celsius) depending on the emissions scenario (Cayan et al. 2008). The predicted impacts on California's ecosystems projected with a high certainty include (1) higher sea level and (2) decreased suitable habitat for many terrestrial species as climate change intensifies human impacts [for example isolated patches of vernal pools can be so poorly connected with other patches that migrations required by climate change may be difficult or impossible without human intervention (Field et al. 1999)]. Climate change threatens to increase the loss of pollinators if the abundance of flowers preferred by pollinators decreases. Pollinator emergence times may also be altered by a warming climate. If this occurs, the synchrony of bloom periods and pollinator emergence could be disrupted. The loss of pollinators would further reduce the amount of seed produced by the listed plants because of the plants' limited ability to self-pollinate. Although there currently are no data available regarding changes in plant bloom periods or emergence dates of pollinators in the Santa Rosa Plain in response to climate change, Forister and Shapiro (2003) found that over a period of 31 years, warmer and drier winter conditions were associated with earlier butterfly appearance in the Central Valley of California. Although the loss of seed produced in a single year would not likely lead to the extirpation of the species, the continued reduction of the seed crop or dependence on self-pollination would reduce the seedbank, genetic variation, and the potential for population expansion. Monitoring of vernal pool ecosystems to determine effects from climate change is necessary to determine what adaptive land management practices would be the most appropriate to ensure the sustainability of vernal pool species (Pyke and Marty 2005), including B. bakeri, L. burkei, and L. vinculans. (USFWS< 2016)

**Stressor:** Extirpation due to Stochastic Events, Isolated Occurrences, and Small Size of Occurrences (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Chance events constitute a serious threat to Blennosperma bakeri. Because the known occurrences of B. bakeri are limited in number and in range, the species are vulnerable to stochastic (random) events—natural but damaging environmental perturbations and catastrophes such as droughts, storm damage, disease outbreaks, and fires, from which large wide-ranging populations can generally recover, but may lead to extirpation of small isolated

populations (Gilpin and Soule 1986). The majority of the remaining habitat associated with the three species is vernal pools and swales in the Santa Rosa Plain. The nature of the vernal pool and swale habitat associated with the three plants may also increase the effects of drought. Vernal pools and swales are inundated only briefly and may not fill during dry years. As a result, we consider stochastic events to be of significant concern for these species. Isolated, small occurrences may also be at risk from a decrease in reproductive rate resulting from decreasing population density. The correlation of reproductive rate with population density, called the Allee effect, may be the result of either increased density or quality of compatible mates, or increased pollination, or both (Stephens et al. 1999). In small populations, if either the plants or their pollinators decline, consequences on the reproductive output of the other may result in an extinction vortex in which each generation is more likely to go extinct (Gilpin and Soulé 1986, Soulé and Mills1998). (USFWS, 2016)

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Service found that many existing regulatory mechanisms were not sufficient to protect plants, including section 404 of the Clean Water Act, the protections of the California Endangered Species Act, and the California Environmental Quality Act. The 1991 final rule also found that listing the plants under the Federal Endangered Species Act would provide better protection by requiring the Army Corps of Engineers (and other Federal agencies) to consult with the Service prior to final determinations on a proposed activity. (USFWS, 2016)

**Stressor:** Non-native invasive species (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Creating a drier habitat and facilitating the invasion of non-native upland species, may permanently change the plant community and the non-native plants may outcompete the listed species (Bauder 2000, Marty 2005, competition discussed further below). With insufficient water, the distribution of plant species that are normally found higher on the edge of the vernal pools may shift downward along the moisture gradient in response to the introduction of invasive plants that now flourish at pool edges. Non-native grasses maintain dominance at pool edges, sequestering light and soil moisture, promoting thatch build-up, and shortening inundation periods. Species strongly associated with vernal pools may disappear from shallow pools as a result of invasion by upland non-native plants. In addition, the invasive species can further alter the hydrology of the site by reducing the inundation period (Marty 2005). Reduction in inundation period is thought to be due to increased evapo-transpiration associated with dense cover of nonnative plants at the vernal pools (Marty 2005). Once non-native, invasive plants are introduced to vernal pools, competition with native species can come from several interactions including root competition (roots of one species are more efficient at absorbing moisture and nutrients from the soil) and pollination success (one species will set more seed and produce more plants). Plant size can also confer superiority when competing with smaller plants. A larger plant can shade smaller or shorter plants and seedlings, depriving them of adequate sunlight which is necessary for plant and seedling growth and survival, and in some cases necessary for seed germination (Barbour et al. 1987). (USFWS, 2016)

***Recovery***

**Reclassification Criteria:**

A/1: Seventy-five percent of extant, native occurrences, not protected as of December 2014, within each core area (Windsor Core Area, Alton Lane Core Area, and Lasthenia burkei Southern Core Area) are permanently protected and managed to maintain the habitat and the current geographic, elevational, and ecological distribution of the species. Priority should be given to occurrences that are isolated and/or genetically unique.(USFWS, 2016)

A/2: The following additional habitat is needed in order to delist or downlist L. burkei. New preserves consist of a minimum of 50 ac in the Windsor Core Area, a minimum 400 ac in the Alton Lane Core Area, and a minimum of 400 ac in the Lasthenia burkei Southern Core Area. These preserves will consist of occupied habitat that is not protected as of December 2014. The ecological integrity (e.g., water quality, hydrology, and uplands condition) of these areas is not threatened by adverse habitat modification. Buffers between the protected habitat and incompatible land uses must be sufficient to ensure that there are no significant adverse effects to Lasthenia burkei, such as changes in hydrology, or contamination by pesticides or herbicides, currently and into the foreseeable future. (USFWS, 2016)

A/3: New preserves (comprised of restored or created habitat) must be 10 ac or greater; however, preserves with existing native occurrences or those providing protection to a large occurrence are less than 10 ac. The preserves are as near to new or existing preserves as possible. (USFWS, 2016)

A/4: New preserves have no greater than 20 percent wetlands at each site (no more than 2 ac of vernal pools and swales in each 10 ac preserve). The total new preserve acreage in the core areas includes a minimum of 125 ac of vernal pools and swales distributed among the Alton Lane Core Area, Lasthenia burkei Southern Core Areas, and Windsor Core Area. (USFWS, 2016)

A/5: Service-approved conservation and management plans that protect vernal pool habitat and upland habitat and address effects of invasive plants are developed and are being effectively implemented. (USFWS, 2016)

A/6: Service shall work with Mosquito Abatement Districts so that their practices in the core and management areas are implemented to avoid impacts to the species. (USFWS, 2016)

E/1: All native occurrences, extant as of December 2014, are replicated at 1:2 (tripled in numbers of occurrences) in permanently protected sites in the three core areas. Replication is accomplished by collecting seed or inoculum from a natural occurrence and planting it at additional sites. For example: collecting seed or inoculum at one site and planting it at two additional sites increases the original single occurrence to 3 occurrences (1:2); planting it at three additional sites increases the original occurrence to 4 occurrences (1:3). (USFWS, 2016)

E/2: The preserves noted in Factor A are occupied by Lasthenia burkei at a density of 500 plants per square meter when measured on a 25- year moving average which includes at least one above average and one average rainfall year, and a multi-year drought. A multi-year drought is defined as a period of 3 or more years of below average local rainfall. (USFWS, 2016)

E/3: Service-approved conservation and management plans that protect vernal pool habitat and upland habitat and address effects of small occurrence size and climate change, among other threats, are developed and are being effectively implemented. (USFWS, 2016)

Recovery Priority Number: 2C

**Delisting Criteria:**
A/1: At least 90 percent of native occurrences of Lasthenia burkei, extant as of December 2014, have been protected in perpetuity. (USFWS, 2016)

A/2: New preserves have no greater than 20 percent wetlands at each site (no more than 2 ac of vernal pools and swales in each 10 ac preserve). (USFWS, 2016)

E/1: In addition to replication noted in E/1 of the downlisting criteria for Lasthenia burkei, all occurrences in management areas have been replicated at 1:2 at permanently protected appropriate locations. (USFWS, 2016)

E/2: All replicate occurrences in management areas have achieved the same density (500 plants per square meter) as the core area occurrences. (USFWS, 2016)

E/3: All genetically unique and isolated unprotected sites in management areas are permanently protected in situ. Identification of some genetically unique occurrences is not yet known but will be determined during research as defined in the Recovery Plan. (USFWS, 2016)

**Recovery Actions:**
- 1. Protect extant occurrences and potential habitat for Lasthenia burkei. Natural areas that are known to contain species covered in this recovery plan should be protected in perpetuity through land acquisition, conservation easements, or other means. Protection of these areas will need to be followed by identification of threats and application of appropriate and adaptive management to ensure abatement of these threats. In addition to areas that currently support the species, two other types of natural areas also need to be protected or secured: areas where the endangered plants have been found in the past but not been seen recently, and that retain habitat that can be readily restored so that plants can be reintroduced successfully; and areas where the plants have not been found but are appropriate for vernal pool creation, and subsequent introduction of the endangered plants. (USFWS, 2016)
- 2. Develop a central database for survey data from all natural and created occurrences of Lasthenia burkei including information on protection status. Data should include numbers of plants; area occupied by the species; presence of invasive species; site condition; land ownership; level of management; disturbance; whether the site is natural, restored, or created; and degree of genetic uniqueness. If the site has been seeded, the origin of the seed should be identified by name and location of parcel where seed was collected, location of specific pools where seed was collected, and date of seed collection. Any observations of pollinators, such as species or type of pollinator, should also be recorded. This information will serve as the current baseline for evaluating progress of the Factor A and Factor E comparative downlisting and delisting recovery criteria for each of the three plant species. This database should be updated regularly and should be available to all management agencies (USFWS, 2016). In addition, the database should track the location of source seed

for sites with created occurrences (USFWS, 2019).

- 3. Collect and store seed from all occurrences of Lasthenia burkei. Seed collections for each plant taxon should be representative of both population- and species-level genetic diversity; seeds should be collected from multiple plants at each occurrence. Seed collection guidelines published by the Center for Plant Conservation (1991) should be followed. Seed collection should be conducted with caution to ensure that donor populations are not adversely affected by the collection. No more than 5 percent of the reproductive output should be removed from donor populations. Store seeds at two storage facilities certified by the Center for Plant Conservation. Seeds should be collected every 5 years to ensure that seeds in storage are viable. Permits will be required for collecting federally-listed plant seed on federal lands. (USFWS, 2016)
- 4. Survey historical locations and other potential habitat (not previously surveyed) where Lasthenia burkei may occur. (USFWS, 2016)
- 5. Conduct research necessary to develop a population viability analysis for Lasthenia burkei. Table 2 of the Recovery Plan lists research tasks needed for the development of a population viability analysis for all three species in the Recovery Plan. All research tasks need to be performed for each of the three species. To maximize efficiency, it may be possible to study the effects of an experimental factor on all three species in the Recovery Plan via the same experiment. (USFWS, 2016)
- 6. Conduct necessary biological research on Lasthenia burkei and use results to guide recovery efforts. Table 6 of the Recovery Plan the needed research tasks for the recovery of Blennosperma bakeri, Lasthenia burkei, and Limnanthes vinculans. All research tasks need to be performed for each of the three species. To maximize efficiency, it may be possible to study the effects of an experimental factor on all three species via the same experiment. (USFWS, 2016)
- 7. Habitat management for Lasthenia burkei. Develop adaptive management plans and implement appropriate management actions for all protected sites. Work with local agricultural commissions to track conversion of agricultural uses to vineyards or other non-suitable agricultural uses. Decrease acreage of vernal pool habitat within priority preservation and restoration areas that are subjected to altered hydrologic regimes through irrigation practices. Develop treatment protocol with mosquito abatement district to avoid impacts to listed species and vernal pool habitat during treatment. (USFWS, 2016)
- 8. Restore or create vernal wetlands, followed by reintroduction of the species per a restoration techniques white paper and a Reintroduction and Genetic Management Plan. As noted in the Factor A discussion, much of the habitat and occurrences of the three listed plants has been destroyed or fragmented by urban development and conversion to agricultural use. Restoration or creation of habitat, when appropriate, will be necessary to maintain the numbers of plants and occurrences at levels sufficient for survival of the species. Restoration and creation of vernal pool habitat has been conducted for many years in the Santa Rosa Plain for the three plants. To better understand these processes and their rates of success, a white paper and a Reintroduction and Genetic Management Plan should be developed. (USFWS, 2016)
- 9. Monitor all protected occurrences. Monitoring plans should be developed and implemented for all protected natural and replicated occurrences. Protected occurrences should be monitored annually for plant density, area occupied by the listed species, site condition, changes in hydrology, application of recycled water and wastewater, effects of grazing, invasive species, vandalism, and whether management is appropriate for the listed

species' needs. The responsible party for monitoring should also keep an ongoing record of management activities and precipitation on the site, so that changes in rare plant populations can be related to changes in management activities. Monitoring efforts for co-occurring species should be coordinated to increase efficiency and reduce costs. (USFWS, 2016)

- 10. Engage and educate the public about Lasthenia burkei recovery. Public education and outreach is important to inform residents and land managers in the Santa Rosa Plain and other areas that support habitat for the species about the significance of the plants and the importance of management and protection of habitat for their persistence. Education and outreach activities should include: (1) develop a public outreach plan, (2) outreach to enhance public understanding of vernal wetlands in general and of imperiled vernal wetland species in particular, (3) information on regulatory responsibilities with regard to endangered species, (4) programs to encourage local interest and involvement in site stewardship, and (5) programs including conservation easements and incentive programs that are available to landowners who may have the vernal pool species on their land. (USFWS, 2016)
- 13. Agency coordination. Partner with California Department of Fish and Wildlife, Army Corps of Engineers, Regional Water Quality Control Board, Sonoma County, Marin/Sonoma Mosquito and Vector Control District, and Cities of Santa Rosa, Cotati, Rohnert Park, and Windsor to ensure resource management practices are aligned with species conservation needs. Resource management practices to be addressed include: irrigation of vernal pool habitat with recycled water and wastewater within priority preservation and restoration areas; protection of habitat buffers; stream ordinances, grading ordinances, and water quality regulations; and vineyard conversion or other agricultural conversion of areas adjacent to vernal pool habitat that contribute to hydrologic regime and/or provide upland habitat for sustaining the Sonoma County California tiger salamander. Provide legal assurances to willing landowners who implement projects that provide a net conservation benefit. (USFWS, 2016)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of Burke's goldfields. Some of these recommendations have already been discussed in previous recovery documents (Service 2016, pp. 91–103; Service 2019, p. 5) and remain valid. Recommendations from the recovery plan contain their action number in parentheses (Service 2016, pp. 91–103). 1. Habitat Acquisition, Management, and Restoration. Roughly only 44% of extant occurrences are currently protected. All extant occurrences of and potential habitat for Burke's goldfields present should be protected (Action 1.0). Resource agencies and private partner groups should work to ensure land protection through acquisition or easement, and large unprotected areas currently occupied by the species should be given the highest priority. Large, formerly occupied sites that are unoccupied but have a high restoration potential should also be considered. Protected lands must also be adequately managed or restored based on the best available science (Action 7.0). Vernal wetland restoration or creation and subsequent reintroduction of Burke's goldfields may be necessary to maintain occurrences at levels sufficient for survival of the species. To better understand these processes and their rates of success, a white paper and a Reintroduction and Genetic Management Plan should be developed (Action 8.0). 2. Determine Population Distribution and Abundance through Regular Monitoring. Since the 2019 review, seven of the 36 Diversity Database occurrences have been observed, but most occurrences have not been seen in five to ten years, with Occurrence

#36 recorded as not being seen since 1929. Conducting comprehensive surveys of historical and natural Burke's goldfields Diversity Database occurrences and continuous monitoring of all protected occurrences is vital to understanding population shifts and threats (Action 9.0). To better understand the extent of Burke's goldfields, the Service recommends surveying historical locations and other potential habitat (not previously surveyed) where Burke's goldfields may occur (Action 4.0). These results should also be used to help inform decisionmakers about the acquisition of appropriate sites where Burke's goldfields occur but are unprotected, to suggest sites that could be acquired for restoration, and to develop an adaptive management program that will achieve the recovery of Burke's goldfields. 3. Seed Collection, Research, and Planting. Seed collection and germination and genetic analyses are crucial to understanding which Burke's goldfields occurrences contain the seeds with the highest possibility of success during reintroduction to other locations. The Service recommends collecting and storing Burke's goldfields seeds from extant populations found during comprehensive surveys (Action 3.0). Seed collection results should be compiled into a list that qualitatively describes the environmental conditions of the collection site and the treatment techniques used. Partner groups should conduct further research on the genetic diversity of seedlings from different occurrences, germination success rate, and replanting success rate. 4. Explore the effect of climate change on vernal pool hydrology and species viability. Assess how climate change impacts, including increased variability in temperature and precipitation, more frequent extreme weather events, and a trend of warmer and drier conditions, will impact vernal pool hydrology. Assess how future climate conditions will impact population dynamics through changes in survival, reproduction, and resilience of the soil seed bank. Determine which Burke's goldfields populations are most vulnerable to climate change to prioritize conservation actions. 5. Public and Agency Engagement. Engage and educate the public about Burke's goldfields recovery (Action 10.0). Partner with agencies such as the Department, Army Corps of Engineers, Sonoma County, and the City of Santa Rosa to conduct resource management practices (Action 13.0) (USFWS, 2024).

# SPECIES ACCOUNT: *Lasthenia conjugens* (Contra Costa goldfields)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 06/18/1997; Pacific Southwest (R8) (USFWS, 2017)

**Physical Description**

An annual herb, 1-4 dm tall, that produces showy yellow flower heads in the spring (NatureServe, 2015). The achenes (fruit) of L. conjugens are less than 1.5 millimeters (0.06 inch) long and always lack a pappus (the hair-like or scale-like structures attached to an achene, which assist in dispersal; Ornduff 1969, Ornduff 1993) (USFWS, 2013).

**Taxonomy**

The two closest relatives of Lasthenia conjugens are L. burkei (Burke's goldfields) and L. fremontii (Fremont's goldfields) (USFWS, 2005).

**Historical Range**

Historically occurred in seven vernal pool regions: Central Coast, Lake-Napa, Livermore, Mendocino, Santa Barbara, Santa Rosa, and Solano-Colusa (Keeler-Wolf et al. 1998). In addition, several historical occurrences in Contra Costa County are outside of the defined vernal pool regions (Keeler-Wolf et al. 1998). Ornduff (1966) reported collections from 13 sites in Alameda, Contra Costa, Mendocino, Napa, Santa Barbara, Santa Clara and Solano counties. Although he cited three specimens each from Contra Costa and Santa Barbara Counties, Ornduff (1966; 1979) noted that the species was most common in Solano County. One additional site in Alameda County was documented in 1959 by G. Thomas Robbins, who collected a specimen (# 3963, housed at the Jepson Herbarium) on the "shore of the San Francisco Bay" south of Russell (Service 2005a; USFWS, 2013).

**Current Range**

L. conjugens has been reported in ten counties within California: Alameda, Contra Costa, Marin, Mendocino, Monterey, Napa, Santa Barbara, Santa Clara, Solano, and Sonoma (CNDDB 2012; USFWS, 2013). Currently, the distribution of the species remains as described in our 2013 status review. The Diversity Database now reports 36 occurrences of Contra Costa goldfields (Appendix A; Diversity Database 2023, entire). The two occurrences (occurrences #45 & 46) added to the Diversity Database since the 2013 status review are found in Solano County in proximity to other known occurrences on Travis Air Force Base and are mapped as "transplanted populations" (Diversity Database 2023, p. 41). These occurrences do not represent new populations of Contra Costa goldfields, but are part of ongoing conservation efforts and mitigation for projects on Travis Air Force Base (Collinge 1999, entire) (discussed in Conservation Efforts). These transplanted occurrences are within the previously known range of the species and do not change our understanding of the distribution of the species (USFWS, 2024).

**Critical Habitat Designated**

Yes; 8/6/2003.

**Legal Description**

On August 11, 2005, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Lasthenia conjugens (Contra Costa goldfields) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes eight critical habitat units (CHUs), in California (70 FR 46924-46999).

**Critical Habitat Designation**

The critical habitat designation for Lasthenia conjugens includes eight CHUs in Alameda, Contra Costa, Mendocino, Napa, and Solano counties, California. This species critical habitat encompasses approximately 14,730 acres (71 FR 7118-7316).

Unit 1: Mendocino County, California. From USGS 1:24,000 scale quadrangle Point Arena.

Unit 2: Napa County, California. From USGS 1:24,000 scale quadrangles Yountville, Capell Valley.

Unit 3: Napa County, California. From USGS 1:24,000 scale quadrangles Napa, Cuttings Wharf.

Unit 4: Solano County, California. (i) Unit 4A: Solano County, California. From USGS 1:24,000 scale quadrangle Fairfield South. (ii) Unit 4B: Solano County, California. From USGS 1:24,000 scale quadrangles Fairfield South. (iii) Unit 4C: Solano County, California. From USGS 1:24,000 scale quadrangles Elmira, Denverton.

Unit 5: Solano County, California. (i) Unit 5A: Solano County, California. From USGS 1:24,000 scale quadrangle Elmira. (ii) Unit 5B: Solano County, California. From USGS 1:24,000 scale quadrangles Elmira, Denverton.

Unit 6: Contra Costa County, California. From USGS 1:24,000 scale quadrangle Benicia.

Unit 7: Contra Costa County, California. From USGS 1:24,000 scale quadrangles Byron Hot Springs, Clifton Court Forebay.

Unit 8: Alameda County, California. (i) Unit 8A: Alameda County, California. (ii) Unit 8B: Alameda County, California. From USGS 1:24,000 scale quadrangles Milpitas, Niles.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Lasthenia conjugens critical habitat consists of two components (70 FR 46924-46999):

(i) Topographic features characterized by isolated mound and intermound complex within a matrix of surrounding uplands that result in continuously, or intermittently, flowing surface water in the depressional features including swales connecting the pools described below in paragraph (2)(ii), providing for dispersal and promoting hydroperiods of adequate length in the pools;

(ii) Depressional features including isolated vernal pools with underlying restrictive soil layers that become inundated during winter rains and that continuously hold water or whose soils are saturated for a period long enough to promote germination, flowering, and seed production of predominantly annual native wetland species and typically exclude both native and nonnative upland plant species in all but the driest years. As these features are inundated on a seasonal basis, they do not promote the development of obligate wetland vegetation habitats typical of permanently flooded emergent wetlands;

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the areas determined to be essential for conservation may require special management considerations or protections. As we undertake the process of designating critical habitat for a species, we first evaluate lands defined by those physical and biological features essential to the conservation of the species for inclusion in the designation pursuant to section 3(5)(A) of the Act. Secondly, we then evaluate lands defined by those features to assess whether they may require special management considerations or protection. In designating critical habitat, we also have considered how this designation highlights habitat that needs special management considerations or protection. For example, we have many regional HCPs under development, and this designation will be useful in helping applicants determine what vernal pool habitat areas should be highest priority for special management or protection, and where there may be more flexibility in conservation options. This designation will guide them and us in ensuring that all local habitat conservation planning efforts are consistent with conservation objectives for these species. Once a vernal pool habitat has been protected from direct filling, it is still necessary to ensure that the habitat is not rendered unsuitable for vernal pool species because of factors such as altered hydrology, contamination, nonnative species invasions, or other incompatible land uses. Many of the factors that cause the decline and localized extirpation of vernal pool species can be avoided. Actions that should be avoided include the following: (1) Actions that increase competition from invasive species as many of the species addressed in this rule are threatened by invasion of nonnative species (CNDDB 2001). (2) Alteration of natural hydrology such as construction of dams or other structures that artificially increase the length of vernal pool inundation or construction of ditches that artificially drain vernal pools. (3) Human degradation of vernal pools such as off-road vehicle use, dumping, and vandalism that threatens many of the species addressed in this rule.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: cross-pollination (USFWS, 2013)

**Lifespan**

Adult: One year (see physical description)

**Breeding Season**

Adult: March - June (USFWS, 2013)

**Key Resources Needed for Breeding**

Adult: Insect pollinators (USFWS, 2005)

**Reproduction Narrative**

Adult: L. conjugens flowers from March to June (Ornduff 1966, Ornduff 1976) and is self-incompatible (USFWS, 2013). Although L. conjugens has not been the subject of pollinator studies, observations suggest that the same insects visit all outcrossed species of Lasthenia, rather than concentrating on any particular species (Thorp 1976). Insect visitors to flowers of

Lasthenia belong to five orders: Coleoptera, Diptera, Hemiptera (true bugs), Hymenoptera, and Lepidoptera (Thorp and Leong 1998). Most of these insects are generalist pollinators. All of the specialist pollinators of Lasthenia are solitary bees (family Andrenidae); these pollinators include two species in the subgenus Diandrena (Andrena submoesta and A. puthua) and five or six species in the subgenus Hesperandrena (Andrena baeriae, A. duboisi, A. lativentris, and two or three undescribed species) (Thorp and Leong 1998) (USFWS, 2005).

**Habitat Type**

Adult: Wetland (USFWS, 2013)

**Habitat Vegetation or Surface Water Classification**

Adult: Northern Basalt Flow, Northern Claypan, and Northern Volcanic Ashflow vernal pools (USFWS, 2013)

**Geographic or Habitat Restraints or Barriers**

Adult: Typically occurs < 200 ft. elevation, but may occur up to 1465 ft. (USFWS, 2013)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Inhabits vernal pools in open grassy areas at elevations up to 470 m (NatureServe, 2015). Lasthenia conjugens typically grows in vernal pools, swales, and low depressions in open valley and foothill grasslands and have been found in three types of vernal pools: Northern Basalt Flow, Northern Claypan, and Northern Volcanic Ashflow (Sawyer and Keeler-Wolf 1995). This species is commonly found at elevations less than 61 meters (m) (200 feet (ft)) but has been documented at 445 m (1465ft) in Napa County and at 137 m (450ft) in Monterey County (CNDDB 2012)(USFWS, 2013).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seed dispersal mechanisms in Lasthenia conjugens are unknown. However, the lack of a pappus or even hairs on the achenes makes wind dispersal unlikely (Ornduff 1976) (USFWS, 2005).

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

25 presumed extant occurrences (USFWS, 2024)

**Population Narrative:**

Of the 23 presumed extant records, four occurrences may now be extirpated: (1) an occurrence in Mendocino County has not been observed since 1937; (2) an occurrence in Alameda County has not been observed since 1959; (3) in 1987, a single plant was observed in Napa County and has not been documented since; (4) an occurrence in Solano County was noted on a field checklist in1996 and the location is unknown (CNDDB 2012). Ramp Neale et al. (2008) found high levels of genetic diversity and moderate levels of differentiation among populations (USFWS, 2013). Currently, the distribution of the species remains as described in our 2013 status review. The Diversity Database now reports 36 occurrences of Contra Costa goldfields (Appendix A; Diversity Database 2023, entire). The two occurrences (occurrences #45 & 46) added to the Diversity Database since the 2013 status review are found in Solano County in proximity to other known occurrences on Travis Air Force Base and are mapped as “transplanted populations” (Diversity Database 2023, p. 41). These occurrences do not represent new populations of Contra Costa goldfields, but are part of ongoing conservation efforts and mitigation for projects on Travis Air Force Base (Collinge 1999, entire) (discussed in Conservation Efforts). These transplanted occurrences are within the previously known range of the species and do not change our understanding of the distribution of the species. Seven occurrences continue to be considered extirpated and four are considered potentially extirpated (Diversity Database 2023, entire). The majority of the presumed extant occurrences are located in Solano County, where 13 occurrences are presumed extant (Diversity Database 2023, pp. 4–41). Other large concentrations of occurrences are in Monterey County and Alameda County, each with three occurrences (Diversity Database 2023, p. 25). Of the 25 presumed extant records, 4 occurrences may now be extirpated having not been seen for some time or the exact location is unknown (Diversity Database 2023, p. 39): (1) An occurrence (occurrence #16) in Mendocino County has not been observed since 1937; (2) An occurrence (occurrence #37) in Alameda County has not been observed since 1959; (3) A single plant (occurrence #21) was observed in Napa County in 1987 and has not been documented since; and (4) An occurrence (occurrence #43) in Solano County was noted on a field checklist in 1996 and the specific location of the occurrence is unknown. The distribution of Contra Costa goldfields is uncertain due in part to the difficulty of relocating sites and because this species may reappear on a site after several years of it being absent. In December 2022, Vollmar Natural Lands Consulting, as part of the Contra Costa goldfields captive propagation and reintroduction to Contra Costa County project (discussed in Conservation efforts), conducted a status survey of 20 subpopulations associated with 9 known Contra Costa goldfields occurrences (occurrences # 1, 3, 7, 20, 23, 24, 30, & 33). Data from these status surveys have not yet been added to the Diversity Database. Their findings are in line with previous understanding of Contra Costa goldfields habitat requirements. They found that while Contra Costa goldfields occurs in a wide range of habitats, all occupied sites have similar characteristics: grassland habitat grazed by cattle, seasonally wetted soils, and fine-grained soil with high clay or silt content that is likely alkaline. Abundance: The final listing rule provided no abundance data for Contra Costa goldfields. The 2008 status review stated that informal status surveys had occurred at five occurrences and that annual monitoring had been initiated at various localities in Solano County in support of development of the Solano Habitat Conservation Plan (Service 2008, p. 14). The 2013 status review presented the results of informal status surveys conducted at several occurrences and monitoring data for the five Solano County occurrences that were censused annually for 3- or 4-year periods between 2006 and 2011 (Service 2013, p. 6). Overall, Contra Costa goldfields population size can vary greatly season to season based on rainfall and other site-specific factors (e.g., prevalence of invasives, thatch ground cover, grazing practices, etc.). Only a few of the known occurrences have long term monitoring in place from which population dynamics and trends can be identified, which are described below. Initial abundance estimates from the Contra Costa goldfields captive propagation and reintroduction to Contra Costa County project (discussed in Conservation efforts) are presented in Appendix A. Additional years of monitoring are needed to better understand the population dynamics and trends at these locations (Vollmar 2022, pp. 5– 6). The 2019 annual report for the Noonan Ranch Conservation Bank (Conservation Bank) in Solano County, California, was submitted to the Service by LSA Associates, Inc. in February 2020. The report includes the results of the initial years (2008–2013 and 2019) of long-term monitoring for the Contra Costa goldfields population at the Conservation Bank (Occurrence #24). Monitoring for Contra Costa goldfields on the Conservation Bank will continue every five years. Table 1 below provides a summary of the monitoring results through 2019. According to the report, Contra Costa goldfields continues to occur in the majority of the wetlands on the Conservation Bank with distribution, emergence, and density varying within individual wetlands (LSA 2020, entire). Contra Costa goldfields populations are only found within wetlands with specific hydrologic characteristics (LSA 2020, pp. 2–6). Average percent cover on the Conservation Bank during this time period varied from 9.9 percent in 2012 to 31 percent in 2019 (LSA 2020, pp. 2–5). This variation in average percent cover is largely attributed to the number of small wetlands present on the Conservation Bank in a given year. The number of small wetlands with conditions suitable for Contra Costa goldfields germination and growth on the landscape is highly dependent on the seasonal timing of rainfall (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (NatureServe, 2015)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** One of the primary threats to L conjugens is conversion of landuse, for example residential and industrial development, wetland drainage, and agricultural land conversion (including vineyards) (USFWS 2008). Since 65% of this species occurs on private land and is not protected, this is an ongoing problem (USFWS 2008). Just as significant are such associated threats as introduced invasive plants (like Italian ryegrass and waxy mannagrass), recreational uses (such as off-road, equestrian, and mountain bike traffic), road construction and widening, and the resulting habitat fragmentation (USFWS 2008). Other threats to the species include landfill expansion, gravel mining, and both intensive grazing practices and the lack of grazing (USFWS 2008). Moderate grazing (in stocking numbers, frequency, and duration) is important to keeping invasive plants in check and improving soil conditions when burning is not possible (USFWS 2008) (NatureServe, 2015).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Endangered Species Act is the primary Federal law that provides protection for this species since its listing as endangered in 1997. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent its status under the Act. Therefore, the Service believes other laws and regulations have limited ability to protect the species in absence of the Endangered Species Act (USFWS, 2013).

**Stressor:** Invasive plants (USFWS, 2013)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Competition from invasive plant species poses a primary threat to this species. Non-native grasses occur commonly in vernal pool complexes and have become a threat to native vernal pool species through their capacity to change pool hydrology. Non-native grasses maintain dominance at pool edges, sequestering light and soil moisture. Lolium multiflorum and Glyceria declinata (waxy mannagrass) increase thatch buildup, which leads to increased oxygen depletion in the pools (Dunne and Leopold 1978) and contributes to the shortening of inundation periods through increased evapotranspiration (Marty 2005). As vernal pool complexes become surrounded by residential development and disturbed habitat, the likelihood of invasion by nonnative plants increases (Zedler and Black 2004) (USFWS, 2013).

**Stressor:** Inappropriate grazing regimes (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Both lack of grazing and excessive grazing may cause an increase in organic matter in the habitat that can eliminate the natural vernal pool invertebrate community and promote opportunistic and invasive nonnative species, such as Lolium spp., that outcompete the obligate vernal pool species (Rogers 1998; Rogers 2006). The cessation of cattle grazing has been found to exacerbate the negative effects of invasive non-native plants on vernal pool inundation period. Appropriate levels of grazing may help maintain soil conditions and limit the amount of thatch accumulation near vernal pools (Rogers 2006). Increased grass cover in and around ungrazed pools may lead to an increase in evapotranspiration rates, resulting in a decreased hydroperiod (Marty 2005). In areas where long-term grazing has been in effect, moderate grazing (in both stocking numbers and amount of time) may be an important tool in combating non-native plant species, when burning is not an option. Moderate grazing may be a necessary tool to maintain the species diversity of the natural vernal pool ecosystem (Marty 2005) (USFWS, 2013).

**Stressor:** Climate change (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** It is unknown at this time if climate change in California will result in a localized, relatively small cooling and drying trend, or a warmer trend with higher precipitation events (Pyke 2005). Lasthenia conjugens is dependent upon vernal pool wetlands that signify the importance of water availability on the survival and recovery for this species. If California receives more rainfall through intense precipitation events, suitable vernal pool habitat for L. conjugens may increase, which would benefit the species. However, if California enters into a drying trend, the resulting droughts could adversely affect L. conjugens. While drought conditions are a normal part of environmental variability in California, a severe drought would exacerbate adverse effects associated with small, disjunct populations of Lasthenia conjugens, and would place additional strains on vernal pool ecosystems (USFWS, 2013).

***Recovery***

**Reclassification Criteria:**

1. Habitat protection: Accomplish habitat protection that promotes vernal pool ecosystem function sufficient to contribute to population viability of the covered species. 1A. Suitable vernal pool habitat within each prioritized core area for the species is protected. 1B. Species localities distributed across the species' geographic range and genetic range are protected. Protection of extreme edges of populations protects the genetic differences that occur there. 1C. Reintroduction and introductions must be carried out and meet success criteria. 1D. Additional localities that are detected (and determined essential to recovery goals) are permanently protected. 1E. Habitat protection results in protection of hydrology essential to vernal pool ecosystem function, and monitoring indicates that hydrology that contributes to population viability has been maintained through at least one multi-year period that includes above average, average, and below average local rainfall as defined above, a multi-year drought, and a minimum of 5 years of post-drought monitoring (USFWS, 2013).

2. Adaptive Habitat Management and Monitoring: 2A. Habitat management and monitoring plans that facilitate maintenance of vernal pool ecosystem function and population viability have been developed and implemented for all habitat protected, as previously discussed in sections 1A-E. 2B. Mechanisms are in place to provide for management in perpetuity and long-term monitoring of 1A-E, as previously discussed (funding, personnel, etc.). 2C. Monitoring indicates that ecosystem function has been maintained in areas protected under 1A-D for at least one multi-year period that includes above average, average, and below average local rainfall, a multi-year drought, and a minimum of 5 years of postdrought monitoring. 2D. Seed banking actions have been completed for species that would require it as insurance against risk of stochastic extirpations or that will require reintroductions or introductions to contribute to meeting recovery criteria (USFWS, 2013).

3. Status Surveys: 3A. Status surveys, 5-year reviews, and population monitoring show populations within each vernal pool region where the species occur are viable (e.g., evidence of reproduction and recruitment) and have been maintained (stable or increasing) for at least one multiyear period that includes above average, average, and below average local rainfall, a multiyear drought, and a minimum of 5 years of post-drought monitoring. 3B. Status surveys, status reviews, and habitat monitoring show that threats identified during and since the listing process have been ameliorated or eliminated. Site-specific threats identified through standardized site assessments and habitat management planning also must be ameliorated or eliminated (USFWS, 2013).

4. Research: 4A. Research actions necessary for recovery and conservation of the covered species have been identified (these are research actions that have not been specifically identified in the recovery actions but for which a process to develop them has been identified). Research actions (both specifically identified in the recovery actions and determined through the process) on species biology and ecology, habitat management and restoration, and methods to eliminate or ameliorate threats have been completed and incorporated into habitat protection, habitat management and monitoring, and species monitoring plans, and refinement of recovery criteria and actions. 4B. Research on genetic structure has been completed (for species where necessary - for reintroduction and introduction, seed banking) and results incorporated into a habitat protection plan to ensure that within- and among-population genetic variation is fully representative by populations protected in the Habitat Protection section of this document, described previously in sections 1A-E. 4C. Research necessary to determine appropriate parameters to measure population viability for each species has been

completed (USFWS, 2013).

5. Participation and Outreach: 5A. Recovery Implementation Team is established and functioning to oversee rangewide recovery efforts. 5B. Vernal pool regional working groups are established and functioning to oversee regional recovery efforts. 5C. Participation plans for each vernal pool region have been completed and implemented. 5D. Vernal pool region working groups have developed and implemented outreach incentive programs that develop partnerships contributing to achieving recovery criteria 1- 4 (USFWS, 2013).

Recovery Priority Number: 5C

**Delisting Criteria:**
See reclassification criteria.

**Recovery Actions:**
- Protect vernal pool habitat in the largest blocks possible from loss, fragmentation, degradation, and incompatible uses (USFWS, 2005).
- Manage, restore, and monitor vernal pool habitat to promote the recovery of listed species and the long-term conservation of the species of concern (USFWS, 2005).
- Conduct range-wide status surveys and status reviews for all species addressed in this recovery plan to determine species status and progress toward achieving recovery of listed species and long-term conservation of species of concern (USFWS, 2005).
- Conduct research and use results to refine recovery actions and criteria, and guide overall recovery and long-term conservation efforts (USFWS, 2005).
- Develop and implement participation programs (USFWS, 2005).
- L. conjugens occurrences that are currently protected and managed for the benefit of the species include: (1) the North Suisun Mitigation Bank, in Solano County, (2) Travis AFB, in Solano County, (3) the State Route 4 Preserve, in Contra Costa County, (4) Don Edwards San Francisco Bay NWR, in Alameda County, and (5) the former Fort Ord, in Monterey County. Protection of additional localities of this species is necessary to recover this species. Protecting occurrences in Sonoma, Marin, and Napa Counties should be a priority over the next five years, as this is the northwestern edge of the species' range, and no occurrences in these counties are protected at this time (USFWS, 2013).
- Once additional sites are protected, management plans should be prepared. Results from standardized monitoring discussed in item 3, below, should be included in the management plans for these protected sites. Grazing management and invasive weed control should be primary components of these management plans (USFWS, 2013).
- Conduct research at as many of the presumed extant localities as possible to incorporate research recommendations outlined in the Recovery Plan. The following research should be prioritized over the next five years: a. Develop a standardized method to monitor species status and population trends at all known locations. This will better our understanding of potential threats to the species, and will aid in the development of methods to ameliorate these threats. b. Conduct research on invasive weedy plant species to determine the most appropriate methods to control these plants and increase population numbers of L. conjugens and other listed vernal pools plants. c. Conduct further research on the genetic structure of the species to determine the feasibility of introducing L. conjugens to biologically appropriate vernal pool regions and soil types from which status surveys

indicate the species has been extirpated (USFWS, 2013).
- Regional vernal pool working groups should be created in regions where L. conjugens is known to occur to aid with monitoring and management efforts (USFWS, 2013).
- Conduct additional research on how L. conjugens is pollinated. If certain insects are found to be important to pollination, and therefore to seed production, their habitat must be protected in each core area to contribute to the recovery of L. conjugens (USFWS, 2013).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of Contra Costa goldfields. Some of these recommendations have already been discussed in previous recovery documents (Service 2013, pp. 28–29) and remain valid. 1. The majority of known localities of this species are on private land and not protected. Protection of additional localities is necessary to recover this species. Protecting occurrences in Sonoma, Marin, and Napa counties should be a priority over the next five years, as this is the northwestern edge of the species' range, and no occurrences in these counties are protected at this time. 2. Once additional sites are protected, management plans should be prepared. Results from standardized monitoring discussed in item 3, below, should be included in the management plans for these protected sites. Grazing management and invasive weed control should be primary components of these management plans. 3. Conduct monitoring and research at as many of the presumed extant localities as possible to incorporate research recommendations outlined in the Recovery Plan. The following research should be prioritized over the next five years: a. Develop a standardized method to monitor species status and population trends at all known locations. This will better our understanding of potential threats to the species and will aid in the development of methods to ameliorate these threats. b. Conduct research on invasive weedy plant species to determine the most appropriate methods to control these plants and increase population numbers of Contra Costa goldfields and other listed vernal pool plants. c. Conduct further research on the genetic structure of the species to determine the feasibility of introducing Contra Costa goldfields to biologically appropriate vernal pool regions and soil types from which status surveys indicate the species has been extirpated. 4. Regional vernal pool working groups should be created in regions where Contra Costa goldfields is known to occur to aid with monitoring and management efforts. 5. Conduct additional research on how Contra Costa goldfields is pollinated. If certain insects are found to be important to pollination, and therefore to seed production, their habitat should be protected in each core area to contribute to the recovery of Contra Costa goldfields. 6. Expand studies on captive propagation and reintroduction to areas outside of Contra Costa County (USFWS, 2024).

# SPECIES ACCOUNT: *Layia carnosa* (Beach layia)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 05/2/2022; Pacific Southwest (R8) (USFWS, 2022)

**Physical Description**

The unbranched to highly branched plants range up to 6 inches tall and 16 inches across. Characteristics distinguishing Layia carnosa from similar species include its fleshy leaves, inconspicuous flower heads with short, 0.08 to 0.1 inch long white ray flowers and yellow disk flowers, and bristles around the top of the one-seeded achene, or dry fruit (USFWS 1998). The number of seed-heads on individual plants varies with plant size. Typically unbranched, short plants on dry, exposed sites will produce a single head, while highly branched plants in moist dune hollows may produce more than 100 heads (USFWS, 2012).

**Taxonomy**

A member of the sunflower family (Asteraceae) (USFWS, 2012). In 1841, Thomas Nuttall described this species as Madarog/ossa carnosa based on specimens he collected in 1835. In 1843, John Torrey and Asa Gray transferred this species to the genus Layia. In 1892, Edward Greene transferred it to the genus Blepharipappus. However, subsequent taxonomic considerations ofthis species agreed with Torrey and Gray (Munz and Keck 1959; Ferris 1960) (USFWS, 1998).

**Historical Range**

California endemic; Humboldt, Monterey, Marin, and Santa Barbara counties. Believed to be extirpated from San Francisco county (NatureServe, 2015).

**Current Range**

The current distribution includes occurrences spread across six very isolated dune systems (Freshwater Lagoon, Humboldt Bay, mouth of the Mattole River, Point Reyes, Monterey Peninsula, Vandenberg [a part of the Guadalupe-Nipomo Dunes), over about 500 miles of shoreline in northern and central California. Beginning at Freshwater Lagoon Spit in northern Humboldt County, Layia carnosa occurs intermittently over 70 miles of shoreline as far south as the mouth of the Mattole River. From there, it jumps some 170 miles to Point Reyes NS (Marin County), and then another 120 miles to the Monterey Peninsula (Monterey County). From Monterey, a gap of about 150 miles separates it from the southernmost site at Vandenberg AFB, in Santa Barbara County. Five historical occurrences located in San Francisco, Monterey and Humboldt counties are believed to have been extirpated (U.S. Department of the Interior 1998) (USFWS, 2012).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: cross-pollination (based on closely related species) (NatureServe, 2015)

**Lifespan**

Adult: One year (USFWS, 2012)

**Breeding Season**

Adult: April - June (USFWS, 2012)

**Key Resources Needed for Breeding**

Adult: Spring rains (NatureServie, 2015)

**Reproduction Narrative**

Adult: Based on other Layia species, which are self-incompatible, this species would be an obligate outcrosser. It is dependent on spring rains as an annual (NatureServe, 2015). As a winter annual, Layia carnosa germinates during the rainy season between fall and mid-winter, blooms in spring (April to June), and completes its life cycle before the dry season (USFWS, 2012). The number ofseed-heads on individual plants varies with plant size, ranging from unbranched, short, erect plants on dry, exposed sites with a single head to highlybranched plants in moist hollows in dunes with over 100 heads (USFWS, 1998).

**Habitat Type**

Adult: Terrestrial (USFWS, 2012)

**Habitat Vegetation or Surface Water Classification**

Adult: Coastal sand dune (USFWS, 2012)

**Geographic or Habitat Restraints or Barriers**

Adult: Excessive shading (inferred from USFWS, 2012); typically occurs between 0 - 100 ft. elevation (USFWS, 2012)

**Spatial Arrangements of the Population**

Adult: Patchy colonies (USFWS, 2012)

**Environmental Specificity**

Adult: Very narrow (Natureserve, 2015)

**Tolerance Ranges/Thresholds**

Adult: Moderate (USFWS, 2012)

**Habitat Narrative**

Adult: The environmental specificity is very narrow; it is only known from narrow coastal strand in three main areas in California (NatureServe, 2015). Populations tend to be patchy and subject to large annual fluctuations in size and dynamic changes in local distribution associated with the shifts in dune blowouts, remobilization, and natural dune stabilization that occur in the coastal dune ecosystem. Colonies often occur where sparse vegetation traps wind-dispersed seeds, but causes minimal shading. Layia carnosa is restricted to openings in coastal sand dunes ranging in elevation from 0 to over 100 feet, where it colonizes sparsely vegetated, semi-stabilized dunes and blowouts. The species often occurs in narrow bands of moderately disturbed habitat along the edges of trails and roads (USFWS, 2012).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seeds are dispersed by wind mostly during late spring and summer months (USFWS 1998; USFWS, 2012).

***Population Information and Trends***

**Population Trends:**

Decline of 50-70% (NatureServe, 2015); stable distribution since listing (USFWS, 2012)

**Number of Populations:**

18 (NatureServe, 2015)

**Population Size:**

Unknown, > 10 million (USFWS, 2012)

**Adaptability:**

Low (NatureServe, 2015)

**Population Narrative:**

Highly vulnerable due to annual habit and sensitivity of coastal habitat. Long term trend is severe decline (50-70%). Numbers of this annual fluctuate depending on spring rain and available open sand. In 2005, the CNDDB knew of 24 total EO's, 6 of which were historical or extirpated (NatureServe, 2015). No significant change in the distribution of Layia carnosa has occurred since the species was listed. Accurate estimation of population size is difficult and costly for diminutive, short-lived annual species such as Layia carnosa, which tends to occur in small patches scattered across large areas of habitat. Overall total habitat occupied by Layia carnosa, based on data collected between 1999 and 2010, is estimated on the order of 456 acres, which may be conservative given the difficulty in detecting the plant and conducting thorough surveys. The Humboldt Bay population clearly is the largest across the range, likely exceeding 10 million individuals. The population at the mouth of the Mattole, estimated in the millions, occupies about 27 acres, and at least for the present, is relatively free of invasive species. The Point Reyes population has not been accurately censused, but appears to number in the 10’s of thousands or higher (USFWS, 2012).

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The threat of off-road vehicles has reduced significantly, with the exception of some of the privately held habitat located in Humboldt County. The remaining occupied habitat most susceptible to human destruction or modification includes the dunes located near the mouth of McNutt Gulch, and the Signal Hill Dunes on the Monterey Peninsula. Although livestock trampling

was indicated as a threat when Layia carnosa was listed, the only population known to be currently exposed to livestock is near the mouth of McNutt Gulch. No information is available on the size of that population, or degree of impacts by livestock. Many populations of Layia carnosa across its range continue to be impacted by uncontrolled pedestrian or equestrian traffic. However, evidence suggests that, for many sites where natural dune processes may be lacking, at least some recreation-related mortality may be a necessary consequence of the need for adequate disturbance to preclude overstabilization of the habitat. Acute levels of foot traffic clearly directly eliminate Layia carnosa from the center of traveled pathways, but at the same time, monitoring data and anecdotal evidence has consistently documented a strong preference by Layia carnosa for moderately disturbed habitat located along roads and trails (whether pedestrian or equestrian) in what otherwise would be unoccupied habitat.

**Stressor:** Climate change (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** It is expected that sea level may rise at least 16 inches along the California coast by 2050, with a 50-inch rise predicted by 2100 (Heberger et al. 2009). Beyond the direct influence of ocean-rise in potentially inundating the lower range of Layia carnosa habitat, even small changes in water level may cause significant changes in wave energy and the potential for shoreline damage from wave forces (California Coastal Commission 2001). Another coastal process that has the potential to affect Layia carnosa habitat, at least at Humboldt Bay, is vertical land deformation. Recent investigation suggests that deformation is occurring both during and between seismic events, and appears to vary in its direction (i.e., subsidence or uplift) and magnitude across the bay region (Walters 2011). Enhanced dune erosion may already be occurring in portions of the Humboldt Bay dune system, evidenced by the recent development of two unusually large, moving dune blowouts that show no sign of stabilizing, as well as a general loss of dune habitat on the North Spit (A. Pickart, pers. comm. 2011b) (USFWS, 2012).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** While those and other statutes (CEQA, California Coastal Act, Federal Coastal Zone Management Act) all provide limited protections for Layia carnosa on private and public property, many of its current threats are either unregulated, or of a kind not affected by land use regulations (invasive species encroachment, pedestrian impacts). Thus regulatory restrictions, even when applicable, are currently inadequate to conserve this species (USFWS, 2012).

**Stressor:** Invasive plants (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Layia carnosa was listed, in part, due to the past introduction and invasion of its habitat by a variety of invasive, non-native plant species. These species threaten virtually the entire distribution of Layia carnosa, through direct competition for space, stabilization of the dunes, and in some cases, enrichment of the soils which then stimulates invasion by other aggressive species. In Humboldt County the primary threats are invasive annual grasses,

European beachgrass, yellow bush lupine, iceplant, and jubata grass (Cortaderia jubata). Iceplant, annual grasses, and in some cases European beachgrass, are the primary threats farther south in its range. Evidence suggests these taxa will continue to invade Layia carnosa habitat, necessitating routine and long-term management action. While the threat posed by invasive species has been addressed to some extent, at least temporarily, no mechanism has been implemented which ensures continued funding and implementation of an invasive species control program, or the monitoring necessary to effectively implement such a program (USFWS, 2012).

**Stressor:** Stochastic events (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Annual species such as Layia carnosa are vulnerable to random fluctuations (stochasticity) and variation in annual weather patterns or other environmental factors (USFWS 1998). All of the Monterey and Santa Barbara County populations, and the Freshwater Lagoon Spit site in Humboldt County, due to their relatively small size and area of occupied habitat, continue to be vulnerable to stochastic extinction (USFWS, 2012).

***Recovery***

**Reclassification Criteria:**
Not available

Recovery Priority Number: 8

**Delisting Criteria:**
Protection ofhabitat presently occupied by the species, with long-term commitments to conserving the species and the native vegetation (USFWS, 1998).

In protected habitat, successful control ofinvasive non-native plants (and snails) and successful management oflesser problems, including grazing, pedestrians, and off-road vehicles. Management success must be demonstrated through ten years of biological monitoring. The time is needed to observe the effectiveness ofmanagement in dry and wet years (USFWS, 1998).

The threatened Chorizanthe pungens var. pungens may be considered for delisting when permanent protection has been implemented, as currently planned, in the Fort Ord disposal and reuse process and the coastal populations receive protected status (USFWS, 1998).

**Recovery Actions:**
- Protect existing populations and habitats (USFWS, 1998).
- Minimize the threats to the plants and butterfly (USFWS, 1998).
- Develop management strategies incorporating ecological and land use strategies (USFWS, 1998).
- Manage populations and habitats to achieve delisting (USFWS, 1998).
- Monitor population trends to evaluate recovery success (USFWS, 1998).
- Coordinate recovery actions to protect other listed and sensitive species (USFWS, 1998).

- Develop and implement an outreach program (USFWS, 1998).
- Continued collaboration with Redwood NP, CDPR, BLM, Manila CSD, City of Eureka, Point Reyes NS, Vandenberg AFB, and perhaps private landowners is essential to the successful recovery of this species (USFWS, 2012).
- The type locality population for Layia carnosa at the Point Pinos dunes has not been detected since 1919 (CDFG 2007). The Point Pinos dunes are currently undergoing restoration and endangered species augmentation as part of a plan related to expansion of the golf course and transfer of the property from the US Coast Guard to the City of Pacific Grove. Unfortunately Layia carnosa was not included in the restoration plan. An attempt should be made to reintroduce Layia carnosa to Point Pinos from seed collected at nearby Asilomar SB or Indian Dunes. Whether or not the recovery goal for that population can be met is unknown. However, the attempt to establish a vigorous population there is called for under one of the delisting criteria, and could reestablish a historically significant population. In addition, the planned reintroduction of Layia carnosa to restored habitat near the historical occurrence at the mouth of Little River should be pursued (Forys 2006) (USFWS, 2012).
- Population and Occupied Habitat Inventories: Habitat owned by the USFWS, BLM, City of Eureka, Manila CSD, Point Reyes NS, CDPR and Pebble Beach Company (Indian Village Dunes) have been the focus of one or more dunes restoration projects. Periodic reassessment of these populations and occupied habitat at these sites, employing consistent methodology, is critical to establish trends, provide feedback on the restoration efforts, and determine whether the current recreational management is compatible with conservation of the species. Baseline population and habitat inventories are needed for the City of Eureka Elk River Spit, the privately held dunes near the mouth of McNutt Gulch, and the Signal Hill site owned by Pebble Beach Company on the Monterey Peninsula. Where populations are too large to census, a uniform methodology similar to that utilized by the USFWS and BLM at Humboldt Bay should be adopted (USFWS, 2012).
- Disturbance Monitoring: Habitat disturbance is known to be a necessary element in the ecology of Layia carnosa; however, too much or too little disturbance is detrimental. Therefore, in order to effectively tailor recreational management to the needs of Layia carnosa, quantitative data are needed indicating its response to specific recreational use. Research is needed to measure the rate of establishment and mortality of Layia carnosa in response to varying types and levels of disturbance (USFWS, 2012).
- Priorities for increased protection, by fee acquisition, conservation easement, or other legal protective mechanism, include: • Signal Hill Dunes, on the Monterey Peninsula • City of Eureka dunes habitat located on the North Spit, and Elk River Spits of Humboldt Bay. • Private owned dunes habitat on the North Spit of Humboldt Bay, and north of the mouth of the Mattole River. The monitoring and restoration conservation easement proposed by Pebble Beach Company as part of the Spyglass Hill Golf Course project could serve as a template for future agreements needed to ensure future conservation of critical dunes habitat for this species. Such agreements would in many cases contribute to recovery of multiple listed species, including the Monterey spineflower (Chorizanthe pungens var. pungens, sand gilia (Gilia tenuiflora ssp. arenaria), Tidestrom's lupine (Lupinus tidestromii) and Menzies' wallflower (Erysimum menziesii ssp. menziesii) on the Monterey Peninsula; Tidestrom's lupine at Point Reyes NS; and Menzies wallflower (E. m. Eurekense) in the Humboldt Bay portion of the range (USFWS, 2012).

- Due to the vulnerability of its habitat to stabilization by invasive species, and as a result, the highly transient nature of its habitat, the requirement to ensure future maintenance of Layia carnosa habitat is paramount to the recovery effort. It is imperative that efforts to control invasive species continue across the range, and that restoration methods incorporate the most cost-effective means available. Manual removal, or where existing populations will not be impacted, mechanical removal or burning followed with herbicide post-treatment has shown to be particularly effective. The problem species could change overtime, but inevitably, encroachment by invasive species and resulting over-stabilization of its habitat will continue to threaten Layia carnosa in perpetuity. Therefore, habitat monitoring followed by removal of invasive species, when warranted, must be considered a permanent element in maintaining Layia carnosa, even after the delisting (USFWS, 2012).
- Efforts should be made to determine which of the following three options for ensuring long-term protection best applies to individual sites and ownership: 1) endowment of conservation easements specifically written to include the necessary monitoring and habitat maintenance needed to conserve the species; 2) incorporation of language within the management guidance documents for each of the agencies that own property supporting significant populations of Layia carnosa, which emphasizes invasive species monitoring and control efforts in perpetuity, and at least some level of Layia carnosa population monitoring, even after it is delisted; 3) implementation of conservation agreements which combine the necessary elements of the above two options in ensuring future maintenance of Layia carnosa habitat after it is delisted (USFWS, 2012).
- Permanent Funding: With respect to the privately held habitat, the level of funding necessary to adequately monitor Layia carnosa populations and habitat, and implement maintenance actions prior to onset of population decline needs to be determined. Opportunities should then be pursued to secure permanent funding in the form of an endowment or trust fund, which ensures that the responsive management is conducted in perpetuity (USFWS, 2012).
- The California Shoreline Mapping Project, implemented in 2010, will provide high resolution LIDAR photography enabling development of accurate DEM’s (California Ocean Protection Council 2011). Those data should be analyzed in conjunction with occupied habitat maps and periodic population monitoring data for sites across the range, particularly the Humboldt Bay, Mattole River, and Point Reyes populations, to help evaluate future trends in population and habitat as they correlate with elevation (USFWS, 2012).
- Future dunes habitat restoration projects across the range, but most importantly at Humboldt Bay, the mouth of the Mattole River, and at Point Reyes should utilize elevation data available from the DEM for those areas, and begin focusing restoration efforts in areas at sufficient elevation, and if possible, located geographically so as to insulate Layia carnosa as much as possible from the effects of ocean-rise (USFWS, 2012).
- Research should include a comparison of climate and soil factors, and other factors that may affect reproductive success in populations of Layia carnosa, both at the limits of its range, and within the center of its range (for example, Humboldt Bay). As soon as those results are available, the feasibility and practicality of meeting the existing delisting recovery criteria for the species should be evaluated, and recommendations made regarding adequacy of the existing recovery criteria (USFWS, 2012).
- Focused inventories for Layia carnosa should be conducted at all the significant dune systems located along the coast between the Monterey Peninsula and Vandenberg AFB, which constitutes a 150 mile long gap in the known distribution for the species (USFWS,

2012).

- Initial efforts have been made to restore near-shore dunes habitat at Vandenberg AFB, and expand the relatively small population of Layia carnosa. The results of the Layia carnosa life history study, scheduled to be initiated in fall 2011, hopefully should indicate whether range limiting factors, or simply the absence of an appropriate disturbance regime is preventing this population from expanding. Due to the fact it is the southernmost site for the species, and in accordance with the recovery plan, seed from this site should be deposited at an approved seedbank as soon as adequate seed are available (USFWS, 2012).

# SPECIES ACCOUNT: *Leavenworthia crassa* (Fleshy-fruit gladecress)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015) 8/1/2014

**Physical Description**

A winter annual from a basal rosette of leaves. Flowers (March-May) are whitish-yellow with yellow to orange claws. the first flowers are borne on erect stalks; those forming later usually are borne in loose clusters on true stems arising from the axils of the rosette leaves. Fruits are fleshy, 6-12 mm long. (NatureServe, 2015)

**Taxonomy**

Two questionably distinct varieties (crassa and elongata) are often recognized (e.g., Rollins, 1993; Kartesz 1994 and 1999). The USFWS (2004) does not maintain the varieties, citing evidence that the ranges of variation in fruit lengths overlap (McDaniel and Lyons, unpublished status report, 1987). (NatureServe, 2015)

**Historical Range**

See current range/distribution.

**Current Range**

Endemic to a 13-mile radius area in Lawrence and Morgan counties in northwest Alabama. (NatureServe, 2015)

**Critical Habitat Designated**

Yes; 8/26/2014.

**Legal Description**

On August 26, 2014, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Leavenworthia crassa under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes seven critical habitat units (CHUs), in Alabama (79 FR 50990-51039).

**Critical Habitat Designation**

The critical habitat designation for Leavenworthia crassa includes seven CHUs in Lawrence and Morgan Counties, Alabama. This species critical habitat encompasses approximately 20.6 acres (ac) (8.4 hectares (ha)) (79 FR 50990-51039).

Unit 1: Bluebird Glades: Unit 1 consists of 0.2 ha (0.5 ac) of privately owned land located in southeast Lawrence County, Alabama. The unit contains two subpopulations and is located along Alabama State Route 157 approximately 3.5 km (2.2 mi) southeast of the intersections of State Routes 36 and 157, approximately 3.7 km (2.3 mi) southwest of Danville, Alabama. These plants are located within a highly disturbed, limestone glade within a former mobile home site. Well-lighted, open areas (PCE 2), with shallow soils and exposed limestone bedrock or gravel that are dominated by characteristic glade vegetation (PCE 1), are present within the unit. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats of the invasion of exotic species into open glades and possible changes in land use, including road widening or development. Due to human-caused disturbances, exotic species, most notably Chinese privet and Japanese honeysuckle, threaten this site (Schotz 2009, pp. 13–14).

Unit 2: Stover Branch Glades: Unit 2 consists of 3.2 ha (7.8 ac) of privately owned land located in southeast Lawrence County, Alabama. The unit contains two subpopulations; one subpopulation is located on the southwest side of County Road 203 approximately 1.4 km (0.9 mi) southsoutheast of Alabama State Route 157, and one subpopulation is located along the southwest side of State Route 157, approximately 1.6 to 2.1 km (1 to 1.3 mi) southeast of State Route 36, in Speake, Alabama. These subpopulations are located within a pasture and are actively maintained by livestock grazing. Well-lighted, open areas (PCE 2), with shallow soils and exposed limestone bedrock or gravel that are dominated by characteristic glade vegetation (PCE 1), are present within the unit. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats of invasive species into open glades and incompatible livestock grazing. Invasive species encroachment and continuous livestock grazing during the plant’s reproductive cycle constitute ongoing threats to this site (Schotz 2009, pp. 15–16).

Unit 3: Indian Tomb Hollow Glade: Unit 3 consists of 0.5 ha (1.1 ac) of federally owned land located within the Bankhead National Forest in Lawrence County, Alabama. The unit is located on the west and northwest side of County Road 86 at a point roughly 4.5 km (2.8 mi) south of State Route 36 near Speake, Alabama. Habitat in this unit consists of a relatively small glade characterized by a flat limestone outcrop that is heavily buffered by nearly impenetrable tangles of eastern red cedar and upland swamp privet. Well-lighted, open areas (PCE 2), with shallow soils and exposed limestone bedrock or gravel that are dominated by characteristic glade vegetation (PCE 1), are present within the unit. The U.S. Forest Service provides management to control encroachment of invasive species (PCE 3). The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats of the invasion of exotic species into open glade and damage from vehicles. Moderate encroachment of exotic species, most notably Chinese privet and Japanese honeysuckle, threatens this site along the glade periphery (Schotz 2009, pp. 18–19). This site also shows minimal incidence of trash disposal and damage from recreational vehicles.

Unit 4: Cedar Plains South: Unit 4 consists of 0.04 ha (0.1 ac) of privately owned land located in Morgan County, Alabama. This unit is located on Cedar Plains Road, 1.2 km (0.75 mi) south of County Road 55 and approximately 8 km (5 mi) west of the junction of U.S. Highway 31 and County Road 55 in Falkville. This population represents an excellent landscape context but contains the smallest number of plants of any of the known occurrences. Habitat in this unit consists of a well-lighted limestone glade opening (PCE 2) located within a limestone forest primarily comprised of eastern red cedar and various other hardwoods. Herbaceous vegetation characteristic of glade communities is present within the well-lighted glade (PCE 1), and competition and shading from native and invasive, nonnative plants are currently not a threat to the habitat in this unit (PCE 3). The features essential to the conservation of the species in this unit may require special management considerations or protections to prevent future adverse effects due to competition and shading caused by encroachment of native and invasive, nonnative plants.

Unit 5: Cedar Plains North: Unit 5 consists of 1.7 ha (4.2 ac) of privately owned land located in Morgan County, Alabama. This unit is located on Cedar Plains Road, from 0.6 to 1 km (0.4 to 0.6 mi) north of County Road 55, approximately 8 km (5 mi) west of the junction of U.S. Highway 31 and County Road 55 in Falkville. These populations are located within a pasture and are actively maintained by livestock grazing. Well-lighted, open areas (PCE 2), with shallow soils and exposed limestone bedrock or gravel that are dominated by characteristic glade vegetation (PCE 1), are present within the unit. This glade complex, although subjected to ongoing agricultural interests, represents the greatest concentration of plants currently known for the species. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats of invasive species into open glades and incompatible livestock grazing. Invasive species encroachment and continuous livestock grazing during the plant's reproductive cycle constitute ongoing threats to this site (Schotz 2009, pp. 23–24).

Unit 6: Massey Glade: Unit 6 consists of 2.75 ha (6.8 ac) of privately owned land located in Morgan County, Alabama. This unit is located on County Road 55, 0.3 to 0.6 km (0.2 to 0.4 mi) west of Cedar Plains Road, approximately 8.3 km (5.2 mi) west of the junction of U.S. Highway 31 and County Road 55 in Falkville. This population is located within a highly disturbed complex of limestone pavement barrens scattered in an actively utilized pasture and within the yards and fields of nearby homes. Welllighted, open areas (PCE 2), with shallow soils and exposed limestone bedrock or gravel that are dominated by characteristic glade vegetation (PCE 1), are present within the unit. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats of invasive species into open glades and incompatible livestock grazing. Invasive species encroachment and continuous livestock grazing during the plant's reproductive cycle constitute ongoing threats to this site (Schotz 2009, pp. 25–26).

Unit 7. Hillsboro Glade: Unit 7 consists of 0.04 ha (0.1 ac) of privately owned land in Lawrence County, Alabama. This unit is currently occupied and is located within a powerline right-of-way approximately 400 feet south of the intersection of County Roads 217 and 222, near Hillsboro. Habitat in this unit consists of a relatively small limestone glade outcrop within a powerline right-of-way that is bordered by a forested area. Wellilluminated, open areas (Primary Constituent Element (PCE 2), with shallow soils and exposed limestone bedrock that are dominated by characteristic glade vegetation (PCE 1), are present within the unit. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats of the invasion of exotic species into open glades, indiscriminate herbicide use or mowing for electrical transmission line right-of-way maintenance, and possible changes in land use, including agriculture or development.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Leavenworthia crassa critical habitat consists of three components (79 FR 50990-51039):

(i) Shallow-soiled, open areas with exposed limestone bedrock or gravel that are dominated by herbaceous vegetation characteristic of glade communities.

(ii) Open or well-lighted areas of exposed limestone bedrock or gravel that ensure fleshy-fruit gladecress plants remain unshaded for a significant portion of the day.

(iii) Glade habitat that is protected from both native and invasive, nonnative plants to minimize competition and shading of fleshy-fruit gladecress.

**Special Management Considerations or Protections**

The features essential to the conservation of fleshy-fruit gladecress may require special management considerations or protection to reduce the following threats: (1) Actions that remove the soils and alter the surface geology of the glades; (2) building or paving over the glades; (3) construction or excavation up slope that alters water movement (sheet flow or seepage) down slope to gladecress sites; (4) planting trees adjacent to the edges of an outcrop resulting in shading of the glade and accumulations of leaf litter and tree debris; (5) encroachment by nonnative and native invading trees, shrubs, and vines that shade the glade; (6) the use and timing of application of certain herbicides that can harm gladecress seedlings; and (7) access by cattle to gladecress sites where habitat and plants may be trampled. Management activities that could ameliorate these threats include (but are not limited to): (1) Avoiding limestone glades when planning development, conversion to agriculture, and other disturbances to glade complexes; (2) avoiding above-ground construction and/or excavations in locations that would interfere with natural water movement to gladecress habitat sites; (3) locating suitable habitat and determining the presence or absence of the species and identifying areas with glade complexes and protecting or restoring as many complexes as possible; (4) reaching out to all landowners, including private and State landowners, to raise awareness of the plant and its specialized habitat; (5) providing technical or financial assistance to landowners to help in the design and implementation of management actions that protect the plant and its habitat; (6) avoiding pine tree plantings near glades; and (7) managing, including brush removal, to maintain an intact native glade vegetation community. More information on the special management considerations for each critical habitat unit is provided in the individual unit descriptions below.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollinated (USFWS, 2013)

**Reproduction Narrative**

Adult: Fleshy-fruit gladecress is an annual, spring-flowering member of the mustard family (Brassicaceae). As an annual, the seeds germinate in the fall, overwinter as rosettes, and commence a month-long flowering period beginning in mid-March. The first seeds mature in late April, and during most years the plants dry and drop all of their seeds by the end of May. It is unlikely that all seeds produced in spring germinate the next fall, but the length of dormancy in the soil is not known (McDaniel and Lyons 1987, p. 10); thus we do not know whether the species is capable of forming a seed bank. Native bees in the families' Andrenidae and Halictidae (sweat bees), including the species Halictus ligatus (sweat bee), were observed carrying pollen from Leavenworthia crassa (fleshy-fruit gladecress) and L. alabamica (Alabama gladecress) in northern Alabama (Lloyd 1965) (USFWS, 2013).

**Habitat Type**

Adult: Glades (USFWS, 2013)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2013)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from USFWS, 2013)

**Site Fidelity**

Adult: High (inferred from USFWS, 2013)

**Habitat Narrative**

Adult: This species is a component of glade flora and occurs in association with limestone outcroppings. The terms ‘‘glade’’ and ‘‘cedar glades’’ are used interchangeably to refer to shallow soiled, open areas that are dominated by herbaceous plants and characterized by exposed sheets of limestone or gravel. Eastern red cedar (Juniperus virginiana) trees are frequent in the deeper soils along the edges of the glades (Hilton 1997, p. 1; Baskin et al. 1986, p. 138; Baskin and Baskin 1985, p. 1). Glades can vary in size from as small as a few square meters to larger than 1 square kilometer (km2) (0.37 square miles (mi2)) and are characterized as having an open, sunny aspect (lacking canopy) (Quarterman 1950, p. 1; Rollins 1963, p. 5). Historically, glades in northern Alabama occurred as glade complexes where sparsely vegetated patches of exposed, or nearly exposed, limestone occurred in a matrix of woody vegetation to form a mosaic of habitats grading into one another (Hilton 1997, pp. 1, 5, 64). Herbaceous diversity was irregular over these complexes, affected by changes in soil gradient and moisture, and the presence or absence of a woody vegetation component. Few undisturbed examples of this community type remain (Hilton 1997, pp. 5, 8; McDaniel and Lyons 1987, p. 11; Baskin and Baskin 1985, p. 1; Rollins 1963, p. 5–6) (USFWS, 2013). High ecological integrity of the population and site fidelity along with low tolerance ranges are inferred based on this species specific habitat requirements.

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Decreasing (NatureServe, 2015)

**Resiliency:**

In the Status Quo scenario, resilience is expected to remain the same for most populations in 20 years. While both Danville populations are likely extirpated in the future given the poor condition of all resilience factors, the drastic change in the resilience of the Cedar Plains South population is due population size becoming a limiting factor in the viability of this population. In the Increased Management scenario, resilience for all populations is expected to increase, as habitat management increases both the habitat and land use condition. Even with the downranking of land use condition for populations under private ownership, the majority of populations are assessed to be resilient (e.g., high or very high resilience) under this scenario. In the Introductions scenario, the initial population size of new populations will be determined by the introduction strategy (number of plants, timing of plantings, locations). The overall resilience of introduced populations in the Introductions scenario cannot be quantitatively assessed at this time. (USFWS, 2020a)

**Representation:**

Representation and redundancy is reduced for L. crassa in the Status Quo, increased in the Increased Management and could be greatly increased in the Introductions scenario. Under the Status Quo scenario, two resilient populations remain, with one containing both SI and SC individuals, and one with an unknown mating system. The Increased Management scenario does not lose any populations, and resilient populations include one SI, one SI/SC, two SC, and two with an unknown mating system. The Introductions scenario could focus on gathering seed from populations likely to become extirpated under Status Quo that also utilize mating systems that are not well represented, or that better contribute to genetic diversity and adaptive potential (e.g., SI). The total number of resilient populations should increase from three currently to nine under the Introductions scenario, given increased management is also co-occurring. If populations are added at the same rate (three per decade) following the initial 10-year planning period (and all populations are robust), the Introductions scenario could add 12 resilient populations within 50 years. To achieve eight to ten introduced populations in 50 years, the introduction program would need to maintain its momentum, though two to four introduced populations could be below resilient status (not assessed as having high or very high resilience) and the introduction goal could still be met within a 50-year period. (USFWS, 2020a)

**Redundancy:**

Representation and redundancy is reduced for L. crassa in the Status Quo, increased in the Increased Management and could be greatly increased in the Introductions scenario. Under the Status Quo scenario, two resilient populations remain, with one containing both SI and SC individuals, and one with an unknown mating system. The Increased Management scenario does not lose any populations, and resilient populations include one SI, one SI/SC, two SC, and two with an unknown mating system. The Introductions scenario could focus on gathering seed from populations likely to become extirpated under Status Quo that also utilize mating systems that are not well represented, or that better contribute to genetic diversity and adaptive potential (e.g., SI). The total number of resilient populations should increase from three currently to nine under the Introductions scenario, given increased management is also co-occurring. If populations are added at the same rate (three per decade) following the initial 10-year planning period (and all populations are robust), the Introductions scenario could add 12 resilient populations within 50 years. To achieve eight to ten introduced populations in 50 years, the introduction program would need to maintain its momentum, though two to four introduced populations could be below resilient status (not assessed as having high or very high resilience) and the introduction goal could still be met within a 50-year period. (USFWS, 2020a)

**Number of Populations:**

8 (USFWS, 2020)

**Population Narrative:**

Being a seed-banking winter annual, this species has good survival but poor competitive abilities (USFWS 2004). The very low numbers of fruiting individuals seen most years suggest that the populations may be highly vulnerable to stochastic factors as well. The plants are usually self-incompatible (Rollins 1993), thus requiring cross-pollination for seed production. However, given proper habitat conditions, this species is able to grow and reproduce quickly. More than 50% of the appropriate glade habitat has been lost in north-central Alabama, with only five glades remaining in good condition (Hilton 1997 cited by Everson 2009). Fifteen historical occurrences have been lost. Also, the range may have contracted significantly, if an unconfirmed historical record from Lauderdale County is accepted. Some of the extant occurrences have been degraded by grazing, road construction, and plowing or cultivation (Everson 2009). Decline of 70-90% Population size value left blank for this seed-banking annual because the large number of individuals suggests a sense of security that is not warranted. Abundant locally, with some sites containing thousands of individuals. Individual populations range from <50 individuals to up to 10,000. In March 2009, a total of approximately 12,000 individuals were counted in the six occurrences (Schotz 2009). Endemic to northwest Alabama, where six occurrences were verified extant in 2009 (Schotz 2009) (NatureServe, 2015). NatureServe (2015) notes that the short term trend is a decline of 30-50% and the Long-term trend is a decline of 70-90%. USFWS (2013) notes there are 5 extant populations. Low resiliency, representation and redundancy are inferred based on the number of populations and the relatively small geographic area this species is known to inhabit. The Service is aware of ten occurrences of fleshy-fruit gladecress in eight populations in the Moulton and Tennessee valleys in Alabama, with four occurrences discovered 2008–2016 and one occurrence newly discovered since listing (Service 2019). One additional occurrence was extirpated prior to the species listing in 2014. Little trend data is available for these populations, but the Service has no evidence any extant population known at the time of listing is extirpated. (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Agricultural conversion (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Conversion of this species habitat to agriculture (pasture) is listed as a threat to this species (USFWS, 2013).

**Stressor:** Incompatible agricultural practices (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Agricultural practices such as herbicide use at the wrong time of year are listed as a threat to this species (USFWS, 2013).

**Stressor:** Rights-of-way maintenance (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Rights-of way maintenance (including herbicide use and mowing prior to seed set) is listed as a threat to this species (USFWS, 2013).

**Stressor:** Industrial development (USFWS, 2013)
**Exposure:**
**Response:**

**Consequence:** Loss of habitat
**Narrative:** Industrial development is listed as a threat to this species (USFWS, 2013).

**Stressor:** Shading and competition (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Shading and competition by non-native exotic plants and natural forest succession are listed as a major threat to this species (USFWS, 2013).

**Stressor:** Off-road vehicle use (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat/loss of individual plants
**Narrative:** Off-road vehicle use is listed as a threat to this species (USFWS, 2013).

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 2

CRITERION 1. At least 15 geographically distinct populations – separated by at least 1 kilometer – of at least moderate size (at least 100 individuals) are distributed across the species' range, maintaining a mixture of self-incompatible and self-compatible populations, with each of the 2 known ecoregions (Eastern Highland Rim and Dissected Plateau)1 supporting at least 6 such populations, including 1 population within each of the 7 designated critical habitat units (USFWS, 2023).

CRITERION 2. At least 3 large populations (at least 500 individuals), protected by long-term conservation mechanisms, occur in each of the two known ecoregions, for a total of 6 protected populations, and are managed to promote open-canopied habitat, native plant community integrity, and support resilient populations2 of fleshy-fruit gladecress (USFWS, 2023).

CRITERION 3. Monitoring demonstrates that these populations (described in Criteria 1 and 2) are viable, as evidenced by natural recruitment and having stable to increasing populations for at least 10 years (approximately 10 generations) (USFWS, 2023).

**Delisting Criteria:**
Fleshy-fruit gladecress may be considered for delisting when the above criteria are met and when: CRITERION 4. At least 15 additional geographically distinct populations of at least moderate size occur within the species' known range for a total of at least 30 extant populations (USFWS, 2023).

CRITERION 5. At least 2 additional large populations are protected and managed as described in Criterion 2 within each of the 2 known ecoregions, for a total of at least 10 protected populations (USFWS, 2023).

CRITERION 6. Monitoring demonstrates that these additional populations (described in Criteria 1, 2, 4, and 5) are viable, as evidenced by natural recruitment and having stable to increasing populations for at least 10 years (approximately 10 generations) (USFWS, 2023).

**Recovery Actions:**

- Work with partner biologists, state agencies, non-governmental conservation organizations, and private landowners to obtain protection for populations on privately owned lands (USFWS, 2023).
- Work with roadside rights-of-way stakeholders to develop and implement management agreements (USFWS, 2023).
- Develop and implement management plans for all populations (USFWS, 2023).
- Work with partners and stakeholders to develop and implement a monitoring strategy for all populations (USFWS, 2023).
- Increase the representation and genetic diversity of ex situ (off-site) safeguarding collections of fleshy-fruit gladecress (USFWS, 2023).
- Continue to facilitate and support surveys to identify new populations (USFWS, 2023).
- Conduct research that enhances knowledge of fleshy-fruit gladecress to facilitate the development of scientifically sound management plans, population viability models, and species/habitat distribution models (USFWS, 2023).
- Augment protected populations that are unable to grow in response to habitat management due to low population size and/or establish populations in suitable, but unoccupied, managed habitat on conservation lands (USFWS, 2023).
- Continue to coordinate with federal, state, county, and local agencies, private landowners, and other stakeholders to promote fleshy-fruit gladecress recovery and identify innovative ways to increase public awareness of the need to protect this species and its habitats (USFWS 2023).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS We will prepare a recovery plan for Leavenworthia crassa that includes objective and measurable criteria which, when met, will ensure the conservation of the species. Recovery criteria will address all meaningful threats to the species, as well as estimate the time and the cost to achieve recovery. The priority need is to address habitat-directed recovery actions. Viability of fleshy-fruit gladecress depends on protecting occurrences and suitable habitat from further degradation and fragmentation; restoring potentially suitable habitat within its historical range; evaluating and reducing threats from incompatible land uses, shading, and nonnative plants; increasing the size of current populations; conserving genetic diversity; and potentially establishing populations where suitable conditions are present on protected lands. The core actions include monitoring and protecting existing populations, long term conservation easements to protect existing populations (though the likelihood of landowner participation is uncertain), restoration of habitat through removal of woody invasive species (i.e., cedar and privet), and education and outreach. Detailed actions for fleshy-fruit gladecress conservation include: • Encourage landowner partnerships and proactive management with best management practices for species protection. Potential habitat protection mechanisms with landowners include fee simple purchase, conservation easement, or establishing a conservation agreement to ensure habitat receives necessary management and is protected from incompatible land uses. • Develop agreements with Departments of Transportation, railroad authorities, and transmission line companies to ensure population protection extends onto rights-of-ways in the species range to address issues such as invasive nonnative species and proactively curb herbicide use and mowing during sensitive periods of the year. • Continue to support efforts by the U.S. Forest Service to protect and manage the Indian Tomb Hollow Glade population on Bankhead National Forest. • Encourage and support additional surveys for populations. • Establish methods to effectively monitor, and if necessary, develop a captive propagation and reintroduction program for fleshy-fruit gladecress. • Initiate regular monitoring at each site, to include counts from discrete clusters, where possible. Monitoring should include periodic checks of viability and germination rates in order to evaluate whether diminished reproductive fitness poses a long-term threat to populations. • Determine the number of populations required to recover fleshy-fruit gladecress – i.e., to reduce the risk of extinction to the point that the species is no longer threatened or endangered. • Continue to coordinate with federal, state, county agencies, and non-governmental conservation agencies to promote plant recovery and find innovative ways to increase public awareness of the need to protect this species and its habitat. • Initiate public education efforts and direct contact with landowners to inform the public about the species and its habitat, and opportunities to participate in conservation efforts. • Work with partners to study missing data related to the species biology and life history to support understanding of species resiliency, representation, and redundancy, including: o Length of seed dormancy in soil and implications of potential seed banking. o Understanding the impact of increasing levels of self-fertilization in light of pollinator declines. o Conditions and techniques in a propagation and reintroduction plan to inform a captive propagation program. o Determination of the mating systems of populations that are currently unknown and/or confirm the presence of two mating systems in a population (USFWS, 2020)

# SPECIES ACCOUNT: *Leavenworthia exigua laciniata* (Kentucky gladecress)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 06/05/2014; Southeast Region (Region 4) (USFWS, 2016)

**Physical Description**

A winter annual. Plants are about 5 to 10 cm (1.97 to 3.94 in) in height with early leaves that are simple with a slender petiole (central stalk of the leaf) and mature leaves that are sharply lobed (appear as disconnected pieces along the main leaf vein), somewhat squarish at the ends and arranged as a rosette (circular cluster of leaves) (Evans and Hannan 1990). The flowers are small (3 to 6 mm (0.12 to 0.24 in)), white to lilac in color with four petals, green rather than lavender sepals (the outer of two floral leaves that make up the flower), and leafless stems. Leaves typically disappear by the time the plant is in fruit (Evans and Hannan 1990). The fruit is flat and pod-shaped. Flowering begins in March, with seed dispersal occurring by mid-May. (USFWS, 2016; NatureServe, 2015)

**Historical Range**

See current range/distribution.

**Current Range**

Kentucky: Bullitt and Jefferson counties. (NatureServe, 2015)

**Critical Habitat Designated**

Yes; 5/6/2014.

**Legal Description**

On May 6, 2014, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Leavenworthia exigua laciniata (Kentucky glade cress) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six critical habitat units (CHUs), in Kentucky (79 FR 25689-25707).

**Critical Habitat Designation**

The critical habitat designation for Leavenworthia exigua laciniata includes six CHUs (sixteen sub-units) in Bullitt and Jefferson Counties, Kentucky. This species critical habitat encompasses approximately 2,053 acres (ac) (830 hectares (ha)) (79 FR 25689-25707).

Unit 1: McNeely Lake, Jefferson County, Kentucky: Unit 1 consists of 18 acres (ac) (7 hectares (ha)) within McNeely Lake Park in Jefferson County, Kentucky. This critical habitat unit is under county government ownership. This critical habitat unit occurs at the northwestern edge of the species' range, where there is little remaining habitat and few occurrences, and therefore this unit is important to the distribution of the species. Habitat degradation (e.g., erosion, invasive species) is impacting the species' ability to persist within this unit; however, the landowner has received funding and is working with the Service and KSNPC to develop a management plan for the site and to implement habitat improvement practices. These planned activities are expected to improve population numbers and viability at this important site. This unit helps to maintain the geographical range of the species and provides opportunity for population growth. Within Unit 1, the features essential to the conservation of the species may require special management considerations or protection to address potential adverse effects associated with encroachment by nonnative plants or forage species, and forest encroachment due to fire suppression.
